1. **Add** a **Stage** to the packet capture configuration and define a **File** name for the resulting packet capture.

   For example, select **receive** as the **Stage** and set the **File** name to `telnet-test-received`.

2. Continue to **Add** each **Stage** you want to capture (**firewall**, **transmit**, and **drop**) and set a unique **File** name for each stage.

Step 5 Set **Packet Capture** to **ON**.

Note the warning that system performance can be degraded and then click **OK**. If you define filters, the packet capture should have little impact on performance, but you should always turn **Off** packet capture after the firewall captures the data that you want to analyze.

**Take a Custom Packet Capture (Continued)**

Step 6 Generate traffic that matches the filters that you defined.

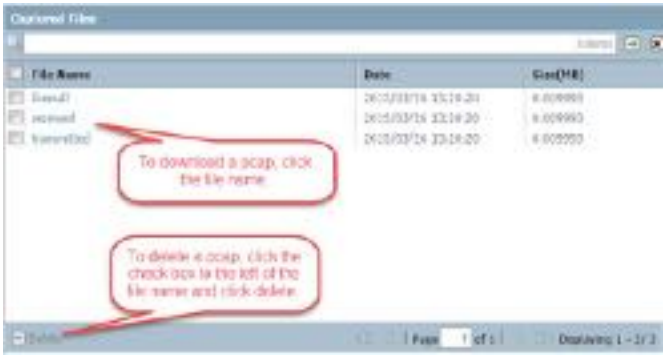
For this example, generate traffic from the source system to the Telnet-enabled server by running the following command from the source system (192.168.2.10):

```
telnet 10.43.14.55
```

Step 7 Turn packet capture **OFF** and then click the refresh icon to see the packet capture files.

Notice that in this case, there were no dropped packets, so the firewall did not create a file for the drop stage.

Step 8 Download the packet captures by clicking the filename in the File Name column.



Step 9 View the packet capture files using a network packet analyzer, such as Wireshark.

In this example, the received.pcap packet capture shows a failed Telnet session from the source system at 192.168.2.10 to the Telnet-enabled server at 10.43.14.55. The source system sent the Telnet request to the server, but the server did not respond. In this example, the server may not have Telnet enabled, so check the server.

Step 10 Enable the Telnet service on the destination server (10.43.14.55) and turn on packet capture to take a new packet capture.

Step 11 Generate traffic that will trigger the packet capture.

Run the Telnet session again from the source system to the Telnet-enabled server

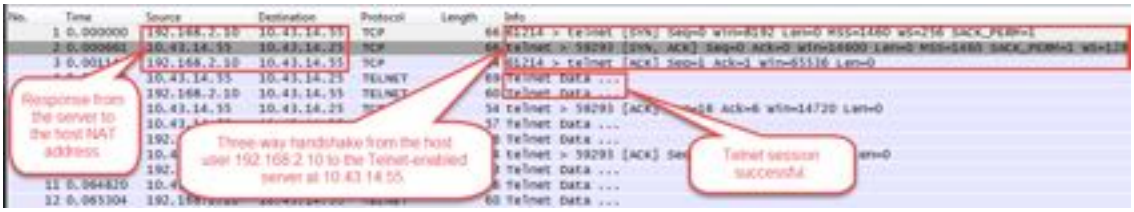
```
telnet 10.43.14.55
```

 © Palo Alto Networks, Inc.

**Take a Custom Packet Capture (Continued)**

Step 12 Download and open the received.pcap file and view it using a network packet analyzer.

The following packet capture now shows a successful Telnet session from the host user at 192.168.2.10 to the Telnet-enabled server at 10.43.14.55. Note that you also see the NAT address 10.43.14.25. When the server responds, it does so to the NAT address. You can see the session is successful as indicated by the three-way handshake between the host and the server and then you see Telnet data.



## Take a Threat Packet Capture

To configure the firewall to take a packet capture (pcap) when it detects a threat, enable packet capture on Antivirus, Anti-Spyware, and Vulnerability Protection security profiles.

**Take a Threat Packet Capture**

Step 1 Enable the packet capture option in the security profile.

Some security profiles allow you to define a single-packet capture, or extended-capture. If you choose extended-capture, define the capture length. This will allow the firewall to capture more packets to provide additional context related to the threat.

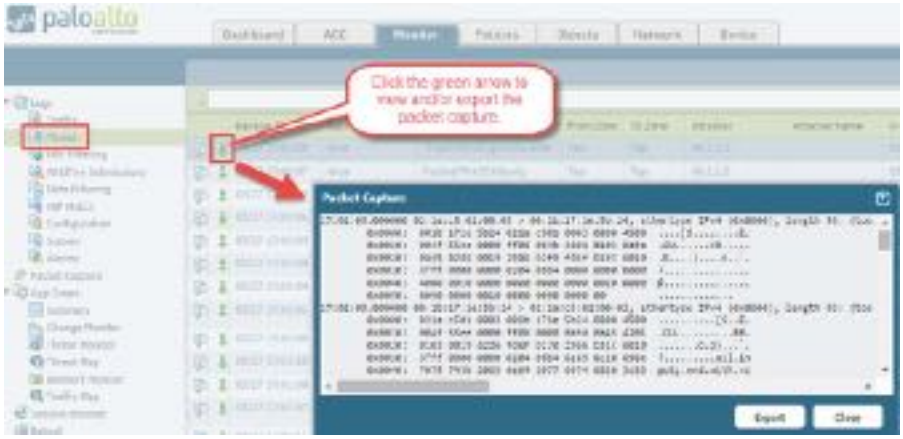
The firewall can only capture packets if the action for a given threat is set to allow or alert.

1. Select **Objects > Security Profiles** and enable the packet capture option for the supported profiles as follows:
   - **Antivirus**—Select a custom antivirus profile and in the **Antivirus** tab select the **Packet Capture** check box.
   - **Anti-Spyware**—Select a custom Anti-Spyware profile, click the **DNS Signatures** tab and in the **Packet Capture** drop-down, select **single-packet** or **extended-capture**.
   - **Vulnerability Protection**—Select a custom Vulnerability Protection profile and in the **Rules** tab, click **Add** to add a new rule, or select an existing rule. Set **Packet Capture** to **single-packet** or **extended-capture**. Note that if the profile has signature exceptions defined, click the **Exceptions** tab and in the **Packet Capture** column for a signature, set **single-packet** or **extended-capture**.
2. (Optional) If you selected **extended-capture** for any of the profiles, define the extended packet capture length.
   a. Select **Device > Setup > Content-ID** and edit the Content-ID Settings.
   b. In the **Extended Packet Capture Length (packets)** section, specify the number of packets that the firewall will capture (range is 1-50; default is 5).
   c. Click **OK**.

| Take a Threat Packet Capture (Continued) | | |
|---|---|---|
| Step 2 | Add the security profile (with packet capture enabled) to a Security Policy rule. | 1. Select **Policies > Security** and select a rule.<br>2. Select the **Actions** tab.<br>3. In the Profile Settings section, select a profile that has packet capture enabled.<br>For example, click the **Antivirus** drop-down and select a profile that has packet capture enabled. |

Step 3 View/export the packet capture from the Threat logs.

1. Select **Monitor > Logs > Threat**.
2. In the log entry that you are interested in, click the green packet capture icon in the second column. View the packet capture directly or **Export** it to your system.



## Take an Application Packet Capture

The following topics describe two ways that you can configure the firewall to take application packet captures:

- Take a Packet Capture for Unknown Applications
- Take a Custom Application Packet Capture

### Take a Packet Capture for Unknown Applications

Palo Alto Networks firewalls automatically generate a packet capture for sessions that contain an application that it cannot identify. Typically, the only applications that are classified as unknown traffic—tcp, udp or non-syn-tcp—are commercially available applications that do not yet have App-ID signatures, are internal or custom applications on your network, or potential threats. You can use these packet captures to gather more context related to the unknown application or use the information to analyze the traffic for potential threats. You can also Manage Custom or Unknown Applications by controlling them through security policy or by

 © Palo Alto Networks, Inc.

writing a custom application signature and creating a security rule based on the custom signature. If the application is a commercial application, you can submit the packet capture to Palo Alto Networks to have an App-ID signature created.

### Identify Unknown Applications in Traffic Logs and View Packet Captures

Step 1 Verify that unknown application packet capture is enabled. This option is on by default.

1. To view the unknown application capture setting, run the following CLI command:

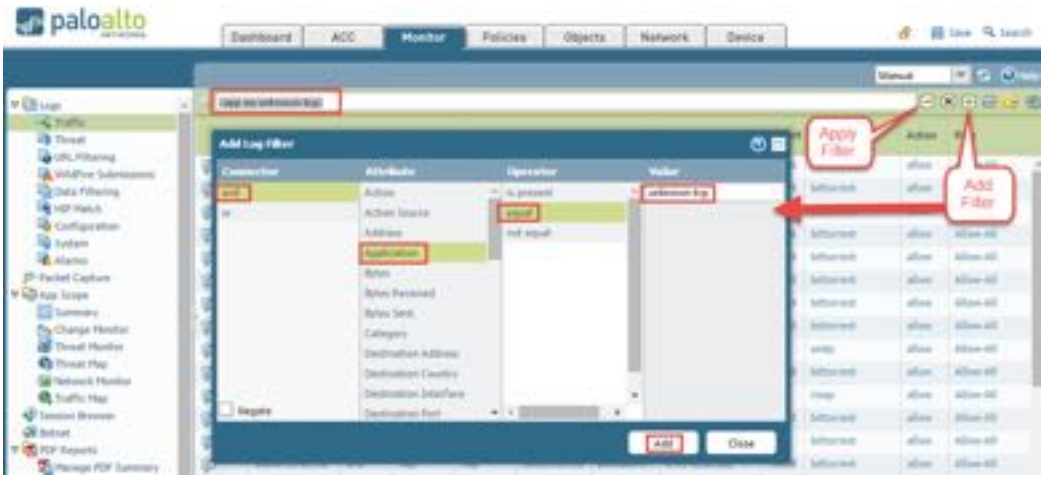
   ```
   admin@PA-200> show running application setting | match "Unknown capture"
   ```

2. If the unknown capture setting option is off, enable it:

   ```
   admin@PA-200> set application dump-unknown yes
   ```

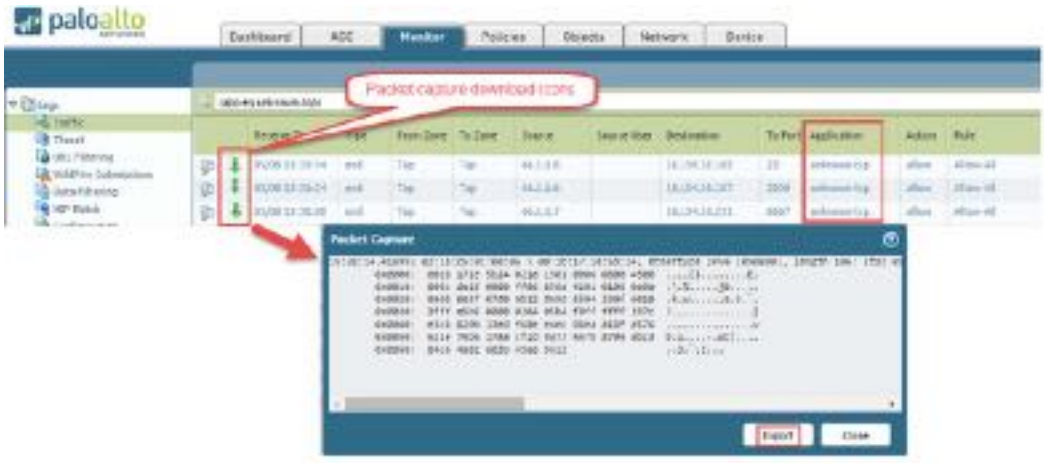
Step 2 Locate unknown application by filtering the traffic logs.

1. Select **Monitor > Logs > Traffic**.
2. Click **Add Filter** and select the filters as shown in the following example.



3. Click **Add** and **Apply Filter**.

Step 3 Click the packet capture icon to view the packet capture or **Export** it to your local system.



## Take a Custom Application Packet Capture

You can configure a Palo Alto Networks firewall to take a packet capture based on an application name and filters that you define. You can then use the packet capture to troubleshoot issues with controlling an application. When configuring an application packet capture, you must use the application name defined in the App-ID database. You can view a list of all App-ID applications using Applipedia or from the web interface on the firewall in **Objects > Applications**.

| Take a Custom Application Packet Capture | |
|---|---|
| Step 1 | Using a terminal emulation application, such as PuTTY, launch an SSH session to the firewall. |
| Step 2 | Turn on the application packet capture and define filters.<br>`admin@PA-200> set application dump on application <application-name> rule <rule-name>`<br>For example, to capture packets for the facebook-base application that matches the security rule named rule1, run the following CLI command:<br>`admin@PA-200> set application dump on application facebook-base rule rule1`<br> You can also apply other filters, such as source IP address and destination IP address. |

 © Palo Alto Networks, Inc.

**Take a Custom Application Packet Capture (Continued)**

Step 3 View the output of the packet capture settings to ensure that the correct filters are applied. The output appears after enabling the packet capture.

In the following output, you see that application filtering is now on based on the facebook-base application for traffic that matches rule1.

```
Application setting:
Application cache             : yes
Supernode                     : yes
Heuristics                    : yes
Cache Threshold               : 16
Bypass when exceeds queue limit: no
Traceroute appid              : yes
Traceroute TTL threshold      : 30
Use cache for appid           : no
Unknown capture               : on
Max. unknown sessions         : 5000
Current unknown sessions      : 0
Application capture           : on
Max. application sessions     : 5000
Current application sessions  : 0
Application filter setting:
    Rule                      : rule1
    From                      : any
    To                        : any
    Source                    : any
    Destination               : any
    Protocol                  : any
    Source Port               : any
    Dest. Port                : any
    Application               : facebook-base
Current APPID Signature
   Signature Usage            : 21  MB (Max. 32  MB)
      TCP 1 C2S               : 15503  states
      TCP 1 S2C               : 5070   states
      TCP 2 C2S               : 2426   states
      TCP 2 S2C               : 702    states
      UDP 1 C2S               : 11379  states
      UDP 1 S2C               : 2967   states
      UDP 2 C2S               : 755    states
      UDP 2 S2C               : 224    states
```

Step 4 To turn off application packet capture after the traffic you are interested in has traversed the firewall:

```
admin@PA-200> set application dump off
```

**Take a Custom Application Packet Capture (Continued)**

Step 5 View/export the packet capture.

1. Log in to the web interface on the firewall and select **Monitor > Logs > Traffic**.
2. In the log entry that you are interested in, click the green packet capture icon in the second column.

3. View the packet capture directly or **Export** it to your local system. The following screen capture shows the facebook-base packet capture.

## Take a Packet Capture on the Management Interface

The `tcpdump` CLI command enables you to capture packets that traverse the management interface (MGT) on a Palo Alto Networks firewall.

Each platform has a default number of bytes that `tcpdump` captures. The PA-200, PA-500, and PA-2000 Series firewalls capture 68 bytes of data from each packet and anything over that is truncated. The PA-3000, PA-4000, PA-5000 Series, the PA-7000 Series firewalls, and VM-Series firewalls capture 96 bytes of data from each packet. To define the number of packets that `tcpdump` will capture, use the `snaplen` (snap length) option (range 0-65535). Setting the `snaplen` to 0 will cause the firewall to use the maximum length required to capture whole packets.

**Take a Management Interface Packet Capture**

Step 1 Using a terminal emulation application, such as PuTTY, launch an SSH session to the firewall.

 © Palo Alto Networks, Inc.

**Take a Management Interface Packet Capture (Continued)**

Step 2 To start a packet capture on the MGT interface, run the following command:

```
admin@PA-200> tcpdump filter "<filter-option> <IP-address>" snaplen length
```

For example, to capture the traffic that is generated when and administrator authenticates to the firewall using RADIUS, filter on the destination IP address of the RADIUS server (10.5.104.99 in this example):

```
admin@PA-200> tcpdump filter "dst 10.5.104.99" snaplen 0
```

You can also filter on src (source IP address), host, net, and you can exclude content. For example, to filter on a subnet and exclude all SCP, SFTP, and SSH traffic (which uses port 22), run the following command:

```
admin@PA-200> tcpdump filter "net 10.5.104.0/24 and not port 22" snaplen 0
```

Each time `tcpdump` takes a packet capture, it stores the content in a file named mgmt.pcap. This file is overwritten each time you run `tcpdump`.

Step 3 After the traffic you are interested in has traversed the MGT interface, press `Ctrl` + `C` to stop the capture.

Step 4 View the packet capture by running the following command:

```
admin@PA-200> view-pcap mgmt-pcap mgmt.pcap
```

The following output shows the packet capture from the MGT port (10.5.104.98) to the RADIUS server (10.5.104.99):

```
09:55:29.139394 IP 10.5.104.98.43063 > 10.5.104.99.radius: RADIUS, Access Request (1), id: 0x00 length: 89
09:55:29.144354 arp reply 10.5.104.98 is-at 00:25:90:23:94:98 (oui Unknown)
09:55:29.379290 IP 10.5.104.98.43063 > 10.5.104.99.radius: RADIUS, Access Request (1), id: 0x00 length: 70
09:55:34.379262 arp who-has 10.5.104.99 tell 10.5.104.98
```

Step 5 (Optional) Export the packet capture from the firewall using SCP (or TFTP). For example, to export the packet capture using SCP, run the following command:

```
admin@PA-200> scp export mgmt-pcap from mgmt.pcap to username@host:path
```

For example, to export the pcap to an SCP enabled server at 10.5.5.20 to a temp folder named temp-SCP, run the following CLI command:

```
admin@PA-200> scp export mgmt-pcap from mgmt.pcap to admin@10.5.5.20:c:/temp-SCP
```

Enter the login name and password for the account on the SCP server and the firewall will copy the packet capture to the SCP enabled server to c:\temp-SCP.

Step 6 You can now view the packet capture files using a network packet analyzer, such as Wireshark.

# Monitor Applications and Threats

All Palo Alto Networks next-generation firewalls come equipped with the App-ID technology, which identifies the applications traversing your network, irrespective of protocol, encryption, or evasive tactic. You can then Use the Application Command Center to monitor the applications. The ACC graphically summarizes the data from a variety of log databases to highlight the applications traversing your network, who is using them, and their potential security impact. ACC is dynamically updated, using the continuous traffic classification that App-ID performs; if an application changes ports or behavior, App-ID continues to see the traffic, displaying the results in ACC. Additional visibility into URL categories, threats, and data provides a complete and well-rounded picture of network activity. With ACC, you can very quickly learn more about the traffic traversing the network and then translate that information into a more informed security policy

You can also Use the Dashboard to monitor the network.

 © Palo Alto Networks, Inc.

# Monitor and Manage Logs

All Palo Alto Networks next-generation firewalls can generate log files that provide an audit trail of the activities and events on the firewall. There are separate logs for separate types of activities and events. For example, the Threat logs record all traffic that causes the firewall to generate a security alarm, URL Filtering logs record all traffic that matches a URL Filtering profile attached to a security rule, and Config logs record all changes to the firewall configuration. The firewall uses log data to generate reports (**Monitor > Reports**), which display the data in a tabular or graphical format. See Manage Reporting for details.

The following topics describe how to view logs locally on the firewall. You can also Use External Services for Monitoring logs.

- View the Log Files
- Filter Log Data
- Configure Log Storage Quotas and Expiration Periods
- Log Severity Levels and WildFire Verdicts
- Schedule Log Exports to an SCP or FTP Server

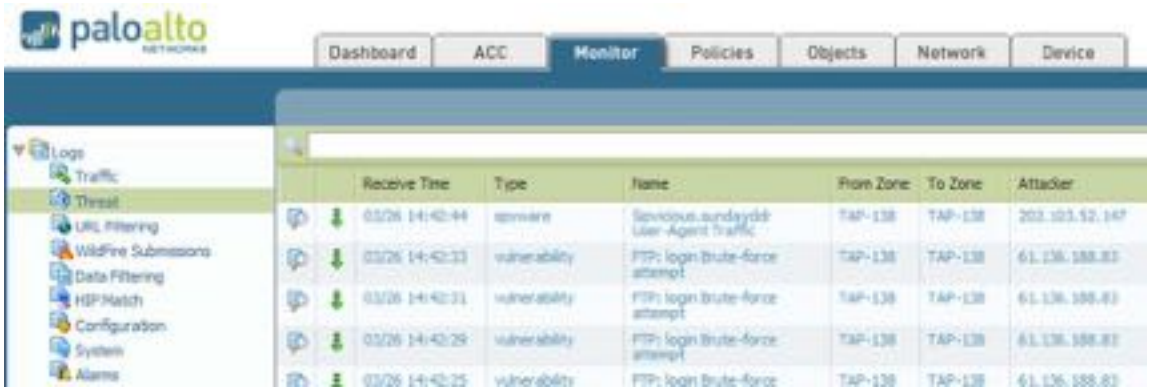
© Palo Alto Networks, Inc.

## View the Log Files

The firewall maintains logs for WildFire, configurations, system events, alarms, traffic flows, threats, URL filtering, data filtering, and Host Information Profile (HIP) matches. You can view the current logs at any time. To locate specific entries, you can apply filters to most of the log fields.

The firewall displays the information in logs so that role-based administration permissions are respected. When you display logs, only the information that you have permission to see is included. For information on administrator permissions, see Administrative Roles.

By default all log files are generated and stored locally on the firewall. You can view these log files in the **Monitor > Logs** pages:



To display additional details, click the spyglass icon for an entry.

 © Palo Alto Networks, Inc.

The following table includes information on each log type:

| Log Description Charts | Description |
|---|---|
| Traffic | Displays an entry for the start and end of each session. Each entry includes the date and time, source and destination zones, addresses and ports, application name, security rule name applied to the flow, rule action (**allow**, **deny**, or **drop**), ingress and egress interface, number of bytes, and session end reason.<br>Click next to an entry to view additional details about the session, such as whether an ICMP entry aggregates multiple sessions between the same source and destination (the **Count** value will be greater than one).<br>The **Type** column indicates whether the entry is for the start or end of the session, or whether the session was denied or dropped. A **drop** indicates that the security rule that blocked the traffic specified **any** application, while a **deny** indicates the rule identified a specific application.<br>If traffic is dropped before the application is identified, such as when a rule drops all traffic for a specific service, the application is shown as **not-applicable**. |
| Threat | Displays an entry when traffic matches a Security Profile (Antivirus, Anti-Spyware, Vulnerability, URL Filtering, File Blocking, Data Filtering, or DoS Protection) that is attached to a security rule on the firewall. Each entry includes the date and time, a threat name or URL, the source and destination zones, addresses, and ports, the application name, and the alarm action (**allow** or **block**) and severity.<br>Click next to an entry to view additional details about the threat, such as whether the entry aggregates multiple threats of the same type between the same source and destination (the **Count** value will be greater than one).<br>The **Type** column indicates the type of threat, such as "virus" or "spyware." The Name column is the threat description or URL, and the **Category** column is the threat category (such as "keylogger") or URL category.<br>If local packet captures are enabled, click next to an entry to access the captured packets. To enable local packet captures, see Take Packet Captures.<br>For details on threat severity levels, see Log Severity Levels and WildFire Verdicts. |
| URL Filtering | Displays logs for all traffic that matches a URL Filtering profile attached to a security rule. For example, if rule blocks access to specific web sites and web site categories or if rule is configured to generate an alert when a web site is accessed. For information on defining URL filtering profiles, see URL Filtering. |
| WildFire Submissions | Displays logs for files that are uploaded and analyzed by the WildFire cloud; log data is sent back to the device after analysis, along with the analysis results.<br>For details on WildFire verdicts (benign or malicious), see Log Severity Levels and WildFire Verdicts. |

| Log Description Charts | Description |
|---|---|
| Data Filtering | Displays logs for the security rules that help prevent sensitive information such as credit card or social security numbers from leaving the area protected by the firewall. See Set Up Data Filtering for information on defining data filtering profiles.<br>This log also shows information for file-blocking profiles. For example, if you are blocking .exe files, the log will show the files that were blocked. If you forward files to WildFire, you will see the results of that action. In this case, if you are forwarding PE files to WildFire, for example, the log will show that the file was forwarded and will also show the status on whether or not it was uploaded to WildFire successfully. |
| Configuration | Displays an entry for each configuration change. Each entry includes the date and time, the administrator username, the IP address from where the change was made, the type of client (XML, Web or CLI), the type of command executed, whether the command succeeded or failed, the configuration path, and the values before and after the change. |
| System | Displays an entry for each system event. Each entry includes the date and time, the event severity, and an event description.<br>For details on System log severity levels, see Log Severity Levels and WildFire Verdicts. |
| HIP Match | Displays traffic flows that match a HIP Object or HIP Profile that you have configured. |

 © Palo Alto Networks, Inc.

## Filter Log Data

Each log page has a filter area at the top of the page.

Use the filter area as follows:

- Click any of the underlined links in the log listing to add that item as a log filter option. For example, if you click the **Host** link in the log entry for 10.0.0.252 and **Web Browsing**, both items are added, and the search will find entries that match both (AND search).
- To define other search criteria, click **Add Log Filter**. Select the type of search (and/or), the attribute to include in the search, the matching operator, and the values for the match, if appropriate. Click **Add** to add the criterion to the filter area on the log page, and then click **Close** to close the pop-up window. Click **Apply Filter** to display the filtered list.

If the **Value** string matches an **Operator** (such as **has** or **in**), enclose the string in quotation marks to avoid a syntax error. For example, if you filter by destination country and use `IN` as a **Value** to specify INDIA, enter the filter as `( dstloc eq "IN" )`.

You can combine filter expressions added on the log page with those you define in the Add Log Filter dialog. The filter field on the log page displays each filter as an entry.

If you add a **Receive Time** filter with the **Operator** set to **in** and the **Value** set to **Last 60 seconds**, some of the page links on the log viewer might not show results because the number of pages might grow or shrink due to the dynamic nature of the selected time.

- To clear filters and redisplay the unfiltered list, click **Clear Filter**.
- To save your selections as a new filter, click **Save Filter**, enter a name for the filter, and click **OK**.
- To export the current log listing (as shown on the page, including any applied filters) click **Save Filter**. Select whether to open the file or save it to disk, and select the check box if you want to always use the same option. Click **OK**.
- To export the current log listing in CSV Format, select the **Export to CSV** icon. By default, exporting the log listing to CSV format generates a CSV report with up to 2,000 rows of logs. To change the limit for rows displayed in CSV reports, use the **Max Rows in CSV Export** field on the **Log Export and Reporting** tab (select **Device > Setup > Management > Logging and Reporting Settings**).

To change the automatic refresh interval, select an interval from the drop-down (**1 min**, **30 seconds**, **10 seconds**, or **Manual**).

To change the number of log entries per page, select the number of rows from the **Rows** drop-down.

Log entries are retrieved in blocks of 10 pages. Use the paging controls at the bottom of the page to navigate through the log list. Select the **Resolve Hostname** check box to begin resolving external IP addresses to domain names.

© Palo Alto Networks, Inc.

## Configure Log Storage Quotas and Expiration Periods

The firewall automatically deletes logs that exceed the expiration period. When the firewall reaches the storage quota for a log type, it automatically deletes older logs of that type to create space even if you don't set an expiration period.

If you want to manually delete logs, select **Device > Log Settings** and, in the Manage Logs section, click the links to clear logs by type.

| Configure Log Storage Quotas and Expiration Periods | |
|---|---|
| Step 1 | Select **Device > Setup > Management** and edit the Logging and Reporting Settings. |
| Step 2 | In the **Log Storage** tab, select the **Log Storage** check box and enter the **Quota (%)** for each log type. When you change a percentage value, the dialog refreshes to display the corresponding absolute value (Quota GB/MB column). |
| Step 3 | Enter the **Max Days** (expiration period) for each log type (range is 1-2,000). The fields are blank by default, which means the logs never expire.<br> The firewall synchronizes expiration periods across high availability (HA) pairs. Because only the active HA peer generates logs, the passive peer has no logs to delete unless failover occurs and it starts generating logs. |
| Step 4 | Click **OK** and **Commit**. |

 © Palo Alto Networks, Inc.

## Log Severity Levels and WildFire Verdicts

The following table summarizes the Threat severity levels:

| Severity | Description |
|---|---|
| **Critical** | Serious threats, such as those that affect default installations of widely deployed software, result in root compromise of servers, and the exploit code is widely available to attackers. The attacker usually does not need any special authentication credentials or knowledge about the individual victims and the target does not need to be manipulated into performing any special functions. |
| **High** | Threats that have the ability to become critical but have mitigating factors; for example, they may be difficult to exploit, do not result in elevated privileges, or do not have a large victim pool. |
| **Medium** | Minor threats in which impact is minimized, such as DoS attacks that do not compromise the target or exploits that require an attacker to reside on the same LAN as the victim, affect only non-standard configurations or obscure applications, or provide very limited access. In addition, WildFire Submissions log entries with a malware verdict are logged as Medium. |
| **Low** | Warning-level threats that have very little impact on an organization's infrastructure. They usually require local or physical system access and may often result in victim privacy or DoS issues and information leakage. Data Filtering profile matches are logged as Low. |
| **Informational** | Suspicious events that do not pose an immediate threat, but that are reported to call attention to deeper problems that could possibly exist. URL Filtering log entries and WildFire Submissions log entries with a benign verdict are logged as Informational. |

The following table summarizes the System log severity levels. For a partial list of System log messages and their corresponding severity levels, refer to System Log Events.

| Severity | Description |
|---|---|
| **Critical** | Hardware failures, including HA failover and link failures. |
| **High** | Serious issues, including dropped connections with external devices, such as LDAP and RADIUS servers. |
| **Medium** | Mid-level notifications, such as antivirus package upgrades. |
| **Low** | Minor severity notifications, such as user password changes. |
| **Informational** | Log in/log off, administrator name or password change, any configuration change, and all other events not covered by the other severity levels. |

The following table summarizes the Correlation log severity levels:

| Severity | Description |
|---|---|
| **Critical** | Confirms that a host has been compromised based on correlated events that indicate an escalation pattern. For example, a critical event is logged when a host that received a file with a malicious verdict by WildFire, exhibits the same command-and control activity that was observed in the WildFire sandbox for that malicious file. |

| Severity | Description |
|---|---|
| **High** | Indicates that a host is very likely compromised based on a correlation between multiple threat events, such as malware detected anywhere on the network that matches the command and control activity being generated from a particular host. |
| **Medium** | Indicates that a host is likely compromised based on the detection of one or multiple suspicious events, such as repeated visits to known malicious URLs that suggests a scripted command-and-control activity. |
| **Low** | Indicates that a host is possibly compromised based on the detection of one or multiple suspicious events, such as a visit to a malicious URL or a dynamic DNS domain. |
| **Informational** | Detects an event that may be useful in aggregate for identifying suspicious activity; each event is not necessarily significant on its own. |

The following table summarizes the WildFire verdicts:

| Severity | Description |
|---|---|
| **Benign** | Indicates that the entry received a WildFire analysis verdict of benign. Files categorized as benign are safe and do not exhibit malicious behavior. |
| **Grayware** | Indicates that the entry received a WildFire analysis verdict of grayware. Files categorized as grayware do not pose a direct security threat, but might display otherwise obtrusive behavior. Grayware can include, adware, spyware, and Browser Helper Objects (BHOs). |
| **Malware** | Indicates that the entry received a WildFire analysis verdict of malware. Files categorized as malware are malicious in intent or nature and can pose a security threat. Malware can include viruses, worms, Trojans, Remote Access Tools (RATs), rootkits, and botnets. For files that are identified as malware, a signature is generated and distributed by the WildFire cloud to prevent against future exposure. |

 © Palo Alto Networks, Inc.

# Schedule Log Exports to an SCP or FTP Server

You can schedule exports of Traffic, Threat, URL Filtering, Data Filtering, HIP Match, and WildFire Submission logs to a Secure Copy (SCP) server or File Transfer Protocol (FTP) server. Perform this task for each log type you want to export.

You can use Secure Copy (SCP) commands from the CLI to export the entire log database to an SCP server and import it to another firewall. Because the log database is too large for an export or import to be practical on the following platforms, they do not support these options: PA-7000 Series firewalls (all PAN-OS releases), Panorama virtual appliance running Panorama 6.0 or later releases, and Panorama M-Series appliances (all Panorama releases).

| Schedule Log Exports to an SCP or FTP Server | |
|---|---|
| Step 1 | Select **Device > Scheduled Log Export** and click **Add**. |
| Step 2 | Enter a **Name** for the scheduled log export and **Enable** it. |
| Step 3 | Select the **Log Type** to export. |
| Step 4 | Select the daily **Scheduled Export Start Time**. The options are in 15-minute increments for a 24-hour clock (00:00 - 23:59). |
| Step 5 | Select the **Protocol** to export the logs: **SCP** (secure) or **FTP**. |
| Step 6 | Enter the **Hostname** or IP address of the server. |
| Step 7 | Enter the **Port** number. By default, FTP uses port 21 and SCP uses port 22. |
| Step 8 | Enter the **Path** or directory in which to save the exported logs. |
| Step 9 | Enter the **Username** and, if necessary, the **Password** (and **Confirm Password**) to access the server. |
| Step 10 | (FTP only) Select the **Enable FTP Passive Mode** check box if you want to use FTP passive mode, in which the firewall initiates a data connection with the FTP server. By default, the firewall uses FTP active mode, in which the FTP server initiates a data connection with the firewall. Choose the mode based on what your FTP server supports and on your network requirements. |
| Step 11 | (SCP only) Click **Test SCP server connection**. The connection is not established until the firewall accepts the host key for the SCP server. |
| Step 12 | Click **OK** and **Commit**. |

# Manage Reporting

The reporting capabilities on the firewall allow you to keep a pulse on your network, validate your policies, and focus your efforts on maintaining network security for keeping your users safe and productive.

- Report Types
- View Reports
- Configure the Report Expiration Period
- Disable Predefined Reports
- Generate Custom Reports
- Generate Botnet Reports
- Manage PDF Summary Reports
- Generate User/Group Activity Reports
- Manage Report Groups
- Schedule Reports for Email Delivery

 © Palo Alto Networks, Inc.

## Report Types

The firewall includes predefined reports that you can use as-is, or you can build custom reports that meet your needs for specific data and actionable tasks, or you can combine predefined and custom reports to compile information you need. The firewall provides the following types of reports:

- **Predefined Reports—**Allow you to view a quick summary of the traffic on your network. A suite of predefined reports are available in four categories—Applications, Traffic, Threat, and URL Filtering. See View Reports.
- **User or Group Activity Reports—**Allow you to schedule or create an on-demand report on the application use and URL activity for a specific user or for a user group. The report includes the URL categories and an estimated browse time calculation for individual users. See Generate User/Group Activity Reports.
- **Custom Reports**—Create and schedule custom reports that show exactly the information you want to see by filtering on conditions and columns to include. You can also include query builders for more specific drill down on report data. See Generate Custom Reports.
- **PDF Summary Reports**—Aggregate up to 18 predefined or custom reports/graphs from Threat, Application, Trend, Traffic, and URL Filtering categories into one PDF document. See Manage PDF Summary Reports.
- **Botnet Reports**—Allow you to use behavior-based mechanisms to identify potential botnet-infected hosts in the network. See Generate Botnet Reports.
- **Report Groups**—Combine custom and predefined reports into report groups and compile a single PDF that is emailed to one or more recipients. See Manage Report Groups.

Reports can be generated on demand, on a recurring schedule, and can be scheduled for email delivery.

# View Reports

The firewall provides an assortment of over 40 predefined reports that it generates every day. You can view these reports directly on the firewall. You can also view custom reports and summary reports.

About 200 MB of storage is allocated for saving reports on the firewall. You can't configure this limit but you can Configure the Report Expiration Period: the firewall will automatically delete reports that exceed the period. Keep in mind that when the firewall reaches its storage limit, it automatically deletes older reports to create space even if you don't set an expiration period. Another way to conserve system resources on the firewall is to Disable Predefined Reports. For long-term retention of reports, you can export the reports (as described below) or Schedule Reports for Email Delivery.

Unlike other reports, you can't save User/Group Activity reports on the firewall. You must Generate User/Group Activity Reports on demand or schedule them for email delivery.

**View Reports**

Step 1 Select **Monitor > Reports**.

The reports are chunked into sections on the right-hand side of the window: **Custom Reports**, **Application Reports**, **Traffic Reports**, **Threat Reports**, **URL Filtering Reports**, and **PDF Summary Reports**.

Step 2 Select a report to view. When you select a report, the previous day's report is displayed onscreen.

To view reports for any of the previous days, select an available date from the calendar at the bottom of the page and select a report within the same section. If you change sections, the time selection is reset.

Step 3 To view a report offline, you can export the report to PDF, CSV or to XML formats. Click **Export to PDF**, **Export to CSV**, or **Export to XML** at the bottom of the page. Then print or save the file.

 © Palo Alto Networks, Inc.

## Configure the Report Expiration Period

When you set the **Report Expiration Period**, it applies to all Report Types. The firewall automatically deletes reports that exceed the period.

| Configure Report Expiration Periods | |
|---|---|
| Step 1 | Select **Device > Setup > Management**, edit the Logging and Reporting Settings, and select the **Log Export and Reporting** tab. |
| Step 2 | Enter the **Report Expiration Period** in days (range is 1-2000, default is no expiration).<br> You can't change the storage that the firewall allocates for saving reports: it is predefined at about 200 MB. When the firewall reaches the storage maximum, it automatically deletes older reports to create space even if you don't set a **Report Expiration Period**. |
| Step 3 | Click **OK** and **Commit**. |

# Disable Predefined Reports

The firewall includes about 40 predefined reports that it automatically generates daily. If you do not use some or all of these, you can disable selected reports to conserve system resources on the firewall.

Make sure that no report group or PDF summary report includes the predefined reports you will disable. Otherwise, the firewall will render the PDF summary report or report group without any data.

**Disable Predefined Reports**

Step 1 Select **Device > Setup > Management** and edit the Logging and Reporting Settings.

Step 2 Select the **Pre-Defined Reports** tab and clear the check box for each report you want to disable. To disable all predefined reports, click **Deselect All**.

Step 3 Click **OK** and **Commit**.

 © Palo Alto Networks, Inc.

## Generate Custom Reports

In order to create purposeful custom reports, you must consider the attributes or key pieces of information that you want to retrieve and analyze. This consideration guides you in making the following selections in a custom report:

| Selection | Description |
|---|---|
| Data Source | The data file that is used to generate the report. The firewall offers two types of data sources—Summary databases and Detailed logs.<br>• Summary databases are available for traffic, threat, and application statistics. The firewall aggregates the detailed logs on traffic, application, and threat at 15-minute intervals. The data is condensed—duplicate sessions are grouped together and incremented with a repeat counter, and some attributes (or columns) are not included in the summary—to allow faster response time when generating reports.<br>• Detailed logs are itemized and are a complete listing of all the attributes (or columns) that pertain to the log entry. Reports based on detailed logs take much longer to run and are not recommended unless absolutely necessary. |
| Attributes | The columns that you want to use as the match criteria. The attributes are the columns that are available for selection in a report. From the list of **Available Columns**, you can add the selection criteria for matching data and for aggregating the details (the **Selected Columns**). |
| Sort By/ Group By | The **Sort By** and the **Group By** criteria allow you to organize/segment the data in the report; the sorting and grouping attributes available vary based on the selected data source.<br>The Sort By option specifies the attribute that is used for aggregation. If you do not select an attribute to sort by, the report will return the first N number of results without any aggregation.<br>The Group By option allows you to select an attribute and use it as an anchor for grouping data; all the data in the report is then presented in a set of top 5, 10, 25 or 50 groups. For example, when you select Hour as the Group By selection and want the top 25 groups for a 24-hr time period, the results of the report will be generated on an hourly basis over a 24-hr period. The first column in the report will be the hour and the next set of columns will be the rest of your selected report columns. |

| Selection | Description |
|---|---|
| | The following example illustrates how the **Selected Columns** and **Sort By**/**Group By** criteria work together when generating reports:<br>  <br>The columns circled in red (above) depict the columns selected, which are the attributes that you match against for generating the report. Each log entry from the data source is parsed and these columns are matched on. If multiple sessions have the same values for the selected columns, the sessions are aggregated and the repeat count (or sessions) is incremented.<br>The column circled in blue indicates the chosen sort order. When the sort order (**Sort By**) is specified, the data is sorted (and aggregated) by the selected attribute.<br>The column circled in green indicates the **Group By** selection, which serves as an anchor for the report. The **Group By** column is used as a match criteria to filter for the top N groups. Then, for each of the top N groups, the report enumerates the values for all the other selected columns. |

 © Palo Alto Networks, Inc.

| Selection | Description |
|---|---|
| | For example, if a report has the following selections<br>  <br>The output will display as follows:<br> <br>The report is anchored by **Day** and sorted by **Sessions**. It lists the 5 days (**5 Groups**) with maximum traffic in the **Last 7 Days** time frame. The data is enumerated by the **Top 5** sessions for each day for the selected columns—**App Category**, **App Subcategory** and **Risk**. |
| Time Period | The date range for which you want to analyze data. You can define a custom range or select a time period ranging from last 15 minutes to the last 30 days. The reports can be run on demand or scheduled to run at a daily or weekly cadence. |
| Query Builder | The query builder allows you to define specific queries to further refine the selected attributes. It allows you see just what you want in your report using **and** and **or** operators and a match criteria, and then include or exclude data that matches or negates the query in the report. Queries enable you to generate a more focused collation of information in a report. |

| Generate Custom Reports | |
|---|---|
| Step 1 | Select **Monitor > Manage Custom Reports**. |
| Step 2 | Click **Add** and then enter a **Name** for the report.<br>To base a report on an predefined template, click **Load Template** and choose the template. You can then edit the template and save it as a custom report. |

**Generate Custom Reports**

Step 3 Select the **Database** to use for the report.

Each time you create a custom report, a **Log View** report is automatically created. This report show the logs that were used to build the custom report. The log view report uses the same name as the custom report, but appends the phrase (Log View) to the report name.

When creating a report group, you can include the log view report with the custom report. For more information, see Manage Report Groups.

Step 4 Select the **Scheduled** check box to run the report each night. The report is then available for viewing in the **Reports** column on the side.

Step 5 Define the filtering criteria. Select the **Time Frame**, the **Sort By** order, **Group By** preference, and select the columns that must display in the report.

Step 6 (Optional) Select the **Query Builder** attributes if you want to further refine the selection criteria. To build a report query, specify the following and click **Add**. Repeat as needed to construct the full query.

- **Connector**—Choose the connector (and/or) to precede the expression you are adding.
- **Negate**—Select the check box to interpret the query as a negation. If, for example, you choose to match entries in the last 24 hours and/or are originating from the untrust zone, the negate option causes a match on entries that are not in the past 24 hours and/or are not from the untrust zone.
- **Attribute**—Choose a data element. The available options depend on the choice of database.
- **Operator**—Choose the criterion to determine whether the attribute applies (such as =). The available options depend on the choice of database.
- **Value**—Specify the attribute value to match.

For example, the following figure (based on the Traffic Log database) shows a query that matches if the traffic log entry was received in the past 24 hours and is from the "untrust" zone.

Step 7 To test the report settings, select **Run Now**. Modify the settings as required to change the information that is displayed in the report.

Step 8 Click **OK** to save the custom report.

 © Palo Alto Networks, Inc.

## Generate Custom Reports

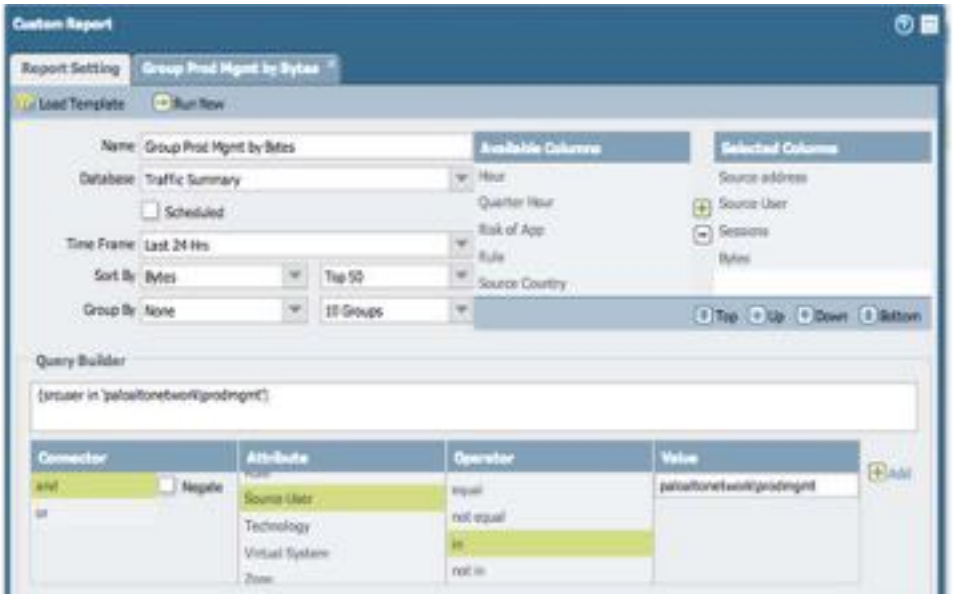
### Examples of Custom Reports

If you want to set up a simple report in which you use the traffic summary database from the last 30 days, and sort the data by the top 10 sessions and these sessions are grouped into 5 groups by day of the week. You would set up the custom report to look like this:

And the PDF output for the report would look as follows:

## Generate Custom Reports

Now, if you want to use the query builder to generate a custom report that represents the top consumers of network resources within a user group, you would set up the report to look like this:



The report would display the top users in the product management user group sorted by bytes, as follows:

 © Palo Alto Networks, Inc.

# Generate Botnet Reports

The botnet report enables you to use heuristic and behavior-based mechanisms to identify potential malware- or botnet-infected hosts in your network. To evaluate botnet activity and infected hosts, the firewall correlates user and network activity data in Threat, URL, and Data Filtering logs with the list of malware URLs in PAN-DB, known dynamic DNS domain providers, and domains registered within the last 30 days. You can configure the report to identify hosts that visited those sites, as well as hosts that communicated with Internet Relay Chat (IRC) servers or that used unknown applications. Malware often use dynamic DNS to avoid IP blacklisting, while IRC servers often use bots for automated functions.

The firewall requires Threat Prevention and URL Filtering licenses to use the botnet report.
You can Use the Automated Correlation Engine to monitor suspicious activities based on additional indicators besides those that the botnet report uses. However, the botnet report is the only tool that uses newly registered domains as an indicator.

- ▲ Configure a Botnet Report
- ▲ Interpret Botnet Report Output

## Configure a Botnet Report

You can schedule a botnet report or run it on demand. The firewall generates scheduled botnet reports every 24 hours because behavior-based detection requires correlating traffic across multiple logs over that timeframe.

| **Configure a Botnet Report** | | |
|---|---|---|
| Step 1 | Define the types of traffic that indicate possible botnet activity. | 1. Select **Monitor > Botnet** and click **Configuration** on the right side of the page.<br>2. **Enable** and define the **Count** for each type of HTTP Traffic that the report will include.<br>The **Count** values represent the minimum number of events of each traffic type that must occur for the report to list the associated host with a higher confidence score (higher likelihood of botnet infection). If the number of events is less than the **Count**, the report will display a lower confidence score or (for certain traffic types) won't display an entry for the host. For example, if you set the **Count** to three for **Malware URL visit**, then hosts that visit three or more known malware URLs will have higher scores than hosts that visit less than three. For details, see Interpret Botnet Report Output.<br>3. Define the thresholds that determine whether the report will include hosts associated with traffic involving Unknown TCP or Unknown UDP applications.<br>4. Select the **IRC** check box to include traffic involving IRC servers.<br>5. Click **OK** to save the report configuration. |

| Configure a Botnet Report (Continued) | |
|---|---|
| Step 2 Schedule the report or run it on demand. | 1. Click **Report Setting** on the right side of the page.<br>2. Select a time interval for the report in the **Test Run Time Frame** drop-down.<br>3. Select the **No. of Rows** to include in the report.<br>4. (Optional) **Add** queries to the Query Builder to filter the report output by attributes such as source/destination IP addresses, users, or zones.<br>For example, if you know in advance that traffic initiated from the IP address 10.3.3.15 contains no potential botnet activity, you can add `not (addr.src in 10.0.1.35)` as a query to exclude that host from the report output. For details, see Interpret Botnet Report Output.<br>5. Select **Scheduled** to run the report daily or click **Run Now** to run the report immediately.<br>6. Click **OK** and **Commit**. |

## Interpret Botnet Report Output

The botnet report displays a line for each host that is associated with traffic you defined as suspicious when configuring the report. For each host, the report displays a confidence score of 1 to 5 to indicate the likelihood of botnet infection, where 5 indicates the highest likelihood. The scores correspond to threat severity levels: 1 is informational, 2 is low, 3 is medium, 4 is high, and 5 is critical. The firewall bases the scores on:

- **Traffic type**—Certain HTTP traffic types are more likely to involve botnet activity. For example, the report assigns a higher confidence to hosts that visit known malware URLs than to hosts that browse to IP domains instead of URLs, assuming you defined both those activities as suspicious.
- **Number of events**—Hosts that are associated with a higher number of suspicious events will have higher confidence scores based on the thresholds (**Count** values) you define when you Configure a Botnet Report.
- **Executable downloads**—The report assigns a higher confidence to hosts that download executable files. Executable files are a part of many infections and, when combined with the other types of suspicious traffic, can help you prioritize your investigations of compromised hosts.

When reviewing the report output, you might find that the sources the firewall uses to evaluate botnet activity (for example, the list of malware URLs in PAN-DB) have gaps. You might also find that these sources identify traffic that you consider safe. To compensate in both cases, you can add query filters when you Configure a Botnet Report.

 © Palo Alto Networks, Inc.

# Manage PDF Summary Reports

PDF summary reports contain information compiled from existing reports, based on data for the top 5 in each category (instead of top 50). They also contain trend charts that are not available in other reports.

| Generate PDF Summary Reports | |
|---|---|
| Step 1 Set up a **PDF Summary Report**. | 1. Select **Monitor > PDF Reports > Manage PDF Summary**.<br>2. Click **Add** and then enter a **Name** for the report.<br>3. Use the drop-down for each report group and select one or more of the elements to design the PDF Summary Report. You can include a maximum of 18 report elements.<br>  <br>• To remove an element from the report, click the **x** icon or clear the selection from the drop-down for the appropriate report group.<br>• To rearrange the reports, drag and drop the icons to another area of the report.<br>4. Click **OK t**o save the report.<br>5. **Commit** the changes. |

| Generate PDF Summary Reports | |
|---|---|
| Step 2 View the report. | To download and view the PDF Summary Report, see View Reports.   |

 © Palo Alto Networks, Inc.

# Generate User/Group Activity Reports

User/Group Activity reports summarize the web activity of individual users or user groups. Both reports include the same information except for the **Browsing Summary by URL Category** and **Browse time calculations**, which only the User Activity report includes.

You must configure User-ID on the firewall to access the list of users and user groups.

| **Generate User/Group Activity Reports** | | |
|---|---|---|
| Step 1 | Configure the browse times and number of logs for User/Group Activity reports.<br><br>Required only if you want to change the default values. | 1. Select **Device > Setup > Management**, edit the Logging and Reporting Settings, and select the **Log Export and Reporting** tab.<br>2. For the **Max Rows in User Activity Report**, enter the maximum number of rows that the detailed user activity report supports (range is 1-1048576, default is 5000). This determines the number of logs that the report analyzes.<br>3. Enter the **Average Browse Time** in seconds that you estimate users should take to browse a web page (range is 0-300, default is 60). Any request made after the average browse time elapses is considered a new browsing activity. The calculation uses Container Pages (logged in the URL Filtering logs) as the basis and ignores any new web pages that are loaded between the time of the first request (start time) and the average browse time. For example, if you set the **Average Browse Time** to two minutes and a user opens a web page and views that page for five minutes, the browse time for that page will still be two minutes. This is done because the firewall can't determine how long a user views a given page. The average browse time calculation ignores sites categorized as web advertisements and content delivery networks.<br>4. For the **Page Load Threshold**, enter the estimated time in seconds for page elements to load on the page (default is 20). Any requests that occur between the first page load and the page load threshold are assumed to be elements of the page. Any requests that occur outside of the page load threshold are assumed to be the user clicking a link within the page.<br>5. Click **OK** to save your changes. |

| Generate User/Group Activity Reports (Continued) | |
|---|---|
| Step 2 Generate the User/Group Activity report. | 1. Select **Monitor > PDF Reports > User Activity Report**.<br>2. Click **Add** and then enter a **Name** for the report.<br>3. Create the report:<br>• User Activity Report—Select **User** and enter the **Username** or **IP address** (IPv4 or IPv6) of the user.<br>• Group Activity Report—Select **Group** and select the **Group Name** of the user group.<br>4. Select the **Time Period** for the report.<br>5. Optionally, select the **Include Detailed Browsing** check box (default is cleared) to include detailed URL logs in the report.<br>The detailed browsing information can include a large volume of logs (thousands of logs) for the selected user or user group and can make the report very large.<br>6. To run the report on demand, click **Run Now**.<br>7. To save the report configuration, click **OK**. You can't save the output of User/Group Activity reports on the firewall. To schedule the report for email delivery, see Schedule Reports for Email Delivery. |

 © Palo Alto Networks, Inc.

# Manage Report Groups

Report groups allow you to create sets of reports that the system can compile and send as a single aggregate PDF report with an optional title page and all the constituent reports included.

| Set up Report Groups | |
|---|---|
| Step 1 Set up report groups.<br><br>You must set up a **Report Group** to email report(s). | 1. Create an Email server profile.<br>2. Define the **Report Group**. A report group can compile predefined reports, PDF Summary reports, custom reports, and Log View report into a single PDF.<br>a. Select **Monitor > Report Group**.<br>b. Click **Add** and then enter a **Name** for the report group.<br>c. (Optional) Select **Title Page** and add a **Title** for the PDF output.<br>d. Select reports from the left column and click **Add** to move each report to the report group on the right.<br><br>  <br><br>The **Log View** report is a report type that is automatically created each time you create a custom report and uses the same name as the custom report. This report will show the logs that were used to build the contents of the custom report.<br><br>To include the log view data, when creating a report group, add your custom report under the **Custom Reports** list and then add the log view report by selecting the matching report name from the **Log View** list. The report will include the custom report data and the log data that was used to create the custom report.<br>e. Click **OK** to save the settings.<br>f. To use the report group, see Schedule Reports for Email Delivery. |

## Schedule Reports for Email Delivery

Reports can be scheduled for daily delivery or delivered weekly on a specified day. Scheduled reports are executed starting at 2:00 AM, and email delivery starts after all scheduled reports have been generated.

| Schedule Reports for Email Delivery | |
|---|---|
| Step 1 | Select **Monitor > PDF Reports > Email Scheduler** and click **Add**. |
| Step 2 | Enter a **Name** to identify the schedule. |
| Step 3 | Select the **Report Group** for email delivery. To set up a report group; see Manage Report Groups. |
| Step 4 | For the **Email Profile**, select an Email Server profile to use for delivering the reports, or click the **Email Profile** link to Create an Email server profile. |
| Step 5 | Select the frequency at which to generate and send the report in **Recurrence**. |
| Step 6 | The **Override Recipient email(s)** allows you to send this report exclusively to the recipients specified in this field. When you add recipients to the field, the report is not sent to the recipients configured in the email server profile. Use this option for those occasions when the report is for the attention of someone other than the administrators or recipients defined in the email server profile.<br>  |

 © Palo Alto Networks, Inc.

# Use External Services for Monitoring

Using an external service to monitor the firewall enables you to receive alerts for important events, archive monitored information on systems with dedicated long-term storage, and integrate with third-party security monitoring tools. The following are some common scenarios for using external services:

- For immediate notification about important system events or threats, you can Monitor Device Statistics Using SNMP, Forward Traps to an SNMP Manager, or Configure Email Alerts.
- For long-term log storage and centralized firewall monitoring, you can Configure Syslog Monitoring to send log data to a syslog server. This enables integration with third-party security monitoring tools such as Splunk! or ArcSight.
- For monitoring statistics on the IP traffic that traverses firewall interfaces, you can Configure NetFlow Exports to view the statistics in a NetFlow collector.

You can Configure Log Forwarding from the firewalls directly to external services or from the firewalls to Panorama and then configure Panorama to forward logs to the servers. Refer to Log Forwarding Options for the factors to consider when deciding where to forward logs.

You can't aggregate NetFlow records on Panorama; you must send them directly from the firewalls to a NetFlow collector.

# Configure Log Forwarding

To use Panorama or Use External Services for Monitoring the firewall, you must configure the firewall to forward its logs. Before forwarding to external services, the firewall automatically converts the logs to the necessary format: syslog messages, SNMP traps, or email notifications. Before starting this procedure, ensure that Panorama or the external server that will receive the log data is already set up.

The PA-7000 Series firewall can't forward logs to Panorama, only to external services. However, when you use Panorama to monitor logs or generate reports for a device group that includes a PA-7000 Series firewall, Panorama queries the PA-7000 Series firewall in real-time to display its log data.

You can forward logs from the firewalls directly to external services or from the firewalls to Panorama and then configure Panorama to forward logs to the servers. Refer to Log Forwarding Options for the factors to consider when deciding where to forward logs.

You can use Secure Copy (SCP) commands from the CLI to export the entire log database to an SCP server and import it to another firewall. Because the log database is too large for an export or import to be practical on the PA-7000 Series firewall, it does not support these options. You can also use the web interface on all platforms to Schedule Log Exports to an SCP or FTP Server, but only on a per log type basis, not the entire log database.

| Configure Log Forwarding | | |
|---|---|---|
| Step 1 | Configure a server profile for each external service that will receive log data.<br><br>You can use separate profiles to send each log type to a different server. To increase availability, define multiple servers in a single profile. | • Create an Email server profile.<br>• Configure an SNMP Trap server profile. To enable the SNMP manager (trap server) to interpret firewall traps, you must load the Palo Alto Networks Supported MIBs into the SNMP manager and, if necessary, compile them. For details, refer to your SNMP management software documentation.<br>• Configure a Syslog server profile. If the syslog server requires client authentication, you must also Create a certificate to secure syslog communication over SSL. |
| Step 2 | Create a log forwarding profile.<br><br>The profile defines the destinations for Traffic, Threat, and WildFire Submission logs. (Threat logs include URL Filtering and Data Filtering logs.) | 1. Select **Objects > Log Forwarding** and click **Add**.<br>2. Enter a **Name** to identify the profile. If you want the firewall to automatically assign the profile to new security rules and zones, enter `default`. If you don't want a default profile, or you want to override an existing default profile, enter a **Name** that will help you identify the profile when assigning it to security rules and zones.<br><br>If no log forwarding profile named `default` exists, the profile selection is set to **None** by default in new security rules (**Log Forwarding** field) and new security zones (**Log Setting** field), although you can change the selection.<br>3. Perform the following steps for each log type and each severity level or WildFire verdict:<br>a. Select the **Panorama** check box if you want to aggregate firewall logs on Panorama. (You can then configure Panorama to forward the logs to external services.)<br>b. Select the **SNMP Trap**, **Email**, or **Syslog** server profile you configured for this log type, and click **OK**. |

© Palo Alto Networks, Inc.

| Configure Log Forwarding (Continued) | | |
|---|---|---|
| Step 3 | Assign the log forwarding profile to security rules.<br><br>To trigger log generation and forwarding, the rules require certain Security Profiles according to log type:<br>• Traffic logs—No security profile is necessary; the traffic only needs to match a specific security rule.<br>• Threat logs—The traffic must match any security profile assigned to a security rule.<br>• WildFire logs—The traffic must match a WildFire Analysis profile assigned to a security rule. | Perform the following steps for each rule that will trigger log forwarding:<br>1. Select **Policies > Security** and click the rule.<br>2. Select the **Actions** tab and select the **Log Forwarding** profile you just created.<br>3. In the **Profile Type** drop-down, select **Profiles** or **Group**, and then select the security profiles or **Group Profile** required to trigger log generation and forwarding.<br>4. For Traffic logs, select one or both of the **Log At Session Start** and **Log At Session End** check boxes, and click **OK**. |
| Step 4 | Configure the destinations of System, Config, HIP Match, and Correlation logs. | 1. Select **Device > Log Settings**.<br>2. Perform the following steps for each log type. For System and Correlation logs, start by clicking the Severity level. For Config and HIP Match logs, start by clicking the Edit icon.<br>a. Select the **Panorama** check box if you want to aggregate firewall logs on Panorama. You can then configure Panorama to forward the logs to the external services.<br>b. Select the **SNMP Trap**, **Email**, or **Syslog** server profile you configured for this log type and click **OK**. |
| Step 5 | (PA-7000 Series firewalls only) Configure a log card interface to perform log forwarding. | 1. Select **Network > Interfaces > Ethernet** and click **Add Interface**.<br>2. Select the **Slot** and **Interface Name**.<br>3. For the **Interface Type**, select **Log Card**.<br>4. Enter the **IP Address**, **Default Gateway**, and (for IPv4 only) **Netmask**.<br>5. Select **Advanced** and specify the **Link Speed**, **Link Duplex**, and **Link State**.<br>These fields default to **auto**, which specifies that the firewall automatically determines the values based on the connection. However, the minimum recommended **Link Speed** for any connection is **1000** (Mbps).<br>6. Click **OK** to save your changes. |

| Configure Log Forwarding (Continued) | |
|---|---|
| Step 6 Commit and verify your changes. | 1. Click **Commit** to complete the log forwarding configuration.<br>2. Verify the log destinations you configured are receiving firewall logs:<br>• Panorama—If the firewall forwards logs to an M-Series appliance, you must configure a Collector Group before Panorama will receive the logs. You can then verify log forwarding.<br>• Email server—Verify that the specified recipients are receiving logs as email notifications.<br>• Syslog server—Refer to the documentation for your syslog server to verify it is receiving logs as syslog messages.<br>• SNMP manager—Use an SNMP Manager to Explore MIBs and Objects to verify it is receiving logs as SNMP traps. |

 © Palo Alto Networks, Inc.

# Configure Email Alerts

You can configure email alerts for System, Config, HIP Match, Correlation, Threat, WildFire Submission, and Traffic logs.

| Configure Email Alerts | | |
|---|---|---|
| Step 1 | Create an Email server profile.<br> <br>You can use separate profiles to send email notifications for each log type to a different server. To increase availability, define multiple servers (up to four) in a single profile. | 1. Select **Device > Server Profiles > Email**.<br>2. Click **Add** and then enter a **Name** for the profile.<br>3. If the firewall has more than one virtual system (vsys), select the **Location** (vsys or **Shared**) where this profile is available.<br>4. For each Simple Mail Transport Protocol (SMTP) server (email server), click **Add** and define the following information:<br>• **Name**—Name to identify the SMTP server (1-31 characters). This field is just a label and doesn't have to be the hostname of an existing email server.<br>• **Email Display Name**—The name to show in the From field of the email.<br>• **From**—The email address from which the Palo Alto Networks device sends emails.<br>• **To**—The email address to which the Palo Alto Networks device sends emails.<br>• **Additional Recipient**—If you want to send emails to a second account, enter the address here. You can add only one additional recipient. For multiple recipients, add the email address of a distribution list.<br>• **Email Gateway**—The IP address or hostname of the SMTP gateway to use for sending emails.<br>5. (Optional) Select the **Custom Log Format** tab and customize the format of the email messages. For details on how to create custom formats for the various log types, refer to the Common Event Format Configuration Guide.<br>6. Click **OK** to save the Email server profile. |
| Step 2 | Configure email alerts for Traffic, Threat, and WildFire Submission logs. | 1. Create a log forwarding profile.<br>a. Select **Objects > Log Forwarding**, click **Add**, and enter a **Name** to identify the profile.<br>b. For each log type and each severity level or WildFire verdict, select the Email server profile and click **OK**.<br>2. Assign the log forwarding profile to security rules. |
| Step 3 | Configure email alerts for System, Config, HIP Match, and Correlation logs. | 1. Select **Device > Log Settings**.<br>2. For System and Correlation logs, click each Severity level, select the **Email** server profile, and click **OK**.<br>3. For Config and HIP Match logs, click the Edit icon, select the **Email** server profile, and click **OK**.<br>4. Click **Commit**. |

# Use Syslog for Monitoring

Syslog is a standard log transport mechanism that enables the aggregation of log data from different network devices—such as routers, firewalls, printers—from different vendors into a central repository for archiving, analysis, and reporting. Palo Alto Networks devices can forward every type of log they generate to an external syslog server. You can use TCP or SSL for reliable and secure log forwarding, or UDP for non-secure forwarding.

- Configure Syslog Monitoring
- Syslog Field Descriptions

## Configure Syslog Monitoring

To Use Syslog for Monitoring a Palo Alto Networks device, create a Syslog server profile and assign it to the device log settings for each log type. Optionally, you can configure the header format used in syslog messages and enable client authentication for syslog over SSL.

| Configure Syslog Monitoring | | |
|---|---|---|
| Step 1 | Configure a Syslog server profile.<br> You can use separate profiles to send syslogs for each log type to a different server. To increase availability, define multiple servers (up to four) in a single profile. | 1. Select **Device > Server Profiles > Syslog**.<br>2. Click **Add** and enter a **Name** for the profile.<br>3. If the firewall has more than one virtual system (vsys), select the **Location** (vsys or **Shared**) where this profile is available.<br>4. For each syslog server, click **Add** and enter the information that the firewall requires to connect to it:<br>• **Name**—Unique name for the server profile.<br>• **Server**—IP address or fully qualified domain name (FQDN) of the syslog server.<br>• **Transport**—Select TCP, UDP, or SSL as the method of communication with the syslog server.<br>• **Port**—The port number on which to send syslog messages (default is UDP on port 514); you must use the same port number on the firewall and the syslog server.<br>• **Format**—Select the syslog message format to use: **BSD** (the default) or **IETF**. Traditionally, **BSD** format is over UDP and **IETF** format is over TCP or SSL.<br>• **Facility**—Select a syslog standard value (default is **LOG_USER**) to calculate the priority (PRI) field in your syslog server implementation. Select the value that maps to how you use the PRI field to manage your syslog messages.<br>5. (Optional) To customize the format of the syslog messages that the firewall sends, select the **Custom Log Format** tab. For details on how to create custom formats for the various log types, refer to the Common Event Format Configuration Guide.<br>6. Click **OK** to save the server profile. |
| Step 2 | Configure syslog forwarding for Traffic, Threat, and WildFire Submission logs. | 1. Create a log forwarding profile.<br>a. Select **Objects > Log Forwarding**, click **Add**, and enter a **Name** to identify the profile.<br>b. For each log type and each severity level or WildFire verdict, select the **Syslog** server profile and click **OK**.<br>2. Assign the log forwarding profile to security rules. |

| Configure Syslog Monitoring (Continued) | | |
|---|---|---|
| Step 3 | Configure syslog forwarding for System, Config, HIP Match, and Correlation logs. | 1. Select **Device > Log Settings**.<br>2. For System and Correlation logs, click each Severity level, select the **Syslog** server profile, and click **OK**.<br>3. For Config, HIP Match, and Correlation logs, click the Edit icon, select the **Syslog** server profile, and click **OK**. |
| Step 4 | (Optional) Configure the header format of syslog messages.<br><br>The log data includes the unique identifier of the device that generated the log. Choosing the header format provides more flexibility in filtering and reporting on the log data for some Security Information and Event Management (SIEM) servers.<br><br>This is a global setting and applies to all syslog server profiles configured on the device. | 1. Select **Device > Setup > Management** and edit the Logging and Reporting Settings.<br>2. Select the **Log Export and Reporting** tab and select the **Syslog HOSTNAME Format**:<br>• **FQDN** (default)—Concatenates the hostname and domain name defined on the sending device.<br>• **hostname**—Uses the hostname defined on the sending device.<br>• **ipv4-address**—Uses the IPv4 address of the device interface used to send logs. By default, this is the MGT interface.<br>• **ipv6-address**—Uses the IPv6 address of the device interface used to send logs. By default, this is the MGT interface.<br>• **none**—Leaves the hostname field unconfigured on the device. There is no identifier for the device that sent the logs.<br>3. Click **OK** to save your changes. |
| Step 5 | Create a certificate to secure syslog communication over SSL.<br><br>Required only if the syslog server uses client authentication. The syslog server uses the certificate to verify that the device is authorized to communicate with the syslog server.<br><br>Ensure the following conditions are met:<br>• The private key must be available on the sending device; the keys can't reside on a Hardware Security Module (HSM).<br>• The subject and the issuer for the certificate must not be identical.<br>• The syslog server and the sending device must have certificates that the same trusted certificate authority (CA) signed. Alternatively, you can generate a self-signed certificate on the device, export the certificate from the device, and import it in to the syslog server. | 1. Select **Device > Certificate Management > Certificates > Device Certificates** and click **Generate**.<br>2. Enter a **Name** for the certificate.<br>3. In the **Common Name** field, enter the IP address of the device sending logs to the syslog server.<br>4. In **Signed by**, select the trusted CA or the self-signed CA that the syslog server and the sending device both trust.<br>The certificate can't be a **Certificate Authority** nor an **External Authority** (certificate signing request [CSR]).<br>5. Click **Generate**. The device generates the certificate and key pair.<br>6. Click the certificate Name to edit it, select the **Certificate for Secure Syslog** check box, and click **OK**. |

 © Palo Alto Networks, Inc.

| Configure Syslog Monitoring (Continued) | | |
|---|---|---|
| Step 6 | Commit your changes and review the logs on the syslog server. | 1. Click **Commit**.<br>2. To review the logs, refer to the documentation of your syslog management software. You can also review the Syslog Field Descriptions. |

# Syslog Field Descriptions

The following topics list the standard fields of each log type that Palo Alto Networks devices can forward to an external server, as well as the severity levels, custom formats, and escape sequences. To facilitate parsing, the delimiter is a comma: each field is a comma-separated value (CSV) string. The FUTURE_USE tag applies to fields that the devices do not currently implement.

WildFire Submission logs are a subtype of Threat log and use the same syslog format.

- Traffic Logs
- Threat Logs
- HIP Match Logs
- Config Logs
- System Logs
- Correlated Events (Logs)
- Syslog Severity
- Custom Log/Event Format
- Escape Sequences

## Traffic Logs

**Format:** FUTURE_USE, Receive Time, Serial Number, Type, Subtype, FUTURE_USE, Generated Time, Source IP, Destination IP, NAT Source IP, NAT Destination IP, Rule Name, Source User, Destination User, Application, Virtual System, Source Zone, Destination Zone, Ingress Interface, Egress Interface, Log Forwarding Profile, FUTURE_USE, Session ID, Repeat Count, Source Port, Destination Port, NAT Source Port, NAT Destination Port, Flags, Protocol, Action, Bytes, Bytes Sent, Bytes Received, Packets, Start Time, Elapsed Time, Category, FUTURE_USE, Sequence Number, Action Flags, Source Location, Destination Location, FUTURE_USE, Packets Sent, Packets Received, Session End Reason, Device Group Hierarchy Level 1*, Device Group Hierarchy Level 2*, Device Group Hierarchy Level 3*, Device Group Hierarchy Level 4*, Virtual System Name*, Device Name*, Action Source*

| Field Name | Description |
|---|---|
| Receive Time (receive_time) | Time the log was received at the management plane |
| Serial Number (serial) | Serial number of the device that generated the log |
| Type (type) | Specifies type of log; values are traffic, threat, config, system and hip-match |

 © Palo Alto Networks, Inc.

| Field Name | Description |
|---|---|
| Subtype (subtype) | Subtype of traffic log; values are start, end, drop, and deny<br>• Start—session started<br>• End—session ended<br>• Drop—session dropped before the application is identified and there is no rule that allows the session.<br>• Deny—session dropped after the application is identified and there is a rule to block or no rule that allows the session. |
| Generated Time (time_generated) | Time the log was generated on the dataplane |
| Source IP (src) | Original session source IP address |
| Destination IP (dst) | Original session destination IP address |
| NAT Source IP (natsrc) | If Source NAT performed, the post-NAT Source IP address |
| NAT Destination IP (natdst) | If Destination NAT performed, the post-NAT Destination IP address |
| Rule Name (rule) | Name of the rule that the session matched |
| Source User (srcuser) | Username of the user who initiated the session |
| Destination User (dstuser) | Username of the user to which the session was destined |
| Application (app) | Application associated with the session |
| Virtual System (vsys) | Virtual System associated with the session |
| Source Zone (from) | Zone the session was sourced from |
| Destination Zone (to) | Zone the session was destined to |
| Ingress Interface (inbound_if) | Interface that the session was sourced form |
| Egress Interface (outbound_if) | Interface that the session was destined to |
| Log Forwarding Profile (logset) | Log Forwarding Profile that was applied to the session |
| Session ID (sessionid) | An internal numerical identifier applied to each session |
| Repeat Count (repeatcnt) | Number of sessions with same Source IP, Destination IP, Application, and Subtype seen within 5 seconds; used for ICMP only |
| Source Port (sport) | Source port utilized by the session |
| Destination Port (dport) | Destination port utilized by the session |
| NAT Source Port (natsport) | Post-NAT source port |
| NAT Destination Port (natdport) | Post-NAT destination port |

© Palo Alto Networks, Inc.

| Field Name | Description |
|---|---|
| Flags (flags) | 32-bit field that provides details on session; this field can be decoded by AND-ing the values with the logged value:<br>• 0x80000000—session has a packet capture (PCAP)<br>• 0x02000000—IPv6 session<br>• 0x01000000—SSL session was decrypted (SSL Proxy)<br>• 0x00800000—session was denied via URL filtering<br>• 0x00400000—session has a NAT translation performed (NAT)<br>• 0x00200000—user information for the session was captured via the captive portal (Captive Portal)<br>• 0x00080000—X-Forwarded-For value from a proxy is in the source user field<br>• 0x00040000—log corresponds to a transaction within a http proxy session (Proxy Transaction)<br>• 0x00008000—session is a container page access (Container Page)<br>• 0x00002000—session has a temporary match on a rule for implicit application dependency handling. Available in PAN-OS 5.0.0 and above.<br>• 0x00000800—symmetric return was used to forward traffic for this session |
| Protocol (proto) | IP protocol associated with the session |
| Action (action) | Action taken for the session; possible values are:<br>• Allow—session was allowed by policy<br>• Deny—session was denied by policy<br>• Drop—session was dropped silently<br>• Drop ICMP—session was silently dropped with an ICMP unreachable message to the host or application<br>• Reset both—session was terminated and a TCP reset is sent to both the sides of the connection<br>• Reset client—session was terminated and a TCP reset is sent to the client<br>• Reset server—session was terminated and a TCP reset is sent to the server |
| Bytes (bytes) | Number of total bytes (transmit and receive) for the session |
| Bytes Sent (bytes_sent) | Number of bytes in the client-to-server direction of the session<br>Available on all models except the PA-4000 Series |
| Bytes Received (bytes_received) | Number of bytes in the server-to-client direction of the session<br>Available on all models except the PA-4000 Series |
| Packets (packets) | Number of total packets (transmit and receive) for the session |
| Start Time (start) | Time of session start |
| Elapsed Time (elapsed) | Elapsed time of the session |
| Category (category) | URL category associated with the session (if applicable) |

 © Palo Alto Networks, Inc.

| Field Name | Description |
|---|---|
| Sequence Number (seqno) | A 64-bit log entry identifier incremented sequentially; each log type has a unique number space. This field is not supported on PA-7000 Series firewalls. |
| Action Flags (actionflags) | A bit field indicating if the log was forwarded to Panorama |
| Source Location (srcloc) | Source country or Internal region for private addresses; maximum length is 32 bytes |
| Destination Location (dstloc) | Destination country or Internal region for private addresses. Maximum length is 32 bytes |
| Packets Sent (pkts_sent) | Number of client-to-server packets for the session<br>Available on all models except the PA-4000 Series |
| Packets Received (pkts_received) | Number of server-to-client packets for the session<br>Available on all models except the PA-4000 Series |
| Session End Reason (session_end_reason) | The reason a session terminated. If the termination had multiple causes, this field displays only the highest priority reason. The possible session end reason values are as follows, in order of priority (where the first is highest):<br>• threat—The firewall detected a threat associated with a reset, drop, or block (IP address) action.<br>• policy-deny—The session matched a security rule with a deny or drop action.<br>• tcp-rst-from-client—The client sent a TCP reset to the server.<br>• tcp-rst-from-server—The server sent a TCP reset to the client.<br>• resources-unavailable—The session dropped because of a system resource limitation. For example, the session could have exceeded the number of out-of-order packets allowed per flow or the global out-of-order packet queue.<br>• tcp-fin—One host or both hosts in the connection sent a TCP FIN message to close the session.<br>• tcp-reuse—A session is reused and the firewall closes the previous session.<br>• decoder—The decoder detects a new connection within the protocol (such as HTTP-Proxy) and ends the previous connection.<br>• aged-out—The session aged out.<br>• unknown—This value applies in the following situations:<br>  • Session terminations that the preceding reasons do not cover (for example, a `clear session all` command).<br>  • For logs generated in a PAN-OS release that does not support the session end reason field (releases older than PAN-OS 6.1), the value will be `unknown` after an upgrade to the current PAN-OS release or after the logs are loaded onto the firewall.<br>  • In Panorama, logs received from firewalls for which the PAN-OS version does not support session end reasons will have a value of `unknown`.<br>• n/a—This value applies when the traffic log type is not `end`. |

| Field Name | Description |
|---|---|
| Device Group Hierarchy (dg_hier_level_1 to dg_hier_level_4)<br>New in v7.0! | A sequence of identification numbers that indicate the device group's location within a device group hierarchy. The firewall (or virtual system) generating the log includes the identification number of each ancestor in its device group hierarchy. The shared device group (level 0) is not included in this structure.<br>If the log values are 12, 34, 45, 0, it means that the log was generated by a firewall (or virtual system) that belongs to device group 45, and its ancestors are 34, and 12. To view the device group names that correspond to the value 12, 34 or 45, use one of the following methods:<br>CLI command in configure mode: **`show readonly dg-meta-data`**<br>API query:<br>`/api/?type=op&cmd=<show><dg-hierarchy></dg-hierarchy></show>` |
| Virtual System Name (vsys_name)<br>New in v7.0! | The name of the virtual system associated with the session; only valid on firewalls enabled for multiple virtual systems. |
| Device Name (device_name)<br>New in v7.0! | The hostname of the firewall on which the session was logged. |
| Action Source (action_source)<br>New in v7.0! | Specifies whether the action taken to allow or block an application was defined in the application or in policy. The actions can be allow, deny, drop, reset- server, reset-client or reset-both for the session. |

## Threat Logs

**Format**: FUTURE_USE, Receive Time, Serial Number, Type, Subtype, FUTURE_USE, Generated Time, Source IP, Destination IP, NAT Source IP, NAT Destination IP, Rule Name, Source User, Destination User, Application, Virtual System, Source Zone, Destination Zone, Ingress Interface, Egress Interface, Log Forwarding Profile, FUTURE_USE, Session ID, Repeat Count, Source Port, Destination Port, NAT Source Port, NAT Destination Port, Flags, Protocol, Action, Miscellaneous, Threat ID, Category, Severity, Direction, Sequence Number, Action Flags, Source Location, Destination Location, FUTURE_USE, Content Type, PCAP_id, Filedigest, Cloud, URL Index*, User Agent, File Type, X-Forwarded-For, Referer, Sender, Subject, Recipient, Report ID, Device Group Hierarchy Level 1*, Device Group Hierarchy Level 2*, Device Group Hierarchy Level 3*, Device Group Hierarchy Level 4*, Virtual System Name*, Device Name*, FUTURE_USE,

| Field Name | Description |
|---|---|
| Receive Time (receive_time) | Time the log was received at the management plane |
| Serial Number (serial) | Serial number of the device that generated the log |
| Type (type) | Specifies type of log; values are traffic, threat, config, system and hip-match |
| Subtype (subtype) | Subtype of threat log. Values include the following:<br>• data—Data pattern matching a Data Filtering profile.<br>• file—File type matching a File Blocking profile.<br>• flood—Flood detected via a Zone Protection profile.<br>• packet—Packet-based attack protection triggered by a Zone Protection profile.<br>• scan—Scan detected via a Zone Protection profile.<br>• spyware—Spyware detected via an Anti-Spyware profile.<br>• url—URL filtering log.<br>• virus—Virus detected via an Antivirus profile.<br>• vulnerability—Vulnerability exploit detected via a Vulnerability Protection profile.<br>• wildfire—A WildFire verdict generated when the firewall submits a file to WildFire per a WildFire Analysis profile and a verdict (malicious, grayware, or benign, depending on what you are logging) is logged in the WildFire Submissions log.<br>• wildfire-virus—Virus detected via an Antivirus profile. |
| Generated Time (time_generated) | Time the log was generated on the dataplane |
| Source IP (src) | Original session source IP address |
| Destination IP (dst) | Original session destination IP address |
| NAT Source IP (natsrc) | If source NAT performed, the post-NAT source IP address |
| NAT Destination IP (natdst) | If destination NAT performed, the post-NAT destination IP address |
| Rule Name (rule) | Name of the rule that the session matched |
| Source User (srcuser) | Username of the user who initiated the session |

| Field Name | Description |
|---|---|
| Destination User (dstuser) | Username of the user to which the session was destined |
| Application (app) | Application associated with the session |
| Virtual System (vsys) | Virtual System associated with the session |
| Source Zone (from) | Zone the session was sourced from |
| Destination Zone (to) | Zone the session was destined to |
| Ingress Interface (inbound_if) | Interface that the session was sourced from |
| Egress Interface (outbound_if) | Interface that the session was destined to |
| Log Forwarding Profile (logset) | Log Forwarding Profile that was applied to the session |
| Session ID (sessionid) | An internal numerical identifier applied to each session |
| Repeat Count (repeatcnt) | Number of sessions with same Source IP, Destination IP, Application, and Subtype seen within 5 seconds; used for ICMP only |
| Source Port (sport) | Source port utilized by the session |
| Destination Port (dport) | Destination port utilized by the session |
| NAT Source Port (natsport) | Post-NAT source port |
| NAT Destination Port (natdport) | Post-NAT destination port |
| Flags (flags) | 32-bit field that provides details on session; this field can be decoded by AND-ing the values with the logged value:<br>• 0x80000000—session has a packet capture (PCAP)<br>• 0x02000000—IPv6 session<br>• 0x01000000—SSL session was decrypted (SSL Proxy)<br>• 0x00800000—session was denied via URL filtering<br>• 0x00400000—session has a NAT translation performed (NAT)<br>• 0x00200000—user information for the session was captured via the captive portal (Captive Portal)<br>• 0x00080000—X-Forwarded-For value from a proxy is in the source user field<br>• 0x00040000—log corresponds to a transaction within a http proxy session (Proxy Transaction)<br>• 0x00008000—session is a container page access (Container Page)<br>• 0x00002000—session has a temporary match on a rule for implicit application dependency handling. Available in PAN-OS 5.0.0 and above<br>• 0x00000800—symmetric return was used to forward traffic for this session |

 © Palo Alto Networks, Inc.

| Field Name | Description |
|---|---|
| Protocol (proto) | IP protocol associated with the session |
| Action (action) | Action taken for the session; values are alert, allow, deny, drop, drop-all-packets, reset-client, reset-server, reset-both, block-url.<br>• Alert—threat or URL detected but not blocked<br>• Allow—flood detection alert<br>• Deny—flood detection mechanism activated and deny traffic based on configuration<br>• Drop—threat detected and associated session was dropped<br>• Drop-all-packets—threat detected and session remains, but drops all packets<br>• Reset-client—threat detected and a TCP RST is sent to the client<br>• Reset-server—threat detected and a TCP RST is sent to the server<br>• Reset-both—threat detected and a TCP RST is sent to both the client and the server<br>• Block-url—URL request was blocked because it matched a URL category that was set to be blocked |
| Miscellaneous (misc) | Field with variable length with a maximum of 1023 characters<br>The actual URI when the subtype is URL<br>File name or file type when the subtype is file<br>File name when the subtype is virus<br>File name when the subtype is WildFire |
| Threat ID (threatid) | Palo Alto Networks identifier for the threat. It is a description string followed by a 64-bit numerical identifier in parentheses for some Subtypes:<br>• 8000 – 8099—scan detection<br>• 8500 – 8599—flood detection<br>• 9999—URL filtering log<br>• 10000 – 19999—sypware phone home detection<br>• 20000 – 29999—spyware download detection<br>• 30000 – 44999—vulnerability exploit detection<br>• 52000 – 52999—filetype detection<br>• 60000 – 69999—data filtering detection<br>• 100000 – 2999999—virus detection<br>• 3000000 – 3999999—WildFire signature feed<br>• 4000000-4999999—DNS Botnet signatures |
| Category (category) | For URL Subtype, it is the URL Category; For WildFire subtype, it is the verdict on the file and is either ‘malicious’, ‘grayware’, or ‘benign’; For other subtypes, the value is ‘any’. |
| Severity (severity) | Severity associated with the threat; values are informational, low, medium, high, critical |

| Field Name | Description |
|---|---|
| Direction (direction) | Indicates the direction of the attack, client-to-server or server-to-client:<br>• 0—direction of the threat is client to server<br>• 1—direction of the threat is server to client |
| Sequence Number (seqno) | A 64-bit log entry identifier incremented sequentially. Each log type has a unique number space. This field is not supported on PA-7000 Series firewalls. |
| Action Flags (actionflags) | A bit field indicating if the log was forwarded to Panorama. |
| Source Location (srcloc) | Source country or Internal region for private addresses. Maximum length is 32 bytes. |
| Destination Location (dstloc) | Destination country or Internal region for private addresses. Maximum length is 32 bytes. |
| Content Type (contenttype) | Applicable only when Subtype is URL.<br>Content type of the HTTP response data. Maximum length 32 bytes. |
| PCAP ID (pcap_id) | The packet capture (pcap) ID is a 64 bit unsigned integral denoting an ID to correlate threat pcap files with extended pcaps taken as a part of that flow. All threat logs will contain either a pcap_id of 0 (no associated pcap), or an ID referencing the extended pcap file. |
| File Digest (filedigest) | Only for WildFire subtype; all other types do not use this field<br>The filedigest string shows the binary hash of the file sent to be analyzed by the WildFire service. |
| Cloud (cloud) | Only for WildFire subtype; all other types do not use this field.<br>The cloud string displays the FQDN of either the WildFire appliance (private) or the WildFire cloud (public) from where the file was uploaded for analysis. |
| URL Index (url_idx)<br>New in v7.0! | Used in URL Filtering and WildFire subtypes.<br>When an application uses TCP keepalives to keep a connection open for a length of time, all the log entries for that session have a single session ID. In such cases, when you have a single threat log (and session ID) that includes multiple URL entries, the url_idx is a counter that allows you to correlate the order of each log entry within the single session.<br>For example, to learn the URL of a file that the firewall forwarded to WildFire for analysis, locate the session ID and the url_idx from the WildFire Submissions log and search for the same session ID and url_idx in your URL filtering logs. The log entry that matches the session ID and url_idx will contain the URL of the file that was forwarded to WildFire. |
| User Agent (user_agent) | Only for the URL Filtering subtype; all other types do not use this field.<br>The User Agent field specifies the web browser that the user used to access the URL, for example Internet Explorer. This information is sent in the HTTP request to the server. |
| File Type (filetype) | Only for WildFire subtype; all other types do not use this field.<br>Specifies the type of file that the firewall forwarded for WildFire analysis. |

 © Palo Alto Networks, Inc.

| Field Name | Description |
|---|---|
| X-Forwarded-For (xff) | Only for the URL Filtering subtype; all other types do not use this field.<br>The X-Forwarded-For field in the HTTP header contains the IP address of the user who requested the web page. It allows you to identify the IP address of the user, which is useful particularly if you have a proxy server on your network that replaces the user IP address with its own address in the source IP address field of the packet header. |
| Referer (referer) | Only for the URL Filtering subtype; all other types do not use this field.<br>The Referer field in the HTTP header contains the URL of the web page that linked the user to another web page; it is the source that redirected (referred) the user to the web page that is being requested. |
| Sender (sender) | Only for WildFire subtype; all other types do not use this field.<br>Specifies the name of the sender of an email that WildFire determined to be malicious when analyzing an email link forwarded by the firewall. |
| Subject (subject) | Only for WildFire subtype; all other types do not use this field.<br>Specifies the subject of an email that WildFire determined to be malicious when analyzing an email link forwarded by the firewall. |
| Recipient (recipient) | Only for WildFire subtype; all other types do not use this field.<br>Specifies the name of the receiver of an email that WildFire determined to be malicious when analyzing an email link forwarded by the firewall. |
| Report ID (reportid) | Only for WildFire subtype; all other types do not use this field.<br>Identifies the analysis request on the WildFire cloud or the WildFire appliance. |
| Device Group Hierarchy (dg_hier_level_1 to dg_hier_level_4)<br>New in v7.0! | A sequence of identification numbers that indicate the device group's location within a device group hierarchy. The firewall (or virtual system) generating the log includes the identification number of each ancestor in its device group hierarchy. The shared device group (level 0) is not included in this structure.<br>If the log values are 12, 34, 45, 0, it means that the log was generated by a firewall (or virtual system) that belongs to device group 45, and its ancestors are 34, and 12. To view the device group names that correspond to the value 12, 34 or 45, use one of the following methods:<br>CLI command in configure mode: **`show readonly dg-meta-data`**<br>API query:<br>`/api/?type=op&cmd=<show><dg-hierarchy></dg-hierarchy></show>` |
| Virtual System Name (vsys_name)<br>New in v7.0! | The name of the virtual system associated with the session; only valid on firewalls enabled for multiple virtual systems. |
| Device Name (device_name)<br>New in v7.0! | The hostname of the firewall on which the session was logged. |

## HIP Match Logs

**Format:** FUTURE_USE, Receive Time, Serial Number, Type, Subtype, FUTURE_USE, Generated Time, Source User, Virtual System, Machine name, OS, Source Address, HIP, Repeat Count, HIP Type, FUTURE_USE, FUTURE_USE, Sequence Number, Action Flags, Device Group Hierarchy Level 1*, Device Group Hierarchy Level 2*, Device Group Hierarchy Level 3*, Device Group Hierarchy Level 4*, Virtual System Name*, Device Name*

| Field Name | Description |
|---|---|
| Receive Time (receive_time) | Time the log was received at the management plane |
| Serial Number (serial) | Serial number of the device that generated the log |
| Type (type) | Type of log; values are traffic, threat, config, system and hip-match |
| Subtype (subtype) | Subtype of HIP match log; unused |
| Generated Time (time_generated) | Time the log was generated on the dataplane |
| Source User (srcuser) | Username of the user who initiated the session |
| Virtual System (vsys) | Virtual System associated with the HIP match log |
| Machine Name (machinename) | Name of the user's machine |
| OS | The operating system installed on the user's machine or device (or on the client system) |
| Source Address (src) | IP address of the source user |
| HIP (matchname) | Name of the HIP object or profile |
| Repeat Count (repeatcnt) | Number of times the HIP profile matched |
| HIP Type (matchtype) | Whether the hip field represents a HIP object or a HIP profile |
| Sequence Number (seqno) | A 64-bit log entry identifier incremented sequentially; each log type has a unique number space. This field is not supported on PA-7000 Series firewalls. |
| Action Flags (actionflags) | A bit field indicating if the log was forwarded to Panorama |
| Device Group Hierarchy (dg_hier_level_1 to dg_hier_level_4) New in v7.0! | A sequence of identification numbers that indicate the device group's location within a device group hierarchy. The firewall (or virtual system) generating the log includes the identification number of each ancestor in its device group hierarchy. The shared device group (level 0) is not included in this structure.<br>If the log values are 12, 34, 45, 0, it means that the log was generated by a firewall (or virtual system) that belongs to device group 45, and its ancestors are 34, and 12. To view the device group names that correspond to the value 12, 34 or 45, use one of the following methods:<br>CLI command in configure mode: **`show readonly dg-meta-data`**<br>API query: `/api/?type=op&cmd=<show><dg-hierarchy></dg-hierarchy></show>` |

 © Palo Alto Networks, Inc.

| Field Name | Description |
|---|---|
| Virtual System Name (vsys_name)<br>New in v7.0! | The name of the virtual system associated with the session; only valid on firewalls enabled for multiple virtual systems. |
| Device Name (device_name)<br>New in v7.0! | The hostname of the firewall on which the session was logged. |

## Config Logs

**Format:** FUTURE_USE, Receive Time, Serial Number, Type, Subtype, FUTURE_USE, Generated Time, Host, Virtual System, Command, Admin, Client, Result, Configuration Path, Sequence Number, Action Flags, Before Change Detail, After Change Detail, Device Group Hierarchy Level 1*, Device Group Hierarchy Level 2*, Device Group Hierarchy Level 3*, Device Group Hierarchy Level 4*, Virtual System Name*, Device Name*

| Field Name | Description |
|---|---|
| Receive Time (receive_time) | Time the log was received at the management plane |
| Serial Number (serial) | Serial number of the device that generated the log |
| Type (type) | Type of log; values are traffic, threat, config, system and hip-match |
| Subtype (subtype) | Subtype of configuration log; unused |
| Generated Time (time_generated) | Time the log was generated on the dataplane |
| Host (host) | Hostname or IP address of the client machine |
| Virtual System (vsys) | Virtual System associated with the configuration log |
| Command (cmd) | Command performed by the Admin; values are add, clone, commit, delete, edit, move, rename, set. |
| Admin (admin) | Username of the Administrator performing the configuration |
| Client (client) | Client used by the Administrator; values are Web and CLI |
| Result (result) | Result of the configuration action; values are Submitted, Succeeded, Failed, and Unauthorized |
| Configuration Path (path) | The path of the configuration command issued; up to 512 bytes in length |
| Sequence Number (seqno) | A 64bit log entry identifier incremented sequentially; each log type has a unique number space. This field is not supported on PA-7000 Series firewalls. |
| Action Flags (actionflags) | A bit field indicating if the log was forwarded to Panorama. |
| Before Change Detail (before_change_detail) | This field is in custom logs only; it is not in the default format.<br>It contains the full xpath before the configuration change. |

| Field Name | Description |
|---|---|
| After Change Detail (after_change_detail) | This field is in custom logs only; it is not in the default format.<br>It contains the full xpath after the configuration change. |
| Device Group Hierarchy (dg_hier_level_1 to dg_hier_level_4)<br>New in v7.0! | A sequence of identification numbers that indicate the device group's location within a device group hierarchy. The firewall (or virtual system) generating the log includes the identification number of each ancestor in its device group hierarchy. The shared device group (level 0) is not included in this structure.<br>If the log values are 12, 34, 45, 0, it means that the log was generated by a firewall (or virtual system) that belongs to device group 45, and its ancestors are 34, and 12. To view the device group names that correspond to the value 12, 34 or 45, use one of the following methods:<br>CLI command in configure mode: **`show readonly dg-meta-data`**<br>API query:<br>`/api/?type=op&cmd=<show><dg-hierarchy></dg-hierarchy></show>` |
| Virtual System Name (vsys_name)<br>New in v7.0! | The name of the virtual system associated with the session; only valid on firewalls enabled for multiple virtual systems. |
| Device Name (device_name)<br>New in v7.0! | The hostname of the firewall on which the session was logged. |

## System Logs

**Format:** FUTURE_USE, Receive Time, Serial Number, Type, Subtype, FUTURE_USE, Generated Time, Virtual System, Event ID, Object, FUTURE_USE, FUTURE_USE, Module, Severity, Description, Sequence Number, Action Flags, Device Group Hierarchy Level 1*, Device Group Hierarchy Level 2*, Device Group Hierarchy Level 3*, Device Group Hierarchy Level 4*, Virtual System Name*, Device Name*

| Field Name | Description |
|---|---|
| Receive Time (receive_time) | Time the log was received at the management plane |
| Serial Number (serial) | Serial number of the device that generated the log |
| Type (type) | Type of log; values are traffic, threat, config, system and hip-match |
| Subtype (subtype) | Subtype of the system log; refers to the system daemon generating the log; values are crypto, dhcp, dnsproxy, dos, general, global-protect, ha, hw, nat, ntpd, pbf, port, pppoe, ras, routing, satd, sslmgr, sslvpn, userid, url-filtering, vpn |
| Generated Time (time_generated) | Time the log was generated on the dataplane |
| Virtual System (vsys) | Virtual System associated with the configuration log |
| Event ID (eventid) | String showing the name of the event |
| Object (object) | Name of the object associated with the system event |
| Module (module) | This field is valid only when the value of the Subtype field is general. It provides additional information about the sub-system generating the log; values are general, management, auth, ha, upgrade, chassis |
| Severity (severity) | Severity associated with the event; values are informational, low, medium, high, critical |
| Description (opaque) | Detailed description of the event, up to a maximum of 512 bytes |
| Sequence Number (seqno) | A 64-bit log entry identifier incremented sequentially; each log type has a unique number space. This field is not supported on PA-7000 Series firewalls. |
| Action Flags (actionflags) | A bit field indicating if the log was forwarded to Panorama |
| Device Group Hierarchy (dg_hier_level_1 to dg_hier_level_4) New in v7.0! | A sequence of identification numbers that indicate the device group's location within a device group hierarchy. The firewall (or virtual system) generating the log includes the identification number of each ancestor in its device group hierarchy. The shared device group (level 0) is not included in this structure.<br>If the log values are 12, 34, 45, 0, it means that the log was generated by a firewall (or virtual system) that belongs to device group 45, and its ancestors are 34, and 12. To view the device group names that correspond to the value 12, 34 or 45, use one of the following methods:<br>CLI command in configure mode: **`show readonly dg-meta-data`**<br>API query:<br>`/api/?type=op&cmd=<show><dg-hierarchy></dg-hierarchy></show>` |

| Field Name | Description |
|---|---|
| Virtual System Name (vsys_name)<br>New in v7.0! | The name of the virtual system associated with the session; only valid on firewalls enabled for multiple virtual systems. |
| Device Name (device_name)<br>New in v7.0! | The hostname of the firewall on which the session was logged. |

 © Palo Alto Networks, Inc.

## Correlated Events (Logs)

**Format:** Receive Time*, Serial Number*, Device Name*, Type*, Virtual System Name*, Virtual System ID*, Device Group Hierarchy Level 1*, Device Group Hierarchy Level 2*, Device Group Hierarchy Level 3*, Device Group Hierarchy Level 4*, Source User*, Source*, Object Name*, Object ID*, Category*, Severity*, Evidence*

*All these fields are new in v7.0.5!

| Field Name | Description |
|---|---|
| Receive Time (receive_time)<br>*New in v7.0! | The time the firewall or Panorama recorded the event match. |
| Serial Number (serial)<br>*New in v7.0! | Serial number of the firewall that generated the log. |
| Device Name (device_name)<br>*New in v7.0! | The hostname of the firewall that generated the log. |
| Type (type)<br>*New in v7.0! | Correlation log |
| Virtual System (vsys)<br>*New in v7.0! | Name of the virtual system on the firewall that generated the correlation log.<br>(not pertinent to Panorama) |
| Virtual System ID(vsys_id)<br>*New in v7.0! | ID of the virtual system on the firewall that generated the correlation log.<br>(not pertinent to Panorama) |
| Device Group Hierarchy (dg_hier_level_1 to dg_hier_level_4)<br>*New in v7.0! | A sequence of identification numbers that indicate the device group's location within a device group hierarchy. The firewall (or virtual system) generating the log includes the identification number of each ancestor in its device group hierarchy. The shared device group (level 0) is not included in this structure.<br>If the log values are 12, 34, 45, 0, it means that the log was generated by a firewall (or virtual system) that belongs to device group 45, and its ancestors are 34, and 12. To view the device group names that correspond to the value 12, 34 or 45, use one of the following methods:<br>CLI command in configure mode: **`show readonly dg-meta-data`**<br>API query:<br>`/api/?type=op&cmd=<show><dg-hierarchy></dg-hierarchy></show>` |
| Source User (srcuser)<br>*New in v7.0! | Username of the user who triggered the event. |
| Source (src)<br>*New in v7.0! | IP address of the user who triggered the event. |
| Object Name (object_name)<br>*New in v7.0! | Name of the correlation object that was matched on. For example, Beacon Detection. |

| Field Name | Description |
|---|---|
| Object ID (object_id)<br>*New in v7.0! | ID of the correlation object associated with the event. |
| Category (category)<br>*New in v7.0! | Category of the correlation object that triggered the match. For example, Compromised Host. |
| Severity (severity)<br>*New in v7.0! | Severity associated with the event; values are informational, low, medium, high, critical |
| Evidence (evidence)<br>*New in v7.0! | A summary statement with evidence to indicate how many times the host has matched against the conditions defined in the correlation object. For example, Host visited known malware URL (19 times). |

## Syslog Severity

The syslog severity is set based on the log type and contents.

| Log Type/Severity | Syslog Severity |
|---|---|
| Traffic | Info |
| Config | Info |
| Threat/System—Informational | Info |
| Threat/System—Low | Notice |
| Threat/System—Medium | Warning |
| Threat/System—High | Error |
| Threat/System—Critical | Critical |

## Custom Log/Event Format

To facilitate the integration with external log parsing systems, the firewall allows you to customize the log format; it also allows you to add custom *Key: Value* attribute pairs. Custom message formats can be configured under **Device > Server Profiles > Syslog > Syslog Server Profile > Custom Log Format**.

To achieve ArcSight Common Event Format (CEF) compliant log formatting, refer to the CEF Configuration Guide.

## Escape Sequences

Any field that contains a comma or a double-quote is enclosed in double quotes. Furthermore, if a double-quote appears inside a field it is escaped by preceding it with another double-quote. To maintain backward compatibility, the Misc field in threat log is always enclosed in double-quotes.

# SNMP Monitoring and Traps

The following topics describe how Palo Alto Networks devices implement Simple Network Management Protocol (SNMP), and the procedures to configure SNMP monitoring and trap delivery.

- SNMP for Palo Alto Networks Devices
- Use an SNMP Manager to Explore MIBs and Objects
- Enable SNMP Services for Firewall-Secured Network Elements
- Monitor Device Statistics Using SNMP
- Forward Traps to an SNMP Manager
- Supported MIBs

© Palo Alto Networks, Inc.

## SNMP for Palo Alto Networks Devices

You can use a Simple Network Management Protocol (SNMP) manager to monitor event-driven alerts and operational statistics for Palo Alto Networks devices and the traffic that those devices secure. The statistics and traps can help you identify resource limitations, system changes or failures, and malware attacks. You configure devices to send the alerts by forwarding log data as traps, and enable devices to send statistics in response to GET messages (requests) from your SNMP manager. Each trap and statistic has an object identifier (OID). Related OIDs are organized hierarchically within the Management Information Bases (MIBs) that you load into the SNMP manager to enable monitoring.

Palo Alto Networks devices support SNMP Version 2c and Version 3. Decide which to use based on the version that other devices in your network support and on your network security requirements. SNMPv3 is more secure and enables more granular access control for device statistics than SNMPv2c. The following table summarizes the security features of each version. You select the version and configure the security features when you Monitor Device Statistics Using SNMP and Forward Traps to an SNMP Manager.

| SNMP Version | Device/User Authentication | Message Privacy | Message Integrity | MIB Access Granularity |
|---|---|---|---|---|
| SNMPv2c | Community string | No (cleartext) | No | SNMP community access for all MIBs on a device |
| SNMPv3 | EngineID, username, and authentication password (SHA hashing for the password) | Privacy password for AES 128 encryption of SNMP messages | Yes | User access based on views that include or exclude specific OIDs |

Figure: SNMP for Palo Alto Networks Devices illustrates a deployment in which firewalls forward traps to an SNMP manager while also forwarding logs to Log Collectors. Alternatively, you could configure the Log Collectors to forward the firewall traps to the SNMP manager. For details on these deployments, refer to Log Forwarding Options. In all deployments, the SNMP manager gets statistics directly from the devices. In this example, a single SNMP manager collects both traps and statistics, though you can use separate managers for these functions if that better suits your network.

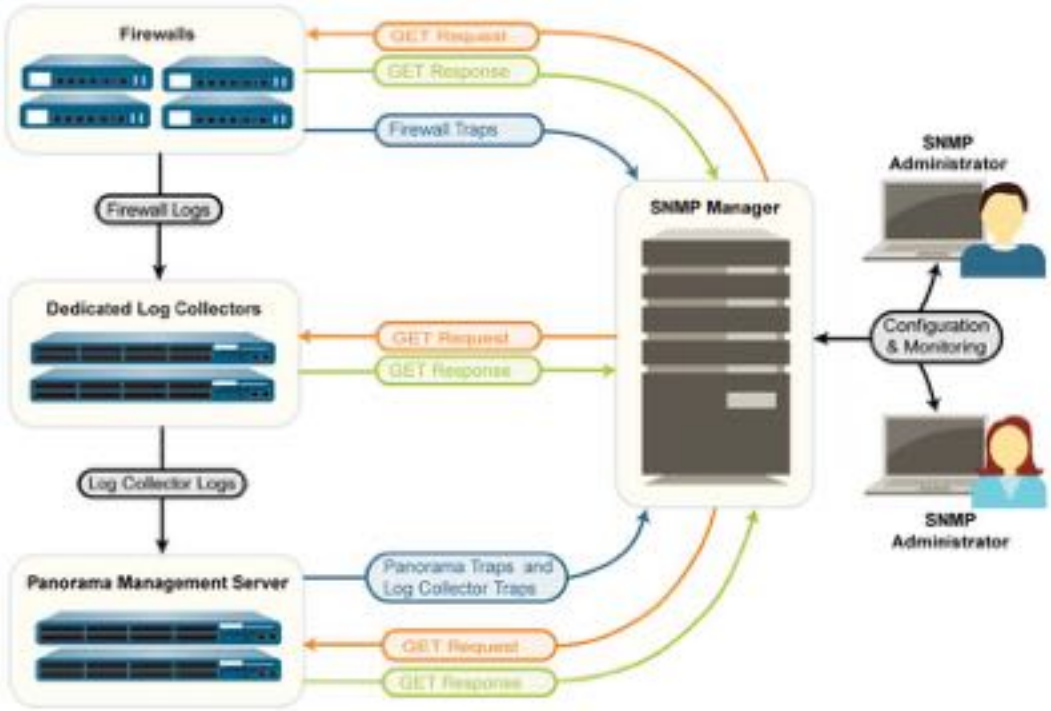
**Figure: SNMP for Palo Alto Networks Devices**



# Use an SNMP Manager to Explore MIBs and Objects

To use SNMP for monitoring Palo Alto Networks devices, you must first load the Supported MIBs into your SNMP manager and determine which object identifiers (OIDs) correspond to the statistics and traps you want to monitor. The following topics provide an overview of how to find OIDs and MIBs in an SNMP manager. For the specific steps to perform these tasks, refer to your SNMP management software.

- Identify a MIB Containing a Known OID
- Walk a MIB
- Identify the OID for a Palo Alto Networks Device Statistic or Trap

## Identify a MIB Containing a Known OID

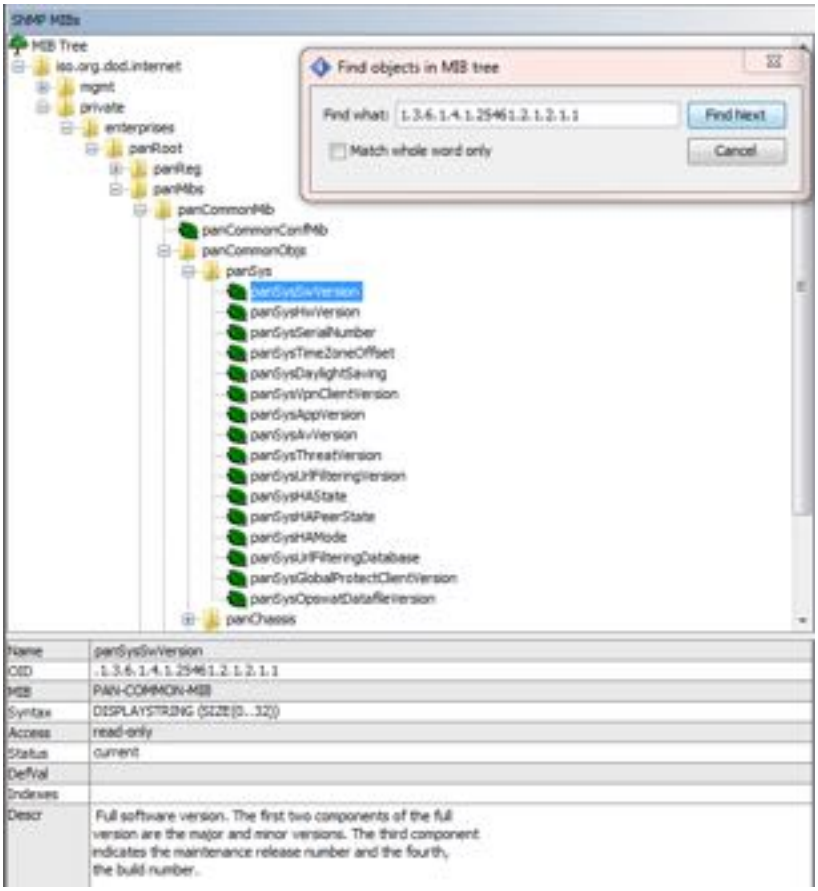
If you already know the OID for a particular SNMP object (device statistic or trap) and want to know the OIDs of similar objects so you can monitor them, you can explore the MIB that contains the known OID.

| **Identify a MIB Containing a Known OID** | |
|---|---|
| Step 1 | Load all the Supported MIBs into your SNMP manager. |

 © Palo Alto Networks, Inc.

**Identify a MIB Containing a Known OID (Continued)**

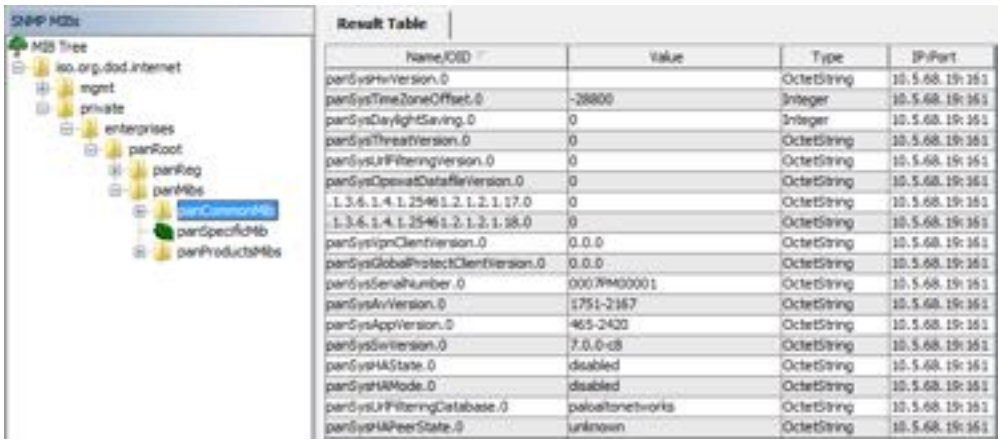
Step 2 Search the entire MIB tree for the known OID. The search result displays the MIB path for the OID, as well as information about the OID (for example, name, status, and description). You can then select other OIDs in the same MIB to see information about them.



Step 3 Optionally, Walk a MIB to display all its objects.

## Walk a MIB

If you want to see which SNMP objects (device statistics and traps) are available for monitoring, displaying all the objects of a particular MIB can be useful. To do this, load the Supported MIBs into your SNMP manager and perform a *walk* on the desired MIB. To list the traps that Palo Alto Networks devices support, walk the panCommonEventEventsV2 MIB. In the following example, walking the PAN-COMMON-MIB.my displays the following list of OIDs and their values for certain device statistics:



## Identify the OID for a Palo Alto Networks Device Statistic or Trap

To use an SNMP manager for monitoring Palo Alto Networks devices, you must know the OIDs of the device statistics and traps you want to monitor.

**Identify the OID for a Palo Alto Networks Device Statistic or Trap**

Step 1 Review the Supported MIBs to determine which one contains the type of statistic you want. For example, the PAN-COMMON-MIB.my contains device version information. The panCommonEventEventsV2 MIB contains all the traps that Palo Alto Networks devices support.

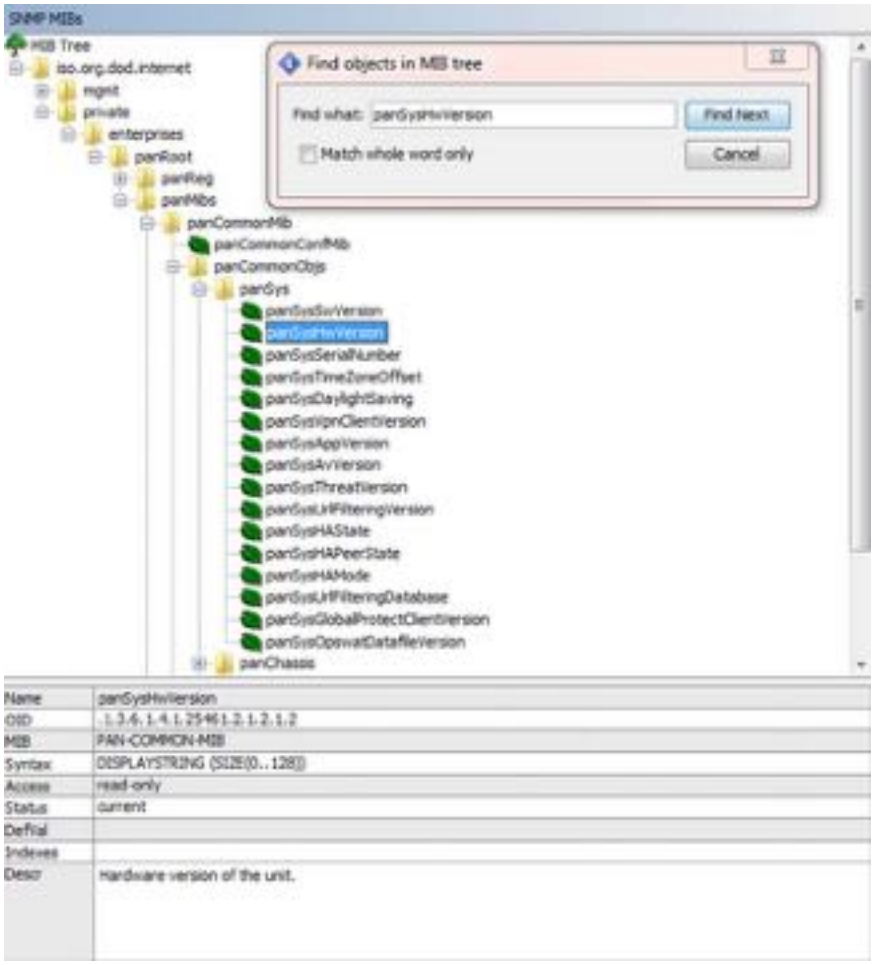
Step 2 Open the MIB in a text editor and perform a keyword search. For example, using **`Hardware version`** as a search string in PAN-COMMON-MIB identifies the panSysHwVersion object:

```
panSysHwVersion OBJECT-TYPE
     SYNTAX      DisplayString (SIZE(0..128))
     MAX-ACCESS  read-only
     STATUS      current
     DESCRIPTION
          "Hardware version of the unit."
     ::= {panSys 2}
```

 © Palo Alto Networks, Inc.

**Identify the OID for a Palo Alto Networks Device Statistic or Trap (Continued)**

Step 3 In a MIB browser, search the MIB tree for the identified object name to display its OID. For example, the panSysHwVersion object has an OID of 1.3.6.1.4.1.25461.2.1.2.1.2.



## Enable SNMP Services for Firewall-Secured Network Elements

If you will use Simple Network Management Protocol (SNMP) to monitor or manage network elements (for example, switches and routers) that are within the security zones of Palo Alto Networks firewalls, you must create a security rule that allows SNMP services for those elements.

You don't need a security rule to enable SNMP monitoring of Palo Alto Networks devices. For details, see Monitor Device Statistics Using SNMP.

| Enable SNMP Services for Firewall-Secured Network Elements | | |
|---|---|---|
| Step 1 | Create an application group. | 1. Select **Objects > Application Group** and click **Add**.<br>2. Enter a **Name** to identify the application group.<br>3. Click **Add**, type `snmp`, and select **snmp** and **snmp-trap** from the drop-down.<br>4. Click **OK** to save the application group. |
| Step 2 | Create a security rule to allow SNMP services. | 1. Select **Policies > Security** and click **Add**.<br>2. In the **General** tab, enter a **Name** for the rule.<br>3. In the **Source** and **Destination** tabs, click **Add** and enter a **Source Zone** and a **Destination Zone** for the traffic.<br>4. In the **Applications** tab, click **Add**, type the name of the applications group you just created, and select it from the drop-down.<br>5. In the **Actions** tab, verify that the **Action** is set to **Allow**, and then click **OK** and **Commit**. |

 © Palo Alto Networks, Inc.

# Monitor Device Statistics Using SNMP

The statistics that a Simple Network Management Protocol (SNMP) manager collects from Palo Alto Networks devices can help you gauge the health of your network (devices and connections), identify resource limitations, and monitor traffic or processing loads. The statistics include information such as interface states (up or down), active user sessions, concurrent sessions, session utilization, temperature, and system uptime.

You can't configure an SNMP manager to control Palo Alto Networks devices (using SET messages), only to collect statistics from them (using GET messages).

For details on how SNMP is implemented for Palo Alto Networks devices, see SNMP for Palo Alto Networks Devices.

| Monitor Device Statistics Using SNMP | | |
|---|---|---|
| Step 1 | Configure the SNMP Manager to get statistics from devices. | The following steps provide an overview of the tasks you perform on the SNMP manager. For the specific steps, refer to the documentation of your SNMP manager.<br>1. To enable the SNMP manager to interpret device statistics, load the Supported MIBs for Palo Alto Networks devices and, if necessary, compile them.<br>2. For each device that the SNMP manager will monitor, define the connection settings (IP address and port) and authentication settings (SNMPv2c community string or SNMPv3 EngineID/username/password) for the device. Note that all Palo Alto Networks devices use port 161.<br>The SNMP manager can use the same or different connection and authentication settings for multiple devices. The settings must match those you define when you configure SNMP on the device (see Step 3). For example, if you use SNMPv2c, the community string you define when configuring the device must match the community string you define in the SNMP manager for that device.<br>3. Determine the object identifiers (OIDs) of the statistics you want to monitor. For example, to monitor the session utilization percentage of a firewall, a MIB browser shows that this statistic corresponds to OID 1.3.6.1.4.1.25461.2.1.2.3.1.0 in PAN-COMMON-MIB.my. For details, see Use an SNMP Manager to Explore MIBs and Objects.<br>4. Configure the SNMP manager to monitor the desired OIDs. |

| Monitor Device Statistics Using SNMP (Continued) | |
|---|---|
| Step 2 Enable SNMP traffic on a device interface.<br><br>This is the interface that will receive statistics requests from the SNMP manager.<br><br>PAN-OS doesn't synchronize management (MGT) interface settings for devices in a high availability (HA) configuration. You must configure the interface for each HA peer. | Perform this step in the device web interface.<br><br>To enable SNMP traffic on the MGT interface:<br>1. Select **Device > Setup > Management** and edit the Management Interface Settings.<br>2. In the **Services** section, select the **SNMP** check box.<br>3. Click **OK** and **Commit**.<br><br>To enable SNMP traffic on any other interface:<br>1. Create an interface management profile for SNMP services:<br>a. Select **Network > Network Profiles > Interface Mgmt** and click **Add**.<br>b. Enter a **Name** for the profile, then select the check boxes for **SNMP** and any other services the interface must support.<br>c. Click **OK** to save the profile.<br>2. Assign the profile to the interface that will receive the SNMP requests:<br>a. Select **Network > Interfaces** and **Add** or edit the interface that will receive the SNMP requests. The interface type must be Layer 3 Ethernet.<br>b. Select **Advanced > Other Info** and select the **Management Profile** you just created.<br>c. Click **OK** and **Commit**. |

 © Palo Alto Networks, Inc.

| Monitor Device Statistics Using SNMP (Continued) | | |
|---|---|---|
| Step 3 | Configure the device to respond to statistics requests from an SNMP manager.<br><br>PAN-OS doesn't synchronize SNMP response settings for devices in a high availability (HA) configuration. You must configure these settings for each HA peer. | 1. Select **Device > Setup > Operations** and, in the Miscellaneous section, click **SNMP Setup**.<br>2. Select the SNMP **Version** and configure the authentication values as follows. For version details, see SNMP for Palo Alto Networks Devices.<br>• **V2c**—Enter the **SNMP Community String**, which identifies a community of SNMP managers and monitored devices, and serves as a password to authenticate the community members to each other.<br>As a best practice, don't use the default community string `public`; it's well known and therefore not secure.<br>• **V3**—Create at least one SNMP view group and one user. User accounts and views provide authentication, privacy, and access control when devices forward traps and SNMP managers get device statistics.<br>– **Views**—Each view is a paired OID and bitwise mask: the OID specifies a MIB and the mask (in hexadecimal format) specifies which objects are accessible within (include matching) or outside (exclude matching) that MIB. Click **Add** in the first list and enter a **Name** for the group of views. For each view in the group, click **Add** and configure the view **Name**, **OID**, matching **Option** (**include** or **exclude**), and **Mask**.<br>– **Users**: Click **Add** in the second list, enter a username under **Users**, select the **View** group from the drop-down, enter the authentication password (**Auth Password**) used to authenticate to the SNMP manager, and enter the privacy password (**Priv Password**) used to encrypt SNMP messages to the SNMP manager.<br>3. Click **OK** and **Commit**. |
| Step 4 | Monitor the firewall statistics in an SNMP manager. | Refer to the documentation of your SNMP manager.<br><br>When monitoring statistics related to firewall interfaces, you must match the interface indexes in the SNMP manager with interface names in the firewall web interface. For details, see Firewall Interface Identifiers in SNMP Managers and NetFlow Collectors. |

# Forward Traps to an SNMP Manager

Simple Network Management Protocol (SNMP) traps can alert you to system events (failures or changes in hardware or software of Palo Alto Networks devices) or to threats (traffic that matches a firewall security rule) that require immediate attention.

To see the list of traps that Palo Alto Networks devices support, use your SNMP Manager to access the panCommonEventEventsV2 MIB. For details, see Use an SNMP Manager to Explore MIBs and Objects.

For details on how for Palo Alto Networks devices implement SNMP, see SNMP for Palo Alto Networks Devices.

| Forward Firewall Traps to an SNMP Manager | | |
|---|---|---|
| Step 1 | Enable the SNMP manager to interpret the traps it receives. | Load the Supported MIBs for Palo Alto Networks devices and, if necessary, compile them. For the specific steps, refer to the documentation of your SNMP manager. |
| Step 2 | Configure an SNMP Trap server profile.<br><br>The profile defines how the device accesses the SNMP managers (trap servers). You can define up to four SNMP managers for each profile.<br><br>Optionally, you can configure separate SNMP Trap server profiles for different log types, severity levels, and WildFire verdicts. | 1. Log in to the web interface of the Palo Alto Networks device.<br>2. Select **Device > Server Profiles > SNMP Trap**.<br>3. Click **Add** and enter a **Name** for the profile.<br>4. If the firewall has more than one virtual system (vsys), select the **Location** (vsys or **Shared**) where this profile is available.<br>5. Select the SNMP **Version** and configure the authentication values as follows. For version details, see SNMP for Palo Alto Networks Devices.<br>• **V2c**—For each server, click **Add** and enter the server **Name**, IP address (**SNMP Manager**), and **Community String**. The community string identifies a community of SNMP managers and monitored devices, and serves as a password to authenticate the community members to each other.<br>As a best practice, don't use the default community string `public`; it's well known and therefore not secure.<br>• **V3**—For each server, click **Add** and enter the server **Name**, IP address (**SNMP Manager**), SNMP **User** account (this must match a username defined in the SNMP manager), **EngineID** used to uniquely identify the device (you can leave the field blank to use the device serial number), authentication password (**Auth Password**) used to authenticate to the server, and privacy password (**Priv Password**) used to encrypt SNMP messages to the server.<br>6. Click **OK** to save the server profile. |

 © Palo Alto Networks, Inc.

| Forward Firewall Traps to an SNMP Manager (Continued) | |
|---|---|
| Step 3 Configure log forwarding. | 1. Configure the destinations of Traffic, Threat, and WildFire traps:<br>a. Create a log forwarding profile. For each log type and each severity level or WildFire verdict, select the **SNMP Trap** server profile.<br>b. Assign the log forwarding profile to security rules. The rules will trigger trap generation and forwarding.<br>2. Configure the destinations of System, Config, HIP Match, and Correlation logs. For each log (trap) type and severity level, select the **SNMP Trap** server profile.<br>3. Click **Commit**. |
| Step 4 Monitor the traps in an SNMP manager. | Refer to the documentation of your SNMP manager.<br> When monitoring traps related to firewall interfaces, you must match the interface indexes in the SNMP manager with interface names in the firewall web interface. For details, see Firewall Interface Identifiers in SNMP Managers and NetFlow Collectors. |

## Supported MIBs

The following table lists the Simple Network Management Protocol (SNMP) management information bases (MIBs) that Palo Alto Networks devices support. You must load these MIBs into your SNMP manager to monitor the objects (device statistics and traps) that are defined in the MIBs. For details, see Use an SNMP Manager to Explore MIBs and Objects.

| MIB Type | Supported MIBs |
|---|---|
| **Standard**—The Internet Engineering Task Force (IETF) maintains most standard MIBs. You can download the MIBs from the IETF website.<br>Palo Alto Networks devices don't support every object (OID) in every one of these MIBs. See the Supported MIBs links for an overview of the supported OIDs. | MIB-II<br>IF-MIB<br>HOST-RESOURCES-MIB<br>ENTITY-MIB<br>ENTITY-SENSOR-MIB<br>ENTITY-STATE-MIB<br>IEEE 802.3 LAG MIB<br>LLDP-V2-MIB.my |
| **Enterprise**—You can download the enterprise MIBs from the Palo Alto Networks Technical Documentation site. | PAN-COMMON-MIB.my<br>PAN-GLOBAL-REG-MIB.my<br>PAN-GLOBAL-TC-MIB.my<br>PAN-LC-MIB.my<br>PAN-PRODUCT-MIB.my<br>PAN-ENTITY-EXT-MIB.my<br>PAN-TRAPS.my |

### MIB-II

MIB-II provides object identifiers (OIDs) for network management protocols in TCP/IP-based networks. Use this MIB to monitor general information about devices and interfaces. For example, you can analyze trends in bandwidth usage by interface type (ifType object) to determine if the firewall needs more interfaces of that type to accommodate spikes in traffic volume.

Palo Alto Networks devices support only the following object groups:

| Object Group | Description |
|---|---|
| system | Provides device information such as the hardware model, system uptime, FQDN, and physical location. |
| interfaces | Provides statistics for physical and logical interfaces such as type, current bandwidth (speed), operational status (for example, up or down), and discarded packets. Logical interface support includes VPN tunnels, aggregate groups, Layer 2 subinterfaces, Layer 3 subinterfaces, loopback interfaces, and VLAN interfaces. |

RFC 1213 defines this MIB.

 © Palo Alto Networks, Inc.

## IF-MIB

IF-MIB supports interface types (physical and logical) and larger counters (64K) beyond those defined in MIB-II. Use this MIB to monitor interface statistics in addition to those that MIB-II provides. For example, to monitor the current bandwidth of high-speed interfaces (greater than 2.2Gps) such as the 10G interfaces of the PA-5000 Series firewalls, you must check the ifHighSpeed object in IF-MIB instead of the ifSpeed object in MIB-II. IF-MIB statistics can be useful when evaluating the capacity of your network.

Palo Alto Networks devices support only the ifXTable in IF-MIB, which provides interface information such as the number of multicast and broadcast packets transmitted and received, whether an interface is in promiscuous mode, and whether an interface has a physical connector.

RFC 2863 defines this MIB.

## HOST-RESOURCES-MIB

HOST-RESOURCES-MIB provides information for host computer resources. Use this MIB to monitor CPU and memory usage statistics for devices. For example, checking the current CPU load (hrProcessorLoad object) can help you troubleshoot performance issues on the firewall.

Palo Alto Networks devices support portions of the following object groups:

| Object Group | Description |
|---|---|
| hrDevice | Provides information such as CPU load, storage capacity, and partition size. The hrProcessorLoad OIDs provide an average of the cores that process packets. For the PA-5060 firewall, which has multiple dataplanes (DPs), the average is of the cores across all the three DPs that process packets. |
| hrSystem | Provides information such as device uptime, number of current user sessions, and number of current processes. |
| hrStorage | Provides information such as the amount of used storage. |

RFC 2790 defines this MIB.

## ENTITY-MIB

ENTITY-MIB provides OIDs for multiple logical and physical components. Use this MIB to determine what physical components are loaded on a device (for example, fans and temperature sensors) and see related information such as models and serial numbers. You can also use the index numbers for these components to determine their operational status in the ENTITY-SENSOR-MIB and ENTITY-STATE-MIB.

Palo Alto Networks devices support only portions of the entPhysicalTable group:

| Object | Description |
|---|---|
| entPhysicalIndex | A single namespace that includes disk slots and disk drives. |
| entPhysicalDescr | The component description. |

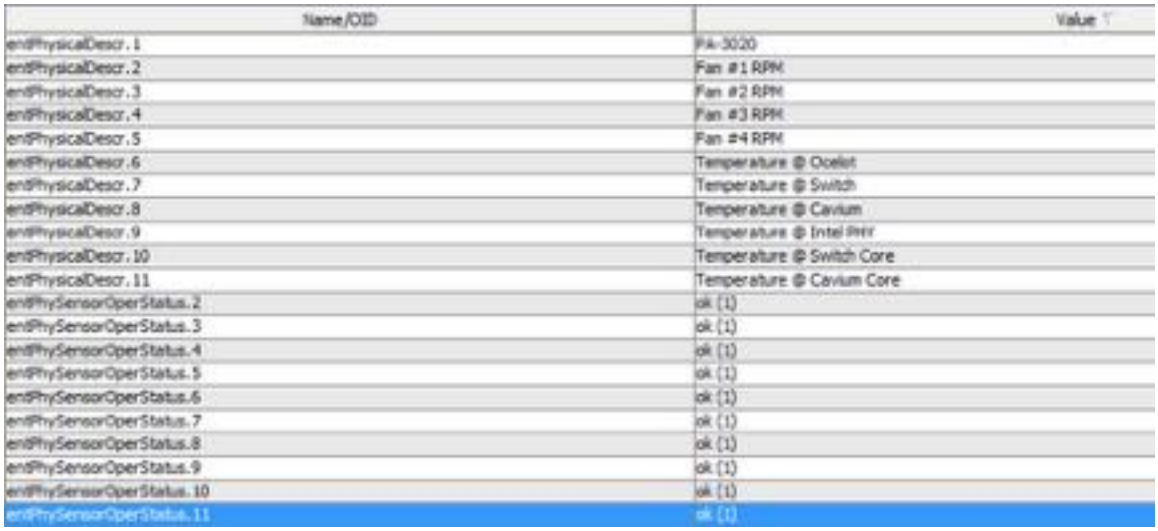
| Object | Description |
|---|---|
| entPhysicalVendorType | The sysObjectID (see PAN-PRODUCT-MIB.my) when it is available (chassis and module objects). |
| entPhysicalContainedIn | The value of entPhysicalIndex for the component that contains this component. |
| entPhysicalClass | Chassis (3), container (5) for a slot, power supply (6), fan (7), sensor (8) for each temperature or other environmental, and module (9) for each line card. |
| entPhysicalParentRelPos | The relative position of this *child* component among its *sibling* components. Sibling components are defined as entPhysicalEntry components that share the same instance values of each of the entPhysicalContainedIn and entPhysicalClass objects. |
| entPhysicalName | Supported only if the management (MGT) interface allows for naming the line card. |
| entPhysicalHardwareRev | The vendor-specific hardware revision of the component. |
| entPhysicalFirwareRev | The vendor-specific firmware revision of the component. |
| entPhysicalSoftwareRev | The vendor-specific software revision of the component. |
| entPhysicalSerialNum | The vendor-specific serial number of the component. |
| entPhysicalMfgName | The name of the manufacturer of the component. |
| entPhysicalMfgDate | The date when the component was manufactured. |
| entPhysicalModelName | The disk model number. |
| entPhysicalAlias | An alias that the network manager specified for the component. |
| entPhysicalAssetID | A user-assigned asset tracking identifier that the network manager specified for the component. |
| entPhysicalIsFRU | Indicates whether the component is a field replaceable unit (FRU). |
| entPhysicalUris | The Common Language Equipment Identifier (CLEI) number of the component (for example, URN:CLEI:CNME120ARA). |

RFC 4133 defines this MIB.

## ENTITY-SENSOR-MIB

ENTITY-SENSOR-MIB adds support for physical sensors of networking equipment beyond what ENTITY-MIB defines. Use this MIB in tandem with the ENTITY-MIB to monitor the operational status of the physical components of a device (for example, fans and temperature sensors). For example, to troubleshoot issues that might result from environmental conditions, you can map the entity indexes from the ENTITY-MIB (entPhysicalDescr object) to operational status values (entPhysSensorOperStatus object) in the ENTITY-SENSOR-MIB. In the following example, all the fans and temperature sensors for a PA-3020 firewall are working:

 © Palo Alto Networks, Inc.



| Name/OID | Value |
|---|---|
| entPhysicalDescr.1 | PA-3020 |
| entPhysicalDescr.2 | Fan #1 RPM |
| entPhysicalDescr.3 | Fan #2 RPM |
| entPhysicalDescr.4 | Fan #3 RPM |
| entPhysicalDescr.5 | Fan #4 RPM |
| entPhysicalDescr.6 | Temperature @ Ocelot |
| entPhysicalDescr.7 | Temperature @ Switch |
| entPhysicalDescr.8 | Temperature @ Cavium |
| entPhysicalDescr.9 | Temperature @ Intel PHY |
| entPhysicalDescr.10 | Temperature @ Switch Core |
| entPhysicalDescr.11 | Temperature @ Cavium Core |
| entPhySensorOperStatus.2 | ok (1) |
| entPhySensorOperStatus.3 | ok (1) |
| entPhySensorOperStatus.4 | ok (1) |
| entPhySensorOperStatus.5 | ok (1) |
| entPhySensorOperStatus.6 | ok (1) |
| entPhySensorOperStatus.7 | ok (1) |
| entPhySensorOperStatus.8 | ok (1) |
| entPhySensorOperStatus.9 | ok (1) |
| entPhySensorOperStatus.10 | ok (1) |
| entPhySensorOperStatus.11 | ok (1) |

The same OID might refer to different sensors on different device platforms. Use the ENTITY-MIB for the targeted platform to match the value to the description.

Palo Alto Networks devices support only portions of the entPhySensorTable group. The supported portions vary by platform. The devices support only thermal (temperature in Celsius) and fan (in RPM) sensors.

RFC 3433 defines the ENTITY-SENSOR-MIB.

## ENTITY-STATE-MIB

ENTITY-STATE-MIB provides information about the state of physical components beyond what ENTITY-MIB defines, including the administrative and operational state of components in chassis-based platforms. Use this MIB in tandem with the ENTITY-MIB to monitor the operational state of the components of a PA-7000 Series firewall (for example, line cards, fan trays, and power supplies). For example, to troubleshoot log forwarding issues for Threat logs, you can map the log processing card (LPC) indexes from the ENTITY-MIB (entPhysicalDescr object) to operational state values (entStateOper object) in the ENTITY-STATE-MIB. The operational state values use numbers to indicate state: 1 for unknown, 2 for disabled, 3 for enabled, and 4 for testing. The PA-7000 Series firewall is the only Palo Alto Networks device that supports this MIB.

RFC 4268 defines the ENTITY-STATE-MIB.

## IEEE 802.3 LAG MIB

Use the IEEE 802.3 LAG MIB to monitor the status of aggregate groups that have Link Aggregation Control Protocol (LACP) enabled. When the firewall logs LACP events, it also generates traps that are useful for troubleshooting. For example, the traps can tell you whether traffic interruptions between the firewall and an LACP peer resulted from lost connectivity or from mismatched interface speed and duplex values.

PAN-OS implements the following SNMP tables for LACP. Note that the dot3adTablesLastChanged object indicates the time of the most recent change to dot3adAggTable, dot3adAggPortListTable, and dot3adAggPortTable.

| Table | Description |
|---|---|
| Aggregator Configuration Table (dot3adAggTable) | This table contains information about every aggregate group that is associated with a firewall. Each aggregate group has one entry.<br>Some table objects have restrictions, which the dot3adAggIndex object describes. This index is the unique identifier that the local system assigns to the aggregate group. It identifies an aggregate group instance among the subordinate managed objects of the containing object. The identifier is read-only.<br> The ifTable MIB (a list of interface entries) does not support logical interfaces and therefore does not have an entry for the aggregate group. |
| Aggregation Port List Table (dot3adAggPortListTable) | This table lists the ports associated with each aggregate group in a firewall. Each aggregate group has one entry.<br>The dot3adAggPortListPorts attribute lists the complete set of ports associated with an aggregate group. Each bit set in the list represents a port member. For non-chassis platforms, this is a 64-bit value. For chassis platforms, the value is an array of eight 64-bit entries. |
| Aggregation Port Table (dot3adAggPortTable) | This table contains LACP configuration information about every port associated with an aggregate group in a firewall. Each port has one entry. The table has no entries for ports that are not associated with an aggregate group. |
| LACP Statistics Table (dot3adAggPortStatsTable) | This table contains link aggregation information about every port associated with an aggregate group in a firewall. Each port has one row. The table has no entries for ports that are not associated with an aggregate group. |

The IEEE 802.3 LAG MIB includes the following LACP-related traps:

| Trap Name | Description |
|---|---|
| panLACPLostConnectivityTrap | The peer lost connectivity to the firewall. |
| panLACPUnresponsiveTrap | The peer does not respond to the firewall. |
| panLACPNegoFailTrap | LACP negotiation with the peer failed. |
| panLACPSpeedDuplexTrap | The link speed and duplex settings on the firewall and peer do not match. |
| panLACPLinkDownTrap | An interface in the aggregate group is down. |
| panLACPLacpDownTrap | An interface was removed from the aggregate group. |
| panLACPLacpUpTrap | An interface was added to the aggregate group. |

For the MIB definitions, refer to IEEE 802.3 LAG MIB.

 © Palo Alto Networks, Inc.

## LLDP-V2-MIB.my

Use the LLDP-V2-MIB to monitor Link Layer Discovery Protocol (LLDP) events. For example, you can check the lldpV2StatsRxPortFramesDiscardedTotal object to see the number of LLDP frames that were discarded for any reason. The Palo Alto Networks firewall uses LLDP to discover neighboring devices and their capabilities. LLDP makes troubleshooting easier, especially for virtual wire deployments where the ping or traceroute utilities won't detect the firewall.

Palo Alto Networks devices support all the LLDP-V2-MIB objects except:

- The following lldpV2Statistics objects:
  - lldpV2StatsRemTablesLastChangeTime
  - lldpV2StatsRemTablesInserts
  - lldpV2StatsRemTablesDeletes
  - lldpV2StatsRemTablesDrops
  - lldpV2StatsRemTablesAgeouts
- The following lldpV2RemoteSystemsData objects:
  - The lldpV2RemOrgDefInfoTable table
  - In the lldpV2RemTable table: lldpV2RemTimeMark

RFC 4957 defines this MIB.

## PAN-COMMON-MIB.my

Use the PAN-COMMON-MIB to monitor the following information for Palo Alto Networks devices:

| Object Group | Description |
|---|---|
| panSys | Contains such objects as device software/hardware versions, dynamic content versions, serial number, HA mode/state, and global counters.<br>The global counters include those related to Denial of Service (DoS), IP fragmentation, TCP state, and dropped packets. Tracking these counters enables you to monitor traffic irregularities that result from DoS attacks, device or connection faults, or resource limitations. PAN-COMMON-MIB supports global counters for firewalls but not for Panorama. |
| panChassis | Chassis type and M-Series appliance mode (Panorama or Log Collector). |
| panSession | Session utilization information. For example, the total number of active sessions on the firewall or a specific virtual system. |
| panMgmt | Status of the connection from the firewall to the Panorama management server. |
| panGlobalProtect | GlobalProtect gateway utilization as a percentage, maximum tunnels allowed, and number of active tunnels. |

| Object Group | Description |
|---|---|
| panLogCollector | Log Collector information such as the logging rate, log database storage duration (in days), and RAID disk usage. |

## PAN-GLOBAL-REG-MIB.my

PAN-GLOBAL-REG-MIB.my contains global, top-level OID definitions for various sub-trees of Palo Alto Networks enterprise MIB modules. This MIB doesn't contain objects for you to monitor; it is required only for referencing by other MIBs.

## PAN-GLOBAL-TC-MIB.my

PAN-GLOBAL-TC-MIB.my defines conventions (for example, character length and allowed characters) for the text values of objects in Palo Alto Networks enterprise MIB modules. All Palo Alto Networks products use these conventions. This MIB doesn't contain objects for you to monitor; it is required only for referencing by other MIBs.

## PAN-LC-MIB.my

PAN-LC-MIB.my contains definitions of managed objects that Log Collectors (M-Series appliances in Log Collector mode) implement. Use this MIB to monitor the logging rate, log database storage duration (in days), and disk usage (in MB) of each logical disk (up to four) on a Log Collector. For example, you can use this information to determine whether you should add more Log Collectors or forward logs to an external server (for example, a syslog server) for archiving.

## PAN-PRODUCT-MIB.my

PAN-PRODUCT-MIB.my defines sysObjectID OIDs for all Palo Alto Networks products. This MIB doesn't contain objects for you to monitor; it is required only for referencing by other MIBs.

## PAN-ENTITY-EXT-MIB.my

Use PAN-ENTITY-EXT-MIB.my in tandem with the ENTITY-MIB to monitor power usage for the physical components of a PA-7000 Series firewall (for example, fan trays, and power supplies), which is the only Palo Alto Networks device that supports this MIB. For example, when troubleshooting log forwarding issues, you might want to check the power usage of the log processing cards (LPCs): you can map the LPC indexes from the ENTITY-MIB (entPhysicalDescr object) to values in the PAN-ENTITY-EXT-MIB (panEntryFRUModelPowerUsed object).

 © Palo Alto Networks, Inc.

## PAN-TRAPS.my

Use PAN-TRAPS.my to see a complete listing of all the generated traps and information about them (for example, a description). For a list of traps that Palo Alto Networks devices support, refer to the PAN-COMMON-MIB.my **> panCommonEvents > panCommonEventsEvents > panCommonEventEventsV2** object.

# NetFlow Monitoring

NetFlow is an industry-standard protocol that the firewall can use to export statistics about the IP traffic that traverses its interfaces. The firewall exports the statistics as NetFlow fields to a NetFlow collector. The NetFlow collector is a server you use to analyze network traffic for security, administration, accounting and troubleshooting. All Palo Alto Networks firewalls support NetFlow (Version 9) except the PA-4000 Series and PA-7000 Series firewalls. The firewalls support only unidirectional NetFlow, not bidirectional. You can enable NetFlow exports on all interface types except HA, log card, or decrypt mirror. To identify firewall interfaces in a NetFlow collector, see Firewall Interface Identifiers in SNMP Managers and NetFlow Collectors. The firewall supports standard and enterprise (PAN-OS specific) NetFlow templates.

- Configure NetFlow Exports
- NetFlow Templates

## Configure NetFlow Exports

| Configure NetFlow Exports | | |
|---|---|---|
| Step 1 | Create a NetFlow server profile. | 1. Select **Device > Server Profiles > NetFlow** and click **Add**.<br>2. Enter a **Name** for the profile.<br>3. Specify the frequency at which the firewall refreshes NetFlow Templates in **Minutes** (default is 30) or **Packets** (default is 20), according to the requirements of your NetFlow collector.<br>4. For the **Active Timeout**, specify the frequency in minutes at which the firewall exports records (default is 5).<br>5. Select the **PAN-OS Field Types** check box if you want the firewall to export App-ID and User-ID fields.<br>6. For each NetFlow collector (up to two per profile) that will receive fields, click **Add** and enter an identifying server **Name**, hostname or IP address (**NetFlow Server**), and access **Port** (default is 2055).<br>7. Click **OK** to save the profile. |
| Step 2 | Assign the NetFlow server profile to the interfaces that carry the traffic you want to analyze.<br>In this example, you assign the profile to an existing Ethernet interface. | 1. Select **Network > Interfaces > Ethernet** and click an interface name to edit it.<br>2. In the **NetFlow Profile** drop-down, select the NetFlow server profile and click **OK**.<br>3. Click **Commit**. |
| Step 3 | Monitor the firewall traffic in a NetFlow collector. | Refer to the documentation for your NetFlow collector.<br>When monitoring statistics, you must match the interface indexes in the NetFlow collector with interface names in the firewall web interface. For details, see Firewall Interface Identifiers in SNMP Managers and NetFlow Collectors. |

 © Palo Alto Networks, Inc.

## NetFlow Templates

NetFlow collectors use templates to decipher the fields that the firewall exports. The firewall selects a template based on the type of exported data: IPv4 or IPv6 traffic, with or without NAT, and with standard or enterprise-specific (PAN-OS specific) fields. The firewall periodically refreshes templates to re-evaluate which one to use (in case the type of exported data changes) and to apply any changes to the fields in the selected template. When you Configure NetFlow Exports, you set the refresh frequency according to the requirements of your NetFlow collector.

The Palo Alto Networks firewall supports the following NetFlow templates:

| Template | ID |
|---|---|
| IPv4 Standard | 256 |
| IPv4 Enterprise | 257 |
| IPv6 Standard | 258 |
| IPv6 Enterprise | 259 |
| IPv4 with NAT Standard | 260 |
| IPv4 with NAT Enterprise | 261 |
| IPv6 with NAT Standard | 262 |
| IPv6 with NAT Enterprise | 263 |

The following table lists the NetFlow fields that the firewall can send, along with the templates that define them:

| Value | Field | Description | Templates |
|---|---|---|---|
| 1 | IN_BYTES | Incoming counter with length N * 8 bits for the number of bytes associated with an IP flow. By default, N is 4. | All templates |
| 2 | IN_PKTS | Incoming counter with length N * 8 bits for the number of packets associated with an IP glow. By default, N is 4. | All templates |
| 4 | PROTOCOL | IP protocol byte. | All templates |
| 5 | TOS | Type of Service byte setting when entering the ingress interface. | All templates |
| 6 | TCP_FLAGS | Total of all the TCP flags in this flow. | All templates |
| 7 | L4_SRC_PORT | TCP/UDP source port number (for example, FTP, Telnet, or equivalent). | All templates |
| 8 | IPV4_SRC_ADDR | IPv4 source address. | IPv4 standard<br>IPv4 enterprise<br>IPv4 with NAT standard<br>IPv4 with NAT enterprise |

| Value | Field | Description | Templates |
|---|---|---|---|
| 10 | INPUT_SNMP | Input interface index. The value length is 2 bytes by default, but higher values are possible. For details on how Palo Alto Networks firewalls generate interface indexes, see Firewall Interface Identifiers in SNMP Managers and NetFlow Collectors. | All templates |
| 11 | L4_DST_PORT | TCP/UDP destination port number (for example, FTP, Telnet, or equivalent). | All templates |
| 12 | IPV4_DST_ADDR | IPv4 destination address. | IPv4 standard<br>IPv4 enterprise<br>IPv4 with NAT standard<br>IPv4 with NAT enterprise |
| 14 | OUTPUT_SNMP | Output interface index. The value length is 2 bytes by default, but higher values are possible. For details on how Palo Alto Networks firewalls generate interface indexes, see Firewall Interface Identifiers in SNMP Managers and NetFlow Collectors. | All templates |
| 21 | LAST_SWITCHED | System uptime in milliseconds when the last packet of this flow was switched. | All templates |
| 22 | FIRST_SWITCHED | System uptime in milliseconds when the first packet of this flow was switched. | All templates |
| 27 | IPV6_SRC_ADDR | IPv6 source address. | IPv6 standard<br>IPv6 enterprise<br>IPv6 with NAT standard<br>IPv6 with NAT enterprise |
| 28 | IPV6_DST_ADDR | IPv6 destination address. | IPv6 standard<br>IPv6 enterprise<br>IPv6 with NAT standard<br>IPv6 with NAT enterprise |
| 32 | ICMP_TYPE | Internet Control Message Protocol (ICMP) packet type. This is reported as:<br>ICMP Type * 256 + ICMP code | All templates |
| 61 | DIRECTION | Flow direction:<br>• 0 = ingress<br>• 1 = egress | All templates |

 © Palo Alto Networks, Inc.

| Value | Field | Description | Templates |
|---|---|---|---|
| 148 | flowId | An identifier of a flow that is unique within an observation domain. You can use this information element to distinguish between different flows if flow keys such as IP addresses and port numbers are not reported or are reported in separate records. The flowID corresponds to the session ID field in Traffic and Threat logs. | All templates |
| 233 | firewallEvent | Indicates a firewall event:<br>• 0 = Ignore (invalid)<br>• 1 = Flow created<br>• 2 = Flow deleted<br>• 3 = Flow denied<br>• 4 = Flow alert<br>• 5 = Flow update (the session state changed from active to deny) | All templates |
| 225 | postNATSourceIPv4Address | The definition of this information element is identical to that of sourceIPv4Address, except that it reports a modified value that the firewall produced during network address translation after the packet traversed the interface. | IPv4 with NAT standard<br>IPv4 with NAT enterprise |
| 226 | postNATDestinationIPv4Address | The definition of this information element is identical to that of destinationIPv4Address, except that it reports a modified value that the firewall produced during network address translation after the packet traversed the interface. | IPv4 with NAT standard<br>IPv4 with NAT enterprise |
| 227 | postNAPTSourceTransportPort | The definition of this information element is identical to that of sourceTransportPort, except that it reports a modified value that the firewall produced during network address port translation after the packet traversed the interface. | IPv4 with NAT standard<br>IPv4 with NAT enterprise |
| 228 | postNAPTDestinationTransportPort | The definition of this information element is identical to that of destinationTransportPort, except that it reports a modified value that the firewall produced during network address port translation after the packet traversed the interface. | IPv4 with NAT standard<br>IPv4 with NAT enterprise |

© Palo Alto Networks, Inc.

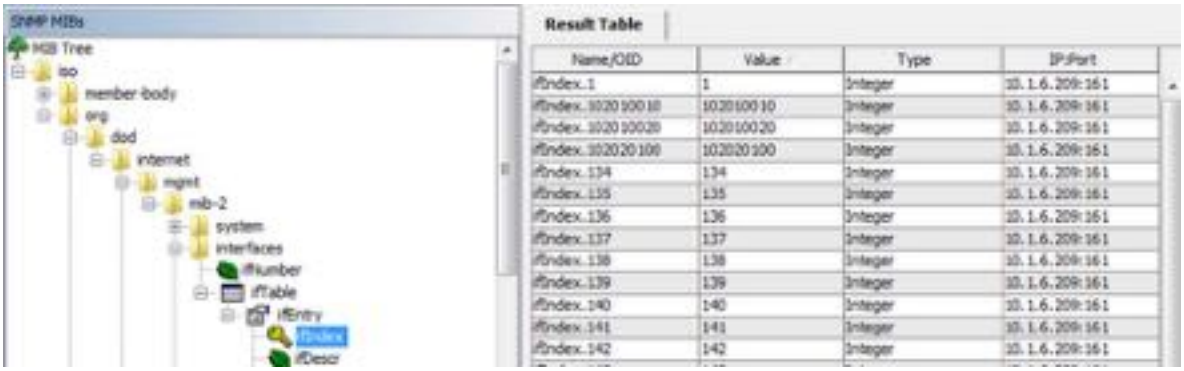
| Value | Field | Description | Templates |
|---|---|---|---|
| 281 | postNATSourceIPv6Address | The definition of this information element is identical to the definition of information element sourceIPv6Address, except that it reports a modified value that the firewall produced during NAT64 network address translation after the packet traversed the interface. See RFC 2460 for the definition of the source address field in the IPv6 header. See RFC 6146 for NAT64 specification. | IPv6 with NAT standard<br>IPv6 with NAT enterprise |
| 282 | postNATDestinationIPv6Address | The definition of this information element is identical to the definition of information element destinationIPv6Address, except that it reports a modified value that the firewall produced during NAT64 network address translation after the packet traversed the interface. See RFC 2460 for the definition of the destination address field in the IPv6 header. See RFC 6146 for NAT64 specification. | IPv6 with NAT standard<br>IPv6 with NAT enterprise |
| 346 | privateEnterpriseNumber | This is a unique private enterprise number that identifies Palo Alto Networks: 25461. | IPv4 enterprise<br>IPv4 with NAT enterprise<br>IPv6 enterprise<br>IPv6 with NAT enterprise |
| 56701 | App-ID | The name of an application that App-ID identified. The name can be up to 32 bytes. | IPv4 enterprise<br>IPv4 with NAT enterprise<br>IPv6 enterprise<br>IPv6 with NAT enterprise |
| 56702 | User-ID | A username that User-ID identified. The name can be up to 64 bytes. | IPv4 enterprise<br>IPv4 with NAT enterprise<br>IPv6 enterprise<br>IPv6 with NAT enterprise |

 © Palo Alto Networks, Inc.

# Firewall Interface Identifiers in SNMP Managers and NetFlow Collectors

When you use a NetFlow collector (see NetFlow Monitoring) or SNMP manager (see SNMP Monitoring and Traps) to monitor the Palo Alto Networks firewall, an interface index (SNMP ifindex object) identifies the interface that carried a particular flow (see Figure: Interface Indexes in an SNMP Manager). In contrast, the firewall web interface uses interface names as identifiers (for example, ethernet1/1), not indexes. To understand which statistics that you see in a NetFlow collector or SNMP manager apply to which firewall interface, you must be able to match the interface indexes with interface names.

**Figure: Interface Indexes in an SNMP Manager**



You can match the indexes with names by understanding the formulas that the firewall uses to calculate indexes. The formulas vary by platform and interface type: physical or logical.

Physical interface indexes have a range of 1-9999, which the firewall calculates as follows:

| Firewall Platform | Calculation | Example Interface Index |
|---|---|---|
| Non-chassis based:<br>VM-Series, PA-200, PA-500, PA-2000 Series, PA-3000 Series, PA-4000 Series, PA-5000 Series<br>The PA-4000 Series platform supports SNMP but not NetFlow. | MGT port + physical port offset<br>• MGT port—This is a constant that depends on the platform:<br>  • 2 for hardware-based firewalls (for example, the PA-5000 Series firewall)<br>  • 1 for the VM-Series firewall<br>• Physical port offset—This is the physical port number. | PA-5000 Series firewall, Eth1/4 =<br>2 (MGT port) + 4 (physical port) = **6** |

| Firewall Platform | Calculation | Example Interface Index |
|---|---|---|
| Chassis based:<br>PA-7000 Series firewalls<br>This platform supports SNMP but not NetFlow. | (Max. ports * slot) + physical port offset + MGT port<br>• Maximum ports—This is a constant of 64.<br>• Slot—This is the chassis slot number of the network interface card.<br>• Physical port offset—This is the physical port number.<br>• MGT port—This is a constant of 5 for PA-7000 Series firewalls. | PA-7000 Series firewall, Eth3/9 =<br>[64 (max. ports) * 3 (slot)] + 9 (physical port) + 5 (MGT port) = **206** |

Logical interface indexes for all platforms are nine-digit numbers that the firewall calculates as follows:

| Interface Type | Range | Digit 9 | Digits 7-8 | Digits 5-6 | Digits 1-4 | Example Interface Index |
|---|---|---|---|---|---|---|
| Layer 3 subinterface | 101010001-199999999 | Type: 1 | Interface slot: 1-9 (01-09) | Interface port: 1-9 (01-09) | Subinterface: suffix 1-9999 (0001-9999) | Eth1/5.22 = 100000000 (type) + 100000 (slot) + 50000 (port) + 22 (suffix) = **101050022** |
| Layer 2 subinterface | 101010001-199999999 | Type: 1 | Interface slot: 1-9 (01-09) | Interface port: 1-9 (01-09) | Subinterface: suffix 1-9999 (0001-9999) | Eth2/3.6 = 100000000 (type) + 200000 (slot) + 30000 (port) + 6 (suffix) = **102030006** |
| Vwire subinterface | 101010001-199999999 | Type: 1 | Interface slot: 1-9 (01-09) | Interface port: 1-9 (01-09) | Subinterface: suffix 1-9999 (0001-9999) | Eth4/2.312 = 100000000 (type) + 400000 (slot) + 20000 (port) + 312 (suffix) = **104020312** |
| VLAN | 200000001-200009999 | Type: 2 | 00 | 00 | VLAN suffix: 1-9999 (0001-9999) | VLAN.55 = 200000000 (type) + 55 (suffix) = **200000055** |
| Loopback | 300000001-300009999 | Type: 3 | 00 | 00 | Loopback suffix: 1-9999 (0001-9999) | Loopback.55 = 300000000 (type) + 55 (suffix) = **300000055** |
| Tunnel | 400000001-400009999 | Type: 4 | 00 | 00 | Tunnel suffix: 1-9999 (0001-9999) | Tunnel.55 = 400000000 (type) + 55 (suffix) = **400000055** |
| Aggregate group | 500010001-500089999 | Type: 5 | 00 | AE suffix: 1-8 (01-08) | Subinterface: suffix 1-9999 (0001-9999) | AE5.99 = 500000000 (type) + 50000 (AE Suffix) + 99 (suffix) = **500050099** |

© Palo Alto Networks, Inc.

# User-ID

The User Identification (User-ID™) feature of the Palo Alto Networks next-generation firewall enables you to create policies and perform reporting based on users and groups rather than individual IP addresses.

- User-ID Overview
- User-ID Concepts
- Enable User-ID
- Map Users to Groups
- Map IP Addresses to Users
- Configure a Firewall to Share User Mapping Data with Other Firewalls
- Enable User- and Group-Based Policy
- Enable Policy for Users with Multiple Accounts
- Verify the User-ID Configuration
- Deploy User-ID in a Large-Scale Network

# User-ID Overview

User-ID seamlessly integrates Palo Alto Networks firewalls with a range of enterprise directory and terminal services offerings, enabling you to tie application activity and policy rules to users and groups—not just IP addresses. Furthermore, with User-ID enabled, the Application Command Center (ACC), App-Scope, reports, and logs all include usernames in addition to user IP addresses.

Palo Alto Networks firewalls support monitoring of the following enterprise services:

- Microsoft Active Directory
- Lightweight Directory Access Protocol (LDAP)
- Novell eDirectory
- Citrix Metaframe Presentation Server or XenApp
- Microsoft Terminal Services

For user- and group-based policies, the firewall requires a list of all available users and their corresponding group mappings that you can select when defining your policies. The firewall collects Group Mapping information by connecting directly to your LDAP directory server.

To enforce user- and group-based policies, the firewall must be able to map the IP addresses in the packets it receives to usernames. User-ID provides many mechanisms to collect this User Mapping information. For example, the User-ID agent monitors server logs for login events, probes clients, and listens for syslog messages from authenticating services. To identify mappings for IP addresses that the agent didn't map, you can configure the firewall to redirect HTTP requests to a Captive Portal login. You can tailor the user mapping mechanisms to suit your environment, and even use different mechanisms at different sites.

User-ID does not work in environments where the source IP addresses of users are subject to NAT translation before the firewall maps the IP addresses to usernames.

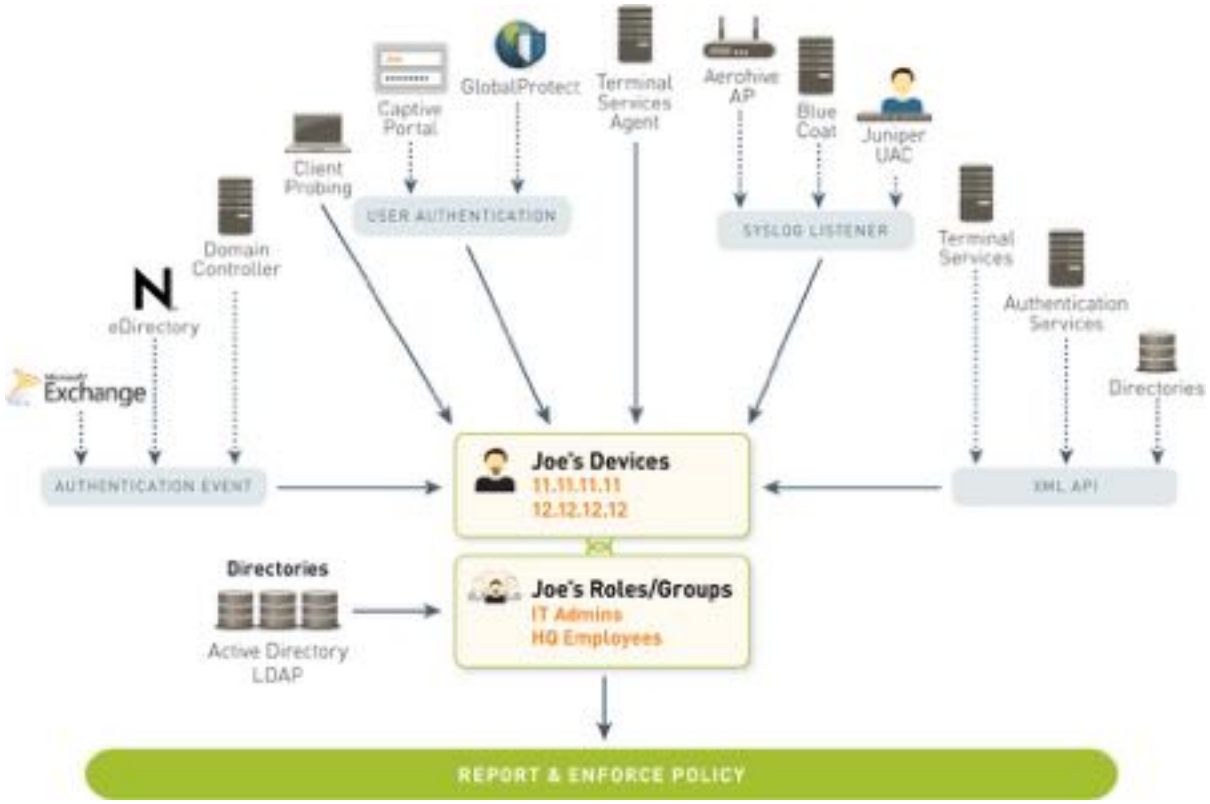
**Figure: User-ID**



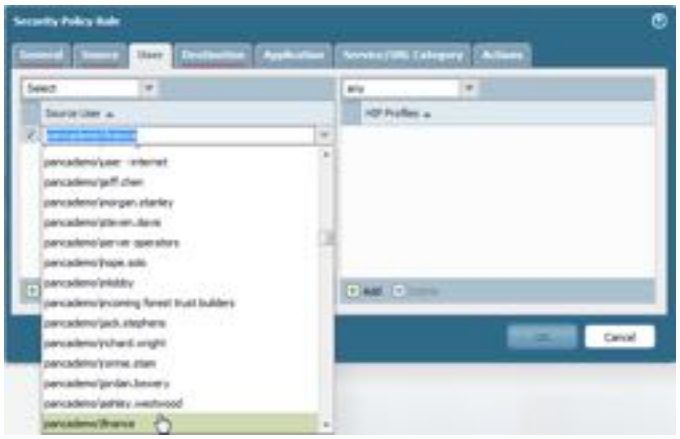
See User-ID Concepts for information on how User-ID works and Enable User-ID for instructions on setting up User-ID.

# User-ID Concepts

▲ Group Mapping
▲ User Mapping

## Group Mapping

To define policy rules based on user or group, first you create an LDAP server profile that defines how the firewall connects and authenticates to your directory server. The firewall supports a variety of directory servers, including Microsoft Active Directory (AD), Novell eDirectory, and Sun ONE Directory Server. The server profile also defines how the firewall searches the directory to retrieve the list of groups and the corresponding list of members. Next you create a group mapping configuration to Map Users to Groups. Then you can select the users or groups when defining policy rules.



Defining policy rules based on group membership rather than on individual users simplifies administration because you don't have to update the rules whenever new users are added to a group. For example, the following security rules allow access to specific internal applications based on group membership:

| Name | Tags | Type | Zone | Address | User | HIP Profile | Application |
|---|---|---|---|---|---|---|---|
| CRM Access | none | universal | trust | any | Finance | Patches | sap |
| Eng access | none | universal | trust | any | Engineering | any | bugzilla |
| | | | | | | | perforce |

When configuring group mapping, you can limit which groups will be available in policy rules. You can specify groups that already exist in your directory service or define custom groups based on LDAP filters. Defining custom groups can be quicker than creating new groups or changing existing ones on an LDAP server, and doesn't require an LDAP administrator to intervene. User-ID maps all the LDAP directory users who match the filter to the custom group. For example, you might want a security policy that allows contractors in the Marketing Department to access social networking sites. If no Active Directory group exists for that department, you can configure an LDAP filter that matches users for whom the LDAP attribute Department is set to Marketing. Log queries and reports that are based on user groups will include custom groups.

 © Palo Alto Networks, Inc.

# User Mapping

Having the names of the users and groups is only one piece of the puzzle. The firewall also needs to know which IP addresses map to which users so that security rules can be enforced appropriately. Figure: User-ID illustrates the different methods that are used to identify users and groups on your network and shows how user mapping and group mapping work together to enable user- and group-based security enforcement and visibility.

The following topics describe the different methods of user mapping:

- Server Monitoring
- Client Probing
- Port Mapping
- Syslog
- Captive Portal
- GlobalProtect
- User-ID XML API

## Server Monitoring

With server monitoring a User-ID agent—either a Windows-based agent running on a domain server in your network, or the integrated PAN-OS User-ID agent running on the firewall—monitors the security event logs for specified Microsoft Exchange Servers, domain controllers, or Novell eDirectory servers for login events. For example, in an AD environment, you can configure the User-ID agent to monitor the security logs for Kerberos ticket grants or renewals, Exchange server access (if configured), and file and print service connections. Note that for these events to be recorded in the security log, the AD domain must be configured to log successful account login events. In addition, because users can log in to any of the servers in the domain, you must set up server monitoring for all servers to capture all user login events.

Because server monitoring requires very little overhead and because the majority of users can generally be mapped using this method, it is recommended as the base user mapping method for most User-ID deployments. See Configure User Mapping Using the Windows User-ID Agent or Configure User Mapping Using the PAN-OS Integrated User-ID Agent for details.

## Client Probing

In a Microsoft Windows environment, you can configure the User-ID agent to probe client systems using Windows Management Instrumentation (WMI). The Windows-based User-ID agent can also perform NetBIOS probing (not supported on the PAN-OS integrated User-ID agent). Probing is particularly useful in environments with a high IP address turnover because changes will be reflected on the firewall more quickly, enabling more accurate enforcement of user-based policies. However, if the correlation between IP addresses and users is fairly static, you probably do not need to enable client probing. Because probing can generate a large amount of network traffic (based on the total number of mapped IP addresses), the agent that will be initiating the probes should be located as close as possible to the end clients.

© Palo Alto Networks, Inc.

If probing is enabled, the agent will probe each learned IP address periodically (every 20 minutes by default, but this is configurable) to verify that the same user is still logged in. In addition, when the firewall encounters an IP address for which it has no user mapping, it will send the address to the agent for an immediate probe.

See Configure User Mapping Using the Windows User-ID Agent or Configure User Mapping Using the PAN-OS Integrated User-ID Agent for details.

## Port Mapping

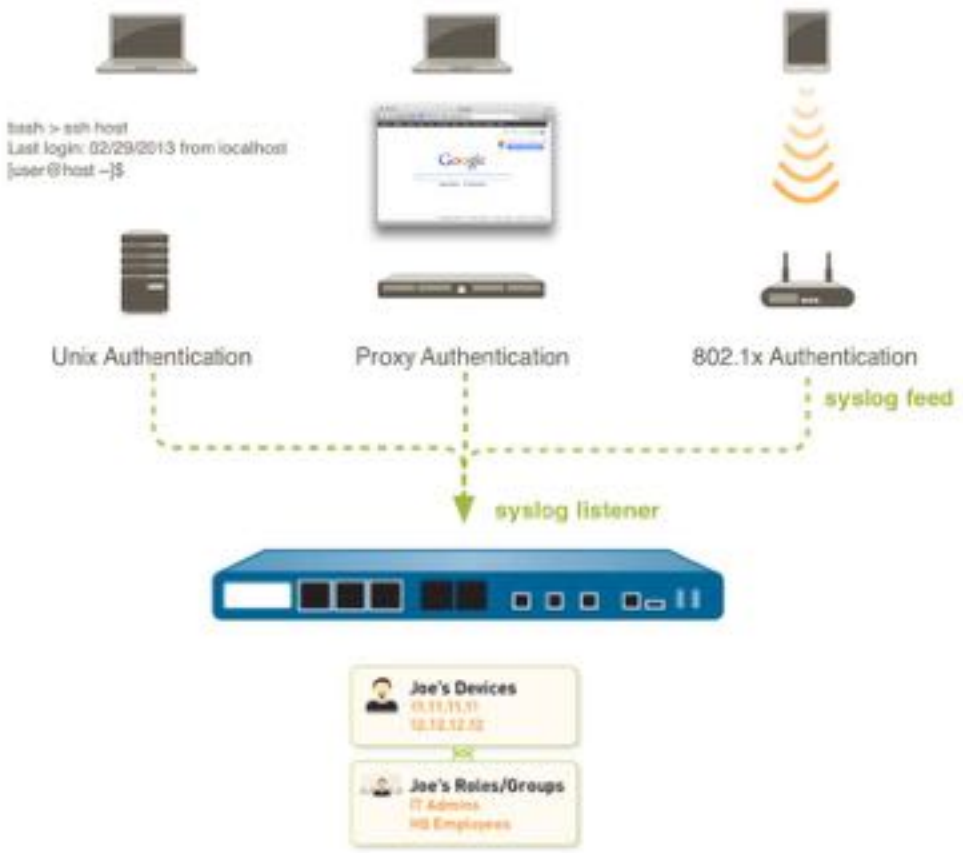
In environments with multi-user systems—such as Microsoft Terminal Server or Citrix environments—many users share the same IP address. In this case, the user-to-IP address mapping process requires knowledge of the source port of each client. To perform this type of mapping, you must install the Palo Alto Networks Terminal Services Agent on the Windows/Citrix terminal server itself to intermediate the assignment of source ports to the various user processes. For terminal servers that do not support the Terminal Services Agent, such as Linux terminal servers, you can use the XML API to send user mapping information from login and logout events to User-ID. See Configure User Mapping for Terminal Server Users for configuration details.

## Syslog

In environments with existing network services that authenticate users—such as wireless controllers, 802.1x devices, Apple Open Directory servers, proxy servers, or other Network Access Control (NAC) mechanisms—the firewall User-ID agent (either the Windows agent or the PAN-OS integrated agent on the firewall) can listen for authentication syslog messages from those services. Syslog filters, which are provided by a content update (integrated User-ID agent only) or configured manually, allow the User-ID agent to parse and extract usernames and IP addresses from authentication syslog events generated by the external service, and add the information to the User-ID IP address-to-username mappings maintained by the firewall. See Configure User-ID to Receive User Mappings from a Syslog Sender for configuration details.

 © Palo Alto Networks, Inc.

**Figure: User-ID Integration with Syslog**



## Captive Portal

If the firewall or the User-ID agent can't map an IP address to a username—for example, if the user isn't logged in or uses an operating system such as Linux that your domain servers don't support—you can configure Captive Portal. Any web traffic (HTTP or HTTPS) that matches a Captive Portal policy rule requires user authentication. You can base the authentication on a transparent browser-challenge (Kerberos Single Sign-On (SSO) or NT LAN Manager (NTLM) authentication), web form (for RADIUS, TACACS+, LDAP, Kerberos, or local database authentication), or client certificates. For details, see Map IP Addresses to Usernames Using Captive Portal.

## GlobalProtect

For mobile or roaming users, the GlobalProtect client provides the user mapping information to the firewall directly. In this case, every GlobalProtect user has an agent or app running on the client that requires the user to enter login credentials for VPN access to the firewall. This login information is then added to the User-ID user mapping table on the firewall for visibility and user-based security policy enforcement. Because GlobalProtect users must authenticate to gain access to the network, the IP address-to-username mapping is

explicitly known. This is the best solution in sensitive environments where you must be certain of who a user is in order to allow access to an application or service. For more information on setting up GlobalProtect, refer to the GlobalProtect Administrator's Guide.

## User-ID XML API

For other types of user access that cannot be mapped using any of the standard user mapping methods or Captive Portal—for example, to add mappings of users connecting from a third-party VPN solution or users connecting to a 802.1x enabled wireless network—you can use the User-ID XML API to capture login events and send them to the User-ID agent or directly to the firewall. See Send User Mappings to User-ID Using the XML API for details.

 © Palo Alto Networks, Inc.

# Enable User-ID

You must complete the following tasks to set up the firewall to user users and groups in policy enforcement, logging, and reporting:

- Map Users to Groups
- Map IP Addresses to Users
- Enable User- and Group-Based Policy
- Verify the User-ID Configuration

© Palo Alto Networks, Inc.

# Map Users to Groups

Use the following procedure to enable the firewall to connect to your LDAP directory and retrieve Group Mapping information:

The following are best practices for group mapping in an Active Directory (AD) environment:

- If you have a single domain, you need only one LDAP server profile that connects the firewall to the domain controller with the best connectivity. You can add additional domain controllers for fault tolerance.
- If you have multiple domains and/or multiple forests, you must create a server profile to connect to a domain server in each domain/forest. Take steps to ensure unique usernames in separate forests.
- If you have Universal Groups, create a server profile to connect to the Global Catalog server.

| Map Users to Groups | |
|---|---|
| Step 1 Add an LDAP server profile.<br><br>The profile defines how the firewall connects to the directory servers from which it collects group mapping information. You can add up to four servers to the profile but they must be the same **Type**. | Configure an LDAP Server Profile:<br>1. Select **Device > Server Profiles > LDAP**, click **Add**, and enter a **Profile Name**.<br>2. For each LDAP server, click **Add** and enter the server **Name**, IP address (**LDAP Server**), and **Port** (default is 389).<br>3. Based on your **Type** selection (for example, **active-directory**), the firewall automatically populates the correct LDAP attributes in the group mapping settings. However, if you customized your LDAP schema, you might need to modify the default settings.<br>4. In the **Base DN** field, enter the Distinguished Name (DN) of the LDAP tree location where you want the firewall to begin its search for user and group information.<br>5. Enter the authentication credentials for binding to the LDAP tree in the **Bind DN**, **Password**, and **Confirm Password** fields. The **Bind DN** can be a fully qualified LDAP name (for example, `cn=administrator,cn=users,dc=acme,dc=local`) or a user principal name (for example, `administrator@acme.local`).<br>6. Click **OK** to save the profile. |

© Palo Alto Networks, Inc.

| Map Users to Groups (Continued) | |
|---|---|
| Step 2 Configure the server settings in a group mapping configuration. | 1. Select **Device > User Identification > Group Mapping Settings**.<br>2. If the firewall has more than one virtual system (vsys), select a **Location** (vsys or **Shared**) for this configuration.<br>3. Click **Add** and enter a unique **Name** to identify the group mapping configuration.<br>4. Select the LDAP **Server Profile** you just created.<br>5. (Optional) By default, the **User Domain** field is blank: the firewall automatically detects the domain names for Active Directory (AD) servers. If you enter a value, it overrides any domain names that the firewall retrieves from the LDAP source. Your entry must be the NetBIOS domain name.<br>6. (Optional) To filter the groups that the firewall tracks for group mapping, in the Group Objects section, enter a **Search Filter** (LDAP query), **Object Class** (group definition), **Group Name**, and **Group Member**.<br>7. (Optional) To filter the users that the firewall tracks for group mapping, in the User Objects section, enter a **Search Filter** (LDAP query), **Object Class** (user definition), and **User Name**.<br>8. (Optional) To match User-ID information with email header information identified in the links and attachments of emails forwarded to WildFire™, enter the list of email domains in your organization in the Mail Domains section, **Domain List** field. Use commas to separate multiple domains (up to 256 characters). After you click **OK**, PAN-OS automatically populates the **Mail Attributes** field based on your LDAP server type (Sun/RFC, Active Directory, or Novell). When a match occurs, the username in the WildFire log email header section will contain a link that opens the **ACC** tab, filtered by user or user group.<br>9. Make sure the **Enabled** check box is selected. |

© Palo Alto Networks, Inc.

| Map Users to Groups (Continued) | |
|---|---|
| Step 3 Limit which groups will be available in policy rules.<br><br>Required only if you want to limit policy rules to specific groups. By default, if you don't specify groups, all groups are available in policy rules.<br><br> Any custom groups you create will also be available in the Allow List of authentication profiles. | 1. Add existing groups from the directory service:<br>a. Select the **Group Include List** tab.<br>b. In the Available Groups list, select the groups you want to appear in policy rules and click the Add icon.<br>2. If you want to base policy rules on user attributes that don't match existing user groups, create custom groups based on LDAP filters:<br>a. Select the **Custom Group** tab and click **Add**.<br>b. Enter a group **Name** that is unique in the group mapping configuration for the current firewall or virtual system. If the **Name** has the same value as the Distinguished Name (DN) of an existing AD group domain, the firewall uses the custom group in all references to that name (for example, in policies and logs).<br>c. Specify an **LDAP Filter** of up to 2,048 UTF-8 characters and click **OK**. The firewall doesn't validate LDAP filters, so it's up to you to ensure they are accurate.<br><br> To minimize the performance impact on the LDAP directory server, use only indexed attributes in the filter.<br>3. Click **OK** and **Commit**. A commit is necessary before custom groups will be available in policies and objects. |

 © Palo Alto Networks, Inc.

# Map IP Addresses to Users

The tasks you perform to map IP addresses to usernames depends on the type and location of the client systems on your network. Complete as many of the following tasks as necessary to enable mapping of your client systems:

- To map users as they log in to your Exchange servers, domain controllers, or eDirectory servers, or Windows clients that can be directly probed, you must configure a User-ID agent to monitor the server logs and probe client systems. You can either Configure User Mapping Using the Windows User-ID Agent (a standalone agent that you install on one or more member servers in the domain that contains the servers and clients that the agent will monitor) or Configure User Mapping Using the PAN-OS Integrated User-ID Agent. For guidance on which agent is appropriate for your network and the required number and placements of agents, refer to Architecting User Identification Deployments.
- If you have clients running multi-user systems in a Windows environment, such as Microsoft Terminal Server or Citrix Metaframe Presentation Server or XenApp, Configure the Palo Alto Networks Terminal Server Agent for User Mapping. For a multi-user system that doesn't run on Windows, you can Retrieve User Mappings from a Terminal Server Using the User-ID XML API.
- To obtain user mappings from existing network services that authenticate users—such as wireless controllers, 802.1x devices, Apple Open Directory servers, proxy servers, or other Network Access Control (NAC) mechanisms—Configure User-ID to Receive User Mappings from a Syslog Sender. You can use either the Windows agent or the agentless user mapping feature on the firewall to listen for authentication syslog messages from the network services.
- If you have users with client systems that aren't logged into your domain servers—for example, users running Linux clients that don't log in to the domain—you can Map IP Addresses to Usernames Using Captive Portal.
- For other clients that you can't map using the preceding methods, you can Send User Mappings to User-ID Using the XML API.
- Because policy is local to each firewall, each firewall needs current user mapping and group mapping information to accurately enforce policy by user and group. However, if you want one firewall to function as the sole, central collection and distribution point for user mappings, you can Configure a Firewall to Share User Mapping Data with Other Firewalls.

# Configure User Mapping Using the Windows User-ID Agent

In most cases, the majority of your network users will have logins to your monitored domain services. For these users, the Palo Alto Networks User-ID agent monitors the servers for login events and performs the IP address to username mapping. The way you configure the User-ID agent depends on the size of your environment and the location of your domain servers. As a best practice, you should locate your User-ID agents near your monitored servers (that is, the monitored servers and the Windows User-ID agent should not be across a WAN link from each other). This is because most of the traffic for user mapping occurs between the agent and the monitored server, with only a small amount of traffic—the delta of IP address mappings since the last update—from the agent to the firewall.

The following topics describe how to install and configure the User-ID Agent and how to configure the firewall to retrieve user mapping information from the agent:

- Install the User-ID Agent
- Configure the User-ID Agent for User Mapping

## Install the User-ID Agent

The following procedure shows how to install the User-ID agent on a member server in the domain and set up the service account with the required permissions. If you are upgrading, the installer will automatically remove the older version, however, it is a good idea to back up the config.xml file before running the installer.

For information about the system requirements for installing the Windows-based User-ID agent and for information on the supported server OS versions are supported, refer to "Operating System (OS) Compatibility User-ID Agent" in the User-ID Agent Release Notes, which are available on the Palo Alto Networks Software Updates page.

| Install the Windows User-ID Agent | | |
|---|---|---|
| Step 1 | Decide where to install the User-ID agent.<br><br>The User-ID agent queries the Domain Controller and Exchange server logs using Microsoft Remote Procedure Calls (MSRPCs), which require a complete transfer of the entire log at each query. Therefore, always install one or more User-ID agents at each site that has servers to be monitored.<br><br> For more detailed information on where to install User-ID agents, refer to Architecting User Identification (User-ID) Deployments. | • You must install the User-ID agent on a system running one of the supported OS versions: see "Operating System (OS) Compatibility User-ID Agent" in the User-ID Agent Release Notes.<br>• Make sure the system that will host the User-ID agent is a member of the same domain as the servers it will monitor.<br>• As a best practice, install the User-ID agent close to the servers it will be monitoring (there is more traffic between the User-ID agent and the monitored servers than there is between the User-ID agent and the firewall, so locating the agent close to the monitored servers optimizes bandwidth usage).<br>• To ensure the most comprehensive mapping of users, you must monitor all servers that contain user login information. You might need to install multiple User-ID agents to efficiently monitor all of your resources. |

 © Palo Alto Networks, Inc.

| Install the Windows User-ID Agent (Continued) | |
|---|---|
| Step 2 Download the User-ID agent installer.<br><br>As a best practice, install the User-ID agent version that is the same as the PAN-OS version running on the firewalls. | 1. Log in to Palo Alto Networks Support site.<br>2. Select **Software Updates** from the Manage Devices section.<br>3. Scroll to the User Identification Agent section of the screen and **Download** the version of the User-ID agent you want to install.<br>4. Save the `UaInstall-x.x.x-xx.msi` file on the system(s) where you plan to install the agent. |
| Step 3 Run the installer as an administrator.<br> | 1. To launch a command prompt as an administrator, click Start and right-click **Command Prompt** and then select **Run as administrator**.<br>2. From the command line, run the .msi file you downloaded. For example, if you saved the .msi file to the Desktop you would enter the following:<br>`C:\Users\administrator.acme>cd Desktop`<br>`C:\Users\administrator.acme\Desktop>UaInstall-6.0.0-1.msi`<br>3. Follow the setup prompts to install the agent using the default settings. By default, the agent gets installed to the `C:\Program Files (x86)\Palo Alto Networks\User-ID Agent` folder, but you can **Browse** to a different location.<br>4. When the installation completes, **Close** the setup window. |
| Step 4 Launch the User-ID Agent application.<br>  | 1. Click Start and select **User-ID Agent**. |
| Step 5 (Optional) Change the service account that the User-ID agent uses to log in.<br> | By default, the agent uses the administrator account used to install the .msi file. However, you may want to switch this to a restricted account as follows:<br>1. Select **User Identification > Setup** and click **Edit**.<br>2. Select the **Authentication** tab and enter the service account name that you want the User-ID agent to use in the **User name for Active Directory** field.<br>3. Enter the **Password** for the specified account. |

| Install the Windows User-ID Agent (Continued) | |
|---|---|
| Step 6 (Optional) Assign account permissions to the installation folder.<br><br>You only need to perform this step if the service account you configured for the User-ID agent is not a member of the administrators group for the domain or a member of both the Server Operators and the Event Log Readers groups. | 1. Give the service account permissions to the installation folder:<br>a. From the Windows Explorer, navigate to `C:\Program Files\Palo Alto Networks` and right-click the folder and select **Properties**.<br>b. On the **Security** tab, **Add** the User-ID agent service account and assign it permissions to **Modify**, **Read & execute**, **List folder contents**, and **Read** and then click **OK** to save the account settings.<br>2. Give the service account permissions to the User-ID Agent registry sub-tree:<br>a. Run `regedit32` and navigate to the Palo Alto Networks sub-tree in one of the following locations:<br>– **32-bit systems**—`HKEY_LOCAL_MACHINE\Software\Palo Alto Networks`<br>– **64-bit systems**—`HKEY_LOCAL_MACHINE\Software\WOW6432Node\Palo Alto Networks`<br>b. Right-click the Palo Alto Networks node and select **Permissions**.<br>c. Assign the User-ID service account **Full Control** and then click **OK** to save the setting.<br>3. On the domain controller, add the service account to the builtin groups to enable privileges to read the security log events (Event Log Reader group) and open sessions (Server Operator group):<br>a. Run the MMC and Launch the Active Directory Users and Computers snap-in.<br>b. Navigate to the Builtin folder for the domain and then right-click each group you need to edit (Event Log Reader and Server Operator) and select **Add to Group** to open the properties dialog.<br>c. Click **Add** and enter the name of the service account that you configured the User-ID service to use and then click **Check Names** to validate that you have the proper object name.<br>d. Click **OK** twice to save the settings. |

## Configure the User-ID Agent for User Mapping

The Palo Alto Networks User-ID agent is a Windows service that connects to servers on your network—for example, Active Directory servers, Microsoft Exchange servers, and Novell eDirectory servers—and monitors the logs for login events. The agent uses this information to map IP addresses to usernames. Palo Alto Networks firewalls connect to the User-ID agent to retrieve this user mapping information, enabling visibility into user activity by username rather than IP address and enables user- and group-based security enforcement.

 © Palo Alto Networks, Inc.

For information about the server OS versions supported by the User-ID agent, refer to "Operating System (OS) Compatibility User-ID Agent" in the *User-ID Agent Release Notes*, which are available on the Palo Alto Networks Software Updates page.

| Map IP Addresses to Users Using the User-ID Agent | | |
|---|---|---|
| Step 1 | Launch the User-ID Agent application. | 1. Select **User-ID Agent** from the Windows Start menu.<br> |
| Step 2 | Define the servers the User-ID agent should monitor to collect IP address to user mapping information.<br>The User-ID agent can monitor a total of up to 100 servers, including syslog senders.<br>Keep in mind that to collect all of the required mappings, you must connect to all servers that your users log in to in order to monitor the security log files on all servers that contain login events. | 1. Select **User Identification > Discovery**.<br>2. In the **Servers** section of the screen, click **Add**.<br>3. Enter a **Name** and **Server Address** for the server to be monitored. The network address can be a FQDN or an IP address.<br>4. Select the **Server Type** (**Microsoft Active Directory**, **Microsoft Exchange**, **Novell eDirectory**, or **Syslog Sender**) and then click **OK** to save the server entry. Repeat this step for each server to be monitored.<br>5. (Optional) To enable the firewall to automatically discover domain controllers on your network using DNS lookups, click **Auto Discover**.<br>The auto-discovery locates domain controllers in the local domain only; you must manually add Exchange servers, eDirectory servers, and syslog senders.<br>6. (Optional) To tune the frequency at which the firewall polls configured servers for mapping information, select **User Identification > Setup** and **Edit** the Setup section. On the **Server Monitor** tab, modify the value in the **Server Log Monitor Frequency (seconds)** field. As a best practice, you should increase the value in this field to 5 seconds in environments with older Domain Controllers or high-latency links. Click **OK** to save the changes. |

| Map IP Addresses to Users Using the User-ID Agent (Continued) | | |
|---|---|---|
| Step 3 | (Optional) If you configured the agent to connect to a Novell eDirectory server, you must specify how the agent should search the directory. | 1. Select **User Identification > Setup** and click **Edit** in the Setup section of the window.<br>2. Select the **eDirectory** tab and then complete the following fields:<br>• **Search Base**—The starting point or root context for agent queries, for example: `dc=domain1, dc=example, dc=com`.<br>• **Bind Distinguished Name**—The account to use to bind to the directory, for example: `cn=admin, ou=IT, dc=domain1, dc=example, dc=com`.<br>• **Bind Password**—The bind account password. The agent saves the encrypted password in the configuration file.<br>• **Search Filter**—The search query for user entries (default is `objectClass=Person`).<br>• **Server Domain Prefix**—A prefix to uniquely identify the user. This is only required if there are overlapping name spaces, such as different users with the same name from two different directories.<br>• **Use SSL**—Select the check box to use SSL for eDirectory binding.<br>• **Verify Server Certificate**—Select the check box to verify the eDirectory server certificate when using SSL. |
| Step 4 | (Optional) Enable client probing.<br>Client probing is useful in environments where IP addresses are not tightly bound to users because it ensures that previously mapped addresses are still valid. However, as the total number of learned IP addresses grows, so does the amount of traffic generated. As a best practice, only enable probing on network segments where IP address turnover is high.<br>For more details on the placement of User-ID agents using client probing, refer to Architecting User Identification (User-ID) Deployments. | 1. On the **Client Probing** tab, select the **Enable WMI Probing** check box and/or the **Enable NetBIOS Probing** check box.<br>2. Make sure the Windows firewall will allow client probing by adding a remote administration exception to the Windows firewall for each probed client.<br> For NetBIOS probing to work effectively, each probed client PC must allow port 139 in the Windows firewall and must also have file and printer sharing services enabled. WMI probing is always preferred over NetBIOS whenever possible. |
| Step 5 | Save the configuration. | Click **OK** to save the User-ID agent setup settings and then click **Commit** to restart the User-ID agent and load the new settings. |

 © Palo Alto Networks, Inc.

| Map IP Addresses to Users Using the User-ID Agent (Continued) | | |
|---|---|---|
| Step 6 | (Optional) Define the set of users for which you do not need to provide IP address-to-user name mappings, such as kiosk accounts.<br><br> You can also use the `ignore-user` list to identify users whom you want to force to authenticate using Captive Portal. | Create an `ignore_user_list.txt` file and save it to the User-ID Agent folder on the domain server where the agent is installed.<br><br>List the user accounts to ignore; there is no limit to the number of accounts you can add to the list. Each user account name must be on a separate line. For example:<br>`SPAdmin`<br>`SPInstall`<br>`TFSReport`<br><br>You can use an asterisk as a wildcard character to match multiple usernames, but only as the last character in the entry. For example, **`corpdomain\it-admin*`** would match all administrators in the **`corpdomain`** domain whose usernames start with the string **`it-admin`**. |
| Step 7 | Configure the firewalls to connect to the User-ID agent. | Complete the following steps on each firewall you want to connect to the User-ID agent to receive user mappings:<br>1. Select **Device > User Identification > User-ID Agents** and click **Add**.<br>2. Enter a **Name** for the User-ID agent.<br>3. Enter the IP address of the Windows **Host** on which the User-ID Agent is installed.<br>4. Enter the **Port** number (1-65535) on which the agent will listen for user mapping requests. This value must match the value configured on the User-ID agent. By default, the port is set to 5007 on the firewall and on newer versions of the User-ID agent. However, some older User-ID agent versions use port 2010 as the default.<br>5. Make sure that the configuration is **Enabled**, then click **OK**.<br>6. **Commit** the changes.<br>7. Verify that the **Connected status** displays as connected (a green light). |
| Step 8 | Verify that the User-ID agent is successfully mapping IP addresses to usernames and that the firewalls can connect to the agent. | 1. Launch the User-ID agent and select **User Identification**.<br>2. Verify that the agent status shows **Agent is running**. If the Agent is not running, click **Start**.<br>3. To verify that the User-ID agent can connect to monitored servers, make sure the Status for each Server is **Connected**.<br>4. To verify that the firewalls can connect to the User-ID agent, make sure the Status for each of the Connected Devices is **Connected**.<br>5. To verify that the User-ID agent is mapping IP addresses to usernames, select **Monitoring** and make sure that the mapping table is populated. You can also **Search** for specific users, or **Delete** user mappings from the list. |

## Configure User Mapping Using the PAN-OS Integrated User-ID Agent

The following procedure shows how to configure the PAN-OS integrated agent on the firewall for user mapping. The integrated User-ID agent performs the same tasks as the Windows-based agent with the exception of NetBIOS client probing (WMI probing is supported).

| Map IP Addresses to Users Using the Integrated User-ID Agent | | |
|---|---|---|
| Step 1 | Create an Active Directory (AD) account for the User-ID agent.<br><br>The account must have the privilege levels required to log in to each service or host that the User-ID agent will monitor to collect user mapping data. | • **Windows 2008 or later domain servers**—Add the account to the Event Log Readers group. If you are using the on-device User-ID agent, the account must also be a member of the Distributed COM Users Group.<br>• **Windows 2003 domain servers**—Assign Manage Auditing and Security Logs permissions through group policy.<br>• **WMI probing**—Make sure the account has rights to read the CIMV2 namespace; by default, Domain Administrator and Server Operator accounts have this permission.<br>• **NTLM authentication**—Because the firewall must join the domain if you are using Captive Portal NTLM authentication with an on-device User-ID agent, the Windows account you create for NTLM access must have administrative privileges. Note that due to AD restrictions on virtual systems running on the same host, if the firewall has multiple virtual systems, only vsys1 will be able to join the domain. |

 © Palo Alto Networks, Inc.

**Map IP Addresses to Users Using the Integrated User-ID Agent (Continued)**

| | | |
|---|---|---|
| Step 2 | Define the servers the firewall should monitor to collect IP address-to-user mapping information. You can define a total of up to 100 servers of all types, including syslog senders.<br><br>Note that to collect all the required mappings, the firewall must connect to all servers that your users log in to so it can monitor the security log files on all servers that contain login events. | 1. Select **Device > User Identification > User Mapping**.<br>2. In the Server Monitoring section of the screen, click **Add**.<br>3. Enter a **Name** and **Network Address** for the server. The network address can be a FQDN or an IP address.<br>4. Select the **Type** of server.<br>5. Make sure the **Enabled** check box is selected and then click **OK**<br>6. (Optional) To enable the firewall to automatically discover domain controllers on your network using DNS lookups, click **Discover**.<br> <br>The auto-discovery feature is for domain controllers only; you must manually add any Exchange servers or eDirectory servers you want to monitor.<br>7. (Optional) Specify the frequency at which the firewall polls Windows servers for mapping information. This is the interval between the end of the last query and the start of the next query.<br>If the query load is high, the observed delay between queries might significantly exceed the specified frequency.<br>a. In the **Palo Alto Networks User ID Agent Setup** section, click the Edit icon.<br>b. Select the **Server Monitor** tab and specify the **Server Log Monitor Frequency** in seconds (default is 2, range is 1-3600).<br>As a best practice, increase the value in this field to 5 seconds in environments with older domain controllers or high-latency links.<br>c. Click **OK** to save the changes. |
| Step 3 | Set the domain credentials for the account the firewall will use to access Windows resources. This is required for monitoring Exchange servers and domain controllers as well as for WMI probing. | 1. Edit the Palo Alto Networks User ID Agent Setup section of the screen.<br>2. On the **WMI Authentication** tab, enter the **User Name** and **Password** for the account that will be used to probe the clients and monitor servers. Enter the user name using the domain\username syntax.<br> |

| Map IP Addresses to Users Using the Integrated User-ID Agent (Continued) | | |
|---|---|---|
| Step 4 | (Optional) Enable WMI probing.<br> The on-device agent does not support NetBIOS probing; it is supported on the Windows-based User-ID agent only. | 1. On the **Client Probing** tab, select the **Enable Probing** check box.<br>2. (Optional) If necessary, modify the **Probe Interval** (in minutes) to ensure it is long enough for the User-ID agent to probe all the learned IP addresses (default is 20, range is 1-1440). This is the interval between the end of the last probe request and the start of the next request.<br> If the request load is high, the observed delay between requests might significantly exceed the specified interval.<br>3. Make sure the Windows firewall will allow client probing by adding a remote administration exception to the Windows firewall for each probed client. |
| Step 5 | Save the configuration. | 1. Click **OK** to save the User-ID agent setup settings.<br>2. Click **Commit** to save the configuration. |
| Step 6 | (Optional) Define the set of users for which you do not need to provide IP address-to-user name mappings, such as kiosk accounts.<br> You can also use the `ignore-user` list to identify users whom you want to force to authenticate using Captive Portal. | 1. Open a CLI session to the firewall.<br>2. To add the list of user accounts for which you do not want the firewall to perform mapping, run the following command:<br>**set user-id-collector ignore-user <value>**<br>where <value> is a list of the user accounts to ignore; there is no limit to the number of accounts you can add to the list. Separate entries with a space and do not include the domain name with the username. For example:<br>`set user-id-collector ignore-user SPAdmin SPInstall TFSReport`<br>3. **Commit** your changes. |
| Step 7 | Verify the configuration. | 1. From the CLI, enter the following command:<br>`show user server-monitor state all`<br>2. On the **Device > User Identification > User Mapping** tab in the web interface, verify that the **Status** of each server you configured for server monitoring is **Connected**. |

# Configure User-ID to Receive User Mappings from a Syslog Sender

The following topics describe how to configure the User-ID agent (either the Windows agent or the integrated agent on the firewall) as a Syslog listener:

- Configure the Integrated User-ID Agent as a Syslog Listener
- Configure the Windows User-ID Agent as a Syslog Listener

## Configure the Integrated User-ID Agent as a Syslog Listener

The following workflow describes how to configure the PAN-OS integrated User-ID agent to receive syslog messages from authenticating services.

The PAN-OS integrated User-ID agent accepts syslogs over SSL and UDP only. However, you must use caution when using UDP to receive syslog messages because it is an unreliable protocol and as such there is no way to verify that a message was sent from a trusted syslog server. Although you can restrict syslog messages to specific source IP addresses, an attacker can still spoof the IP address, potentially allowing the injection of unauthorized syslog messages into the firewall. As a best practice, always use SSL to listen for syslog messages. However, if you must use UDP, make sure that the syslog server and client are both on a dedicated, secure VLAN to prevent untrusted hosts from sending UDP traffic to the firewall.

| **Collect User Mappings from Syslog Senders** | |
|---|---|
| Step 1 Determine whether there is a pre-defined syslog filter for your particular syslog sender(s).<br><br>Palo Alto Networks provides several pre-defined syslog filters, which are delivered as Application content updates and are therefore updated dynamically as new filters are developed. The pre-defined filters are global to the firewall, whereas manually-defined filters apply to a single virtual system only.<br><br> Any new syslog filters in a given content release will be documented in the corresponding release note along with the specific regex used to define the filter. | 1. Verify that your Application or Application and Threat database is up to date:<br>a. Select **Device > Dynamic Updates**.<br>b. Click **Check Now** (located in the lower left-hand corner of the window) to check for the latest updates.<br>c. If a new update is available, **Download** and **Install** it.<br>2. Check to see what pre-defined filters are available:<br>a. Select **Device > User Identification > User Mapping**.<br>b. In the Server Monitoring section of the screen, click **Add**.<br>c. Select **Syslog Sender** as the server **Type**.<br>d. Select the **Filter** drop-down and check to see if there is a filter for the manufacturer and product you plan to forward syslogs from. If the filter you need is available, skip to Step 5 for instructions on defining the servers. If the filter you need is not available, continue to Step 2. |

**Collect User Mappings from Syslog Senders (Continued)**

Step 2 Manually define syslog filter(s) for extracting the User-ID IP address to username mapping information from syslog messages.

In order to be parsed by the User-ID agent, syslog messages must meet the following criteria:

- Each syslog message must be a single-line text string. Line breaks are delimited by a carriage return and a new line (`\r\n`) or a new line (`\n`).
- The maximum allowed size of an individual syslog message is 2048 bytes.
- Syslog messages sent over UDP must be contained in a single packet; messages sent over SSL can span multiple packets.
- A single packet may contain multiple syslog messages.

1. Review the syslogs generated by the authenticating service to identify the syntax of the login events. This enables you to create the matching patterns that will allow the firewall to identify and extract the authentication events from the syslogs.

   While reviewing the syslogs, also determine whether the domain name is included in the log entries. If the authentication logs do not contain domain information, consider defining a default domain name when adding the syslog sender to the monitored servers list in Step 5.
2. Select **Device > User Identification > User Mapping** and edit the Palo Alto Networks User-ID Agent Setup section.
3. On the **Syslog Filters** tab, **Add** a new syslog parse profile.
4. Enter a name for the **Syslog Parse Profile**.
5. Specify the **Type** of parsing to use to filter out the user mapping information by selecting one of the following options:
   - **Regex Identifier**—With this type of parsing, you specify regular expressions to describe search patterns for identifying and extracting user mapping information from syslog messages. Continue to Step 3 for instructions on creating the regex identifiers.
   - **Field Identifier**—With this type of parsing, you specify a string to match the authentication event, and prefix and suffix strings to identify the user mapping information in the syslogs. Continue to Step 4 for instructions on creating the field identifiers.

 © Palo Alto Networks, Inc.

**Collect User Mappings from Syslog Senders (Continued)**

Step 3 If you selected **Regex Identifier** as the parsing **Type**, create the regex matching patterns for identifying the authentication events and extracting the user mapping information.

The example below shows a regex configuration for matching syslog messages with the following format:

```
[Tue Jul 5 13:15:04 2005 CDT] Administrator
authentication success User:johndoe1
Source:192.168.3.212
```

If the syslog contains a standalone space and/or tab as a delimiter, you must use an \s (for a space) and/or \t (for a tab) in order for the agent to parse the syslog.

1. Specify how to match successful authentication events in the syslogs by entering a matching pattern in the **Event Regex** field. For example, when matched against the example syslog message, the following regex instructs the firewall to extract the first `{1}` instance of the string `authentication success`. The backslash before the space is a standard regex escape character that instructs the regex engine not to treat the space as a special character: `(authentication\ success){1}`.
2. Enter the regex for identifying the beginning of the username in the authentication success messages in the **Username Regex** field. For example, the regex `User:([a-zA-Z0-9\\\._]+)` would match the string `User:johndoe1` in the example message and extract `acme\johndoe1` as the User-ID.

   If the syslogs do not contain domain information and you require domain names in your user mappings, be sure to enter the **Default Domain Name** when defining the monitored server entry in Step 5.
3. Enter the regex for identifying the IP address portion of the authentication success messages in the **Address Regex** field. For example, the following regular expression `Source:([0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3})` would match an IPv4 address (`Source:192.168.0.212` in the example syslog).
4. Click **OK**.

**Collect User Mappings from Syslog Senders (Continued)**

Step 4 If you selected **Field Identifier** as the parsing **Type**, define the string matching patterns for identifying the authentication events and extracting the user mapping information.

The example below shows a field identifier configuration for matching syslog messages with the following format:

```
[Tue Jul 5 13:15:04 2005 CDT] Administrator
authentication success User:johndoe1
Source:192.168.3.212
```

If the syslog contains a standalone space and/or tab as a delimiter, you must use an \s (for a space) and/or \t (for a tab) in order for the agent to parse the syslog.

1. Specify how to match successful authentication events in the syslogs by entering a matching pattern in the **Event String** field. For example, when matched against the sample syslog message, you would enter the string `authentication success` to identify authentication events in the syslog.
2. Enter the matching string for identifying the beginning of the username field within the authentication syslog message in the **Username Prefix** field. For example, the string `User:` identifies the beginning of the username field in the sample syslog.
3. Enter the **Username Delimiter** to mark the end of the username field within an authentication syslog message. For example, if the username is followed by a space, you would enter `\s` to indicate that the username field is delimited by a standalone space in the sample log.
4. Enter the matching string for identifying the beginning of the IP address field within the authentication event log in the **Address Prefix** field. For example, the string `Source:` identifies the beginning of the address field in the example log.
5. Enter the **Address Delimiter** to mark the end of the IP address field within the authentication success message within the field. For example, if the address is followed by a line break, you would enter `\n` to indicate that the address field is delimited by a new line.
6. Click **OK**.

Step 5 Define the servers that will send syslog messages to the firewall for user mapping purposes.

You can define a total of up to 100 monitored servers of all types, including syslog senders. The firewall will discard any syslog messages received from servers that are not on this list.

A Syslog sender using SSL to connect will only show a **Status** of **Connected** when there is an active SSL connection. Syslog senders using UDP will not show a **Status** value.

1. Select **Device > User Identification > User Mapping**.
2. In the Server Monitoring section of the screen, click **Add**.
3. Enter a **Name** and **Network Address** for the server.
4. Select **Syslog Sender** as the server **Type**.
5. Make sure the **Enabled** check box is selected.
6. (Optional) If the syslogs that the authenticating device sends do not include domain information in the login event logs, enter the **Default Domain Name** to append to the user mappings.
7. Click **OK** to save the settings.

 © Palo Alto Networks, Inc.

| Collect User Mappings from Syslog Senders (Continued) | | |
|---|---|---|
| Step 6 | Enable syslog listener services in the management profile associated with the interface used for user mapping.<br> <br>Use caution when using UDP to receive syslog messages because it is an unreliable protocol and as such there is no way to verify that a message was sent from a trusted syslog server. Although you can restrict syslog messages to specific source IP addresses, an attacker can still spoof the IP address, potentially allowing the injection of unauthorized syslog messages into the firewall. As a best practice, always use SSL to listen for syslog messages when using agentless User Mapping on a firewall. However, if you must use UDP, make sure that the syslog server and client are both on a dedicated, secure VLAN to prevent untrusted hosts from sending UDP traffic to the firewall. | 1. Select **Network > Network Profiles > Interface Mgmt** and then select an Interface Management profile to edit or click **Add** to create a new profile.<br>2. Select **User-ID Syslog Listener-SSL** and/or **User-ID Syslog Listener-UDP**, depending on the protocols you defined when you set up your syslog senders in the Server Monitor list.<br> <br>On the Windows User-ID agent, the default listening port for syslog over UDP or TCP is 514, but the port value is configurable. For the agentless User Mapping feature on the firewall, only syslog over UDP and SSL are supported and the listening ports (514 for UDP and 6514 for SSL) are not configurable; they are enabled through the management service only.<br>3. Click **OK** to save the interface management profile.<br> <br>Even after enabling the User-ID Syslog Listener service on the interface, the interface will only accept syslog connections from servers that have a corresponding entry in the User-ID monitored servers configuration. Connections or messages from servers that are not on the list will be discarded. |
| Step 7 | Save the configuration. | Click **Commit** to save the configuration. |

**Collect User Mappings from Syslog Senders (Continued)**

Step 8 Verify the configuration by opening an SSH connection to the firewall and then running the following CLI commands:

To see the status of a particular syslog sender:

```
admin@PA-5050> show user server-monitor state Syslog2
        UDP Syslog Listener Service is enabled
        SSL Syslog Listener Service is enabled

Proxy: Syslog2(vsys: vsys1)     Host: Syslog2(10.5.204.41)
        number of log messages                          : 1000
        number of auth. success messages                : 1000
        number of active connections                    : 0
        total connections made                          : 4
```

To see how many log messages came in from syslog senders and how many entries were successfully mapped:

```
admin@PA-5050> show user server-monitor statistics

Directory Servers:
Name                            TYPE     Host            Vsys    Status

------------------------------------------------------------------------------
AD                              AD       10.2.204.43     vsys1   Connected

Syslog Servers:
Name                      Connection Host            Vsys    Status
------------------------------------------------------------------------------
Syslog1                   UDP        10.5.204.40     vsys1   N/A
Syslog2                   SSL        10.5.204.41     vsys1   Not connected
```

To see how many user mappings were discovered through syslog senders:

```
admin@PA-5050> show user ip-user-mapping all type SYSLOG

IP              Vsys   From    User                              IdleTimeout(s) M
axTimeout(s)
--------------- ------ ------- --------------------------------- -------------- -

## Configure the Windows User-ID Agent as a Syslog Listener

The following workflow describes how to configure a Windows-based User-ID agent to listen for syslogs from authenticating services.

The Windows User-ID agent accepts syslogs over TCP and UDP only. However, you must use caution when using UDP to receive syslog messages because it is an unreliable protocol and as such there is no way to verify that a message was sent from a trusted syslog server. Although you can restrict syslog messages to specific source IP addresses, an attacker can still spoof the IP address, potentially allowing the injection of unauthorized syslog messages into the firewall. As a best practice, use TCP instead of UDP. In either case, make sure that the syslog server and client are both on a dedicated, secure VLAN to prevent untrusted hosts from sending syslogs to the User-ID agent.

 © Palo Alto Networks, Inc.

| Configure the Windows User-ID Agent to Collect User Mappings from Syslog Senders | |
|---|---|
| Step 1 Launch the User-ID Agent application. | 1. Click Start and select **User-ID Agent**.<br> |
| Step 2 Manually define syslog filter(s) for extracting the User-ID IP address to username mapping information from syslog messages.<br><br>In order to be parsed by the User-ID agent, syslog messages must meet the following criteria:<br>• Each syslog message must be a single-line text string. Line breaks are delimited by a carriage return and a new line (\r\n) or a new line (\n).<br>• The maximum allowed size of an individual syslog message is 2048 bytes.<br>• Syslog messages sent over UDP must be contained in a single packet; messages sent over SSL can span multiple packets.<br>• A single packet may contain multiple syslog messages. | 1. Review the syslogs generated by the authenticating service to identify the syntax of the login events. This enables you to create the matching patterns that will allow the firewall to identify and extract the authentication events from the syslogs.<br> While reviewing the syslogs, also determine whether the domain name is included in the log entries. If the authentication logs do not contain domain information, consider defining a default domain name when adding the syslog sender to the monitored servers list in Step 5.<br>2. Select **User Identification > Setup** and click **Edit** in the Setup section of the dialog.<br>3. On the **Syslog** tab, **Add** a new syslog parse profile.<br>4. Enter a **Profile Name** and **Description**.<br>5. Specify the **Type** of parsing to use to filter out the user mapping information by selecting one of the following options:<br>• **Regex**—With this type of parsing, you specify regular expressions to describe search patterns for identifying and extracting user mapping information from syslog messages. Continue to Step 3 for instructions on creating the regex identifiers.<br>• **Field**—With this type of parsing, you specify a sting to match the authentication event, and prefix and suffix strings to identify the user mapping information in the syslogs. Continue to Step 4 for instructions on creating the field identifiers. |

**Configure the Windows User-ID Agent to Collect User Mappings from Syslog Senders (Continued)**

Step 3 If you selected **Regex** as the parsing **Type**, create the regex matching patterns for identifying the authentication events and extracting the user mapping information.

The example below shows a regex configuration for matching syslog messages with the following format:

```
[Tue Jul 5 13:15:04 2005 CDT] Administrator
authentication success User:johndoe1
Source:192.168.3.212
```

If the syslog contains a standalone space and/or tab as a delimiter, you must use an \s (for a space) and/or \t (for a tab) in order for the agent to parse the syslog.

1. Specify how to match successful authentication events in the syslogs by entering a matching pattern in the **Event Regex** field. For example, when matched against the example syslog message, the following regex instructs the firewall to extract the first `{1}` instance of the string `authentication success`. The backslash before the space is a standard regex escape character that instructs the regex engine not to treat the space as a special character: `(authentication\ success){1}`.
2. Enter the regex for identifying the beginning of the username in the authentication success messages in the **Username Regex** field. For example, the regex `User:([a-zA-Z0-9\\\._]+)` would match the string `User:johndoe1` in the example message and extract `acme\johndoe1` as the User-ID.

   If the syslogs do not contain domain information and you require domain names in your user mappings, be sure to enter the **Default Domain Name** when defining the monitored server entry in Step 5.
3. Enter the regex for identifying the IP address portion of the authentication success messages in the **Address Regex** field. For example, the following regular expression `Source:([0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3})` would match an IPv4 address (`Source:192.168.0.212` in the example syslog).
4. Click **OK** to save the profile.

 © Palo Alto Networks, Inc.

**Configure the Windows User-ID Agent to Collect User Mappings from Syslog Senders (Continued)**

**Step 4** If you selected **Field Identifier** as the parsing **Type**, define the string matching patterns for identifying the authentication events and extracting the user mapping information.

The example below shows a field identifier configuration for matching syslog messages with the following format:

```
[Tue Jul 5 13:15:04 2005 CDT] Administrator
authentication success User:johndoe1
Source:192.168.3.212
```

If the syslog contains a standalone space and/or tab as a delimiter, you must use an \s (for a space) and/or \t (for a tab) in order for the agent to parse the syslog.

1. Specify how to match successful authentication events in the syslogs by entering a matching pattern in the **Event String** field. For example, when matched against the sample syslog message, you would enter the string `authentication success` to identify authentication events in the syslog.
2. Enter the matching string for identifying the beginning of the username field within the authentication syslog message in the **Username Prefix** field. For example, the string `User:` identifies the beginning of the username field in the sample syslog.
3. Enter the **Username Delimiter** to mark the end of the username field within an authentication syslog message. For example, if the username is followed by a space, you would enter `\s` to indicate that the username field is delimited by a standalone space in the sample log.
4. Enter the matching string for identifying the beginning of the IP address field within the authentication event log in the **Address Prefix** field. For example, the string `Source:` identifies the beginning of the address field in the example log.
5. Enter the **Address Delimiter** to mark the end of the IP address field within the authentication success message within the field. For example, if the address is followed by a line break, you would enter `\n` to indicate that the address field is delimited by a new line.
6. Click **OK** to save the profile.

**Step 5** Enable the syslog listening service on the agent.

As a best practice, make sure that the syslog server and client are both on a dedicated, secure VLAN to prevent untrusted hosts from sending syslogs to the User-ID agent.

1. Select the **Enable Syslog Service** check box.
2. (Optional) Modify the **Syslog Service Port** number to match the port number used by the syslog sender (default=514).
3. To save the agent syslog configuration, click **OK**.

**Step 6** Define the servers that will send syslog messages to the User-ID agent.

You can define up to 100 syslog senders. The User-ID agent will discard any syslog messages received from servers that are not on this list.

1. Select **User Identification > Discovery**.
2. In the **Servers** section of the screen, click **Add**.
3. Enter a **Name** and **Server Address** for the server that will send syslogs to the agent.
4. Select **Syslog Sender** as the **Server Type**.
5. Select a **Filter** you defined in Step 2.
6. (Optional) If the syslogs that the authenticating device sends do not include domain information in the login event logs, enter the **Default Domain Name** to append to the user mappings.
7. Click **OK** to save the settings.

**Step 7** Save the configuration.

Click **Commit** to save the configuration.

**Configure the Windows User-ID Agent to Collect User Mappings from Syslog Senders (Continued)**

Step 8 Verify the configuration by opening an SSH connection to the firewall and then running the following CLI commands:

To see the status of a particular syslog sender:

```
admin@PA-5050> show user server-monitor state Syslog2
        UDP Syslog Listener Service is enabled
        SSL Syslog Listener Service is enabled

Proxy: Syslog2(vsys: vsys1)     Host: Syslog2(10.5.204.41)
        number of log messages                          : 1000
        number of auth. success messages                : 1000
        number of active connections                    : 0
        total connections made                          : 4
```

To see how many log messages came in from syslog senders and how many entries were successfully mapped:

```
admin@PA-5050> show user server-monitor statistics

Directory Servers:

# Map IP Addresses to Usernames Using Captive Portal

If the firewall receives a request from a security zone that has User-ID enabled and the source IP address does not have any user data associated with it yet, the firewall checks its Captive Portal policy rules for a match to determine whether to perform authentication. This is useful in environments where you have clients that are not logged in to your domain servers, such as Linux clients. The firewall triggers this user mapping method only for web traffic (HTTP or HTTPS) that matches a Captive Portal rule but has not been mapped using a different method.

- Captive Portal Authentication Methods
- Captive Portal Modes
- Configure Captive Portal

## Captive Portal Authentication Methods

Captive Portal uses the following methods to obtain user information from the client when a web request matches a Captive Portal rule:

| Authentication Method | Description |
|---|---|
| Kerberos SSO | The firewall uses Kerberos Single Sign-On (SSO) to transparently obtain user credentials. To use this method, your network requires a Kerberos infrastructure, including a key distribution center (KDC) with an authentication server and ticket granting service. The firewall must have a Kerberos account, including a principal name and password.<br>If Kerberos SSO authentication fails, the firewall falls back to NT LAN Manager (NTLM) authentication. If you don't configure NTLM, or NTLM authentication fails, the firewall falls back to web form or client certificate authentication, depending on your Captive Portal configuration. |
| NT LAN Manager (NTLM) | The firewall uses an encrypted challenge-response mechanism to obtain the user credentials from the browser. When configured properly, the browser will transparently provide the credentials to the firewall without prompting the user, but will prompt for credentials if necessary.<br>If you use the Windows-based User-ID agent, NTLM responses go directly to the domain controller where you installed the agent.<br>If you configure Kerberos SSO authentication, the firewall tries that method first before falling back to NTLM authentication. If the browser can't perform NTLM or if NTLM authentication fails, the firewall falls back to web form or client certificate authentication, depending on your Captive Portal configuration.<br>Microsoft Internet Explorer supports NTLM by default. You can configure Mozilla Firefox and Google Chrome to also use NTLM but you can't use NTLM to authenticate non-Windows clients. |

| Authentication Method | Description |
|---|---|
| Web Form | The firewall redirects web requests to a web form for authentication. You can configure Captive Portal to use a local user database, RADIUS server, TACACS+ server, LDAP server, or Kerberos server to authenticate users. Although the firewall always prompts users for credentials, this method works with all browsers and operating systems. |
| Client Certificate Authentication | The firewall prompts the browser to present a valid client certificate to authenticate the user. To use this method, you must provision client certificates on each user system and install the trusted certificate authority (CA) certificate used to issue those certificates on the firewall. |

## Captive Portal Modes

The Captive Portal mode defines how the firewall captures web requests for authentication:

| Mode | Description |
|---|---|
| Transparent | The firewall intercepts the browser traffic per the Captive Portal rule and impersonates the original destination URL, issuing an HTTP 401 to invoke authentication. However, because the firewall does not have the real certificate for the destination URL, the browser displays a certificate error to users attempting to access a secure site. Therefore, you should only use this mode when absolutely necessary, such as in Layer 2 or virtual wire deployments. |
| Redirect | The firewall intercepts unknown HTTP or HTTPS sessions and redirects them to a Layer 3 interface on the firewall using an HTTP 302 redirect to perform authentication. This is the preferred mode because it provides a better end-user experience (no certificate errors). However, it does require additional Layer 3 configuration. Another benefit of the Redirect mode is that it provides for the use of session cookies, which enable the user to continue browsing to authenticated sites without requiring re-mapping each time the time outs expire. This is especially useful for users who roam from one IP address to another (for example, from the corporate LAN to the wireless network) because they won't need to re-authenticate when the IP address changes as long as the session stays open.<br>If you use Kerberos SSO or NTLM authentication, you must use Redirect mode because the browser will provide credentials only to trusted sites. |

## Configure Captive Portal

The following procedure shows how to configure Captive Portal using the PAN-OS integrated User-ID agent to redirect web requests that match a Captive Portal rule to a redirect host. A redirect host is the intranet hostname (a hostname with no period in its name) that resolves to the IP address of the Layer 3 interface on the firewall to which the firewall will redirect requests.

If you use Captive Portal without the other User-ID functions (user mapping and group mapping), you don't need to configure a User-ID agent.

 © Palo Alto Networks, Inc.

| Configure Captive Portal Using the PAN-OS Integrated User-ID Agent | | |
|---|---|---|
| Step 1 | Configure the interfaces that the firewall will use for redirecting web requests, authenticating users, and communicating with directory servers to map usernames to IP addresses.<br><br>The firewall uses the management (MGT) interface for all these functions by default, but you can configure other interfaces. In redirect mode, you must use a Layer 3 interface for redirecting requests. | 1. (MGT interface only) Select **Device > Setup > Management**, edit the Management Interface Settings, select the **User ID** check box, and click **OK**.<br>2. (Non-MGT interface only) Assign an Interface Management profile to the Layer 3 interface that the firewall will use to redirect web requests and/or communicate with directory servers.<br>a. Select **Network > Network Profiles > Interface Mgmt** and **Add** an Interface Management profile with a unique **Name**.<br>b. Select the **Response Pages** and **User ID** check boxes, and click **OK**.<br>c. Select **Network > Interfaces**, click the interface, select the **Advanced** tab, select the Interface **Management Profile** you just created, and click **OK**.<br>3. (Non-MGT interface only) Configure a service route for the interface that the firewall will use to authenticate users. If the firewall has more than one virtual system (vsys), the service route can be global or vsys-specific. The services must include **LDAP** and potentially the following:<br>– **Kerberos**, **RADIUS**, or **TACACS+**—Configure a service route for one of these services only if you will use it for external authentication.<br>– **UID Agent**—Configure this service only if you will enable NT LAN Manager (NTLM) authentication or if you will Configure a Firewall to Share User Mapping Data with Other Firewalls.<br>4. (Redirect mode only) Create a DNS address (A) record that maps the IP address on the Layer 3 interface to the redirect host. If you will use Kerberos SSO, you must also add a DNS pointer (PTR) record that performs the same mapping.<br><br>If your network doesn't support access to the directory servers from any firewall interface, you must Configure User Mapping Using the Windows User-ID Agent. |
| Step 2 | Make sure Domain Name System (DNS) is configured to resolve your domain controller addresses. | To verify proper resolution, ping the server FQDN. For example:<br>`admin@PA-200> ping host dc1.acme.com` |
| Step 3 | Create a Kerberos keytab for the redirect host.<br><br>Required for Kerberos SSO authentication. | Create a Kerberos keytab. A keytab is a file that contains Kerberos account information (principal name and hashed password) for the redirect host (the firewall).<br><br>To support Kerberos SSO, your network must have a Kerberos infrastructure, including a key distribution center (KDC) with an authentication server and ticket granting service. |

| Configure Captive Portal Using the PAN-OS Integrated User-ID Agent (Continued) | |
|---|---|
| Step 4 Configure clients to trust Captive Portal certificates.<br><br>Required for redirect mode—to transparently redirect users without displaying certificate errors. You can generate a self-signed certificate or import a certificate that an external certificate authority (CA) signed. | To use a self-signed certificate, create a root CA certificate and use it to sign the certificate you will use for Captive Portal:<br>1. Select **Device > Certificate Management > Certificates > Device Certificates**.<br>2. Create a Self-Signed Root CA Certificate or import a CA certificate (see Import a Certificate and Private Key).<br>3. Generate a Certificate on the Device to use for Captive Portal. Be sure to configure the following fields:<br>• **Common Name**—Enter the DNS name of the intranet host for the Layer 3 interface.<br>• **Signed By**—Select the CA certificate you just created or imported.<br>• Certificate Attributes—Click **Add**, for the **Type** select **IP** and, for the **Value**, enter the IP address of the Layer 3 interface to which the firewall will redirect requests.<br>4. Configure an SSL/TLS Service Profile. Assign the Captive Portal certificate you just created to the profile.<br>5. Configure clients to trust the certificate:<br>a. Export the CA certificate you created or imported.<br>b. Import the certificate as a trusted root CA into all client browsers, either by manually configuring the browser or by adding the certificate to the trusted roots in an Active Directory (AD) Group Policy Object (GPO). |

 © Palo Alto Networks, Inc.

| Configure Captive Portal Using the PAN-OS Integrated User-ID Agent (Continued) | | |
|---|---|---|
| Step 5 | Configure an authentication server profile.<br><br>Required for external authentication. If you enable Kerberos SSO or NTLM authentication, the firewall uses the external service only if those methods fail. | • Configure a RADIUS Server Profile.<br>• Configure a TACACS+ Server Profile<br>• Configure an LDAP Server Profile<br>• Configure a Kerberos Server Profile<br><br>The PAN-OS web server timeout (default is 3 seconds) must be the same as or greater than the server profile timeout multiplied by the number of servers in the profile. For RADIUS and TACACS+, the default server profile **Timeout** is 3 seconds. For LDAP, the timeout is the total of the **Bind Timeout** (default is 30 seconds) and **Search Timeout** (default is 30 seconds) for each server. For Kerberos, the non-configurable timeout can take up to 17 seconds for each server. Also, the Captive Portal session timeout (default is 30 seconds) must be greater than the web server timeout.<br><br>To change the web server timeout, enter the following firewall CLI command, where **<value>** is 3-30 seconds: **`set deviceconfig setting l3-service timeout <value>`**. To change the Captive Portal session timeout, select **Device > Setup > Session**, edit the Session Timeouts, and enter a new **Captive Portal** value in seconds (range is 1-1,599,999). Keep in mind that the more you raise the web server and Captive Portal session timeouts, the slower Captive Portal will respond to users. |
| Step 6 | Add the users and user groups to the local database on the firewall.<br><br>Required for local database authentication. If you enable Kerberos SSO and/or NTLM authentication, the firewall uses the local database only if those methods fail. | Create the local database. Add the users who will authenticate using Captive Portal. |

| Configure Captive Portal Using the PAN-OS Integrated User-ID Agent (Continued) | |
|---|---|
| Step 7 Add an authentication profile<br><br>The profile defines the authentication methods to use (Kerberos SSO, external service, or local database) when a Captive Portal rule invokes Web Form authentication. Even if you enable NTLM, you must define a secondary authentication method in case NTLM authentication fails or the User-ID agent doesn't support NTLM.<br><br> If you set the authentication **Type** to **RADIUS**, specify a RADIUS **User Domain** in case users don't enter the domain at login. | Configure an authentication profile:<br>1. If the authentication **Type** is an external service (**RADIUS**, **TACACS+**, **LDAP**, or **Kerberos**), select the authentication **Server Profile** you created.<br>2. If you use Kerberos SSO, enter the **Kerberos Realm** (usually the DNS domain of the users, except that the realm is uppercase), and import the **Kerberos Keytab** you created.<br>3. In the Allow List on the **Advanced** tab, **Add** the users and user groups that can authenticate using this profile. If the authentication **Type** is **Local Database**, add the Captive Portal users or user groups you created. You can select **all** to allow every user to authenticate. After you complete the Allow List, click **OK**.<br><br> If your users are in multiple domains or Kerberos realms, you can create an authentication profile for each domain or realm, assign all the profiles to the authentication sequence (Step 8), and assign the sequence to the Captive Portal configuration. |
| Step 8 (Optional) Add an authentication sequence<br><br> If the firewall might try multiple authentication profiles in the sequence for any one user (for example, if some directory server connections are unreliable), then the PAN-OS web server timeout must be the same as or greater than the timeout for the sequence, which is the total of the timeouts for all its authentication profiles. Also, the session timeout for Captive Portal must be greater than the web server timeout. To change these timeouts, see the note in Step 5. | Configure an authentication sequence:<br>1. Select **Device > Authentication Sequence**, click **Add**, and enter a **Name** to identify the authentication sequence.<br>2. Select the **Use domain to determine authentication profile** check box: the device will match the domain name that a user enters during login with the **User Domain** or **Kerberos Realm** of an authentication profile in the sequence, and then use that profile to authenticate the user.<br>3. For each authentication profile to include, click **Add** and select the profile from the drop-down.<br>4. Click **OK** to save the authentication sequence. |

 © Palo Alto Networks, Inc.

| Configure Captive Portal Using the PAN-OS Integrated User-ID Agent (Continued) | |
|---|---|
| Step 9 Configure Client Certificate Authentication.<br><br>Required if Captive Portal will use this authentication method.<br><br>You don't need an authentication profile or sequence for client certificate authentication. If you configure both an authentication profile/sequence and certificate authentication, users must authenticate using both. | 1. Use a root CA certificate to generate a client certificate for each user who will authenticate to Captive Portal. The CA in this case is usually your enterprise CA, not the firewall.<br>2. Export the CA certificate in PEM format to a system that the firewall can access.<br>3. Import the CA certificate onto the firewall: see Import a Certificate and Private Key. After the import, click the imported certificate, select **Trusted Root CA**, and click **OK**.<br>4. Configure a Certificate Profile.<br>• In the **Username Field** drop-down, select the certificate field that contains the user identity information.<br>• In the **CA Certificates** list, click **Add** and select the CA certificate you just imported. |
| Step 10 Enable NT LAN Manager (NTLM) authentication.<br><br>Required for NLTM authentication.<br><br>When using the PAN-OS integrated User-ID agent, the firewall must successfully resolve the DNS name of your domain controller to join the domain (using the credentials you enter in this step). | 1. If you haven't already done so, Create an Active Directory (AD) account for the User-ID agent.<br>2. Select **Device > User Identification > User Mapping** and edit the Palo Alto Networks User ID Agent Setup section.<br>3. On the **NTLM** tab, select the **Enable NTLM authentication processing** check box.<br>4. Enter the **NTLM Domain** against which the User-ID agent on the firewall will check NTLM credentials.<br>5. In the **Admin User Name**, **Password**, and **Confirm Password** fields, enter the username and password of the Active Directory account you created for the User-ID agent.<br>Do not include the domain in the **Admin User Name** field. Otherwise, the firewall will fail to join the domain.<br>Palo Alto Networks recommends that you use a User-ID agent account that is separate from your firewall administrator account.<br>6. You don't need to configure any other settings for the User-ID agent: click **OK**. |

| Configure Captive Portal Using the PAN-OS Integrated User-ID Agent (Continued) | |
|---|---|
| Step 11 Configure the Captive Portal settings. | 1. Select **Device > User Identification > Captive Portal Settings** and edit the settings.<br>2. Make sure the **Enable Captive Portal** check box is selected.<br>3. Select the **SSL/TLS Service Profile** you created for redirect requests over TLS.<br>4. Select the **Mode** (in this example, **Redirect**).<br>5. (Redirect mode only) Specify the **Redirect Host** name that resolves to the IP address of the Layer 3 interface for redirected requests.<br>6. Select the authentication method to use if NTLM fails (or if you don't use NTLM):<br>• To use Kerberos SSO, an external server, or the local database, select the **Authentication Profile** or authentication sequence you created.<br>• To use client certificate authentication, select the **Certificate Profile** you created.<br>7. Click **OK** and **Commit** to save the Captive Portal configuration. |

 © Palo Alto Networks, Inc.

# Configure User Mapping for Terminal Server Users

Individual terminal server users appear to have the same IP address and therefore an IP address-to-username mapping is not sufficient to identify a specific user. To enable identification of specific users on Windows-based terminal servers, the Palo Alto Networks Terminal Services agent (TS agent) allocates a port range to each user. It then notifies every connected firewall about the allocated port range, which allows the firewall to create an IP address-port-user mapping table and enable user- and group-based security policy enforcement. For non-Windows terminal servers, you can configure the User-ID XML API to extract user mapping information.

The following sections describe how to configure user mapping for terminal server users:

- Configure the Palo Alto Networks Terminal Server Agent for User Mapping
- Retrieve User Mappings from a Terminal Server Using the User-ID XML API

## Configure the Palo Alto Networks Terminal Server Agent for User Mapping

Use the following procedure to install the TS agent on the terminal server. You must install the TS agent on all terminal servers that your users log in to in order to successfully map all your users.

For information about the supported terminal servers supported by the TS Agent, refer to "Operating System (OS) Compatibility TS Agent" in the Terminal Services Agent Release Notes, which are available on the Palo Alto Networks Software Updates page.

| **Install the Windows Terminal Server Agent** | |
|---|---|
| Step 1 Download the TS Agent installer. | 1. Log in to the Palo Alto Networks Support site.<br>2. Select **Software Updates** from the Manage Devices section.<br>3. Scroll to the **Terminal Services Agent** section and **Download** the version of the agent you want to install.<br>4. Save the `TaInstall64.x64-x.x.x-xx.msi` or `TaInstall-x.x.x-xx.msi` file (be sure to select the appropriate version based on whether the Windows system is running a 32-bit OS or a 64-bit OS) on the system(s) where you plan to install the agent. |

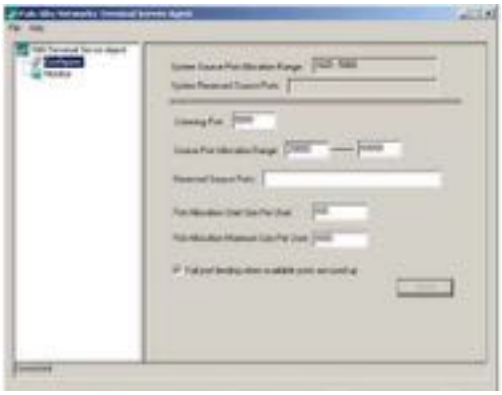
**Install the Windows Terminal Server Agent (Continued)**

| | | |
|---|---|---|
| Step 2 | Run the installer as an administrator.<br> | 1. To launch a command prompt as an administrator, click Start and right-click **Command Prompt** and then select **Run as administrator**.<br>2. From the command line, run the .msi file you downloaded. For example, if you saved the .msi file to the Desktop you would enter the following:<br>`C:\Users\administrator.acme>cd Desktop`<br>`C:\Users\administrator.acme\Desktop>TaInstall-6.0.0-1.msi`<br>3. Follow the setup prompts to install the agent using the default settings. By default, the agent gets installed to the `C:\Program Files (x86)\Palo Alto Networks\Terminal Server Agent` folder, but you can **Browse** to a different location.<br>4. When the installation completes, **Close** the setup window.<br>If you are upgrading to a TS Agent version that has a newer driver than the existing installation, the installation wizard prompts you to reboot the system after upgrading in order to use the new driver. |
| Step 3 | Launch the Terminal Server Agent application. | Click Start and select **Terminal Server Agent**.<br>  |

 © Palo Alto Networks, Inc.

**Install the Windows Terminal Server Agent (Continued)**

Step 4 Define the range of ports for the TS Agent to allocate to end users.



The **System Source Port Allocation Range** and **System Reserved Source Ports** fields specify the range of ports that will be allocated to non-user sessions. Make sure the values specified in these fields do not overlap with the ports you designate for user traffic. These values can only be changed by editing the corresponding Windows registry settings.

1. Select **Configure**.
2. Set the **Source Port Allocation Range** (default 20000-39999). This is the full range of port numbers that the TS Agent will allocate for user mapping. The port range you specify cannot overlap with the **System Source Port Allocation Range**.
3. (Optional) If there are ports/port ranges within the source port allocation that you do not want the TS Agent to allocate to user sessions, specify them as **Reserved Source Ports**. To include multiple ranges, use commas with no spaces, for example: `2000-3000,3500,4000-5000`.
4. Specify the number of ports to allocate to each individual user upon login to the terminal server in the **Port Allocation Start Size Per User** field (default 200).
5. Specify the **Port Allocation Maximum Size Per User**, which is the maximum number of ports the Terminal Server agent can allocate to an individual user.
6. Specify whether to continue processing traffic from the user if the user runs out of allocated ports. By default, the **Fail port binding when available ports are used up** is selected, which indicates that the application will fail to send traffic when all ports are used. To enable users to continue using applications when they run out of ports, clear this check box. Keep in mind that this traffic may not be identified with User-ID.

Step 5 Configure the firewalls to connect to the Terminal Server agent.

Complete the following steps on each firewall you want to connect to the Terminal Server agent to receive user mappings:

1. Select **Device > User Identification > Terminal Server Agents** and click **Add**.
2. Enter a **Name** for the Terminal Server agent.
3. Enter the IP address of the Windows **Host** on which the Terminal Server agent is installed.
4. Enter the **Port** number on which the agent will listen for user mapping requests. This value must match the value configured on the Terminal Server agent. By default, the port is set to 5009 on the firewall and on the agent. If you change it here, you must also change the **Listening Port** field on the Terminal Server agent **Configure** screen.
5. Make sure that the configuration is **Enabled** and then click **OK**.
6. **Commit** the changes.
7. Verify that the **Connected** status displays as connected (a green light).

| Install the Windows Terminal Server Agent (Continued) | |
|---|---|
| Step 6 Verify that the Terminal Server agent is successfully mapping IP addresses to usernames and that the firewalls can connect to the agent.<br>  | 1. Launch the Terminal Server agent and verify that the firewalls can connect by making sure the **Connection Status** for each of Device in the Connection List is **Connected**.<br>2. To verify that the Terminal Server agent is successfully mapping port ranges to usernames, select **Monitoring** and make sure that the mapping table is populated. |

## Retrieve User Mappings from a Terminal Server Using the User-ID XML API

The User-ID XML API is a RESTful API that uses standard HTTP requests to send and receive data. API calls can be made directly from command line utilities such as cURL or using any scripting or application framework that supports RESTful services.

To enable a non-Windows terminal server to send user mapping information directly to the firewall, create scripts that extract the user login and logout events and use them for input to the User-ID XML API request format. Then define the mechanisms for submitting the XML API request(s) to the firewall using cURL or wget and providing the firewall's API key for secure communication. Creating user mappings from multi-user systems such as terminal servers requires use of the following API messages:

- **<multiusersystem>**—Sets up the configuration for an XML API Multi-user System on the firewall. This message allows for definition of the terminal server IP address (this will be the source address for all users on that terminal server). In addition, the `<multiusersystem>` setup message specifies the range of source port numbers to allocate for user mapping and the number of ports to allocate to each individual user upon login (called the *block size*). If you want to use the default source port allocation range (1025-65534) and block size (200), you do not need to send a `<multiusersystem>` setup event to the firewall. Instead, the firewall will automatically generate the XML API Multi-user System configuration with the default settings upon receipt of the first user login event message.
- **<blockstart>**—Used with the `<login>` and `<logout>` messages to indicate the starting source port number allocated to the user. The firewall then uses the block size to determine the actual range of port numbers to map to the IP address and username in the login message. For example, if the `<blockstart>` value is 13200 and the block size configured for the multi-user system is 300, the actual source port range allocated to the user is 13200 through 13499. Each connection initiated by the user should use a unique source port number within the allocated range, enabling the firewall to identify the user based on its IP address-port-user mappings for enforcement of user- and group-based security rules. When a user exhausts all the ports allocated, the terminal server must send a new `<login>` message allocating a new port range for the user so that the firewall can update the IP address-port-user mapping. In addition, a single username can

 © Palo Alto Networks, Inc.

have multiple blocks of ports mapped simultaneously. When the firewall receives a <logout> message that includes a <blockstart> parameter, it removes the corresponding IP address-port-user mapping from its mapping table. When the firewall receives a <logout> message with a username and IP address, but no <blockstart>, it removes the user from its table. And, if the firewall receives a <logout> message with an IP address only, it removes the multi-user system and all mappings associated with it.

The XML files that the terminal server sends to the firewall can contain multiple message types and the messages do not need to be in any particular order within the file. However, upon receiving an XML file that contains multiple message types, the firewall will process them in the following order: multiusersystem requests first, followed by logins, then logouts.

The following workflow provides an example of how to use the User-ID XML API to send user mappings from a non-Windows terminal server to the firewall.

**Use the User-ID XML API to Map Non-Windows Terminal Services Users**

Step 1 — Generate the API key that will be used to authenticate the API communication between the firewall and the Terminal server. To generate the key you must provide login credentials for an administrative account; the API is available to all administrators (including role-based administrators with XML API privileges enabled).

Any special characters in the password must be URL/percent-encoded.

From a browser, log in to the firewall. Then, to generate the API key for the firewall, open a new browser window and enter the following URL:

```
https://<Firewall-IPaddress>/api/?type=keygen&user=<username>&
password=<password>
```

Where <Firewall-IPaddress> is the IP address or FQDN of the firewall and <username> and <password> are the credentials for the administrative user account on the firewall. For example:

```
https://10.1.2.5/api/?type=keygen&user=admin&password=admin
```

The firewall responds with a message containing the key, for example:

```
<response status="success">
   <result>
      <key>k7J335J6hI7nBxIqyfa62sZugWx7ot%2BgzEA9UOnlZRg=</key>
   </result>
</response>
```

**Use the User-ID XML API to Map Non-Windows Terminal Services Users (Continued)**

Step 2 (Optional) Generate a setup message that the terminal server will send to specify the port range and block size of ports per user that your terminal services agent uses.

If the terminal services agent does not send a setup message, the firewall will automatically create a terminal server agent configuration using the following default settings upon receipt of the first login message:

- Default port range: 1025 to 65534
- Per user block size: 200
- Maximum number of multi-user systems: 1000

The following shows a sample setup message:

```
<uid-message>
  <payload>
    <multiusersystem>
      <entry ip="10.1.1.23" startport="20000"
        endport="39999" blocksize="100">
    </multiusersystem>
  </payload>
  <type>update</type>
  <version>1.0</version>
</uid-message>
```

where `entry ip` specifies the IP address assigned to terminal server users, `startport` and `endport` specify the port range to use when assigning ports to individual users, and `blocksize` specifies the number of ports to assign to each user. The maximum blocksize is 4000 and each multi-user system can allocate a maximum of 1000 blocks.

If you define a custom blocksize and or port range, keep in mind that you must configure the values such that every port in the range gets allocated and that there are no gaps or unused ports. For example, if you set the port range to 1000-1499, you could set the block size to 100, but not to 200. This is because if you set it to 200, there would be unused ports at the end of the range.

Step 3 Create a script that will extract the login events and create the XML input file to send to the firewall.

Make sure the script enforces assignment of port number ranges at fixed boundaries with no port overlaps. For example, if the port range is 1000-1999 and the block size is 200, acceptable blockstart values would be 1000, 1200, 1400, 1600, or 1800. Blockstart values of 1001, 1300, or 1850 would be unacceptable because some of the port numbers in the range would be left unused.

The login event payload that the terminal server sends to the firewall can contain multiple login events.

The following shows the input file format for a user-ID XML login event:

```
<uid-message>
<payload>
<login>
<entry name="acme\jjaso" ip="10.1.1.23" blockstart="20000">
<entry name="acme\jparker" ip="10.1.1.23" blockstart="20100">
<entry name="acme\ccrisp" ip="10.1.1.23" blockstart="21000">
</login>
</payload>
<type>update</type>
<version>1.0</version>
</uid-message>
```

The firewall uses this information to populate its user mapping table. Based on the mappings extracted from the example above, if the firewall received a packet with a source address and port of 10.1.1.23:20101, it would map the request to user jparker for policy enforcement.

Each multi-user system can allocate a maximum of 1000 port blocks.

 © Palo Alto Networks, Inc.

**Use the User-ID XML API to Map Non-Windows Terminal Services Users (Continued)**

| | | |
|---|---|---|
| Step 4 | Create a script that will extract the logout events and create the XML input file to send to the firewall.<br><br>Upon receipt of a `logout` event message with a `blockstart` parameter, the firewall removes the corresponding IP address-port-user mapping. If the `logout` message contains a username and IP address, but no `blockstart` parameter, the firewall removes all mappings for the user. If the `logout` message contains an IP address only, the firewall removes the multi-user system and all associated mappings. | The following shows the input file format for a User-ID XML logout event:<br>`<uid-message>`<br>`  <payload>`<br>`  <logout>`<br>`  <entry name="acme\jjaso" ip="10.1.1.23" blockstart="20000">`<br>`  <entry name="acme\ccrisp" ip="10.1.1.23">`<br>`  <entry ip="10.2.5.4">`<br>`  </logout>`<br>`  </payload>`<br>`  <type>update</type>`<br>`  <version>1.0</version>`<br>`</uid-message>`<br><br>You can also clear the multiuser system entry from the firewall using the following CLI command: **`clear xml-api multiusersystem`** |
| Step 5 | Make sure that the scripts you create include a way to dynamically enforce that the port block range allocated using the XML API matches the actual source port assigned to the user on the terminal server and that the mapping is removed when the user logs out or the port allocation changes. | One way to do this would be to use netfilter NAT rules to hide user sessions behind the specific port ranges allocated via the XML API based on the uid. For example, to ensure that a user with the user ID jjaso is mapped to a source network address translation (SNAT) value of 10.1.1.23:20000-20099, the script you create should include the following:<br>`[root@ts1 ~]# iptables -t nat -A POSTROUTING -m owner --uid-owner jjaso -p tcp -j SNAT --to-source 10.1.1.23:20000-20099`<br>Similarly, the scripts you create should also ensure that the IP table routing configuration dynamically removes the SNAT mapping when the user logs out or the port allocation changes:<br>`[root@ts1 ~]# iptables -t nat -D POSTROUTING 1` |
| Step 6 | Define how to package the XML input files containing the setup, login, and logout events into wget or cURL messages for transmission to the firewall. | To apply the files to the firewall using wget:<br>`> wget --post file <filename> "https://<Firewall-IPaddress>/api/?type=user-id&key=<key>&file-name=<input_filename.xml>&client=wget&vsys=<VSYS_name>"`<br>For example, the syntax for sending an input file named login.xml to the firewall at 10.2.5.11 using key `k7J335J6hI7nBxIqyfa62sZugWx7ot%2BgzEA9UOnlZRg` using wget would look as follows:<br>`> wget --post file login.xml "https://10.2.5.11/api/?type=user-id&key=k7J335J6hI7nBxIqyfa62sZugWx7ot%2BgzEA9UOnlZRg&file-name=login.xml&client=wget&vsys=vsys1"`<br>To apply the file to the firewall using cURL:<br>`> curl --form file=@<filename> https://<Firewall-IPaddress>/api/?type=user-id&key=<key>&vsys=<VSYS_name>`<br>For example, the syntax for sending an input file named login.xml to the firewall at 10.2.5.11 using key `k7J335J6hI7nBxIqyfa62sZugWx7ot%2BgzEA9UOnlZRg` using cURL would look as follows:<br>`> curl --form file@login.xml "https://10.2.5.11/api/?type=user-id&key=k7J335J6hI7nBxIqyfa62sZugWx7ot%2BgzEA9UOnlZRg&vsys=vsys1"` |

| Use the User-ID XML API to Map Non-Windows Terminal Services Users (Continued) | |
|---|---|
| Step 7 Verify that the firewall is successfully receiving login events from the terminal servers. | Verify the configuration by opening an SSH connection to the firewall and then running the following CLI commands:<br>To verify if the terminal server is connecting to the firewall over XML:<br>`admin@PA-5050> show user xml-api multiusersystem`<br>`Host Vsys Users Blocks`<br>`----------`<br>`10.5.204.43 vsys1 5 2`<br>To verify that the firewall is receiving mappings from a terminal server over XML:<br>`admin@PA-5050> show user ip-port-user-mapping all`<br>`Global max host index 1, host hash count 1`<br>`XML API Multi-user System 10.5.204.43`<br>`Vsys 1, Flag 3`<br>`Port range: 20000 - 39999`<br>`Port size: start 200; max 2000`<br>`Block count 100, port count 20000`<br>`20000-20199: acme\administrator`<br>`Total host: 1` |

## Send User Mappings to User-ID Using the XML API

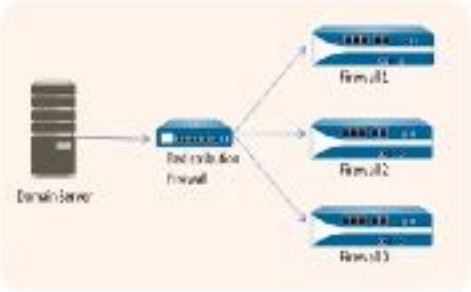
Although the User-ID functionality provides many out-of-the box methods for obtaining user mapping information, you may have some applications or devices that capture user information that cannot be natively integrated with User-ID. In this case you can use the User-ID XML API to create custom scripts that allow you to leverage existing user data and send it to the User-ID agent or directly to the firewall.

The User-ID XML API is a RESTful API that uses standard HTTP requests to send and receive data. API calls can be made directly from command line utilities such as cURL or using any scripting or application framework that supports RESTful services. To leverage user data from an existing system—such as a custom application developed internally or another device that is not supported by one of the existing user mapping mechanisms—you can create custom scripts to extract the data and send it to the firewall or the User-ID agent using the XML API.

To enable an external system to send user mapping information to the User-ID agent or directly to the firewall, you can create scripts that extract the user login and logout events and use them for input to the User-ID XML API request format. Then define the mechanisms for submitting the XML API request(s) to the firewall using cURL or wget using the firewall's API key for secure communication. For more details, refer to the PAN-OS XML API Usage Guide.

# Configure a Firewall to Share User Mapping Data with Other Firewalls

Because policy is local to each firewall, each firewall needs current user mapping and group mapping information to accurately enforce policy by user and group. To simplify administration, you can configure one firewall to be the *redistribution firewall* that collects all the mapping information and shares it with other firewalls. The redistribution firewall can share only the information it collects using local methods (for example, the PAN-OS integrated User-ID agent or Captive Portal); it can't share the information collected from the Windows-based User-ID and Terminal Services agents. You configure the receiving firewalls to retrieve the mapping information from the redistribution firewall; they don't need to communicate directly with domain servers.



The following procedure describes how to set up redistribution of User-ID information.

| Configure a Firewall to Share User Mapping Data with Other Firewalls | | |
|---|---|---|
| Step 1 | Configure the redistribution firewall.<br><br>User-ID configurations apply to a single virtual system only. To redistribute User-ID mappings from multiple virtual systems, you must configure the user mapping settings on each virtual system separately, using a unique pre-shared key in each configuration. | 1. Select **Device > User Identification > User Mapping** and edit the Palo Alto Networks User-ID Agent Setup section.<br>2. Select **Redistribution**.<br>3. Enter a **Collector Name**.<br>4. Enter and confirm the **Pre-Shared Key** that will enable other firewalls to connect to this firewall to retrieve user mapping information.<br>5. Click **OK** to save the redistribution configuration. |
| Step 2 | Create an interface management profile that enables the User-ID service and attach it to the interface that the other firewalls will connect to in order to retrieve user mappings. | 1. Select **Network > Network Profiles > Interface Mgmt** and click **Add**.<br>2. Enter a **Name** for the profile and then select the Permitted Services. At a minimum, select **User-ID Service** and **HTTPS**.<br>3. Click **OK** to save the profile.<br>4. Select **Network > Interfaces > Ethernet** and select the interface you plan to use for redistribution.<br>5. On the **Advanced > Other Info** tab, select the **Management Profile** you just created.<br>6. Click **OK** and **Commit**. |

 © Palo Alto Networks, Inc.

| Configure a Firewall to Share User Mapping Data with Other Firewalls (Continued) | | |
|---|---|---|
| Step 3 | Configure the other firewalls to retrieve user mappings from the redistribution firewall.<br> If the redistribution firewall has multiple virtual systems configured for redistribution, make sure you are using the pre-shared key that corresponds to the virtual system from which you want this firewall to retrieve User-ID mappings. | Perform the following steps on each firewall that you want to be able to retrieve user mappings:<br>1. Select **Device > User Identification > User-ID Agents**.<br>2. Click **Add** and enter a User-ID agent **Name** for the redistribution firewall.<br>3. Enter the hostname or IP address of the firewall interface that you configured for redistribution in the **Host** field.<br>4. Enter 5007 as the **Port** number on which the redistribution firewall will listen for User-ID requests.<br>5. Enter the **Collector Name** that you specified in the redistribution firewall configuration (Step 1-3).<br>6. Enter and confirm the **Collector Pre-Shared Key**. The key value you enter here must match the value configured on the redistribution firewall (Step 1-4).<br>7. (Optional) If you are using the redistribution firewall to retrieve group mappings in addition to user mappings, select the **Use as LDAP Proxy** check box.<br>8. (Optional) If you are using the redistribution firewall for Captive Portal authentication, select the **Use for NTLM Authentication** check box.<br>9. Make sure that the configuration is **Enabled** and then click **OK**.<br>10. **Commit** the changes. |
| Step 4 | Verify the configuration. | On the **User-ID Agents** tab, verify that the redistribution firewall entry you just added shows a green icon in the **Connected** column.<br>If a red icon appears, check traffic logs (**Monitor > Logs > Traffic**) to identify the issue. You can also check to see if any user mapping data has been received by running the following operational commands from the CLI:<br>`show user ip-user-mapping` (to view user mapping information on the dataplane)<br>`show user ip-user-mapping-mp` (to view mappings on the management plane). |

# Enable User- and Group-Based Policy

To enable security policy based on users and user groups, you must enable User-ID for each zone that contains users you want to identify. You can then define policy rules that allow or deny traffic based on username or group membership. Additionally, you can create Captive Portal rules to enable identification for IP addresses that don't yet have any user data associated with them.

For users with multiple usernames, see Enable Policy for Users with Multiple Accounts.

| Enable User- and Group-Based Policy | | |
|---|---|---|
| Step 1 | Enable User-ID on the source zones that contain the users who will send requests that require user-based access controls. | 1. Select **Network > Zones** and click the Name of the zone.<br>2. Select the **Enable User Identification** check box and click **OK**. |
| Step 2 | (Optional) Configure the firewall to read the IP addresses of users from the X-Forwarded-For (XFF) header in client requests for web services when the firewall is between the Internet and a proxy server that would otherwise hide the user IP addresses.<br><br>The firewall matches the IP addresses with usernames that your policy rules reference so that those rules can control and log access for the associated users and groups. For details, see Identify Users Connected through a Proxy Server. | 1. Select **Device > Setup > Content-ID** and edit the X-Forwarded-For Headers settings.<br>2. Select the **X-Forwarded-For Header in User-ID** check box.<br> Selecting the **Strip-X-Forwarded-For Header** check box doesn't disable the use of XFF headers for user attribution in policy rules; the firewall zeroes out the XFF value only after using it for user attribution.<br>3. Click **OK** to save your changes. |

 © Palo Alto Networks, Inc.

| Enable User- and Group-Based Policy (Continued) | |
|---|---|
| Step 3 Create security rules based on user and user group.<br><br> As a best practice, create rules based on group rather than user whenever possible. This prevents you from having to continually update your rules (which requires a commit) whenever your user base changes. | 1. After configuring User-ID, you will be able to choose a user name or group name when defining the source or destination of a security rule:<br>a. Select **Policies > Security** and click **Add** to create a new rule or click on an existing rule name to open the Security Policy Rule dialog.<br>b. Specify which users and/or groups to match in the rule in one of the following ways:<br>– If you want to specify specific users/groups as matching criteria, select the **User** tab and click the **Add** button in the Source User section to display a list of users and groups discovered by the firewall group mapping function. Select the users and/or groups to add to the rule.<br>– If you want the rule to match any user who has or has not successfully authenticated and you don't need to know the specific user or group name, select **known-user** or **unknown** from the drop-down above the **Source User** list.<br>2. Configure the rest of the rule as appropriate and then click **OK** to save it. For details on other fields in the security rule, see Set Up Basic Security Policies. |
| Step 4 Create your Captive Portal rules. | 1. Select **Policies > Captive Portal**.<br>2. Click **Add** and enter a **Name** for the rule.<br>3. Define the matching criteria for the rule by completing the **Source**, **Destination**, and **Service/URL Category** tabs as appropriate to match the traffic you want to authenticate. The matching criteria on these tabs is the same as the criteria you define when creating a security rule. See Set Up Basic Security Policies for details.<br>4. Define the **Action** to take on traffic that matches the rule:<br>• **no-captive-portal**—Allow traffic to pass without presenting a Captive Portal page for authentication.<br>• **web-form**—Present a Captive Portal page for the user to explicitly enter authentication credentials or use client certificate authentication.<br>• **browser-challenge**—Transparently obtain user authentication credentials. If you select this action, you must enable Kerberos Single Sign-On (SSO) or NT LAN Manager (NTLM) authentication when you Configure Captive Portal. If Kerberos SSO authentication fails, the firewall falls back to NTLM authentication. If you didn't configure NTLM, or NTLM authentication fails, the firewall falls back to **web-form** authentication.<br>5. Click **OK** and **Commit**. |

# Enable Policy for Users with Multiple Accounts

If a user in your organization has multiple responsibilities, that user might have multiple usernames (accounts), each with distinct privileges for accessing a particular set of services, but with all the usernames sharing the same IP address (the client system of the user). However, the User-ID agent can map any one IP address (or IP address and port range for terminal server users) to only one username for enforcing policy, and you can't predict which username the agent will map. To control access for all the usernames of a user, you must make adjustments to the rules, user groups, and User-ID agent.

For example, say the firewall has a rule that allows username corp_user to access email and a rule that allows username admin_user to access a MySQL server. The user logs in with either username from the same client IP address. If the User-ID agent maps the IP address to corp_user, then whether the user logs in as corp_user or admin_user, the firewall identifies that user as corp_user and allows access to email but not the MySQL server. On the other hand, if the User-ID agent maps the IP address to admin_user, the firewall always identifies the user as admin_user regardless of login and allows access to the MySQL server but not email. The following steps describe how to enforce both rules in this example.

| **Enable Policy for a User with Multiple Accounts** | | |
|---|---|---|
| Step 1 | Configure a user group for each service that requires distinct access privileges.<br><br>In this example, each group is for a single service (email or MySQL server). However, it is common to configure each group for a set of services that require the same privileges (for example, one group for all basic user services and one group for all administrative services). | If your organization already has user groups that can access the services that the user requires, simply add the username that is used for less restricted services to those groups. In this example, the email server requires less restricted access than the MySQL server, and corp_user is the username for accessing email. Therefore, you add corp_user to a group that can access email (corp_employees) and to a group that can access the MySQL server (network_services).<br><br>If adding a username to a particular existing group would violate your organizational practices, you can create a custom group based on an LDAP filter. For this example, say network_services is a custom group, which you configure as follows:<br>1. Select **Device > User Identification > Group Mapping Settings** and **Add** a group mapping configuration with a unique **Name**.<br>2. Select an LDAP **Server Profile** and ensure the **Enabled** check box is enabled.<br>3. Select the **Custom Group** tab and **Add** a custom group with network_services as a **Name**.<br>4. Specify an **LDAP Filter** that matches an LDAP attribute of corp_user and click **OK**.<br>5. Click **OK** and **Commit**.<br><br>Later, if other users that are in the group for less restricted services are given additional usernames that access more restricted services, you can add those usernames to the group for more restricted services. This scenario is more common than the inverse; a user with access to more restricted services usually already has access to less restricted services. |

 © Palo Alto Networks, Inc.

| Enable Policy for a User with Multiple Accounts (Continued) | | |
|---|---|---|
| Step 2 | Configure the rules that control user access based on the groups you just configured. | Enable User- and Group-Based Policy:<br>1. Configure a security rule that allows the corp_employees group to access email.<br>2. Configure a security rule that allows the network_services group to access the MySQL server. |
| Step 3 | Configure the ignore list of the User-ID agent.<br>This ensures that the User-ID agent maps the client IP address only to the username that is a member of the groups assigned to the rules you just configured. The ignore list must contain all the usernames of the user that are not members of those groups. | In this example, you add admin_user to the ignore list of the Windows-based User-ID agent to ensure that it maps the client IP address to corp_user. This guarantees that, whether the user logs in as corp_user or admin_user, the firewall identifies the user as corp_user and applies both rules that you configured because corp_user is a member of the groups that the rules reference.<br>1. Create an `ignore_user_list.txt` file.<br>2. Open the file and add admin_user.<br>If you later add more usernames, each must be on a separate line.<br>3. Save the file to the User-ID agent folder on the domain server where the agent is installed.<br>If you use the PAN-OS integrated User-ID agent, perform Step 6 under Configure User Mapping Using the PAN-OS Integrated User-ID Agent to configure the ignore list. |
| Step 4 | Configure endpoint authentication for the restricted services.<br>This enables the endpoint to verify the credentials of the user and preserves the ability to enable access for users with multiple usernames. | In this example, you have configured a firewall rule that allows corp_user, as a member of the network_services group, to send a service request to the MySQL server. You must now configure the MySQL server to respond to any unauthorized username (such as corp_user) by prompting the user to enter the login credentials of an authorized username (admin_user).<br>If the user logs in to the network as admin_user, the user can then access the MySQL server without it prompting for the admin_user credentials again.<br>In this example, both corp_user and admin_user have email accounts, so the email server won't prompt for additional credentials regardless of which username the user entered when logging in to the network.<br>The firewall is now ready to enforce rules for a user with multiple usernames. |

# Verify the User-ID Configuration

After you configure group mapping and user mapping and enable User-ID on your security rules and Captive Portal rules, you should verify that it is working properly.

| Verify the User-ID Configuration | |
|---|---|
| Step 1 Verify that group mapping is working. | From the CLI, enter the following command:<br>**show user group-mapping statistics** |
| Step 2 Verify that user mapping is working. | If you are using the on-device User-ID agent, you can verify this from the CLI using the following command:<br>**show user ip-user-mapping-mp all**<br>`IP Vsys From User Timeout (sec)`<br>`----------`<br>`192.168.201.1 vsys1 UIA acme\george 210`<br>`192.168.201.11 vsys1 UIA acme\duane 210`<br>`192.168.201.50 vsys1 UIA acme\betsy 210`<br>`192.168.201.10 vsys1 UIA acme\administrator 210`<br>`192.168.201.100 vsys1 AD acme\administrator 748`<br>`Total: 5 users`<br>`*: WMI probe succeeded` |
| Step 3 Test your security rule. | • From a machine in the zone where User-ID is enabled, attempt to access sites and applications to test the rules you defined in your policy and ensure that traffic is allowed and denied as expected.<br>• You can also use the `test security-policy-match` command to determine whether the policy is configured correctly. For example, suppose you have a rule that blocks user duane from playing World of Warcraft; you could test the policy as follows:<br>`test security-policy-match application worldofwarcraft source-user acme\duane source any destination any destination-port any protocol 6`<br>`"deny worldofwarcraft" {`<br>`from corporate;`<br>`source any;`<br>`source-region any;`<br>`to internet;`<br>`destination any;`<br>`destination-region any;`<br>`user acme\duane;`<br>`category any;`<br>`application/service worldofwarcraft;`<br>`action deny;`<br>`terminal no;`<br>`}` |

 © Palo Alto Networks, Inc.

**Verify the User-ID Configuration (Continued)**

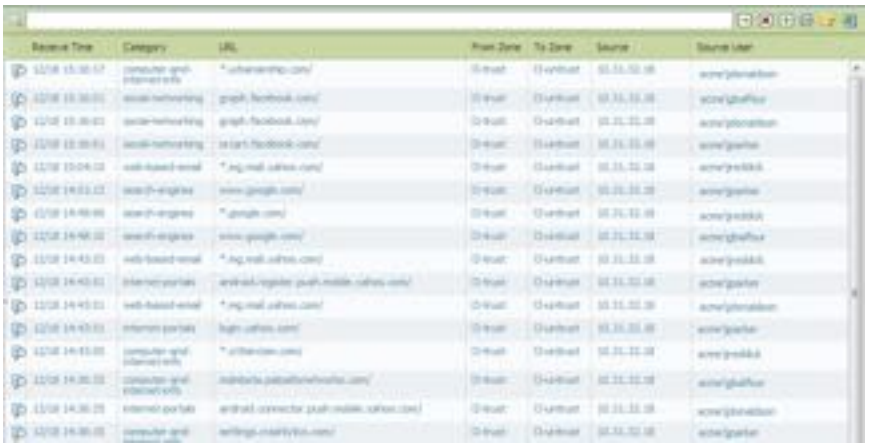
Step 4 Test your Captive Portal configuration.

1. From the same zone, go to a machine that is not a member of your directory, such as a Mac OS system, and try to ping to a system external to the zone. The ping should work without requiring authentication.
2. From the same machine, open a browser and navigate to a web site in a destination zone that matches a Captive Portal rule you defined. You should see the Captive Portal web form.

3. Log in using the correct credentials and confirm that you are redirected to the requested page.
4. You can also test your Captive Portal policy using the `test cp-policy-match` command as follows:

```
test cp-policy-match from corporate to internet
source 192.168.201.10 destination 8.8.8.8
Matched rule: 'captive portal' action: web-form
```

Step 5 Verify that user names are displayed in the log files (**Monitor > Logs**).



**Verify the User-ID Configuration (Continued)**

Step 6 Verify that user names are displayed in reports (**Monitor > Reports**). For example, when drilling down into the denied applications report, you should see a list of the users who attempted to access the applications as in the following example.

 © Palo Alto Networks, Inc.

# Deploy User-ID in a Large-Scale Network

The following topics describe a User-ID deployment in which you use Windows Log Forwarding and Global Catalog servers to simplify user and group mapping in a large-scale network of Microsoft Active Directory (AD) domain controllers or Exchange servers:

- Windows Log Forwarding and Global Catalog Servers
- Plan Your User-ID Implementation for a Large-Scale Network
- Configure Windows Log Forwarding
- Configure User-ID for a Large-Scale Network

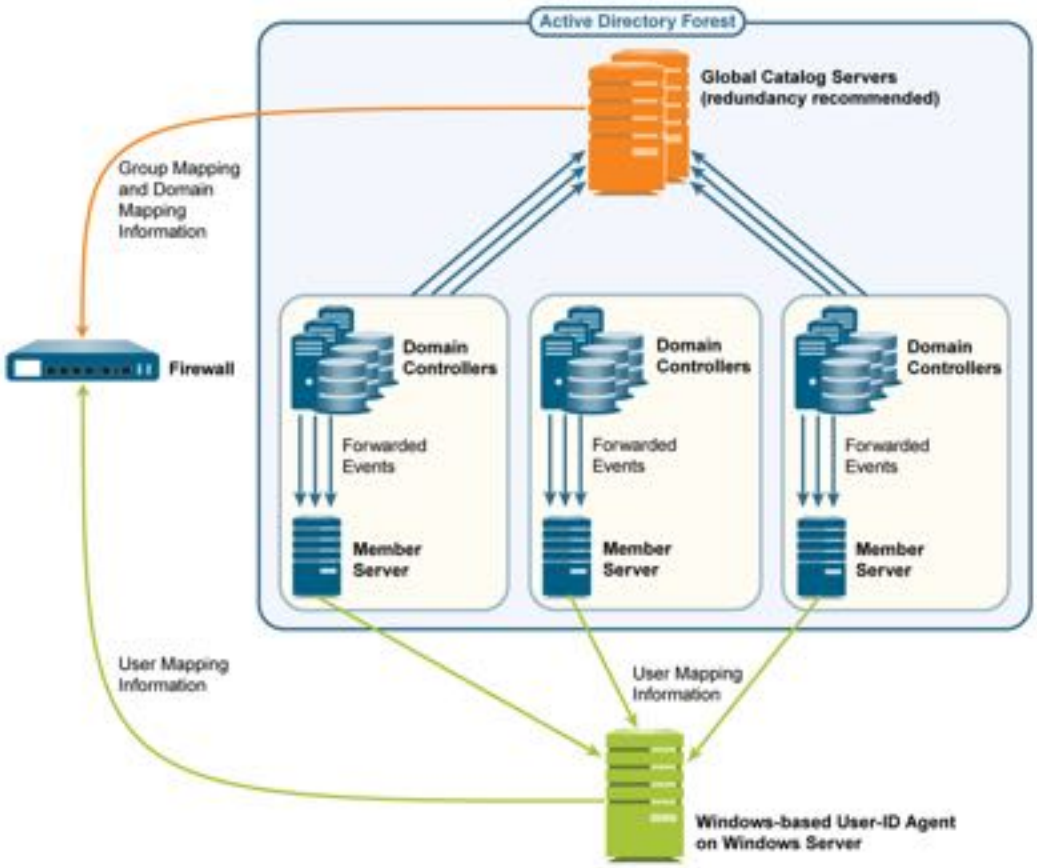
## Windows Log Forwarding and Global Catalog Servers

Because each User-ID agent can monitor up to 100 servers, you need multiple User-ID agents to monitor a network with hundreds of AD domain controllers or Exchange servers. Creating and managing numerous User-ID agents involves considerable administrative overhead, especially in expanding networks where tracking new domain controllers is difficult. Windows Log Forwarding enables you to minimize the administrative overhead by reducing the number of servers to monitor and thereby reducing the number of User-ID agents to manage. When you configure Windows Log Forwarding, multiple domain controllers export their login events to a single domain member from which a User-ID agent collects the user mapping information.

You can configure Windows Log Forwarding for Windows Server versions 2003, 2008, 2008 R2, 2012, and 2012 R2. Windows Log Forwarding is not available for non-Microsoft servers.

To collect username to group mapping information in a large-scale network, you can configure the firewall to query a Global Catalog server that receives account information from the domain controllers.

The following figure illustrates user mapping and group mapping for a large-scale network in which the firewall uses a Windows-based User-ID agent. See Plan Your User-ID Implementation for a Large-Scale Network to determine if this deployment suits your network.



## Plan Your User-ID Implementation for a Large-Scale Network

When deciding whether to use Windows Log Forwarding and Global Catalog servers for your User-ID implementation, consult your system administrator to determine:

- Bandwidth required for domain controllers to forward login events to member servers. The bandwidth is a multiple of the login rate (number of logins per minute) of the domain controllers and the byte size of each login event.

  Note that domain controllers won't forward their entire security logs; they forward only the events that the user mapping process requires per login: three events for Windows Server 2003 or four events for Windows Server 2008/2012 and MS Exchange.

- Whether the following network elements support the required bandwidth:
  - Domain controllers—They must support the processing load associated with forwarding the events.
  - Member Servers—They must support the processing load associated with receiving the events.
  - Connections—The geographic distribution (local or remote) of the domain controllers, member servers, and Global Catalog servers is a factor. Generally, a remote distribution supports less bandwidth.

 © Palo Alto Networks, Inc.

## Configure Windows Log Forwarding

To configure Windows Log Forwarding, you need administrative privileges for configuring group policies on Windows servers. Configure Windows Log Forwarding on every member server that will collect login events from domain controllers. The following is an overview of the tasks; consult your Windows Server documentation for the specific steps.

| Configure Windows Log Forwarding | |
|---|---|
| Step 1 | On every member server that will collect security events, enable event collection, add the domain controllers as event sources, and configure the event collection query (subscription). The events you specify in the subscription vary by domain controller platform:<br>• Windows Server 2003—The event IDs for the required events are 672 (Authentication Ticket Granted), 673 (Service Ticket Granted), and 674 (Ticket Granted Renewed).<br>• Windows Server 2008/2012 (including R2) or MS Exchange—The event IDs for the required events are 4768 (Authentication Ticket Granted), 4769 (Service Ticket Granted), 4770 (Ticket Granted Renewed), and 4624 (Logon Success).<br> You must forward events to the security logs location on the member servers, not to the default forwarded logs location.<br> To forward events as quickly as possible, select the **Minimize Latency** option when configuring the subscription. |
| Step 2 | Configure a group policy to enable Windows Remote Management (WinRM) on the domain controllers. |
| Step 3 | Configure a group policy to enable Windows Event Forwarding on the domain controllers. |

## Configure User-ID for a Large-Scale Network

| Configure User-ID for a Large-Scale Network | | |
|---|---|---|
| Step 1 | Configure Windows Log Forwarding on the member servers that will collect login events. | Configure Windows Log Forwarding. This step requires administrative privileges for configuring group policies on Windows servers. |
| Step 2 | Install the Windows-based User-ID agent. | Install the User-ID Agent on a Windows server that can access the member servers. The Windows server can be inside or outside the Active Directory forest; it doesn't need to be a member server itself. |

| Configure User-ID for a Large-Scale Network (Continued) | | |
|---|---|---|
| Step 3 | Configure the User-ID agent to collect user mapping information from the member servers. | 1. Start the Windows-based User-ID agent.<br>2. Select **User Identification > Discovery** and perform the following steps for each member server that will receive events from domain controllers:<br>a. In the Servers section, click **Add** and enter a **Name** to identify the member server.<br>b. In the **Server Address** field, enter the FQDN or IP address of the member server.<br>c. For the **Server Type**, select **Microsoft Active Directory**.<br>d. Click **OK** to save the server entry.<br>3. Configure the remaining User-ID agent settings: see Configure the User-ID Agent for User Mapping. |
| Step 4 | Configure an LDAP server profile to specify how the firewall connects to the Global Catalog servers (up to four) for group mapping information.<br>To improve availability, use at least two Global Catalog servers for redundancy.<br>You can collect group mapping information only for universal groups, not local domain groups (subdomains). | 1. Select **Device > Server Profiles > LDAP**, click **Add**, and enter a **Name** for the profile.<br>2. In the Servers section, for each Global Catalog, click **Add** and enter the server **Name**, IP address (**LDAP Server**), and **Port**. For a plaintext or Start Transport Layer Security (Start TLS) connection, use **Port** 3268. For an LDAP over SSL connection, use **Port** 3269. If the connection will use Start TLS or LDAP over SSL, select the **Require SSL/TLS secured connection** check box.<br>3. In the **Base DN** field, enter the Distinguished Name (DN) of the point in the Global Catalog server where the firewall will start searching for group mapping information (for example, `DC=acbdomain,DC=com`).<br>4. For the **Type**, select **active-directory**.<br>5. Configure the remaining fields as necessary: see Add an LDAP server profile. |
| Step 5 | Configure an LDAP server profile to specify how the firewall connects to the servers (up to four) that contain domain mapping information.<br>User-ID uses this information to map DNS domain names to NetBIOS domain names. This mapping ensures consistent domain/username references in policy rules.<br>To improve availability, use at least two servers for redundancy. | The steps are the same as for the LDAP server profile you created for Global Catalogs in the Step 4, except for the following fields:<br>• **LDAP Server**—Enter the IP address of the domain controller that contains the domain mapping information.<br>• **Port**—For a plaintext or Start TLS connection, use **Port** 389. For an LDAP over SSL connection, use **Port** 636. If the connection will use Start TLS or LDAP over SSL, select the **Require SSL/TLS secured connection** check box.<br>• **Base DN**—Select the DN of the point in the domain controller where the firewall will start searching for domain mapping information. The value must start with the string: `cn=partitions,cn=configuration` (for example, `cn=partitions,cn=configuration,DC=acbdomain,DC=com`). |

© Palo Alto Networks, Inc.

| Configure User-ID for a Large-Scale Network (Continued) | | |
|---|---|---|
| Step 6 | Create a group mapping configuration for each LDAP server profile you created. | 1. Select **Device > User Identification > Group Mapping Settings**.<br>2. Click **Add** and enter a **Name** to identify the group mapping configuration.<br>3. Select the LDAP **Server Profile** and ensure the **Enabled** check box is selected.<br>4. Configure the remaining fields as necessary: see Map Users to Groups.<br> If the Global Catalog and domain mapping servers reference more groups than your security rules require, configure the **Group Include List** and/or **Custom Group** list to limit the groups for which User-ID performs mapping.<br>5. Click **OK** and **Commit**. |

# App-ID

To safely enable applications on your network, the Palo Alto Networks next-generation firewalls provide both an application and web perspective—App-ID and URL Filtering—to protect against a full spectrum of legal, regulatory, productivity, and resource utilization risks.

App-ID enables visibility into the applications on the network, so you can learn how they work and understand their behavioral characteristics and their relative risk. This application knowledge allows you to create and enforce security policy rules to enable, inspect, and shape desired applications and block unwanted applications. When you define policy rules to allow traffic, App-ID begins to classify traffic without any additional configuration.

- App-ID Overview
- Manage Custom or Unknown Applications
- Manage New App-IDs Introduced in Content Releases
- Use Application Objects in Policy
- Applications with Implicit Support
- Application Level Gateways
- Disable the SIP Application-level Gateway (ALG)

© Palo Alto Networks, Inc.

# App-ID Overview

App-ID, a patented traffic classification system only available in Palo Alto Networks firewalls, determines what an application is irrespective of port, protocol, encryption (SSH or SSL) or any other evasive tactic used by the application. It applies multiple classification mechanisms—application signatures, application protocol decoding, and heuristics—to your network traffic stream to accurately identify applications.

Here's how App-ID identifies applications traversing your network:

- Traffic is matched against policy to check whether it is allowed on the network.
- Signatures are then applied to allowed traffic to identify the application based on unique application properties and related transaction characteristics. The signature also determines if the application is being used on its default port or it is using a non-standard port. If the traffic is allowed by policy, the traffic is then scanned for threats and further analyzed for identifying the application more granularly.
- If App-ID determines that encryption (SSL or SSH) is in use, and a Decryption policy rule is in place, the session is decrypted and application signatures are applied again on the decrypted flow.
- Decoders for known protocols are then used to apply additional context-based signatures to detect other applications that may be tunneling inside of the protocol (for example, Yahoo! Instant Messenger used across HTTP). Decoders validate that the traffic conforms to the protocol specification and provide support for NAT traversal and opening dynamic pinholes for applications such as SIP and FTP.
- For applications that are particularly evasive and cannot be identified through advanced signature and protocol analysis, heuristics or behavioral analysis may be used to determine the identity of the application.

When the application is identified, the policy check determines how to treat the application, for example—block, or allow and scan for threats, inspect for unauthorized file transfer and data patterns, or shape using QoS.

 © Palo Alto Networks, Inc.

# Manage Custom or Unknown Applications

Palo Alto Networks provides weekly application updates to identify new App-ID signatures. By default, App-ID is always enabled on the firewall, and you don't need to enable a series of signatures to identify well-known applications. Typically, the only applications that are classified as *unknown* traffic—*tcp, udp or non-syn-tcp*—in the ACC and the traffic logs are commercially available applications that have not yet been added to App-ID, internal or custom applications on your network, or potential threats.

On occasion, the firewall may report an application as unknown for the following reasons:

- Incomplete data—A handshake took place, but no data packets were sent prior to the timeout.
- Insufficient data—A handshake took place followed by one or more data packets; however, not enough data packets were exchanged to identify the application.

The following choices are available to handle unknown applications:

- Create security policies to control unknown applications by unknown TCP, unknown UDP or by a combination of source zone, destination zone, and IP addresses.
- Request an App-ID from Palo Alto Networks—If you would like to inspect and control the applications that traverse your network, for any unknown traffic, you can record a packet capture. If the packet capture reveals that the application is a commercial application, you can submit this packet capture to Palo Alto Networks for App-ID development. If it is an internal application, you can create a custom App-ID and/or define an application override policy.
- Create a Custom Application with a signature and attach it to a security policy, or create a custom application and define an application override policy—A custom application allows you to customize the definition of the internal application—its characteristics, category and sub-category, risk, port, timeout—and exercise granular policy control in order to minimize the range of unidentified traffic on your network. Creating a custom application also allows you to correctly identify the application in the **ACC** and traffic logs and is useful in auditing/reporting on the applications on your network. For a custom application you can specify a signature and a pattern that uniquely identifies the application and attach it to a security policy that allows or denies the application.

  Alternatively, if you would like the firewall to process the custom application using fast path (Layer-4 inspection instead of using App-ID for Layer-7 inspection), you can reference the custom application in an application override policy rule. An application override with a custom application will prevent the session from being processed by the App-ID engine, which is a Layer-7 inspection. Instead it forces the firewall to handle the session as a regular stateful inspection firewall at Layer-4, and thereby saves application processing time.

  For example, if you build a custom application that triggers on a host header *www.mywebsite.com*, the packets are first identified as *web-browsing* and then are matched as your custom application (whose parent application is web-browsing). Because the parent application is web-browsing, the custom application is inspected at Layer-7 and scanned for content and vulnerabilities.

  If you define an application override, the firewall stops processing at Layer-4. The custom application name is assigned to the session to help identify it in the logs, and the traffic is not scanned for threats.

For more details, refer to the following articles:

- Identifying Unknown Applications

# Manage New App-IDs Introduced in Content Releases

Installing new App-IDs included in a content release version can sometimes cause a change in policy enforcement for the now uniquely-identified application. Before installing a new content release, review the policy impact for new App-IDs and stage any necessary policy updates. Assess the treatment an application receives both before and after the new content is installed. You can then modify existing security policy rules using the new App-IDs contained in a downloaded content release (prior to installing the App-IDs). This enables you to simultaneously update your security policies and install new content, and allows for a seamless shift in policy enforcement. Alternatively, you can also choose to disable new App-IDs when installing a new content release version; this enables protection against the latest threats, while giving you the flexibility to enable the new App-IDs after you've had the chance to prepare any policy changes.

The following options enable you to assess the impact of new App-IDs on existing policy enforcement, disable (and enable) App-IDs, and seamlessly update policy rules to secure and enforce newly-identified applications:

- Review New App-IDs
- Disable or Enable App-IDs
- Prepare Policy Updates For Pending App-IDs

## Review New App-IDs

Review new App-ID signatures introduced in a Applications and/or Threats content update. For each new application signature introduced, you can preview the App-ID details, including a description of the application identified by the App-ID, other existing App-IDs that the new signature is dependent on (such as SSL or HTTP), and the category the application traffic received before the introduction of the new App-ID (for example, an application might be classified as web-browsing traffic before a App-ID signature is introduced that uniquely identifies the traffic). After reviewing the description and details for a new App-ID signature, review the App-ID signature impact on existing policy enforcement. When new application signatures are introduced, the newly-identified application traffic might no longer match to policies that previously enforced the application. Reviewing the policy impact for new application signatures enables you to identify the policies that will no longer enforce the application when the new App-ID is installed.

After downloading a new content release version, review the new App-IDs included in the content version and assess the impact of the new App-IDs on existing policy rules:

- Review New App-IDs Since Last Content Version
- Review New App-ID Impact on Existing Policy Rules

 © Palo Alto Networks, Inc.

# Review New App-IDs Since Last Content Version

**Review New App-IDs Available Since the Last Installed Content Release Version**

Step 1 Select **Device > Dynamic Updates** and select **Check Now** to refresh the list of available content updates.

Step 2 **Download** the latest Applications and Threats content update. When the content update is downloaded, an **Apps** link will appear in the Features column for that content update.

Step 3 Click the **Apps** link in the **Features** column to view details on newly-identified applications:

A list of App-IDs shows all new App-IDs introduced from the content version installed on the firewall, to the selected **Content Version**.

App-ID details that you can use to assess possible impact to policy enforcement include:

- **Depends on**—Lists the application signatures that this App-ID relies on to uniquely identify the application. If one of the application signatures listed in the **Depends On** field is disabled, the dependent App-ID is also disabled.
- **Previously Identified As**—Lists the App-IDs that matched to the application before the new App-ID was installed to uniquely identify the application.
- **App-ID Enabled**—All App-IDs display as enabled when a content release is downloaded, unless you choose to manually disable the App-ID signature before installing the content update (see Disable or Enable App-IDs).

  Multi-vsys firewalls display App-ID status as **vsys-specific**. This is because the status is not applied across virtual systems and must be individually enabled or disabled for each virtual system. To view the App-ID status for a specific virtual system, select **Objects > Applications**, select a **Virtual System**, and select the App-ID.

| Next Steps... | • Disable or Enable App-IDs.<br>• Prepare Policy Updates For Pending App-IDs. |
|---|---|

# Review New App-ID Impact on Existing Policy Rules

**Review the Impact of New App-ID Signatures on Existing Policy Rules**

Step 1 Select **Device > Dynamic Updates**.

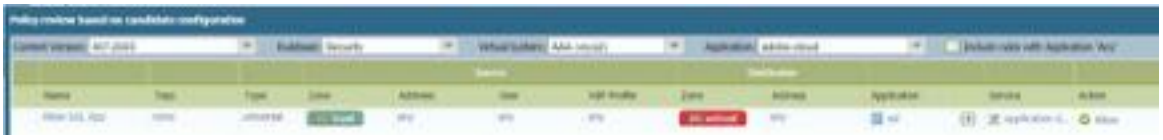
Step 2 You can review the policy impact of new content release versions that are downloaded to the firewall. **Download** a new content release version, and click the **Review Policies** in the Action column. The **Policy review based on candidate configuration** dialog allows you to filter by **Content Version** and view App-IDs introduced in a specific release (you can also filter the policy impact of new App-IDs according to **Rulebase** and **Virtual System**).

Step 3 Select a new App-ID from the **Application** drop-down to view policy rules that currently enforce the application. The rules displayed are based on the applications signatures that match to the application before the new App-ID is installed (view application details to see the list of application signatures that an application was **Previously Identified As** before the new App-ID).

Step 4 Use the detail provided in the policy review to plan policy rule updates to take effect when the App-ID is installed and enabled to uniquely identify the application.

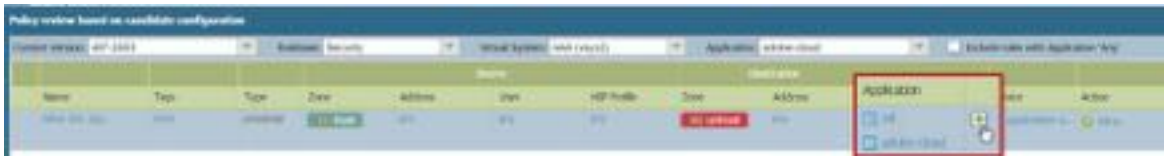
You can continue to Prepare Policy Updates For Pending App-IDs, or you can directly add the new App-ID to policy rules that the application was previously matched to by continuing to use the policy review dialog.

In the following example, the new App-ID adobe-cloud is introduced in a content release. Adobe-cloud traffic is currently identified as SSL and web-browsing traffic. Policy rules configured to enforce SSL or web-browsing traffic are listed to show what policy rules will be affected when the new App-ID is installed. In this example, the rule Allow SSL App currently enforces SSL traffic. To continue to allow adobe-cloud traffic when it is uniquely identified, and no longer identified as SSL traffic.



Add the new App-ID to existing policy rules, to allow the application traffic to continue to be enforced according to your existing security requirements when the App-ID is installed.

In this example, to continue to allow adobe-cloud traffic when it is uniquely identified by the new App-ID, and no longer identified as SSL traffic, add the new App-ID to the security policy rule Allow SSL App.



The policy rule updates take effect only when the application updates are installed.

| Next Steps... | • Disable or Enable App-IDs.<br>• Prepare Policy Updates For Pending App-IDs. |
|---|---|

 © Palo Alto Networks, Inc.

## Disable or Enable App-IDs

Disable new App-IDs included in a content release to immediately benefit from protection against the latest threats while continuing to have the flexibility to later enable App-IDs after preparing necessary policy updates. You can disable all App-IDs introduced in a content release, set scheduled content updates to automatically disable new App-IDs, or disable App-IDs for specific applications.

Policy rules referencing App-IDs only match to and enforce traffic based on enabled App-IDs.

Certain App-IDs cannot be disabled and only allow a status of enabled. App-IDs that cannot be disabled included some application signatures implicitly used by other App-IDs (such as unknown-tcp). Disabling a base App-ID could cause App-IDs which depend on the base App-ID to also be disabled. For example, disabling facebook-base will disable all other Facebook App-IDs.

| **Disable and Enable App-IDs** | |
|---|---|
| Disable all App-IDs in a content release or for scheduled content updates. | • To disable all new App-IDs introduced in a content release, select **Device > Dynamic Updates** and **Install** an Application and Threats content release. When prompted, select **Disable new apps in content update**. Select the check box to disable apps and continue installing the content update; this allows you to be protected against threats, and gives you the option to enable the apps at a later time.<br>• On the **Device > Dynamic Updates** page, select Schedule. Choose to **Disable new apps in content update** for downloads and installations of content releases. |
| Disable App-IDs for one application or multiple applications at a single time. | • To quickly disable a single application or multiple applications at the same time, click **Objects > Applications**. Select one or more application check box and click **Disable**.<br>• To review details for a single application, and then disable the App-ID for that application, select **Objects > Applications** and **Disable App-ID**. You can use this step to disable both pending App-IDs (where the content release including the App-ID is downloaded to the firewall but not installed) or installed App-IDs. |
| Enable App-IDs. | Enable App-IDs that you previously disabled by selecting **Objects > Applications**. Select one or more application check box and click **Enable** or open the details for a specific application and click **Enable App-ID**. |

## Prepare Policy Updates For Pending App-IDs

You can now stage seamless policy updates for new App-IDs. Release versions prior to PAN-OS 7.0 required you to install new App-IDs (as part of a content release) and then make necessary policy updates. This allowed for a period during which the newly-identified application traffic was not enforced, either by existing rules (that the traffic had matched to before being uniquely identified) or by rules that had yet to be created or modified to use the new App-ID.

*Pending* App-IDs can now be added to policy rules to prevent gaps in policy enforcement that could occur during the period between installing a content release and updating security policy. Pending App-IDs includes App-IDs that have been manually disabled, or App-IDs that are downloaded to the firewall but not installed. Pending App-IDs can be used to update policies both before and after installing a new content release. Though they can be added to policy rules, pending App-IDs are not enforced until the App-IDs are both installed and enabled on the firewall.

The names of App-IDs that have been manually disabled display as gray and italicized, to indicate the disabled status:

- Disabled App-ID listed on the **Objects > Applications** page:

- Disabled App-ID included in a security policy rule:

App-IDs that are included in a downloaded content release version might have an App-ID status of enabled, but App-IDs are not enforced until the corresponding content release version is installed.

 © Palo Alto Networks, Inc.

**Perform Seamless Policy Updates for New App-IDs**

To install the content release version now and then update policies:

Do this to benefit from new threat signatures immediately, while you review new application signatures and update your policies.

1. Select **Device > Dynamic Updates** and **Download** the latest content release version.
2. Review the Impact of New App-ID Signatures on Existing Policy Rules to assess the policy impact of new App-IDs.
3. **Install** the latest content release version. Before the content release is installed, you are prompted to **Disable new apps in content update**. Select the check box and continue to install the content release. Threat signatures included in the content release will be installed and effective, while new or updated App-IDs are disabled.
4. Select **Policies** and update **Security**, **QoS**, and **Policy Based Forwarding** rules to match to and enforce the now uniquely identified application traffic, using the pending App-IDs.
5. Select **Objects > Applications** and select one or multiple disabled App-IDs and click **Enable**.
6. **Commit** your changes to seamlessly update policy enforcement for new App-IDs.

To update policies now and then install the content release version:

1. Select **Device > Dynamic Updates** and **Download** the latest content release version.
2. Review the Impact of New App-ID Signatures on Existing Policy Rules to assess the policy impact of new App-IDs.
3. While reviewing the policy impact for new App-IDs, you can use the **Policy Review based on candidate configuration** to add a new App-ID to existing policy rules: .
4. The new App-ID is added to the existing rules as a disabled App-ID.
5. Continue to review the policy impact for all App-IDs included in the latest content release version by selecting App-IDs in the **Applications** drop-down. Add the new App-IDs to existing policies as needed. Click **OK** to save your changes.
6. **Install** the latest content release version.
7. **Commit** your changes to seamlessly update policy enforcement for new App-IDs.

© Palo Alto Networks, Inc.

# Use Application Objects in Policy

- Create an Application Group
- Create an Application Filter
- Create a Custom Application

## Create an Application Group

An application group is an object that contains applications that you want to treat similarly in policy. Application groups are useful for enabling access to applications that you explicitly sanction for use within your organization. Grouping sanctioned applications simplifies administration of your rulebases.: instead of having to update individual policy rules when there is a change in the applications you support, you can instead update only the affected application groups.

When deciding how to group applications, consider how you plan to enforce access to your sanctioned applications and create an application group that aligns with each of your policy goals. For example, you might have some applications that you will only allow your IT administrators to access, and other applications that you want to make available for any known user in your organization. In this case, you would create separate application groups for each of these policy goals. Although you generally want to enable access to applications on the default port only, you may want to group applications that are an exception to this and enforce access to those applications in a separate rule.

| **Create an Application Group** | |
|---|---|
| Step 1 | Select **Objects > Application Groups**. |
| Step 2 | **Add** a group and give it a descriptive **Name**. |
| Step 3 | (Optional) Select **Shared** to create the object in a shared location for access as a shared object in Panorama or for use across all virtual systems in a multiple virtual system firewall. |
| Step 4 | **Add** the applications you want in the group and then click **OK**.<br> |
| Step 5 | **Commit** the configuration. |

© Palo Alto Networks, Inc.

## Create an Application Filter

An application filter is an object that dynamically groups applications based on application attributes that you define, including category, subcategory, technology, risk factor, and characteristic. This is useful when you want to safely enable access to applications that you do not explicitly sanction, but that you want users to be able to access. For example, you may want to enable employees to choose their own office programs (such as Evernote, Google Docs, or Microsoft Office 365) for business use. To safely enable these types of applications, you could create an application filter that matches on the Category **business-systems** and the Subcategory **office-programs**. As new applications office programs emerge and new App-IDs get created, these new applications will automatically match the filter you defined; you will not have to make any additional changes to your policy rulebase to safely enable any application that matches the attributes you defined for the filter.

| **Create an Application Filter** | |
|---|---|
| Step 1 | Select **Objects > Application Filters**. |
| Step 2 | **Add** a filter and give it a descriptive **Name**. |
| Step 3 | (Optional) Select **Shared** to create the object in a shared location for access as a shared object in Panorama or for use across all virtual systems in a multiple virtual system firewall. |
| Step 4 | Define the filter by selecting attribute values from the Category, Subcategory, Technology, Risk, and Characteristic sections. As you select values, notice that the list of matching applications at the bottom of the dialog narrows. When you have adjusted the filter attributes to match the types of applications you want to safely enable, click **OK**.  |
| Step 5 | **Commit** the configuration. |

## Create a Custom Application

To safely enable applications you must classify all traffic, across all ports, all the time. With App-ID, the only applications that are typically classified as unknown traffic—tcp, udp or non-syn-tcp—in the ACC and the Traffic logs are commercially available applications that have not yet been added to App-ID, internal or custom applications on your network, or potential threats.

If you are seeing unknown traffic for a commercial application that does not yet have an App-ID, you can submit a request for a new App-ID here: http://researchcenter.paloaltonetworks.com/submit-an-application/.

To ensure that your internal custom applications do not show up as unknown traffic, create a custom application. You can then exercise granular policy control over these applications in order to minimize the range of unidentified traffic on your network, thereby reducing the attack surface. Creating a custom application also allows you to correctly identify the application in the ACC and Traffic logs, which enables you to audit/report on the applications on your network.

To create a custom application, you must define the application attributes: its characteristics, category and sub-category, risk, port, timeout. In addition, you must define patterns or values that the firewall can use to match to the traffic flows themselves (the *signature*). Finally, you can attach the custom application to a security policy that allows or denies the application (or add it to an application group or match it to an application filter). You can also create custom applications to identify ephemeral applications with topical interest, such as ESPN3-Video for world cup soccer or March Madness.

In order to collect the right data to create a custom application signature, you'll need a good understanding of packet captures and how datagrams are formed. If the signature is created too broadly, you might inadvertently include other similar traffic; if it is defined too narrowly, the traffic will evade detection if it does not strictly match the pattern.

Custom applications are stored in a separate database on the firewall and this database is not impacted by the weekly App-ID updates.

The supported application protocol decoders that enable the firewall to detect applications that may be tunneling inside of the protocol include the following as of content update 424: HTTP, HTTPS, DNS, FTP, IMAP SMTP, Telnet, IRC (Internet Relay Chat), Oracle, RTMP, RTSP, SSH, GNU-Debugger, GIOP (Global Inter-ORB Protocol), Microsoft RPC, Microsoft SMB (also known as CIFS).

The following is a basic example of how to create a custom application.

 © Palo Alto Networks, Inc.

| Create a Custom Application | | |
|---|---|---|
| Step 1 | Gather information about the application that you will be able to use to write custom signatures.<br><br>To do this, you must have an understanding of the application and how you want to control access to it. For example, you may want to limit what operations users can perform within the application (such as uploading, downloading, or live streaming). Or you may want to allow the application, but enforce QoS policing. | • Capture application packets so that you can find unique characteristics about the application on which to base your custom application signature. One way to do this is to run a protocol analyzer, such as Wireshark, on the client system to capture the packets between the client and the server. Perform different actions in the application, such as uploading and downloading, so that you will be able to locate each type of session in the resulting packet captures (PCAPs).<br>• Because the firewall by default takes packet captures for all unknown traffic, if the firewall is between the client and the server you can view the packet capture for the unknown traffic directly from the Traffic log.<br>• Use the packet captures to find patterns or values in the packet *contexts* that you can use to create signatures that will uniquely match the application traffic. For example, look for string patterns in HTTP response or request headers, URI paths, or hostnames. For information on the different string contexts you can use to create application signatures and where you can find the corresponding values in the packet, refer to Creating Custom Threat Signatures. |
| Step 2 | Add the custom application. | 1. Select **Objects > Applications** and click **Add**.<br>2. On the **Configuration** tab, enter a **Name** and a **Description** for the custom application that will help other administrators understand why you created the application.<br>3. (Optional) Select **Shared** to create the object in a shared location for access as a shared object in Panorama or for use across all virtual systems in a multiple virtual system firewall.<br>4. Define the application Properties and Characteristics.<br>  |

| Create a Custom Application (Continued) | |
|---|---|
| Step 3 Define details about the application, such as the underlying protocol, the port number the application runs on, the timeout values, and any types of scanning you want to be able to perform on the traffic. | On the **Advanced** tab, define settings that will allow the firewall to identify the application protocol:<br>• Specify the default ports or protocol that the application uses.<br>• Specify the session timeout values. If you don't specify timeout values, the default timeout values will be used.<br>• Indicate any type of additional scanning you plan to perform on the application traffic.<br>For example, to create a custom TCP-based application that runs over SSL, but uses port 4443 (instead of the default port for SSL, 443), you would specify the port number. By adding the port number for a custom application, you can create policy rules that use the default port for the application rather than opening up additional ports on the firewall. This improves your security posture.<br>  |

 © Palo Alto Networks, Inc.

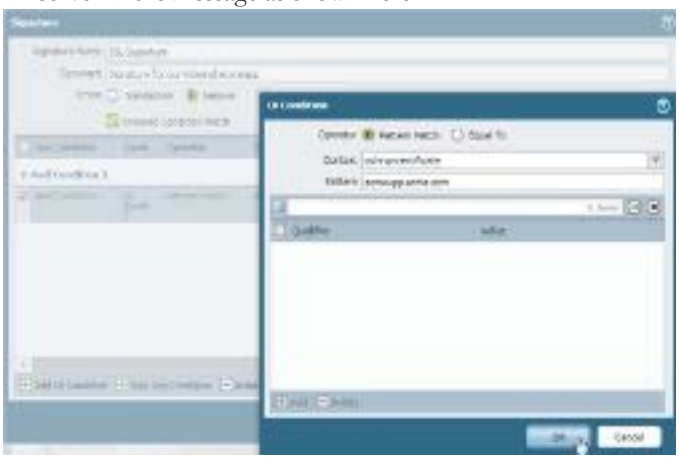
**Create a Custom Application (Continued)**

Step 4 Define the criteria that the firewall will use to match the traffic to the new application.

You will use the information you gathered from the packet captures to specify unique string context values that the firewall can use to match patterns in the application traffic.

1. On the **Signatures** tab, click **Add** and define a **Signature Name** and optionally a **Comment** to provide information about how you intend to use this signature.
2. Specify the **Scope** of the signature: whether it matches to a full **Session** or a single **Transaction**.
3. Specify conditions to define signatures by clicking **Add And Condition** or **Add Or Condition**.
4. Select an **Operator** to define the type of match conditions you will use: **Pattern Match** or **Equal To**.
   - If you selected **Pattern Match**, select the **Context** and then use a regular expression to define the **Pattern** to match the selected context. Optionally, click **Add** to define a qualifier/value pair. The **Qualifier** list is specific to the **Context** you chose.
   - If you selected **Equal To**, select the **Context** and then use a regular expression to define the **Position** of the bytes in the packet header to use match the selected context. Choose from **first-4bytes** or **second-4bytes**. Define the 4-byte hex value for the **Mask** (for example, 0xffffff00) and **Value** (for example, 0xaabbccdd).

   For example, if you are creating a custom application for one of your internal applications, you could use the **ssl-rsp-certificate Context** to define a pattern match for the certificate response message of a SSL negotiation from the server and create a **Pattern** to match the commonName of the server in the message as shown here:



5. Repeat step 3 and 4 for each matching condition.
6. If the order in which the firewall attempts to match the signature definitions is important, make sure the **Ordered Condition Match** check box is selected and then order the conditions so that they are evaluated in the appropriate order. Select a condition or a group and click **Move Up** or **Move Down**. You cannot move conditions from one group to another.
7. Click **OK** to save the signature definition.

| Create a Custom Application (Continued) | | |
|---|---|---|
| Step 5 | Save the application. | 1. Click **OK** to save the custom application definition.<br>2. Click **Commit**. |
| Step 6 | Validate that traffic matches the custom application as expected. | 1. Select **Policies > Security** and **Add** a security policy rule to allow the new application.<br>2. Run the application from a client system that is between the firewall and the application and then check the Traffic logs (**Monitor > Traffic**) to make sure that you see traffic matching the new application (and that it is being handled per your policy rule). |

 © Palo Alto Networks, Inc.

# Applications with Implicit Support

When creating a policy to allow specific applications, you must also be sure that you are allowing any other applications on which the application depends. In many cases, you do not have to explicitly allow access to the dependent applications in order for the traffic to flow because the firewall is able to determine the dependencies and allow them implicitly. This implicit support also applies to custom applications that are based on HTTP, SSL, MS-RPC, or RTSP. Applications for which the firewall cannot determine dependent applications on time will require that you explicitly allow the dependent applications when defining your policies. You can determine application dependencies in Applipedia.

The following table lists the applications for which the firewall has implicit support (as of Content Update 557).

**Table: Applications with Implicit Support**

| Application | Implicitly Supports |
|---|---|
| 360-safeguard-update | http |
| apple-update | http |
| apt-get | http |
| as2 | http |
| avg-update | http |
| avira-antivir-update | http, ssl |

# Application Level Gateways

The Palo Alto Networks firewall does not classify traffic by port and protocol; instead it identifies the application based on its unique properties and transaction characteristics using the App-ID technology. Some applications, however, require the firewall to dynamically open *pinholes* to establish the connection, determine the parameters for the session and negotiate the ports that will be used for the transfer of data; these applications use the application-layer payload to communicate the dynamic TCP or UDP ports on which the application opens data connections. For such applications, the firewall serves as an Application Level Gateway (ALG), and it opens a pinhole for a limited time and for exclusively transferring data or control traffic. The firewall also performs a NAT rewrite of the payload when necessary.

As of Content Release version 504, the Palo Alto Networks firewall provides NAT ALG support for the following protocols: FTP, H.225, H.248, MGCP, MySQL, Oracle/SQLNet/TNS, RPC, RTSP, SCCP, SIP, and UNIStim.

When the firewall serves as an ALG for the Session Initiation Protocol (SIP), by default it performs NAT on the payload and opens dynamic pinholes for media ports. In some cases, depending on the SIP applications in use in your environment, the SIP endpoints have NAT intelligence embedded in their clients. In such cases, you might need to disable the SIP ALG functionality to prevent the firewall from modifying the signaling sessions. When SIP ALG is disabled, if App-ID determines that a session is SIP, the payload is not translated and dynamic pinholes are not opened. See Disable the SIP Application-level Gateway (ALG).

The firewall provides IPv6-to-IPv6 Network Prefix Translation (NPTv6) ALG support for the following protocols: FTP, Oracle, and RTSP. The SIP ALG is not supported for NPTv6 or NAT64.

 © Palo Alto Networks, Inc.

# Disable the SIP Application-level Gateway (ALG)

The Palo Alto Networks firewall uses the Session Initiation Protocol (SIP) application-level gateway (ALG) to open dynamic pinholes in the firewall where NAT is enabled. However, some applications—such as VoIP—have NAT intelligence embedded in the client application. In these cases, the SIP ALG on the firewall can interfere with the signaling sessions and cause the client application to stop working.

One solution to this problem is to define an Application Override Policy for SIP, but using this approach disables the App-ID and threat detection functionality. A better approach is to disable the SIP ALG, which does not disable App-ID or threat detection.

The following procedure describes how to disable the SIP ALG.

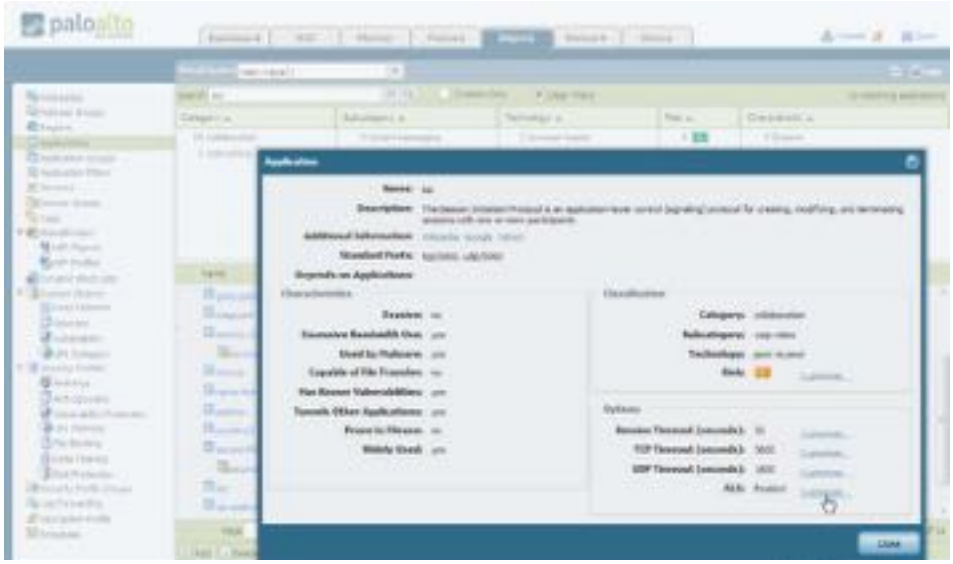
**Disable the SIP ALG**

Step 1 Select **Objects > Applications**.

Step 2 Select the **sip** application.

You can type **sip** in the **Search** box to help find the sip application.

Step 3 Select **Customize...** for **ALG** in the Options section of the Application dialog box.



Step 4 Select the **Disable ALG** check box in the Application - sip dialog box and click **OK**.

Step 5 **Close** the Application dialog box and **Commit** the change.

# Threat Prevention

The Palo Alto Networks next-generation firewall protects and defends your network from commodity threats and advanced persistent threats (APTs). The firewall's multi-pronged detection mechanisms include a signature-based (IPS/Command and Control/Antivirus) approach, heuristics-based (bot detection) approach, sandbox-based (WildFire) approach, and Layer 7 protocol analysis-based (App-ID) approach.

Commodity threats are exploits that are less sophisticated and more easily detected and prevented using a combination of the antivirus, anti-spyware, vulnerability protection and the URL filtering/Application identification capabilities on the firewall.

Advanced threats are perpetuated by organized cyber criminals or malicious groups that use sophisticated attack vectors to target your network, most commonly for intellectual property theft and financial data theft. These threats are more evasive and require intelligent monitoring mechanisms for detailed host and network forensics on malware. The Palo Alto Networks next-generation firewall in conjunction with WildFire and Panorama provides a comprehensive solution that intercepts and break the attack chain and provides visibility to prevent security infringement on your network—including mobile and virtualized—infrastructure.

# Set Up Antivirus, Anti-Spyware, and Vulnerability Protection

The following describes the steps needed to set up the default Antivirus, Anti-Spyware, and Vulnerability Protection Security Profiles.

All anti-spyware and vulnerability protection signatures have a default action defined by Palo Alto Networks. You can view the default action by navigating to **Objects > Security Profiles > Anti-Spyware** or **Objects > Security Profiles >Vulnerability Protection** and then selecting a profile. Click the **Exceptions** tab and then click **Show all signatures** and you will see a list of the signatures with the default action in the Action column. To change the default action, you must create a new profile and then create rules with a non-default action, and/or add individual signature exceptions to **Exceptions** in the profile.

| **Set up Antivirus/Anti-Spyware/Vulnerability Protection** | | |
|---|---|---|
| Step 1 | Verify that you have a Threat Prevention license. | • The Threat Prevention license bundles the antivirus, anti-spyware, and the vulnerability protection features in one license.<br>• Select **Device > Licenses** to verify that the **Threat Prevention** license is installed and check the expiration date. |
| Step 2 | Download the latest antivirus threat signatures. | 1. Select **Device > Dynamic Updates** and click **Check Now** at the bottom of the page to retrieve the latest signatures.<br>In the **Actions** column, click **Download** to install the latest Antivirus and Applications and Threats signatures. |
| Step 3 | Schedule signature updates. | 1. From **Device > Dynamic Updates**, click the text to the right of **Schedule** to automatically retrieve signature updates for **Antivirus** and **Applications and Threats**.<br>2. Specify the frequency and timing for the updates and whether the update will be downloaded and installed or only downloaded. If you select **Download Only**, you would need to manually go in and click the **Install** link in the **Action** column to install the signature. When you click **OK**, the update is scheduled. No commit is required.<br>3. (Optional) You can also enter the number of hours in the **Threshold** field to indicate the minimum age of a signature before a download will occur. For example, if you entered **10**, the signature must be at least 10 hours old before it will be downloaded, regardless of the schedule.<br>4. In an HA configuration, you can also click the **Sync To Peer** option to synchronize the content update with the HA peer after download/install. This will not push the schedule settings to the peer device, you need to configure the schedule on each device. |

© Palo Alto Networks, Inc.

**Set up Antivirus/Anti-Spyware/Vulnerability Protection (Continued)**

### Best Practices for Antivirus Schedules

The general recommendation for antivirus signature update schedules is to perform a **download-and-install** on a daily basis for antivirus and weekly for applications and vulnerabilities.

### Recommendations for HA Configurations:

- **Active/Passive HA**—If the MGT port is used for antivirus signature downloads, you should configure a schedule on both devices and both devices will download/install independently. If you are using a data port for downloads, the passive device will not perform downloads while it is in the passive state. In this case you would set a schedule on both devices and then select the **Sync To Peer** option. This will ensure that whichever device is active, the updates will occur and will then push to the passive device.
- **Active/Active HA**—If the MGT port is used for antivirus signature downloads on both devices, then schedule the download/install on both devices, but do not select the **Sync To Peer** option. If you are using a data port, schedule the signature downloads on both devices and select **Sync To Peer**. This will ensure that if one device in the active/active configuration goes into the active-secondary state, the active device will download/install the signature and will then push it to the active-secondary device.

| | |
|---|---|
| Step 4 Attach the security profiles to a security policy. | 1. Select **Policies > Security**, select the desired policy to modify it and then click the **Actions** tab.<br>2. In **Profile Settings**, click the drop-down next to each security profile you would like to enable. In this example we choose default for **Antivirus, Vulnerability Protection,** and **Anti-Spyware**.<br>If no security profiles have been previously defined, select **Profiles** from the **Profile Type** drop-down. You will then see the list of options to select the security profiles.<br>  |
| Step 5 Save the configuration. | Click **Commit**. |

 © Palo Alto Networks, Inc.

## Set Up Data Filtering

The following describes the steps needed to configure a data filtering profile that will detect Social Security Numbers and a custom pattern identified in .doc and .docx documents.

| Data Filtering Configuration Example | | |
|---|---|---|
| Step 1 | Create a Data Filtering security profile. | 1. Select **Objects > Security Profiles > Data Filtering** and click **Add**.<br>2. Enter a **Name** and a **Description** for the profile. In this example the name is *DF_Profile1* with the description *Detect Social Security Numbers*.<br>3. (Optional) If you want to collect data that is blocked by the filter, select the **Data Capture** check box.<br> You must set a password as described in Step 2 if you are using the data capture feature. |
| Step 2 | (Optional) Secure access to the data filtering logs to prevent other administrators from viewing sensitive data.<br>When you enable this option, you will be prompted for the password when you view logs in **Monitor > Logs > Data Filtering**. | 1. Select **Device > Setup > Content-ID**.<br>2. Click **Manage Data Protection** in the Content-ID Features section.<br>3. Set the password that will be required to view the data filtering logs. |

**Data Filtering Configuration Example (Continued)**

Step 3 Define the data pattern that will be used in the Data Filtering Profile.

In this example, we will use the keyword **confidential** and will set the option to search for SSN numbers with dashes (Example - 987-654-4320).

It is helpful to set the appropriate thresholds and define keywords within documents to reduce false positives.

1. From the Data Filtering Profile page click **Add** and select **New** from the **Data Pattern** drop-down. You can also configure data patterns from **Objects > Custom Signatures > Data Patterns**.
2. For this example, name the Data Pattern signature **Detect SS Numbers** and add the description **Data Pattern to detect Social Security numbers**.
3. In the **Weight** section for **SSN#** enter **3**. See Weight and Threshold Values for more details.

4. (Optional) You can also set **Custom Patterns** that will be subject to this profile. In this case, you specify a pattern in the custom patterns **Regex** field and set a weight. You can add multiple match expressions to the same data pattern profile. In this example, we will create a **Custom Pattern** named **SSN_Custom** with a custom pattern of **confidential** (the pattern is case sensitive) and use a weight of **20**. The reason we use the term **confidential** in this example is because we know that our social security Word docs contain this term, so we define that specifically.

 © Palo Alto Networks, Inc.

| Data Filtering Configuration Example (Continued) | | |
|---|---|---|
| Step 4 | Specify which applications to filter and set the file types. | 1. Set **Applications** to **Any.** This will detect any supported application such as: web-browsing, FTP, or SMTP. If you want to narrow down the application, you can select it from the list. For applications such as Microsoft Outlook Web App that uses SSL, you will need to enable decryption. Also make sure you understand the naming for each application. For example, Outlook Web App, which is the Microsoft name for this application is identified as the application **outlook-web** in the PAN-OS list of applications. You can check the logs for a given application to identify the name defined in PAN-OS.<br>2. Set **File Types** to **doc** and **docx** to only scan doc and docx files. |
| Step 5 | Specify the direction of traffic to filter and the threshold values. | 1. Set the **Direction** to **Both**. Files that are uploaded or downloaded will be scanned.<br>2. Set the **Alert Threshold** to **35.** In this case, an alert will be triggered if 5 instances of Social Security Numbers exist and 1 instance of the term **confidential** exists. The formula is 5 SSN instances with a weight of 3 = 15 plus 1 instance of the term confidential with a weight of 20 = 35.<br>3. Set the **Block Threshold** to **50**. The file will be blocked if the threshold of 50 instances of a SSN and/or the term confidential exists in the file. In this case, if the doc contained 1 instance of the word **confidential** with a weight of 20 that equals 20 toward the threshold, and the doc has 15 Social Security Numbers with a weight of 3 that equals 45. Add 20 and 45 and you have 65, which will exceed the block threshold of 50.<br>  |

**Data Filtering Configuration Example (Continued)**

| | | |
|---|---|---|
| Step 6 | Attach the Data Filtering profile to the security rule. | 1. Select **Policies > Security** and select the security policy rule to which to apply the profile.<br>2. Click the security policy rule to modify it and then click the **Actions** tab. In the **Data Filtering** drop-down, select the new data filtering profile you created and then click **OK** to save. In this example, the data filtering rule name is **DF_Profile1**.<br>  |
| Step 7 | **Commit** the configuration. | |
| Step 8 | Test the data filtering configuration.<br><br>If you have problems getting Data Filtering to work, you can check the Data Filtering log or the Traffic log to verify the application that you are testing with and make sure your test document has the appropriate number of unique Social Security Number instances. For example, an application such as Microsoft Outlook Web App may seem to be identified as web-browsing, but if you look at the logs, the application is **outlook-web**. Also increase the number of SSNs, or your custom pattern to make sure you are hitting the thresholds. | When testing, you must use real Social Security Numbers and each number must be unique. Also, when defining Custom Patterns as we did in this example with the word **confidential**, the pattern is case sensitive. To keep your test simple, you may want to just test using a data pattern first, then test the SSNs.<br>1. Access a client PC in the trust zone of the firewall and send an HTTP request to upload a .doc or .docx file that contains the exact information you defined for filtering.<br>2. Create a Microsoft Word document with one instance of the term confidential and five Social Security numbers with dashes.<br>3. Upload the file to a website. Use an HTTP site unless you have decryption configured, in which case you can use HTTPS.<br>4. Select **Monitoring > Logs > Data Filtering** logs.<br>5. Locate the log that corresponds to the file you just uploaded. To help filter the logs, use the source of your client PC and the destination of the web server. The action column in the log will show **reset-both**. You can now increase the number of Social Security Numbers in the document to test the block threshold. |

 © Palo Alto Networks, Inc.

## Set Up File Blocking

This example will describe the basic steps needed to set up file blocking. In this configuration, we will configure the options needed to prompt users to continue before downloading .exe files from websites. When testing this example, be aware that you may have other systems between you and the source that may be blocking content.

| **Configure File Blocking** | | |
|---|---|---|
| Step 1 | Create the file blocking profile. | 1. Select **Objects > Security Profiles > File Blocking** and click **Add**.<br>2. Enter a **Name** for the file blocking profile, for example *Block_EXE*. Optionally enter a **Description**, such as *Block users from downloading exe files from websites.* |
| Step 2 | Configure the file blocking options. | 1. Click **Add** to define the profile settings.<br>2. Enter a **Name**, such as *BlockEXE*.<br>3. Set the **Applications** for filtering, for example **web-browsing**.<br>4. Set **File Types** to **exe**.<br>5. Set the **Direction** to **download**.<br>6. Set the **Action** to **continue**. By choosing the continue option, users will be prompted with a response page prompting them to click continue before the file will be downloaded.<br> <br>7. Click **OK** to save the profile. |
| Step 3 | Apply the file blocking profile to a security policy. | 1. Select **Policies > Security** and either select an existing policy or create a new policy as described in Set Up Basic Security Policies.<br>2. Click the **Actions** tab within the policy rule.<br>3. In the Profile Settings section, click the drop-down and select the file blocking profile you configured. In this case, the profile name is *Block_EXE*.<br>4. **Commit** the configuration.<br>If no security profiles have been previously defined, select the **Profile Type** drop-down and select **Profiles**. You will then see the list of options to select the security profiles. |

**Configure File Blocking (Continued)**

Step 4 To test your file blocking configuration, access a client PC in the trust zone of the firewall and attempt to download an .exe file from a website in the untrust zone. A response page should display. Click **Continue** to download the file. You can also set other actions, such as alert or block, which will not provide a continue page to the user. The following shows the default response page for File Blocking:

**Example: Default File Blocking Response Page**

Step 5 (Optional) Define custom file blocking response pages (**Device > Response Pages**). This allows you to provide more information to users when they see a response page. You can include information such as company policy information and contact information for a Helpdesk.

When you create a file blocking profile with the action continue, you can only choose the application web-browsing. If you choose any other application, traffic that matches the security policy will not flow through the firewall due to the fact that the users will not be prompted with a continue page. Also, if the website uses HTTPS, you will need to have a decryption policy in place.

You may want to check your logs to confirm what application is being used when testing this feature. For example, if you are using Microsoft SharePoint to download files, even though you are using a web-browser to access the site, the application is actually `sharepoint-base`, or `sharepoint-document`. You may want to set the application type to **Any** for testing.

 © Palo Alto Networks, Inc.

# Prevent Brute Force Attacks

A brute force attack uses a large volume of requests/responses from the same source or destination IP address to break into a system. The attacker employs a trial-and-error method to guess the response to a challenge or a request.

The Vulnerability Protection profile on the firewall includes signatures to protect you from brute force attacks. Each signature has an ID, Threat Name, Severity and is triggered when a pattern is recorded. The pattern specifies the conditions and interval at which the traffic is identified as a brute-force attack; some signatures are associated with another child signature that is of a lower severity and specifies the pattern to match against. When a pattern matches against the signature or child signature, it triggers the default action for the signature.

To enforce protection:

- Attach the vulnerability profile to a security rule. See Set Up Antivirus, Anti-Spyware, and Vulnerability Protection.
- Install content updates that include new signatures to protect against emerging threats. See Manage Content Updates.

# Customize the Action and Trigger Conditions for a Brute Force Signature

The firewall includes two types of predefined brute force signatures—parent signature and child signature. A child signature is a single occurrence of a traffic pattern that matches the signature. A parent signature is associated with a child signature and is triggered when multiple events occur within a time interval and match the traffic pattern defined in the child signature.

Typically, a child signature is of default action *allow* because a single event is not indicative of an attack. In most cases, the action for a child signature is set to allow so that legitimate traffic is not blocked and threat logs are not generated for non-noteworthy events. Therefore, Palo Alto Networks recommends that you only change the default action after careful consideration.

In most cases, the brute force signature is a noteworthy event because of its recurrent pattern. If you would like to customize the action for a brute-force signature, you can do one of the following:

- Create a rule to modify the default action for all signatures in the brute force category. You can define the action to allow, alert, block, reset, or drop the traffic.
- Define an exception for a specific signature. For example, you can search for a CVE and define an exception for it.

  For a parent signature, you can modify both the trigger conditions and the action; for a child signature only the action can be modified.

To effectively mitigate an attack, the **block-ip address** action is recommended over the drop or reset action for most brute force signatures.

| **Customize the Threshold and Action for a Signature** | | |
|---|---|---|
| Step 1 | Create a new Vulnerability Protection profile. | 1. Select **Objects > Security Profiles > Vulnerability Protection**.<br>2. Click **Add** and enter a **Name** for the Vulnerability Protection profile. |
| Step 2 | Create a rule that defines the action for all signatures in a category.<br> | 1. Select **Rules**, click **Add** and enter a **Name** for the rule.<br>2. Set the **Action**. In this example, it is set to **Block**.<br>3. Set **Category** to **brute-force**.<br>4. (Optional) If blocking, specify whether to block server or client, the default is any.<br>5. See Step 3 to customize the action for a specific signature.<br>6. See Step 4 to customize the trigger threshold for a parent signature.<br>7. Click **OK** to save the rule and the profile. |

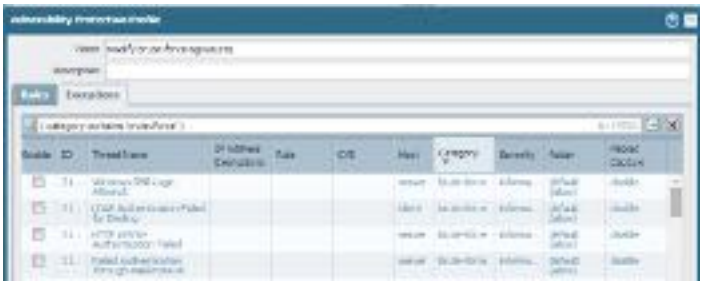
© Palo Alto Networks, Inc.

**Customize the Threshold and Action for a Signature**

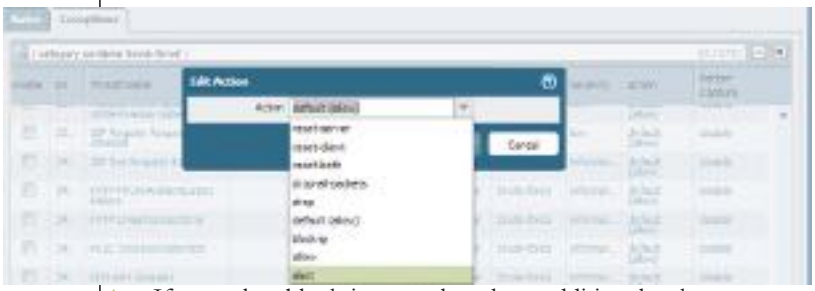
Step 3 (Optional) Customize the action for a specific signature.

1. Select **Exceptions** and click **Show all signatures** to find the signature you want to modify.

   To view all the signatures in the brute-force category, search for (category contains 'brute-force').
2. To edit a specific signature, click the predefined default action in the **Action** column.



3. Set the action to **allow**, **alert** or **block-ip**.



4. If you select block-ip, complete these additional tasks:
   a. Specify the **Time** period (in seconds) after which to trigger the action.
   b. In the **Track By** field, define whether to block the IP address by **IP source** or by **IP source and destination**.

5. Click **OK**
6. For each modified signature, select the check box in the **Enable** column.
7. Click **OK**.

| Customize the Threshold and Action for a Signature | | |
|---|---|---|
| Step 4 | Customize the trigger conditions for a parent signature.<br><br>A parent signature that can be edited is marked with this icon: .<br><br>In this example, the search criteria was brute force category and CVE-2008-1447. | 1. Click to edit the time attribute and the aggregation criteria for the signature.<br> <br>2. To modify the trigger threshold specify the **Number of Hits** *per x* **seconds**.<br>3. Specify whether to aggregate the number of hits by **source**, **destination** or by **source and destination**.<br>4. Click **OK**. |
| Step 5 | Attach this new profile to a security rule. | |
| Step 6 | Save your changes. | 1. Click **Commit**. |

 © Palo Alto Networks, Inc.

# Best Practices for Securing Your Network from Layer 4 and Layer 7 Evasions

To monitor and protect your network from most Layer 4 and Layer 7 attacks, here are a few recommendations.

- Upgrade to the most current PAN-OS software version and content release version to ensure that you have the latest security updates. See Manage Content Updates and Install Software Updates.
- For servers, create security policy rules to only allow the application(s) that you sanction on each server. Verify that the standard port for the application matches the listening port on the server. For example, to ensure that only SMTP traffic is allowed to your email server set the Application to smtp and the Service to application-default. If your server uses only a subset of the standard ports (for example, if your SMTP server uses only port 587 while the smtp application has standard ports defined as 25 and 587), you should create a new custom service that only includes port 587 and use that new service in your security policy rule instead of using application-default. Additionally, make sure to restrict access to specific source and destinations zones and sets of IP addresses.
- Attach the following security profiles to your security policies to provide signature-based protection.
  - Create a Vulnerability Protection profile to block all vulnerabilities with severity low and higher.
  - Create an Anti-Spyware profile to block all spyware.
  - Create an antivirus profile to block all content that matches an antivirus signature.
- Block all unknown applications/traffic using security policy. Typically, the only applications that are classified as unknown traffic are internal or custom applications on your network, or potential threats. Because unknown traffic can be a non-compliant application or protocol that is anomalous or abnormal, or a known application that is using non-standard ports, unknown traffic should be blocked. See Manage Custom or Unknown Applications.
- Create a file blocking profile that blocks Portable Executable (PE) file types for Internet-based SMB (Server Message Block) traffic from traversing the trust to untrust zones, (ms-ds-smb applications).
- Create a zone protection profile that is configured to protect against packet-based attacks:
  - Remove TCP timestamps on SYN packets before the firewall forwards the packet—When you remove the TCP timestamp option in a SYN packet, the TCP stack on both ends of the TCP connection will not support TCP timestamps. Therefore, by disabling the TCP timestamp for a SYN packet, you can prevent an attack that uses different timestamps on multiple packets for the same sequence number.
  - Drop malformed packets.
  - Drop mismatched and overlapping TCP segments—By deliberately constructing connections with overlapping but different data in them, attackers can attempt to cause misinterpretation of the intent of the connection. This can be used to deliberately induce false positives or false negatives. An attacker can use IP spoofing and sequence number prediction to intercept a user's connection and inject his/her own data into the connection. PAN-OS uses this field to discard such frames with mismatched and overlapping data. The scenarios where the received segment will be discarded are when the segment received is contained within another segment, the segment received overlaps with part of another segment, or the segment completely contains another segment.

© Palo Alto Networks, Inc.

- Verify that support for IPv6 is enabled, if you have configured IPv6 addresses on your network hosts. (**Network > Interfaces > Ethernet> IPv6**)

  This allows access to IPv6 hosts and filters IPv6 packets that are encapsulated in IPv4 packets. Enabling support for IPv6 prevents IPv6 over IPv4 multicast addresses from being leveraged for network reconnaissance.

- Enable support for multicast traffic so that the firewall can enforce policy on multicast traffic. (**Network > Virtual Router > Multicast**)

- Enable the following CLI command to clear the URG bit flag in the TCP header and disallow out-of-band processing of packets.

  The urgent pointer in the TCP header is used to promote a packet for immediate processing by removing it from the processing queue and expediting it through the TCP/IP stack on the host. This process is called out-of-band processing. Because the implementation of the urgent pointer varies by host, to eliminate ambiguity, use the following CLI command to disallow out-of-band processing; the out-of-band byte in the payload becomes part of the payload and the packet is not processed urgently. Making this change allows you to remove ambiguity in how the packet is processed on the firewall and the host, and the firewall sees the exact same stream in the protocol stack as the host for whom the packet is destined.

  ```
  set deviceconfig setting tcp urgent-data clear
  ```

- If you configure the firewall to clear the URG bit flag and the packet has no other flags set in the TCP header, use the following CLI command to configure the firewall to drop packets with no flags:

  ```
  set deviceconfig setting tcp drop-zero-flag yes
  ```

- Enable the following CLI command for disabling the bypass-exceed-queue.

  The bypass exceed queue is required for out of order packets. This scenario is most common in an asymmetric environment where the firewall receives packets out of order. For identification of certain applications (App-ID) the firewall performs heuristic analysis. If the packets are received out of order, the data must be copied to a queue in order to complete the analysis for the application.

  ```
  set deviceconfig setting application bypass-exceed-queue no
  ```

- Enable the following CLI commands for disabling the inspection of packets when the out-of-order packet limit is reached. The Palo Alto Networks firewall can collect up to 64 out-of-order packets per session. This counter identifies that packets have exceeded the 64-packet limit. When the bypass setting is set to **no**, the device drops the out-of-order packets that exceed the 64-packet limit. A commit is required.

  ```
  set deviceconfig setting tcp bypass-exceed-oo-queue no
  set deviceconfig setting ctd tcp-bypass-exceed-queue no
  set deviceconfig setting ctd udp-bypass-exceed-queue no
  ```

- Enable the following CLI commands for checking the TCP timestamp. The TCP timestamp records when the segment was sent and allows the firewall to verify that the timestamp is valid for that session. Packets with invalid timestamps are dropped with this setting is enabled.

  ```
  set deviceconfig setting tcp check-timestamp-option yes
  ```

 © Palo Alto Networks, Inc.

- Disable the HTTP Range option. The HTTP Range option allows a client to fetch part of a file only. When a next-generation firewall in the path of a transfer identifies and drops a malicious file, it terminates the TCP session with a RST packet. If the web browser implements the HTTP Range option, it can start a new session to fetch only the remaining part of the file. This prevents the firewall from triggering the same signature again due to the lack of context into the initial session, while at the same time allowing the web browser to reassemble the file and deliver the malicious content. To prevent this, disable the HTTP Range option as follows:

```
set deviceconfig setting ctd skip-block-http-range no
```

# Enable Passive DNS Collection for Improved Threat Intelligence

Passive DNS is an opt-in feature that enables the firewall to act as a passive DNS sensor and send select DNS information to Palo Alto Networks for analysis in order to improve threat intelligence and threat prevention capabilities. The data collected includes non-recursive (i.e. originating from the local recursive resolver, not individual clients) DNS query and response packet payloads. Data submitted via the Passive DNS Monitoring feature consists solely of mappings of domain names to IP addresses. Palo Alto Networks retains no record of the source of this data and does not have the ability to associate it with the submitter at a future date.

The Palo Alto Networks threat research team uses this information to gain insight into malware propagation and evasion techniques that abuse the DNS system. Information gathered through this data collection is used to improve accuracy and malware detection abilities within PAN-DB URL filtering, DNS-based command-and-control signatures, and WildFire.

DNS responses are only forwarded to the Palo Alto Networks and will only occur when the following requirements are met:

- DNS response bit is set
- DNS truncated bit is not set
- DNS recursive bit is not set
- DNS response code is 0 or 3 (NX)
- DNS question count bigger than 0
- DNS Answer RR count is bigger than 0 or if it is 0, the flags need to be 3 (NX)
- DNS query record type are A, NS, CNAME, AAAA, MX

Passive DNS monitoring is disabled by default, but it is recommended that you enable it to facilitate enhanced threat intelligence. Use the following procedure to enable Passive DNS:

| **Enable Passive DNS** | |
|---|---|
| Step 1 | Select **Objects > Security Profiles > Anti-Spyware**. |
| Step 2 | Select an existing profile to modify it or configure a new profile.<br> The Anti-Spyware profile must be attached to a security policy that governs your DNS server's external DNS traffic. |
| Step 3 | Select the **DNS Signatures** tab and click the **Enable Passive DNS Monitoring** check box. |
| Step 4 | Click **OK** and then **Commit**. |

 © Palo Alto Networks, Inc.

# Use DNS Queries to Identify Infected Hosts on the Network

The DNS sinkhole action in Anti-Spyware profiles enables the firewall to forge a response to a DNS query for a known malicious domain, causing the malicious domain name to resolve to an IP address that you define. This allows you to identify hosts on your network that have been infected with malware. The following topics describe the DNS sinkhole action and provide instructions for enabling it and monitoring logs to identify infected hosts.

- DNS Sinkholing
- Configure DNS Sinkholing
- Identify Infected Hosts

## DNS Sinkholing

DNS sinkholing helps you to identify infected hosts on the protected network using DNS traffic in situations where the firewall cannot see the infected client's DNS query (that is, the firewall cannot see the originator of the DNS query). In a typical deployment where the firewall is north of the local DNS server, the threat log will identify the local DNS resolver as the source of the traffic rather than the actual infected host. Sinkholing malware DNS queries solves this visibility problem by forging responses to the client host queries directed at malicious domains, so that clients attempting to connect to malicious domains (for command-and-control, for example) will instead attempt to connect to a sinkhole IP address you define as illustrated in Configure DNS Sinkholing. Infected hosts can then be easily identified in the traffic logs because any host that attempts to connect to the sinkhole IP address are most likely infected with malware.

**Figure: DNS Sinkholing Example**

 © Palo Alto Networks, Inc.

## Configure DNS Sinkholing

To enable DNS Sinkholing, you must enable the action in an Anti-Spyware profile and attach the profile to a security rule. When a client host attempts to access a malicious domain, the firewall forges the destination IP address in the packet using the IP address you configure as the DNS sinkhole address.

| **Configure DNS Sinkholing** | | |
|---|---|---|
| Step 1 | Obtain both an IPv4 and IPv6 address to use as the sinkhole IP addresses.<br><br>The DNS sinkhole address must be in a different zone than the client hosts to ensure that when an infected host attempts to start a session with the sinkhole IP address, it will be routed through the firewall. The reason both IPv4 and IPv6 are needed is because malicious software may perform DNS queries using one or both of these protocols.<br><br> This sinkhole addresses must be reserved for this purpose and do not need to be assigned to a physical host. You can optionally use a honey-pot server as a physical host to further analyze the malicious traffic. | The configuration steps that follow use the following example DNS sinkhole addresses:<br><br>IPv4 DNS sinkhole address—10.15.0.20<br><br>IPv6 DNS sinkhole address—fd97:3dec:4d27:e37c:5:5:5:5 |
| Step 2 | Configure the sinkhole interface and zone.<br><br>Traffic from the zone where the client hosts reside must route to the zone where the sinkhole IP address is defined, so traffic will be logged.<br><br> Use a dedicated zone for sinkhole traffic, because the infected host will be sending traffic to this zone. | 1. Select **Network > Interfaces** and select an interface to configure as your sinkhole interface.<br>2. In the **Interface Type** drop-down, select **Layer3**.<br>3. To add an IPv4 address, select the **IPv4** tab and select **Static** and then click **Add**. In this example, add 10.15.0.20 as the IPv4 DNS sinkhole address.<br>4. Select the **IPv6** tab and click **Static** and then click **Add** and enter an IPv6 address and subnet mask. In this example, enter fd97:3dec:4d27:e37c::/64 as the IPv6 sinkhole address.<br>5. Click **OK** to save.<br>6. To add a zone for the sinkhole, select **Network > Zones** and click **Add**.<br>7. Enter zone **Name**.<br>8. In the **Type** drop-down select **Layer3**.<br>9. In the **Interfaces** section, click **Add** and add the interface you just configured.<br>10. Click **OK**. |

| Configure DNS Sinkholing (Continued) | | |
|---|---|---|
| Step 3 | Enable DNS sinkholing on the Anti-Spyware profile. | 1. Select **Objects > Security Profiles > Anti-Spyware**.<br>2. Modify an existing profile, or select one of the existing defaults and clone it.<br>3. **Name** the profile and then select the **DNS Signatures** tab.<br>4. In the **Action on DNS queries** drop-down, select **sinkhole**.<br>5. In the **Sinkhole IPv4** field enter the sinkhole IPv4 sinkhole address you configured in Step 2 (10.15.0.20 in this example).<br>6. In the **Sinkhole IPv6** field enter the IPv6 sinkhole address you configured in Step 2 (fd97:3dec:4d27:e37c:5:5:5:5 in this example).<br>The default sinkhole address is the loopback address (127.0.0.1 for IPv4 and ::1 for IPv6).<br>7. (Optional) In the **Packet Capture** drop-down, select **single-packet** or **extended-capture**. The single-packet option will capture the first packet of the session or select extended to set between 1-50 packets. You can then use the packet captures for further analysis.<br>8. Click **OK** to save the profile. |
| Step 4 | Edit the security policy rule that allows traffic from client hosts in the trust zone to the untrust zone to include the sinkhole zone as a destination and attach the Anti-Spyware profile.<br>To ensure that you are identifying traffic from infected hosts, make these changes to the security rule(s) that allow traffic from client hosts in the trust zone to the untrust zone. By adding the sinkhole zone as a destination on the rule, you enable infected clients to send bogus DNS queries to the DNS sinkhole. | 1. Select **Policies > Security**.<br>2. Select an existing rule that allows traffic from the client host zone to the untrust zone.<br>3. On the **Destination** tab, **Add** the Sinkhole zone. This allows client host traffic to flow to the sinkhole zone.<br>4. On the **Actions** tab, select the **Log at Session Start** check box to enable logging. This will ensure that traffic from client hosts in the Trust zone will be logged when accessing the Untrust or Sinkhole zones.<br>5. In the **Profile Setting** section, select the **Anti-Spyware** profile in which you enabled DNS sinkholing.<br>6. Click **OK** to save the security rule and then **Commit**. |

 © Palo Alto Networks, Inc.

| Configure DNS Sinkholing (Continued) | | |
|---|---|---|
| Step 5 | To ensure that you will be able to identify infected hosts, verify that traffic going from the client host in the Trust zone to the new Sinkhole zone is being logged.<br><br>In this example, the infected client host is 192.168.2.10 and the Sinkhole IPv4 address is 10.15.0.20. | 1. From a client host in the trust zone, open a command prompt and run the following command:<br>`C:\>ping <sinkhole address>`<br>The following example output shows the ping request to the DNS sinkhole address at 10.15.0.2 and the result, which is `Request timed out` because in this example the sinkhole IP address is not assigned to a physical host:<br>`C:\>ping 10.15.0.20`<br>`Pinging 10.15.0.20 with 32 bytes of data:`<br>`Request timed out.`<br>`Request timed out.`<br>`Ping statistics for 10.15.0.20:`<br>`Packets: Sent = 4, Received = 0, Lost = 4 (100% loss)`<br>2. On the firewall, select **Monitor > Logs > Traffic** and find the log entry with the Source 192.168.2.10 and Destination 10.15.0.20. This will confirm that the traffic to the sinkhole IP address is traversing the firewall zones.<br> You can search and/or filter the logs and only show logs with the destination 10.15.0.20. To do this, click the IP address (10.15.0.20) in the **Destination** column, which will add the filter (addr.dst in 10.15.0.20) to the search field. Click the Apply Filter icon to the right of the search field to apply the filter. |
| Step 6 | Identify a malicious domain that you can use to verify that the DNS sinkhole functionality is configured properly.<br><br>You must test this feature using a malicious domain that is included in the firewall's current antivirus signature database. The DNS Signatures used to identify malicious domains is only part of the full antivirus signature database, which contains hundreds of thousands of signatures. | To find a malicious domain for testing:<br>1. Select **Device > Dynamic Updates** and in the **Antivirus** section click the **Release Notes** link for the current antivirus DB that is installed. You can also find the antivirus release notes on the support site in Dynamic Updates. In most cases, the signature update is an incremental update, so only new viruses and DNS signatures are listed. There are many antivirus signatures and DNS signatures that will already be installed on the firewall.<br>2. In the second column of the release note, locate a line item with a domain extension (for example, .com, .edu, or .net). The left column displays the domain name. For example, in Antivirus release 1117-1560, there is an item in the left column named **tbsbana** and the right column lists **net**.<br>The following shows the content in the release note for this line item:<br>`conficker:tbsbana1 variants: net`<br>Because this domain shows up in the current database, it will work for testing. |

| Configure DNS Sinkholing (Continued) | |
|---|---|
| Step 7 Test the sinkhole action<br><br>This is similar to the action that would be performed if the client host was infected and the malicious application was attempting to reach a hacker server using DNS queries. | 1. From the client host, open a command prompt.<br>2. Perform an NSLOOKUP to a URL that you identified as a known malicious domain in Step 6.<br><br>For example, using the URL `track.bidtrk.com`:<br>`C:\>nslookup track.bidtrk.com`<br>`Server: my-local-dns.local`<br>`Address: 10.0.0.222`<br>`Non-authoritative answer:`<br>`Name: track.bidtrk.com.org`<br>`Addresses: fd97:3dec:4d27:e37c:5:5:5:5`<br>`10.15.0.20`<br><br>In the output, note that the NSLOOKUP to the malicious domain has been forged using the sinkhole IP addresses that we configured (10.15.0.20). Because the domain matched a malicious DNS signature, the sinkhole action was performed.<br>3. Select **Monitor > Logs > Threat** and locate the corresponding threat log entry to verify that the correct action was taken on the NSLOOKUP request.<br>4. Perform a ping to `track.bidtrk.com`, which will generate network traffic to the sinkhole address. |

 © Palo Alto Networks, Inc.

## Identify Infected Hosts

After you have configured DNS sinkholing and verified that traffic to a malicious domain goes to the sinkhole address, you should regularly monitor traffic to the sinkhole address, so that you can track down the infected hosts and eliminate the threat.

| DNS Sinkhole Verification and Reporting | | |
|---|---|---|
| Step 1 | Use App Scope to identify infected client hosts. | 1. Select **Monitor > App Scope** and select **Threat Monitor**.<br>2. Click the **Show spyware** button along the top of the display page.<br>3. Select a time range.<br>The following screenshot shows three instances of Suspicious DNS queries, which were generated when the test client host performed an NSLOOKUP on a known malicious domain. Click the graph to see more details about the event.<br> |

**DNS Sinkhole Verification and Reporting (Continued)**

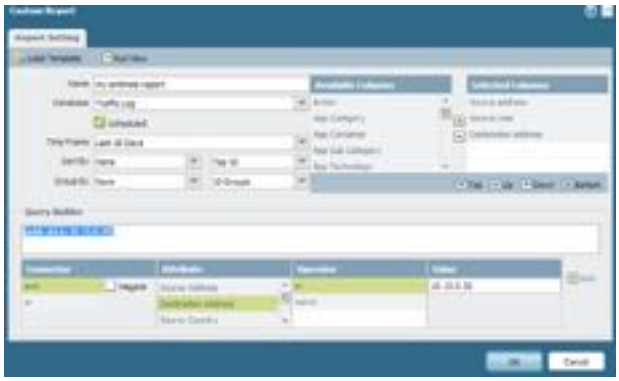
Step 2 Configure a custom report to identify all client hosts that have sent traffic to the sinkhole IP address, which is 10.15.0.20 in this example.

Forward to an SNMP manager, Syslog server and/or Panorama to enable alerts on these events.

In this example, the infected client host performed an NSLOOKUP to a known malicious domain that is listed in the Palo Alto Networks DNS Signature database. When this occurred, the query was sent to the local DNS server, which then forwarded the request through the firewall to an external DNS server. The firewall security policy with the Anti-Spyware profile configured matched the query to the DNS Signature database, which then forged the reply using the sinkhole address of 10.15.0.20 and fd97:3dec:4d27:e37c:5:5:5:5. The client attempts to start a session and the traffic log records the activity with the source host and the destination address, which is now directed to the forged sinkhole address.

Viewing the traffic log on the firewall allows you to identify any client host that is sending traffic to the sinkhole address. In this example, the logs show that the source address 192.168.2.10 sent the malicious DNS query. The host can then be found and cleaned. Without the DNS sinkhole option, the administrator would only see the local DNS server as the system that performed the query and would not see the client host that is infected. If you attempted to run a report on the threat log using the action "Sinkhole", the log would show the local DNS server, not the infected host.

1. Select **Monitor > Manage Custom Reports**.
2. Click **Add** and **Name** the report.
3. Define a custom report that captures traffic to the sinkhole address as follows:
   - **Database**—Select **Traffic Log**.
   - **Scheduled**—Enable **Scheduled** and the report will run every night.
   - **Time Frame**—30 days
   - **Selected Columns**—Select **Source address** or **Source User** (if you have User-ID configured), which will identify the infected client host in the report, and **Destination address**, which will be the sinkhole address.
   - In the section at the bottom of the screen, create a custom query for traffic to the sinkhole address (10.15.0.20 in this example). You can either enter the destination address in the **Query Builder** window (**addr.dst in 10.15.0.20**) or select the following in each column and click **Add**: Connector = and, Attribute = Destination Address, Operator = in, and Value = 10.15.0.20. Click **Add** to add the query.



4. Click **Run Now** to run the report. The report will show all client hosts that have sent traffic to the sinkhole address, which indicates that they are most likely infected. You can now track down the hosts and check them for spyware.

5. To view scheduled reports that have run, select **Monitor > Reports**.

# Content Delivery Network Infrastructure for Dynamic Updates

Palo Alto Networks maintains a Content Delivery Network (CDN) infrastructure for delivering content updates to the Palo Alto Networks devices. The devices access the web resources in the CDN to perform various App-ID and Content-ID functions. For enabling and scheduling the content updates, see Manage Content Updates.

The following table lists the web resources that the firewall accesses for a feature or application:

| Resource | URL | Static Addresses (If a static server is required) |
|---|---|---|
| Application Database | • updates.paloaltonetworks.com:443 | staticupdates.paloaltonetworks.com or the IP address 199.167.52.15 |
| Threat/Antivirus Database | • updates.paloaltonetworks.com:443<br>• downloads.paloaltonetworks.com:443<br>As a best practice, set the update server to updates.paloaltonetworks.com.This allows the Palo Alto Networks device to receive content updates from the server closest to it in the CDN infrastructure. | staticupdates.paloaltonetworks.com or the IP address 199.167.52.15 |
| PAN-DB URL Filtering | *.urlcloud.paloaltonetworks.com<br>Resolves to the primary URL s0000.urlcloud.paloaltonetworks.com and is then redirected to the regional server that is closest:<br>• s0100.urlcloud.paloaltonetworks.com<br>• s0200.urlcloud.paloaltonetworks.com<br>• s0300.urlcloud.paloaltonetworks.com<br>• s0500.urlcloud.paloaltonetworks.com | Static IP addresses are not available. However, you can manually resolve a URL to an IP address and allow access to the regional server IP address. |
| BrightCloud URL Filtering | • database.brightcloud.com:443/80<br>• service.brightcloud.com:80 | Contact BrightCloud Customer Support. |

# Decryption

Palo Alto Networks firewalls provide the capability to decrypt and inspect traffic for visibility, control, and granular security. Decryption on a Palo Alto Networks firewall includes the capability to enforce security policies on encrypted traffic, where otherwise the encrypted traffic might not be blocked and shaped according to your configured security settings. Use decryption on a firewall to prevent malicious content from entering your network or sensitive content from leaving your network concealed as encrypted traffic. Enabling decryption on a Palo Alto Networks firewall can include preparing the keys and certificates required for decryption, creating a decryption policy, and configuring decryption port mirroring. See the following topics to learn about and configure decryption:

- Decryption Overview
- Decryption Concepts
- Configure SSL Forward Proxy
- Configure SSL Inbound Inspection
- Configure SSH Proxy
- Configure Decryption Exceptions
- Enable Users to Opt Out of SSL Decryption
- Configure Decryption Port Mirroring
- Temporarily Disable SSL Decryption

© Palo Alto Networks, Inc.

# Decryption Overview

Secure Sockets Layer (SSL) and Secure Shell (SSH) are encryption protocols used to secure traffic between two entities, such as a web server and a client. SSL and SSH encapsulate traffic, encrypting data so that it is meaningless to entities other than the client and server with the keys to decode the data and the certificates to affirm trust between the devices. Traffic that has been encrypted using the protocols SSL and SSH can be decrypted to ensure that these protocols are being used for the intended purposes only, and not to conceal unwanted activity or malicious content.

Palo Alto Networks firewalls decrypt encrypted traffic by using keys to transform strings (passwords and shared secrets) from ciphertext to plaintext (decryption) and from plaintext back to ciphertext (re-encrypting traffic as it exits the device). Certificates are used to establish the firewall as a trusted third party and to create a secure connection. SSL decryption (both forward proxy and inbound inspection) requires certificates to establish trust between two entities in order to secure an SSL/TLS connection. Certificates can also be used when excluding servers from SSL decryption. You can integrate a hardware security module (HSM) with a firewall to enable enhanced security for the private keys used in SSL forward proxy and SSL inbound inspection decryption. To learn more about storing and generating keys using an HSM and integrating an HSM with your firewall, see Secure Keys with a Hardware Security Module. SSH decryption does not require certificates.

Palo Alto Networks firewall decryption is policy-based, and can be used to decrypt, inspect, and control both inbound and outbound SSL and SSH connections. Decryption policies allow you to specify traffic for decryption according to destination, source, or URL category and in order to block or restrict the specified traffic according to your security settings. The firewall uses certificates and keys to decrypt the traffic specified by the policy to plaintext, and then enforces App-ID and security settings on the plaintext traffic, including Decryption, Antivirus, Vulnerability, Anti-Spyware, URL Filtering, and File-Blocking profiles. After traffic is decrypted and inspected on the firewall, the plaintext traffic is re-encrypted as it exits the firewall to ensure privacy and security. Use policy-based decryption on the firewall to achieve outcomes such as the following:

- Prevent malware concealed as encrypted traffic from being introduced into an corporate network.
- Prevent sensitive corporate information from moving outside the corporate network.
- Ensure the appropriate applications are running on a secure network.
- Selectively decrypt traffic; for example, exclude traffic for financial or healthcare sites from decryption by configuring a decryption exception.

The three decryption policies offered on the firewall, SSL Forward Proxy, SSL Inbound Inspection, and SSH Proxy, all provide methods to specifically target and inspect SSL outbound traffic, SSL inbound traffic, and SSH traffic, respectively. The decryption policies provide the settings for you to specify what traffic to decrypt and decryption profiles can be selected when creating a policy, in order to apply more granular security settings to decrypted traffic, such as checks for server certificates, unsupported modes, and failures. This policy-based decryption on the firewall gives you visibility into and control of SSL and SSH encrypted traffic according to configurable parameters.

You can also choose to extend a decryption configuration on the firewall to include Decryption Mirroring, which allows for decrypted traffic to be forwarded as plaintext to a third party solution for additional analysis and archiving.

 © Palo Alto Networks, Inc.

# Decryption Concepts

To learn about keys and certificates for decryption, decryption policies, and decryption port mirroring, see the following topics:

- Keys and Certificates for Decryption Policies
- SSL Forward Proxy
- SSL Inbound Inspection
- SSH Proxy
- Decryption Exceptions
- Decryption Mirroring

## Keys and Certificates for Decryption Policies

Keys are strings of numbers that are typically generated using a mathematical operation involving random numbers and large primes. Keys are used to transform other strings—such as passwords and shared secrets—from plaintext to ciphertext (called *encryption*) and from ciphertext to plaintext (called *decryption*). Keys can be symmetric (the same key is used to encrypt and decrypt) or asymmetric (one key is used for encryption and a mathematically related key is used for decryption). Any system can generate a key.

X.509 certificates are used to establish trust between a client and a server in order to establish an SSL connection. A client attempting to authenticate a server (or a server authenticating a client) knows the structure of the X.509 certificate and therefore knows how to extract identifying information about the server from fields within the certificate, such as its FQDN or IP address (called a *common name* or *CN* within the certificate) or the name of the organization, department, or user to which the certificate was issued. All certificates must be issued by a certificate authority (CA). After the CA verifies a client or server, the CA issues the certificate and signs it using its private key.

With a decryption policy configured, an SSL/TLS session between the client and the server is established only if the firewall trusts the CA that signed the server certificate. In order to establish trust, the firewall must have the server root CA certificate in its certificate trust list (CTL) and use the public key contained in that root CA certificate to verify the signature. The firewall then presents a copy of the server certificate signed by the Forward Trust certificate for the client to authenticate. You can also configure the firewall to use an enterprise CA as a forward trust certificate for SSL Forward Proxy. If the firewall does not have the server root CA certificate in its CTL, the firewall will present a copy of the server certificate signed by the Forward Untrust certificate to the client. The Forward Untrust certificate ensures that clients are prompted with a certificate warning when attempting to access sites hosted by a server with untrusted certificates.

For detailed information on certificates, see Certificate Management.

To control the trusted CAs that your device trusts, use the **Device > Certificate Management > Certificates > Default Trusted Certificate Authorities** tab on the firewall web interface.

Table: Palo Alto Networks Device Keys and Certificates describes the different keys and certificates used by Palo Alto Networks devices for decryption. As a best practice, use different keys and certificates for each usage.

**Table: Palo Alto Networks Device Keys and Certificates**

| Key/Certificate Usage | Description |
|---|---|
| Forward Trust | The certificate the firewall presents to clients during decryption if the site the client is attempting to connect to has a certificate that is signed by a CA that the firewall trusts. To configure a Forward Trust certificate on the firewall, see Step 2 in the Configure SSL Forward Proxy task. By default, the firewall determines the key size to use for the client certificate based on the key size of the destination server. However, you can also set a specific key size for the firewall to use. See Configure the Key Size for SSL Forward Proxy Server Certificates. For added security, store the forward trust certificate on a Hardware Security Module (HSM), see Store Private Keys on an HSM. |
| Forward Untrust | The certificate the firewall presents to clients during decryption if the site the client is attempting to connect to has a certificate that is signed by a CA that the firewall does not trust. To configure a Forward Untrust certificate on the firewall, see Step 3 in the Configure SSL Forward Proxy task. |

 © Palo Alto Networks, Inc.

| Key/Certificate Usage | Description |
|---|---|
| SSL Exclude Certificate | Certificates for servers that you want to exclude from SSL decryption. For example, if you have SSL decryption enabled, but have certain servers that you do not want included in SSL decryption, such as the web services for your HR systems, you would import the corresponding certificates onto the firewall and configure them as SSL Exclude Certificates. See Exclude a Server from Decryption. |
| SSL Inbound Inspection | The certificate used to decrypt inbound SSL traffic for inspection and policy enforcement. For this application, you would import the server certificate for the servers for which you are performing SSL inbound inspection, or store them on an HSM (see Store Private Keys on an HSM). |

## SSL Forward Proxy

Use an SSL Forward Proxy decryption policy to decrypt and inspect SSL/TLS traffic from internal users to the web. SSL Forward Proxy decryption prevents malware concealed as SSL encrypted traffic from being introduced to your corporate network; for example, if an employee is using her Gmail account from her corporate office and opens an email attachment that contains a virus, SSL Forward Proxy decryption will prevent the virus from infecting the client system and entering the corporate network.

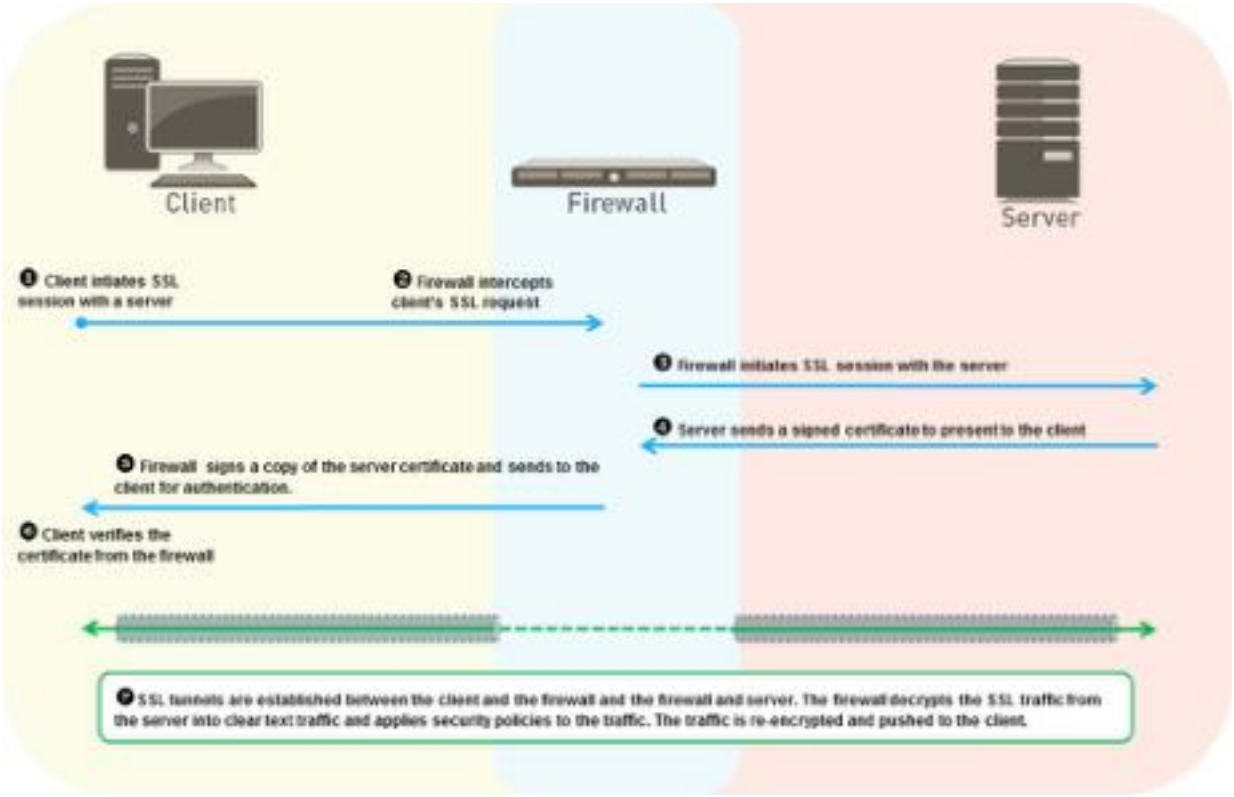
With SSL Forward Proxy decryption, the firewall resides between the internal client and outside server. The firewall uses Forward Trust or Forward Untrust certificates to establish itself as a trusted third party to the session between the client and the server (For details on certificates, see Keys and Certificates for Decryption Policies). When the client initiates an SSL session with the server, the firewall intercepts the client SSL request and forwards the SSL request to the server. The server sends a certificate intended for the client that is intercepted by the firewall. If the server certificate is signed by a CA that the firewall trusts, the firewall creates a copy of the server certificate signed by the Forward Trust certificate and sends the certificate to the client to authenticate. If the server certificate is signed by a CA that the firewall does not trust, the firewall creates a copy of the server certificate and signs it with the Forward Untrust certificate and sends it to the client. In this case, the client sees a block page warning that the site they're attempting to connect to is not trusted and the client can choose to proceed or terminate the session. When the client authenticates the certificate, the SSL session is established with the firewall functioning as a trusted forward proxy to the site that the client is accessing.

As the firewall continues to receive SSL traffic from the server that is destined for the client, it decrypts the SSL traffic into clear text traffic and applies security policies to the traffic. The traffic is then re-encrypted on the firewall and the firewall forwards the encrypted traffic to the client.

Figure: SSL Forward Proxy shows this process in detail.

 © Palo Alto Networks, Inc.

**Figure: SSL Forward Proxy**



See Configure SSL Forward Proxy for details on configuring SSL Forward Proxy.

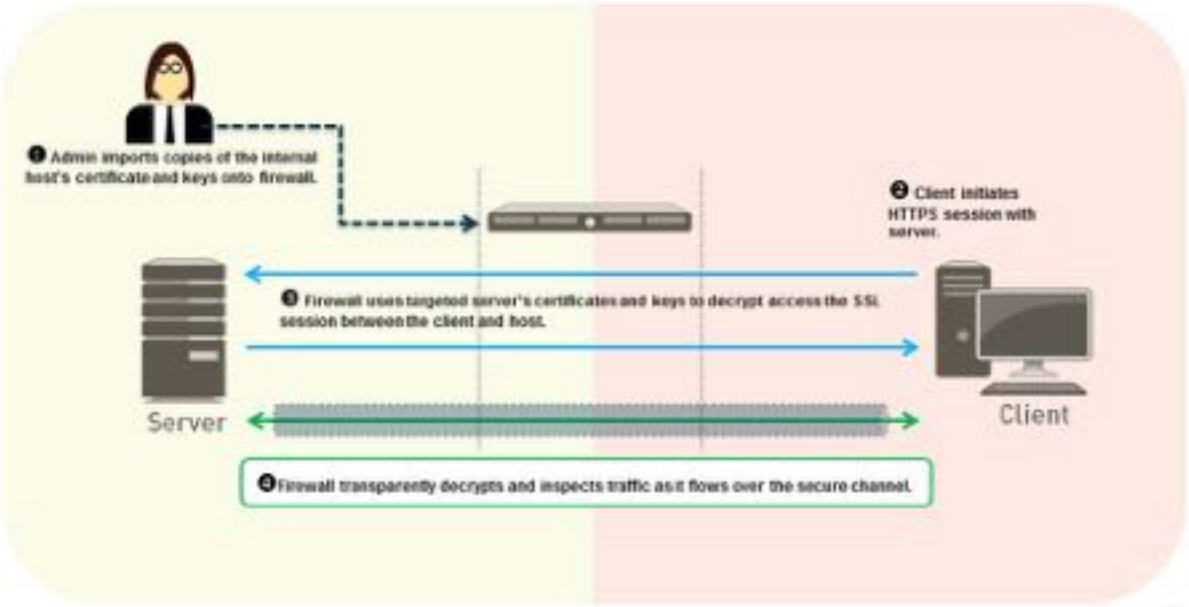
## SSL Inbound Inspection

Use SSL Inbound Inspection to decrypt and inspect inbound SSL traffic from a client to a targeted server (any server you have the certificate for and can import it onto the firewall). For example, if an employee is remotely connected to a web server hosted on the company network and is attempting to add restricted internal documents to his Dropbox folder (which uses SSL for data transmission), SSL Inbound Inspection can be used to ensure that the sensitive data does not move outside the secure company network by blocking or restricting the session.

Configuring SSL Inbound Inspection includes importing the targeted server certificate and key on to the firewall. Because the targeted server certificate and key are imported on the firewall, the firewall is able to access the SSL session between the server and the client and decrypt and inspect traffic transparently, rather than functioning as a proxy. The firewall is able to apply security policies to the decrypted traffic, detecting malicious content and controlling applications running over this secure channel.

Figure: SSL Inbound Inspection shows this process in detail.

**Figure: SSL Inbound Inspection**



See Configure SSL Inbound Inspection for details on configuring SSL Inbound Inspection.

 © Palo Alto Networks, Inc.

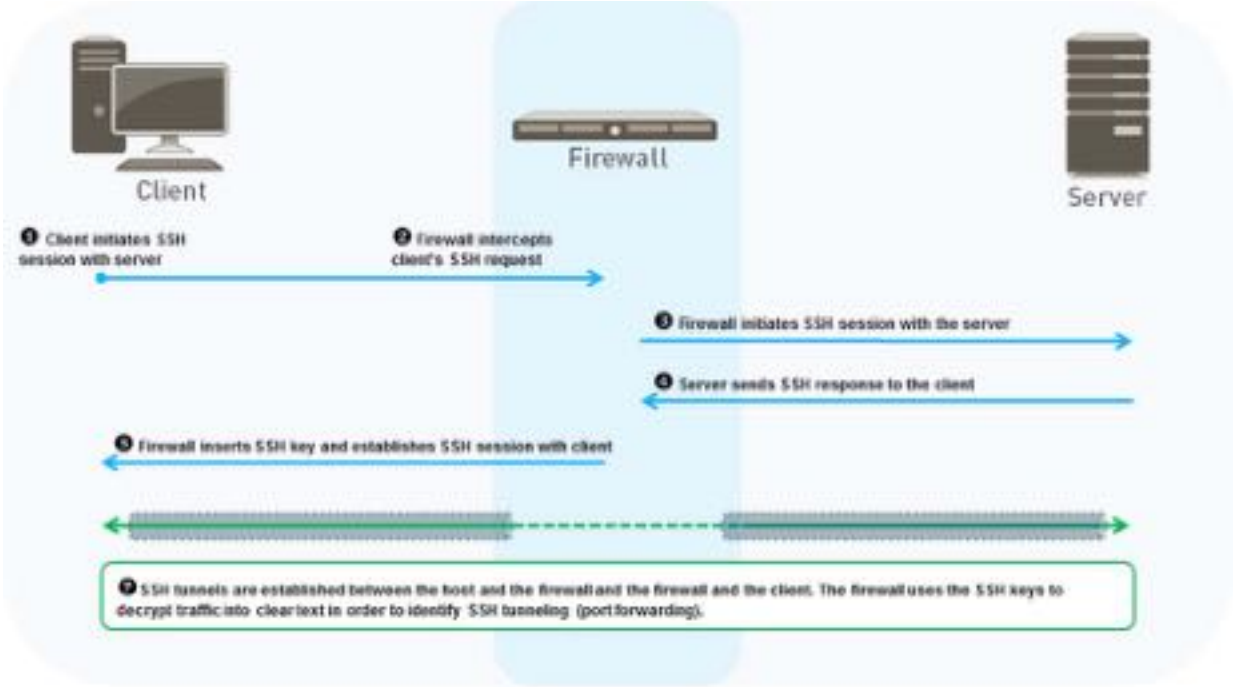
## SSH Proxy

SSH Proxy provides the capability for the firewall to decrypt inbound and outbound SSH connections passing through the firewall, in order to ensure that SSH is not being used to tunnel unwanted applications and content. SSH decryption does not require any certificates and the key used for SSH decryption is automatically generated when the firewall boots up. During the boot up process, the firewall checks to see if there is an existing key. If not, a key is generated. This key is used for decrypting SSH sessions for all virtual systems configured on the device. The same key is also used for decrypting all SSH v2 sessions.

In an SSH Proxy configuration, the firewall resides between a client and a server. When the client sends an SSH request to the server, the firewall intercepts the request and forwards the SSH request to the server. The firewall then intercepts the server response and forwards the response to the client, establishing an SSH tunnel between the firewall and the client and an SSH tunnel between the firewall and the server, with firewall functioning as a proxy. As traffic flows between the client and the server, the firewall is able to distinguish whether the SSH traffic is being routed normally or if it is using SSH tunneling (port forwarding). Content and threat inspections are not performed on SSH tunnels; however, if SSH tunnels are identified by the firewall, the SSH tunneled traffic is blocked and restricted according to configured security policies.

Figure: SSH Proxy Decryption shows this process in detail.

**Figure: SSH Proxy Decryption**



See Configure SSH Proxy for details on configuring an SSH Proxy policy.

## Decryption Exceptions

Traffic can also be excluded from decryption according to matching criteria (using a decryption policy), a targeted server traffic can be excluded from decryption (using certificates), and some applications are excluded from decryption by default.

Applications that do not function properly when decrypted by the firewall and are automatically excluded from SSL decryption. The applications that are excluded from SSL decryption by default are excluded because these applications often fail when decrypted due to the application looking for specific details in the certificate that might not be present in the certificate generated for SSL Forward Proxy. Refer to the KB article List of Applications Excluded from SSL Decryption for a current list of applications excluded by default from SSL decryption on the firewall.

You can configure decryption exceptions for certain URL categories or applications that either do not work properly with decryption enabled or for any other reason, including for legal or privacy purposes. You can use a decryption policy to exclude traffic from decryption based on source, destination, URL category, service (port or protocol), and TCP port numbers. For example, with SSL decryption enabled, you can exclude traffic that is categorized as financial or health-related from decryption using the URL category selection.

You can also exclude servers from SSL decryption based on the Common Name (CN) in the server certificate. For example, if you have SSL decryption enabled but have certain servers that you do not want included in SSL decryption, such as the web services for your HR systems, you can exclude those servers from decryption by importing the server certificate onto the firewall and modifying the certificate to be an **SSL Exclude Certificate**.

To exclude traffic from decryption based on application, source, destination, URL category or to exclude a specific server from decryption, see Configure Decryption Exceptions.

 © Palo Alto Networks, Inc.

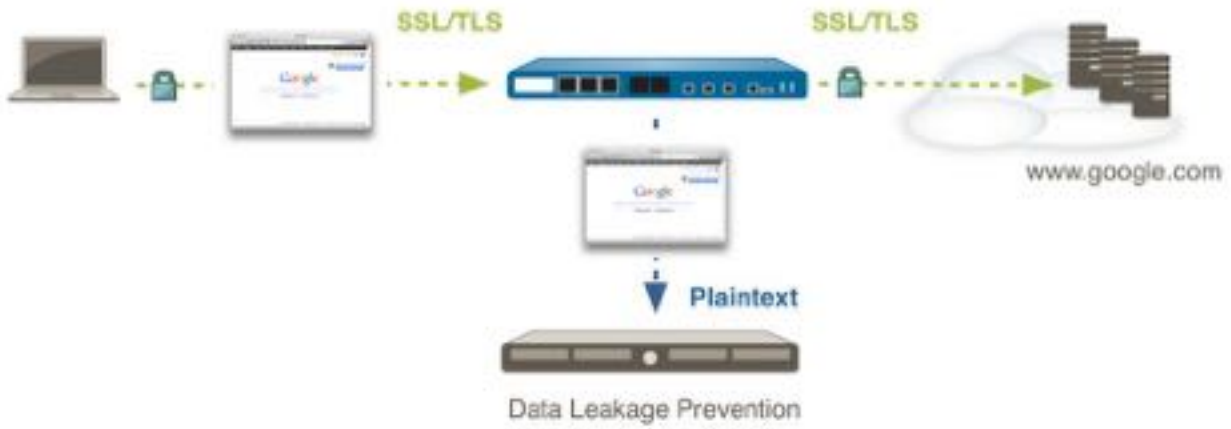
## Decryption Mirroring

The decryption mirroring feature provides the capability to create a copy of decrypted traffic from a firewall and send it to a traffic collection tool that is capable of receiving raw packet captures–such as NetWitness or Solera–for archiving and analysis. This feature is necessary for organizations that require comprehensive data capture for forensic and historical purposes or data leak prevention (DLP) functionality. Decryption mirroring is available on PA-7000 Series, PA-5000 Series and PA-3000 Series platforms only and requires that a free license be installed to enable this feature.

Keep in mind that the decryption, storage, inspection, and/or use of SSL traffic is governed in certain countries and user consent might be required in order to use the decryption mirror feature. Additionally, use of this feature could enable malicious users with administrative access to the firewall to harvest usernames, passwords, social security numbers, credit card numbers, or other sensitive information submitted using an encrypted channel. Palo Alto Networks recommends that you consult with your corporate council before activating and using this feature in a production environment.

Figure: Decryption Port Mirroring shows the process for mirroring decrypted traffic and the section Configure Decryption Port Mirroring describes how to license and enable this feature.

**Figure: Decryption Port Mirroring**



# Configure SSL Forward Proxy

Configuring SSL Forward Proxy decryption on the firewall requires setting up the certificates needed for SSL Forward Proxy decryption and creating an SSL Forward Proxy decryption policy. The firewall can use self-signed certificates or certificates signed by an enterprise CA to perform SSL Forward Proxy decryption.

By default, the firewall determines the key size to use for the client certificates it generates based on the key size of the destination server certificate. You can optionally set a static key size to use regardless of the key size of the destination server certificate. See Configure the Key Size for SSL Forward Proxy Server Certificates.

Use the following task to configure SSL Forward Proxy, including how to set up the certificates and create a decryption policy.

| Configure SSL Forward Proxy | | |
|---|---|---|
| Step 1 | Ensure that the appropriate interfaces are configured as either virtual wire, Layer 2, or Layer 3 interfaces. | View configured interfaces on the **Network > Interfaces > Ethernet** tab. The **Interface Type** column displays if an interface is configured to be a **Virtual Wire** or **Layer 2**, or **Layer 3** interface. You can select an interface to modify its configuration, including what type of interface it is. |

© Palo Alto Networks, Inc.

**Configure SSL Forward Proxy**

Step 2 Configure the forward trust certificate. Use either a self-signed certificate or a certificate signed by an enterprise CA.

**Using self-signed certificates**

When the certificate of the server that the client is connecting to is signed by a CA that is on the firewall trusted CA list, the firewall signs a copy of the server certificate with a self-signed forward trust certificate to present to the client for authentication. In this case, the self-signed certificate must be imported onto each client system so that the client recognizes the firewall as a trusted CA.

Use self-signed certificates for SSL Forward Proxy decryption if you do not use an enterprise CA or if you are only intended to perform decryption for a limited number of client systems (or if you are planning to use a centralized deployment).

**To use a self-signed certificate:**

1. Select **Device > Certificate Management > Certificates**.
2. Click **Generate** at the bottom of the window.
3. Enter a **Certificate Name**, such as *my-fwd-trust*.
4. Enter a **Common Name**, such as **192.168.2.1**. This should be the IP or FQDN that will appear in the certificate. In this case, we are using the IP of the trust interface. Avoid using spaces in this field.
5. Leave the **Signed By** field blank.
6. Click the **Certificate Authority** check box to enable the firewall to issue the certificate. Selecting this check box creates a certificate authority (CA) on the firewall that is imported to the client browsers, so clients trust the firewall as a CA.
7. Click **Generate** to generate the certificate.
8. Click the new certificate *my-fwd-trust* to modify it and enable the **Forward Trust Certificate** option.
9. Export the forward trust certificate for import into client systems by highlighting the certificate and clicking **Export** at the bottom of the window. Choose PEM format, and do not select the **Export private key** option. Because the certificate is self-signed, import it into the browser trusted root CA list on the client systems in order for the clients to trust it. When importing to the client browser, ensure the certificate is added to the Trusted Root Certification Authorities certificate store. On Windows systems, the default import location is the Personal certificate store. You can also simplify this process by using a centralized deployment, such as an Active Directory Group Policy Object (GPO).

   If the forward trust certificate is not imported on the client systems, users will see certificate warnings for each SSL site they visit.
10. Click **OK** to save.

## Configure SSL Forward Proxy

### Using an Enterprise CA

An enterprise CA can issue a signing certificate which the firewall can use to then sign the certificates for sites requiring SSL decryption. Send a Certificate Signing Request (CSR) for the enterprise CA to sign and validate. The firewall can then use the signed enterprise CA certificate for SSL Forward Proxy decryption. Because the enterprise CA is already trusted by the client systems, with this option, you do not need to distribute the certificate to client systems prior to configuring decryption.

**To use an enterprise CA signed certificate, generate a CSR:**

1. Select **Device > Certificate Management > Certificates** and click **Generate**.
2. Enter a **Certificate Name**, such as *my-fwd-proxy*.
3. In the **Signed By** drop-down, select **External Authority (CSR)**.
4. (Optional) If your enterprise CA requires it, add **Certificate Attributes** to further identify the firewall details, such as Country or Department.
5. Click **OK** to save the CSR. The pending certificate is now displayed on the **Device Certificates** tab.
6. Export the CSR:
   a. Select the pending certificate displayed on the **Device Certificates** tab.
   b. Click **Export** to download and save the certificate file.

   Leave **Export private key** unselected in order to ensure that the private key remains securely on the firewall.
   c. Click **OK**.
   d. Provide the certificate file to your enterprise CA. When you receive the signed enterprise CA certificate from your enterprise CA, save the signed enterprise CA certificate for import onto the firewall.
7. Import the signed enterprise CA onto the firewall:
   a. Select **Device > Certificate Management > Certificates** and click **Import**.
   b. Enter the pending **Certificate Name** exactly (in this case, *my-fwd-trust*). The **Certificate Name** that you enter must exactly match the pending certificate name in order for the pending certificate to be validated.
   c. Select the signed **Certificate File** that you received from your enterprise CA.
   d. Click **OK**. The certificate is displayed as valid with the Key and CA check boxes selected.
   e. Select the validated certificate, in this case, *my-fwd-proxy*, to enable it as a **Forward Trust Certificate** to be used for SSL Forward Proxy decryption.
   f. Click **OK**.

© Palo Alto Networks, Inc.

| Configure SSL Forward Proxy | | |
|---|---|---|
| Step 3 | Configure the forward untrust certificate.<br><br>With SSL Forward Proxy decryption, when the site the client is connecting to uses a certificate signed by a CA that is not in the firewall trusted CA list, the firewall presents a forward untrust certificate to the client. The forward untrust certificate ensures that clients are prompted with a certificate warning when attempting to access sites with untrusted certificates. | 1. Click **Generate** at the bottom of the certificates page.<br>2. Enter a **Certificate Name**, such as *my-fwd-untrust*.<br>3. Set the **Common Name**, for example **192.168.2.1**. Leave **Signed By** blank.<br>4. Click the **Certificate Authority** check box to enable the firewall to issue the certificate.<br>5. Click **Generate** to generate the certificate.<br>6. Click **OK** to save.<br>7. Click the new *my-ssl-fw-untrust* certificate to modify it and enable the **Forward Untrust Certificate** option.<br><br> Do not export the forward untrust certificate for import into client systems. If the forward trust certificate is imported on client systems, the users will not see certificate warnings for SSL sites with untrusted certificates.<br><br>8. Click **OK** to save. |
| Step 4 | (Optional) Set the key size of the SSL Forward Proxy certificates that the firewall presents to clients.<br><br> Changing the key size clears the current certificate cache. | 1. Select **Device > Setup > Session** and, in the Decryption Settings section, click **Forward Proxy Server Certificate Settings**.<br>2. Select a **Key Size**: **Defined by destination host** (default), **1024-bit RSA**, or **2048-bit RSA**. |
| Step 5 | (Optional) Create a decryption profile.<br><br>Decryption profiles can be associated with a decryption policy, enabling the firewall to block and control various aspects of traffic that is being decrypted. An SSL Forward Proxy decryption profile can be used to:<br>• Perform checks for server certificates, unsupported modes, and failures.<br>• Block or restrict traffic.<br>• Enforce protocol versions, strong cipher suites, and certificate validation. | 1. Select **Objects > Decryption Profile** and click **Add**.<br>2. Select **SSL Decryption > SSL Forward Proxy** to block and control specific aspects of SSL tunneled traffic. For example, you can choose to terminate sessions if system resources are not available to process decryption by selecting **Block sessions if resources not available**.<br>3. Click **OK** to save the profile. |

| Configure SSL Forward Proxy | |
|---|---|
| Step 6 Configure a decryption policy. | 1. Select **Policies > Decryption** and click **Add**.<br>2. On the **General** tab, give the policy a descriptive **Name**.<br>3. On the **Source** and **Destination** tabs, select **Any** for the **Source Zone** and **Destination Zone** to decrypt all SSL traffic destined for an external server. If you want to specify traffic from or to certain sources or destinations for decryption, click **Add**.<br>4. On the **URL Category** tab, select **Any** to decrypt all traffic. Alternatively, **Add** URL categories to apply the profile to only those websites that fall under the selected categories.<br> The option to decrypt traffic based on URL category is also useful when excluding certain sites (such as financial or healthcare-related sites ) from decryption. See Configure Decryption Exceptions.<br>5. On the **Options** tab, select **Decrypt** and select **SSL Forward Proxy** as the **Type** of decryption to perform.<br>6. (Optional) Select a **Decryption Profile** to apply additional settings to decrypted traffic (see Step 5).<br>7. Click **OK** to save. |
| Step 7 **Commit** the configuration. | With an SSL Forward Proxy decryption policy enabled, all traffic identified by the policy is decrypted. Decrypted traffic is blocked and restricted according to the profiles configured on the firewall (including the decryption profiles associated with the policy and Antivirus, Vulnerability, Anti-Spyware, URL Filtering, and File-Blocking profiles). Traffic is re-encrypted as it exits the firewall. |

© Palo Alto Networks, Inc.

# Configure SSL Inbound Inspection

Configuring SSL Inbound Inspection includes installing the targeted server certificate on the firewall and creating an SSL Inbound Inspection decryption policy.

Use the following task to configure SSL Inbound Inspection.

| Configure SSL Inbound Inspection | | |
|---|---|---|
| Step 1 | Ensure that the appropriate interfaces are configured as either virtual wire, Layer 2, or Layer 3 interfaces. | View configured interfaces on the **Network > Interfaces > Ethernet** tab. The **Interface Type** column displays if an interface is configured to be a **Virtual Wire** or **Layer 2**, or **Layer 3** interface. You can select an interface to modify its configuration, including what type of interface it is. |
| Step 2 | Ensure that the targeted server certificate is installed on the firewall. | On the web interface, select **Device > Certificate Management > Certificates > Device Certificates** to view certificates installed on the firewall.<br>To import the targeted server certificate onto the firewall:<br>1. On the **Device Certificates** tab, select **Import**.<br>2. Enter a descriptive **Certificate Name**.<br>3. Browse for and select the targeted server **Certificate File**.<br>4. Click **OK**. |
| Step 3 | (Optional) Create a Decryption profile.<br>Decryption profiles can be associated with a decryption policy, enabling the firewall to block and control various aspects of traffic that is being decrypted. An SSL Inbound Inspection decryption profile can be used to perform checks for unsupported protocol versions, unsupported cipher suites, and failures. | 1. Select **Objects > Decryption Profile** and click **Add**.<br>2. Select **SSL Decryption > Inbound Inspection** to block and control specific aspects of inbound SSL traffic. For example, you can choose to terminate sessions if system resources are not available to process decryption by selecting **Block sessions if resources not available**.<br>3. Click **OK t**o save the profile. |

| Configure SSL Inbound Inspection | |
|---|---|
| Step 4 Configure a decryption policy. | 1. Select **Policies > Decryption** and click **Add**.<br>2. On the **General** tab, give the policy a descriptive **Name**.<br>3. On the **Destination** tab, **Add** the **Destination Address** of the targeted server.<br>4. On the **URL Category** tab, select **Any** to decrypt all traffic. Alternatively, **Add** URL categories to apply the profile to only those websites that fall under the selected categories.<br> The option to decrypt traffic based on URL category is also useful when excluding certain sites (such as financial or healthcare-related sites ) from decryption. See Configure Decryption Exceptions.<br>5. On the **Options** tab, select **Decrypt** and select **SSL Inbound Inspection** as the **Type** of traffic to decrypt.<br>Select the **Certificate** for the internal server that is the destination of the inbound SSL traffic.<br>6. (Optional) Select a **Decryption Profile** to apply additional settings to decrypted traffic.<br>7. Click **OK** to save. |
| Step 5 **Commit** the configuration. | With an SSL Inbound Inspection decryption policy enabled, all SSL traffic identified by the policy is decrypted and inspected. Decrypted traffic is blocked and restricted according to the profiles configured on the firewall (including the decryption profiles associated with the policy and Antivirus, Vulnerability, Anti-Spyware, URL Filtering, and File-Blocking profiles). Traffic is re-encrypted as it exits the firewall. |

© Palo Alto Networks, Inc.

# Configure SSH Proxy

Configuring SSH Proxy does not require certificates and the key used to decrypt SSH sessions is generated automatically on the firewall during boot up.

Use the following task to configure SSH Proxy decryption.

| Configure SSH Proxy Decryption | | |
|---|---|---|
| Step 1 | Ensure that the appropriate interfaces are configured as either virtual wire, Layer 2, or Layer 3 interfaces. Decryption can only be performed on virtual wire, Layer 2, or Layer 3 interfaces. | View configured interfaces on the **Network > Interfaces > Ethernet** tab. The **Interface Type** column displays if an interface is configured to be a **Virtual Wire** or **Layer 2**, or **Layer 3** interface. You can select an interface to modify its configuration, including what type of interface it is. |
| Step 2 | (Optional) Create a Decryption profile.<br>Decryption profiles can be associated with a decryption policy, enabling the firewall to block and control various aspects of traffic that is being decrypted. An SSH proxy decryption profile can be used to perform checks for unsupported protocol versions, unsupported cipher suites, and for failures. | 1. Select **Objects > Decryption Profile** and click **Add**.<br>2. Select the **SSH** tab to block and control specific aspects of SSH tunneled traffic. For example, you can choose to terminate sessions if system resources are not available to process decryption by selecting **Block sessions if resources not available**.<br>3. Click **OK** to save the profile. |
| Step 3 | Configure a decryption policy. | 1. Select **Policies > Decryption** and click **Add**.<br>2. On the **General** tab, give the policy a descriptive **Name**.<br>3. On the **Source** and **Destination** tabs, select **Any** to decrypt all SSH traffic.<br>4. On the **URL Category** tab, select **Any** to decrypt all SSH traffic.<br>5. On the **Options** tab, select **Decrypt** and select **SSH Proxy** as the **Type** of traffic to decrypt.<br>6. (Optional) Select a **Decryption Profile** to apply additional settings to decrypted traffic.<br>7. Click **OK** to save. |
| Step 4 | **Commit** the configuration. | With the an SSH Proxy decryption policy enabled, all SSH traffic identified by the policy is decrypted and identified as either regular SSH traffic or as SSH tunneled traffic. SSH tunneled traffic is blocked and restricted according to the profiles configured on the firewall. Traffic is re-encrypted as it exits the firewall. |

# Configure Decryption Exceptions

You can purposefully exclude traffic from decryption based on source, destination, URL category, and service (ports and protocols). You can also exclude a specific server from decryption. See the following topics to configure Decryption Exceptions:

- Exclude Traffic from Decryption
- Exclude a Server from Decryption

## Exclude Traffic from Decryption

To exclude applications or certain traffic from decryption, create a decryption policy rule that defines the traffic to be excluded from decryption and set the policy action to **No Decrypt**. Exclude traffic from decryption based on source, destination, URL category, and service (ports and protocols). Because policy rules are compared against incoming traffic in sequence, make sure that a decryption exclusion rule is listed first in your decryption policy.

| **Exclude Traffic from a Decryption Policy** | | |
|---|---|---|
| Step 1 | (Optional) Enable the firewall to block sessions with expired certificates and/or untrusted certificate issuers, without decrypting those sessions. | 1. Select **Objects > Decryption Profile** and click **Add**.<br>2. Give the profile rule a descriptive **Name** such as: Block certs and issues for No Decrypt traffic.<br>3. Select **No Decryption** to block and control specific aspects of traffic that you are excluding from decryption. Select **Block sessions with expired certificates** and/or **Block sessions with untrusted issuers**.<br>4. Click **OK t**o save the profile rule. |
| Step 2 | Configure a decryption policy rule.<br><br>Use a decryption policy rule to exclude traffic from decryption based on source and destination zones and addresses, URL categories, ports, and protocols. This example shows how to exclude traffic categorized as financial or health-related from SSL Forward Proxy decryption. | 1. Go to **Policies > Decryption** and click **Add**.<br>2. Give the rule a descriptive **Name**, such as *No-Decrypt-Finance-Health*.<br>3. On the **Source** and **Destination** tabs, select **Any** for the **Source Zone** and **Destination Zone** to apply the *No-Decrypt-Finance-Health* rule to all SSL traffic destined for an external server.<br>4. On the **URL Category** tab, **Add** the URL categories financial-services and health-and-medicine to the policy, specifying that traffic that matches these categories will not be decrypted.<br>5. On the **Options** tab, select **No Decrypt**.<br>6. (Optional) Attach the decryption profile created in Step 1 to the policy. A decryption profile can be attached to a No Decrypt policy, to block and control aspects of the traffic being excluded from decryption.<br>7. Click **OK** to save the *No-Decrypt-Finance-Health* rule. |

 © Palo Alto Networks, Inc.

| Exclude Traffic from a Decryption Policy | | |
|---|---|---|
| Step 3 | Move the decryption exclusion rule to the to the top of your decryption policy. | On the **Decryption > Policies** page, select the policy *No-Decrypt-Finance-Health*, and click **Move Up** until it appears at the top of the list (or you can drag and drop the rule).<br>Decryption rules are enforced against incoming traffic in sequence and the first rule to match to traffic is enforced—moving the **No Decrypt** rule to the top of the rule list ensures that traffic defined to be excluded from decryption remains encrypted, even if the traffic is also matched to criteria defined in other decryption rules. |
| Step 4 | Save the changes. | **Commit** the configuration. |

## Exclude a Server from Decryption

You can exclude targeted server traffic from SSL decryption based on the common name (CN) in the server certificate. For example, if you have SSL decryption enabled, you could configure a decryption exception for the server on your corporate network that hosts the web services for your HR systems.

| Exclude a Server from Decryption | |
|---|---|
| Step 1 | Import the targeted server certificate onto the firewall:<br>1. On the **Device > Certificate Management > Certificates > Device Certificates** tab, select **Import**.<br>2. Enter a descriptive **Certificate Name**.<br>3. Browse for and select the targeted server **Certificate File**.<br>4. Click **OK**. |
| Step 2 | Select the targeted server certificate on the **Device Certificates** tab and enable it as an SSL Exclude Certificate.<br>With the targeted server certificate imported on the firewall and designated as an SSL Exclude Certificate, the server traffic is not decrypted as it passes through the firewall. |

# Enable Users to Opt Out of SSL Decryption

In some cases, you might need to alert your users to the fact that the firewall is decrypting certain web traffic and allow them to terminate sessions that they do not want inspected. With SSL Opt Out enabled, the first time a user attempts to browse to an HTTPS site or application that matches your decryption policy, the firewall displays a response page notifying the user that it will decrypt the session. Users can either click **Yes** to allow decryption and continue to the site or click **No** to opt out of decryption and terminate the session. The choice to allow decryption applies to all HTTPS sites that users try to access for the next 24 hours, after which the firewall redisplays the response page. Users who opt out of SSL decryption cannot access the requested web page, or any other HTTPS site, for the next minute. After the minute elapses, the firewall redisplays the response page the next time the users attempt to access an HTTPS site.

The firewall includes a predefined SSL Decryption Opt-out Page that you can enable. You can optionally customize the page with your own text and/or images.

| **Enable Users to Opt Out of SSL Decryption** | |
|---|---|
| Step 1 (Optional) Customize the SSL Decryption Opt-out Page. | 1. Select **Device > Response Pages**.<br>2. Select the **SSL Decryption Opt-out Page** link.<br>3. Select the **Predefined** page and click **Export**.<br>4. Using the HTML text editor of your choice, edit the page.<br>5. If you want to add an image, host the image on a web server that is accessible from your end user systems.<br>6. Add a line to the HTML to point to the image. For example:<br>`<img src="http://cdn.slidesharecdn.com/Acme-logo-96x96.jpg?1382722588"/>`<br>7. Save the edited page with a new filename. Make sure that the page retains its UTF-8 encoding.<br>8. Back on the firewall, select **Device > Response Pages**.<br>9. Select the **SSL Decryption Opt-out Page** link.<br>10. Click **Import** and then enter the path and filename in the **Import File** field or **Browse** to locate the file.<br>11. (Optional) Select the virtual system on which this login page will be used from the **Destination** drop-down or select shared to make it available to all virtual systems.<br>12. Click **OK** to import the file.<br>13. Select the response page you just imported and click **Close**. |
| Step 2 Enable SSL Decryption Opt Out. | 1. On the **Device > Response Pages** page, click the **Disabled** link.<br>2. Select the **Enable SSL Opt-out Page** and click **OK**.<br> <br>3. **Commit** the changes. |

 © Palo Alto Networks, Inc.

| Enable Users to Opt Out of SSL Decryption | | |
|---|---|---|
| Step 3 | Verify that the Opt Out page displays when you attempt to browse to a site. | From a browser, go to an encrypted site that matches your decryption policy.<br>Verify that the SSL Decryption Opt-out response page displays.<br> |

# Configure Decryption Port Mirroring

Before you can enable Decryption Mirroring, you must obtain and install a Decryption Port Mirror license. The license is free of charge and can be activated through the support portal as described in the following procedure. After you install the Decryption Port Mirror license and reboot the firewall, you can enable decryption port mirroring.

| Configure Decryption Port Mirroring | |
|---|---|
| Step 1 Request a license for each device on which you want to enable decryption port mirroring. | 1. Log in to the Palo Alto Networks Support site and navigate to the **Assets** tab.<br>2. Select the device entry for the device you want to license and select **Actions**.<br>3. Select **Decryption Port Mirror**. A legal notice displays.<br>4. If you are clear about the potential legal implications and requirements, click **I understand and wish to proceed**.<br>5. Click **Activate**.<br>  |
| Step 2 Install the Decryption Port Mirror license on the firewall. | 1. From the firewall web interface, select **Device > Licenses**.<br>2. Click **Retrieve license keys from license server**.<br>3. Verify that the license has been activated on the firewall.<br> <br>4. Reboot the firewall (**Device > Setup > Operations**). This feature will not be available for configuration until PAN-OS reloads. |

 © Palo Alto Networks, Inc.

| Configure Decryption Port Mirroring (Continued) | | |
|---|---|---|
| Step 3 | Enable the firewall to forward decrypted traffic. Superuser permission is required to perform this step. | **On a firewall with a single virtual system:**<br>1. Select **Device > Setup > Content - ID**.<br>2. Select the **Allow forwarding of decrypted content** check box.<br>3. Click **OK** to save.<br>**On a firewall with multiple virtual systems:**<br>1. Select **Device > Virtual System.**<br>2. Select a Virtual System to edit or create a new Virtual System by selecting **Add**.<br>3. Select the **Allow forwarding of decrypted content** check box.<br>4. Click **OK** to save. |
| Step 4 | Enable an Ethernet interface to be used for decryption mirroring. | 1. Select **Network > Interfaces > Ethernet**.<br>2. Select the Ethernet interface that you want to configure for decryption port mirroring.<br>3. Select **Decrypt Mirror** as the **Interface Type**.<br>This interface type will appear only if the Decryption Port Mirror license is installed.<br>4. Click **OK** to save. |
| Step 5 | Enable mirroring of decrypted traffic. | 1. Select **Objects > Decryption Profile**.<br>2. Select an **Interface** to be used for **Decryption Mirroring**.<br>The **Interface** drop-down contains all Ethernet interfaces that have been defined as the type: **Decrypt Mirror**.<br>3. Specify whether to mirror decrypted traffic before or after policy enforcement.<br>By default, the firewall will mirror all decrypted traffic to the interface before security policies lookup, which allows you to replay events and analyze traffic that generates a threat or triggers a drop action. If you want to only mirror decrypted traffic after security policy enforcement, select the **Forwarded Only** check box. With this option, only traffic that is forwarded through the firewall is mirrored. This option is useful if you are forwarding the decrypted traffic to other threat detection devices, such as a DLP device or another intrusion prevention system (IPS).<br>4. Click **OK** to save the decryption profile. |
| Step 6 | Attach the decryption profile rule (with decryption port mirroring enabled) to a decryption policy rule. All traffic decrypted based on the policy rule is mirrored. | 1. Select **Policies > Decryption**.<br>2. Click **Add** to configure a decryption policy or select an existing decryption policy to edit.<br>3. In the **Options** tab, select **Decrypt** and the **Decryption Profile** created in Step 4.<br>4. Click **OK** to save the policy. |
| Step 7 | Save the configuration. | Click **Commit**. |

# Temporarily Disable SSL Decryption

In some cases you may want to temporarily disable SSL decryption. For example, if your users are having problems accessing an encrypted site or application, you may want to disable SSL decryption in order to troubleshoot the issue. Although you could disable the associated decryption policies, modifying the policies is a configuration change that requires a Commit. Instead, use the following command to temporarily disable SSL decryption and then re-enable it after you finish troubleshooting. This command does not require a commit and it does not persist in your configuration after a reboot.

| **Temporarily Disable SSL Decryption** | |

# URL Filtering Overview

The Palo Alto Networks URL filtering solution compliments App-ID by enabling you to configure the firewall to identify and control access to web (HTTP and HTTPS) traffic and to protect your network from attack.

With URL Filtering enabled, all web traffic is compared against the URL filtering database, which contains a listing of millions of websites that have been categorized into approximately 60-80 categories. You can use these URL categories as a match criteria in policies (Captive Portal, Decryption, Security, and QoS) or attach them as URL filtering profiles in security policy, to safely enable web access and control the traffic that traverses your network.

Although the Palo Alto Networks URL filtering solution supports both BrightCloud and PAN-DB, only the PAN-DB URL filtering solution allows you to choose between the *PAN-DB Public Cloud* and the *PAN-DB Private Cloud*. Use the public cloud solution if the Palo Alto Networks next-generation firewalls on your network can directly access the Internet. If the network security requirements in your enterprise prohibit the firewalls from directly accessing the Internet, you can deploy a PAN-DB private cloud on one or more M-500 appliances that function as PAN-DB servers within your network.

- URL Filtering Vendors
- Interaction Between App-ID and URL Categories
- PAN-DB Private Cloud

 © Palo Alto Networks, Inc.

## URL Filtering Vendors

Palo Alto Networks firewalls support two URL filtering vendors:

- **PAN-DB**—A Palo Alto Networks developed URL filtering database that is tightly integrated into PAN-OS and the Palo Alto Networks threat intelligence cloud. PAN-DB provides high-performance local caching for maximum inline performance on URL lookups, and offers coverage against malicious URLs and IP addresses. As WildFire, which is a part of the Palo Alto Networks threat intelligence cloud, identifies unknown malware, zero-day exploits, and advanced persistent threats (APTs), the PAN-DB database is updated with information on malicious URLs so that you can block malware downloads, and disable Command and Control (C&C) communications to protect your network from cyber threats.

  To view a list of PAN-DB URL filtering categories, refer to https://urlfiltering.paloaltonetworks.com/CategoryList.aspx.

- **BrightCloud**—A third-party URL database that is owned by Webroot, Inc. and is integrated into PAN-OS firewalls. For information on the BrightCloud URL database, visit http://brightcloud.com.

For instructions on configuring the firewall to use one of the supported URL Filtering vendors, see Enable a URL Filtering Vendor.

## Interaction Between App-ID and URL Categories

The Palo Alto Networks URL filtering solution in combination with App-ID provides unprecedented protection against a full spectrum of cyber attacks, legal, regulatory, productivity, and resource utilization risks. While App-ID gives you control over what applications users can access, URL filtering provides control over related web activity. When combined with User-ID, you can enforce controls based on users and groups.

With today's application landscape and the way many applications use HTTP and HTTPS, you will need to use App-ID, URL filtering, or both in order to define comprehensive web access policies. App-ID signatures are granular and they allow you to identify shifts from one web-based application to another; URL filtering allows you to enforce actions based on a specific website or URL category. For example, while you can use URL filtering to control access to Facebook and/or LinkedIn, URL filtering cannot block the use of related applications such as email, chat, or other any new applications that are introduced after you implement policy. When combined with App-ID, you can control the use of related applications because of the granular application signatures that can identify each application and regulate access to Facebook while blocking access to Facebook chat, when defined in policy.

You can also use URL categories as a match criteria in policies. Instead of creating policies limited to either allow all or block all behavior, URL as a match criteria permits exception-based behavior and gives you more granular policy enforcement capabilities. For example, deny access to malware and hacking sites for all users, but allow access to users that belong to the IT-security group.

For some examples, see URL Filtering Use Case Examples.

 © Palo Alto Networks, Inc.

## PAN-DB Private Cloud

The PAN-DB private cloud is an on-premise solution that is suitable for organizations that prohibit or restrict the use of the PAN-DB public cloud service. With this on-premise solution, you can deploy one or more M-500 appliances as PAN-DB servers within your network or data center. The firewalls query the PAN-DB private cloud to perform URL lookups, instead of accessing the PAN-DB public cloud.

The process for performing URL lookups, in both the private and the public cloud is the same for the firewalls on the network. By default, the firewall is configured to access the public PAN-DB cloud. If you deploy a PAN-DB private cloud, you must configure the firewalls with a list of IP addresses or FQDNs to access the server(s) in the private cloud.

Firewalls running PAN-OS 5.0 or later versions can communicate with the PAN-DB private cloud.

When you Set Up the PAN-DB Private Cloud, you can either configure the M-500 appliance(s) to have direct Internet access or keep it completely offline. Because the M-500 appliance requires database and content updates to perform URL lookups, if the appliance does not have an active Internet connection, you must manually download the updates to a server on your network and then, import the updates using SCP into each M-500 appliance in the PAN-DB private cloud. In addition, the appliances must be able to obtain the seed database and any other regular or critical content updates for the firewalls that it services.

To authenticate the firewalls that connect to the PAN-DB private cloud, a set of default server certificates are packaged with the appliance; you cannot import or use another server certificate for authenticating the firewalls. If you change the hostname on the M-500 appliance, the appliance automatically generates a new set of certificates to authenticate the firewalls.

- M-500 Appliance for PAN-DB Private Cloud
- Differences Between the PAN-DB Public Cloud and PAN-DB Private Cloud

### M-500 Appliance for PAN-DB Private Cloud

To deploy a PAN-DB private cloud, you need one or more M-500 appliances. The M-500 appliance ships in Panorama mode, and to be deployed as PAN-DB private cloud you must set it up to operate in PAN-URL-DB mode. In the PAN-URL-DB mode, the appliance provides URL categorization services for enterprises that do not want to use the PAN-DB public cloud.

The M-500 appliance when deployed as a PAN-DB private cloud uses two ports- MGT (Eth0) and Eth1; Eth2 is not available for use. The management port is used for administrative access to the appliance and for obtaining the latest content updates from the PAN-DB public cloud or from a server on your network. For communication between the PAN-DB private cloud and the firewalls on the network, you can use the MGT port or Eth1.

The M-100 appliance cannot be deployed as a PAN-DB private cloud.

The M-500 appliance in PAN-URL-DB mode:

- Does not have a web interface, it only supports a command-line interface (CLI).

- Cannot be managed by Panorama.
- Cannot be deployed in a high availability pair.
- Does not require a URL Filtering license. The firewalls, must have a valid PAN-DB URL Filtering license to connect with and query the PAN-DB private cloud.
- Ships with a set of default server certificates that are used to authenticate the firewalls that connect to the PAN-DB private cloud. You cannot import or use another server certificate for authenticating the firewalls. If you change the hostname on the M-500 appliance, the appliance automatically generates a new set of certificates to authenticate the firewalls that it services.
- Can be reset to Panorama mode only. If you want to deploy the appliance as a dedicated Log Collector, switch to Panorama mode and then set it in log collector mode.

## Differences Between the PAN-DB Public Cloud and PAN-DB Private Cloud

| Differences | PAN-DB Public Cloud | PAN-DB Private Cloud |
|---|---|---|
| Content and Database Updates | Content (regular and critical) updates and full database updates are published multiple times during the day. The firewall checks for critical updates whenever it queries the cloud servers for URL lookups. | Content updates and full URL database updates are available once a day during the work week. |
| URL Categorization Requests | Submit URL categorization change requests using the following options:<br>• Palo Alto Networks Test A Site website.<br>• URL filtering profile setup page on the firewall.<br>• URL filtering log on the firewall. | Submit URL categorization change requests only using the Palo Alto Networks Test A Site website. |
| Unresolved URL Queries | If the firewall cannot resolve a URL query, the request is sent to the servers in the public cloud. | If the firewall cannot resolve a query, the request is sent to the M-500 appliance(s) in the PAN-DB private cloud. If there is no match for the URL, the PAN-DB private cloud sends a category *unknown* response to the firewall; the request is not sent to the public cloud unless you have configured the M-500 appliance to access the PAN-DB public cloud.<br>If the M-500 appliance(s) that constitute your PAN-DB private cloud is configured to be completely offline, it does not send any data or analytics to the public cloud. |

# URL Filtering Concepts

- URL Categories
- URL Filtering Profile
- URL Filtering Profile Actions
- Block and Allow Lists
- Safe Search Enforcement
- Container Pages
- HTTP Header Logging
- URL Filtering Response Pages
- URL Category as Policy Match Criteria

© Palo Alto Networks, Inc.

## URL Categories

Each website defined in the URL filtering database is assigned one of approximately 60 different URL categories. There are two ways to make use of URL categorization on the firewall:

- **Block or allow traffic based on URL category**—You can create a URL Filtering profile that specifies an action for each URL category and attach the profile to a policy. Traffic that matches the policy would then be subject to the URL filtering settings in the profile. For example, to block all gaming websites you would set the block action for the URL category *games* in the URL profile and attach it to the security policy rule(s) that allow web access. See Configure URL Filtering for more information.
- **Match traffic based on URL category for policy enforcement**—If you want a specific policy rule to apply only to web traffic to sites in a specific category, you would add the category as match criteria when you create the policy rule. For example, you could use the URL category *streaming-media* in a QoS policy to apply bandwidth controls to all websites that are categorized as streaming media. See URL Category as Policy Match Criteria for more information.

By grouping websites into categories, it makes it easy to define actions based on certain types of websites. In addition to the standard URL categories, there are three additional categories:

| | |
|---|---|
| not-resolved | Indicates that the website was not found in the local URL filtering database and the firewall was unable to connect to the cloud database to check the category. When a URL category lookup is performed, the firewall first checks the dataplane cache for the URL; if no match is found, it checks the management plane cache, and if no match is found there, it queries the URL database in the cloud. In the case of the PAN-DB private cloud, the URL database in the cloud is not used for queries.<br>Setting the action to block for traffic that is categorized as *not-resolved*, may be very disruptive to users. You could set the action as **continue**, so that users you can notify users that they are accessing a site that is blocked by company policy and provide the option to read the disclaimer and continue to the website.<br>For more information on troubleshooting lookup issues, see Troubleshoot URL Filtering. |
| private-ip-addresses | Indicates that the website is a single domain (no sub-domains), the IP address is in the private IP range, or the URL root domain is unknown to the cloud. |
| unknown | The website has not yet been categorized, so it does not exist in the URL filtering database on the firewall or in the URL cloud database.<br>When deciding on what action to take for traffic categorized as *unknown*, be aware that setting the action to block may be very disruptive to users because there could be a lot of valid sites that are not in the URL database yet. If you do want a very strict policy, you could block this category, so websites that do not exist in the URL database cannot be accessed.<br>See Configure URL Filtering. |

 © Palo Alto Networks, Inc.

## URL Filtering Profile

A URL filtering profile is a collection of URL filtering controls that are applied to individual security policy rules to enforce your web access policy. The firewall comes with a default profile that is configured to block threat-prone categories, such as malware, phishing, and adult. You can use the default profile in a security policy, clone it to be used as a starting point for new URL filtering profiles, or add a new URL filtering profile that will have all categories set to allow for visibility into the traffic on your network. You can then customize the newly added URL profiles and add lists of specific websites that should always be blocked or allowed, which provides more granular control over URL categories. For example, you may want to block social-networking sites, but allow some websites that are part of the social-networking category.

- URL Filtering Profile Actions
- Block and Allow Lists
- Safe Search Enforcement
- Container Pages
- HTTP Header Logging

© Palo Alto Networks, Inc.

## URL Filtering Profile Actions

The URL Filtering profile specifies an action for each known URL category. By default, all URL categories are set to allow when you Create a new URL Filtering profile. This means that the users will be able to browse to all sites freely and the traffic will not be logged. The firewall also comes predefined default URL filtering profile that allows access to all categories except the following threat-prone categories, which it blocks: abused-drugs, adult, gambling, hacking, malware, phishing, questionable, and weapons.

As a best practice, if you want to create a custom URL Filtering category, clone the default URL filtering profile and change the action in all allow categories to either alert or continue so that you have visibility into the traffic. It is also a best practice to set the proxy-avoidance-and-anonymizers category to block.

| Action | Description |
|---|---|
| **alert** | The website is allowed and a log entry is generated in the URL filtering log. |
| **allow** | The website is allowed and no log entry is generated. |
| **block** | The website is blocked and the user will see a response page and will not be able to continue to the website. A log entry is generated in the URL filtering log. |
| **continue** | The user will be prompted with a response page indicating that the site has been blocked due to company policy, but the user is prompted with the option to continue to the website. The **continue** action is typically used for categories that are considered benign and is used to improve the user experience by giving them the option to continue if they feel the site is incorrectly categorized. The response page message can be customized to contain details specific to your company. A log entry is generated in the URL filtering log.<br> The Continue page will not be displayed properly on client machines that are configured to use a proxy server. |
| **override** | The user will see a response page indicating that a password is required to allow access to websites in the given category. With this option, the security admin or helpdesk person would provide a password granting temporary access to all websites in the given category. A log entry is generated in the URL filtering log. See Configure URL Admin Override.<br> The Override page will not be displayed properly on client machines that are configured to use a proxy server. |
| **none** | The **none** action only applies to custom URL categories. Select **none** to ensure that if multiple URL profiles exist, the custom category will not have any impact on other profiles. For example, if you have two URL profiles and the custom URL category is set to **block** in one of the profiles, the other profile should have the action set to **none** if you do not want it to apply.<br>Also, in order to delete a custom URL category, it must be set to **none** in any profile where it is used. |

 © Palo Alto Networks, Inc.

## Block and Allow Lists

In some cases you might want to block a category, but allow a few specific sites in that category. Alternatively, you might want to allow some categories, but block individual sites in the category. You do this by adding the IP addresses or URLs of these sites in the Block list and Allow list sections of the URL Filtering profile to Define websites that should always be blocked or allowed. When entering URLs in the Block List or Allow List, enter each URL or IP address in a new row separated by a new line. When using wildcards in the URLs, follow these rules:

- Do not include HTTP and HTTPS when defining URLs. For example, enter www.paloaltonetworks.com or paloaltonetworks.com instead of https://www.paloaltonetworks.com.
- Entries in the block list must be an exact match and are case-insensitive.

  For example: If you want to prevent a user from accessing any website within the domain paloaltonetworks.com, you would also add *.paloaltonetworks.com, so whatever domain prefix (http://, www, or a sub-domain prefix such as mail.paloaltonetworks.com) is added to the address, the specified action will be taken. The same applies to the sub-domain suffix; if you want to block paloaltonetworks.com/en/US, you would need to add paloaltonetworks.com/* as well.

  Further, if you want to limit access to a domain suffix such as `paloaltonetworks.com.au`, you must add a `/`, so that the match restricts a dot that follows `.com.` In this case, you need to add the entry as `*.paloaltonetworks.com/`

  Block and allow lists support wildcard patterns. The following characters are considered separators:

  .

  /

  ?

  &

  =

  ;

  +

  Every substring that is separated by the characters listed above is considered a token. A token can be any number of ASCII characters that does not contain any separator character or *. For example, the following patterns are valid:

  *.yahoo.com (tokens are: "*", "yahoo" and "com")

  www.*.com (tokens are: "www", "*" and "com")

  www.yahoo.com/search=* (tokens are: "www", "yahoo", "com", "search", "*")

  The following patterns are invalid because the character "*" is not the only character in the token.

  ww*.yahoo.com

  www.y*.com

## Safe Search Enforcement

Many search engines have a safe search setting that filters out adult images and videos in search query return traffic. On the firewall, you can Enable Safe Search Enforcement so that the firewall will block search results if the end user is not using the strictest safe search settings in the search query. The firewall can enforce safe search for the following search providers: Google, Yahoo, Bing, Yandex, and YouTube. This is a best-effort setting and is not guaranteed by the search providers to work with every website.

To use this feature you must enable the **Safe Search Enforcement** option in a URL filtering profile and attach it to a security policy rule.The firewall will then block any matching search query return traffic that is not using the strictest safe search settings. There are two methods for blocking the search results:

- Block Search Results that are not Using Strict Safe Search Settings—When an end user attempts to perform a search without first enabling the strictest safe search settings, the firewall blocks the search query results and displays the URL Filtering Safe Search Block Page. By default, this page will provide a URL to the search provider settings for configuring safe search.
- Enable Transparent Safe Search Enforcement—When an end user attempts to perform a search without first enabling the strict safe search settings, the firewall blocks the search results with an HTTP 503 status code and redirects the search query to a URL that includes the safe search parameters. You enable this functionality by importing a new URL Filtering Safe Search Block Page containing the JavaScript for rewriting the search URL to include the strict safe search parameters. In this configuration, users will not see the block page, but will instead be automatically redirected to a search query that enforces the strictest safe search options. This safe search enforcement method requires content release version 475 or later and is only supported for Google, Yahoo, and Bing searches.

Also, because most search providers now use SSL to return search results, you must also configure a Decryption policy rule for the search traffic to enable the firewall to inspect the search traffic and enforce safe search.

Safe search enforcement enhancements and support for new search providers is periodically added in content releases. This information is detailed in the Application and Threat Content Release Notes. How sites are judged to be safe or unsafe is performed by each search provider, not by Palo Alto Networks.

Safe search settings differ by search provider as detailed in Table: Search Provider Safe Search Settings.

 © Palo Alto Networks, Inc.

**Table: Search Provider Safe Search Settings**

| Search Provider | Safe Search Setting Description |
|---|---|
| Google/YouTube | Offers safe search on individual computers or network-wide through Google's safe search virtual IP address:<br><br>**Safe Search Enforcement for Google Searches on Individual Computers**<br><br>In the Google Search Settings, the **Filter explicit results** setting enables safe search functionality. When enabled, the setting is stored in a browser cookie as `FF=` and passed to the server each time the user performs a Google search.<br><br>Appending `safe=active` to a Google search query URL also enables the strictest safe search settings.<br><br>**Safe Search Enforcement for Google and YouTube Searches using a Virtual IP Address**<br><br>Google provides servers that Lock SafeSearch (forcesafesearch.google.com) settings in every Google and YouTube search. By adding a DNS entry for `www.google.com` and `www.youtube.com` (and other relevant Google and YouTube country subdomains) that includes a CNAME record pointing to `forcesafesearch.google.com` to your DNS server configuration, you can ensure that all users on your network are using strict safe search settings every time they perform a Google or YouTube search. Keep in mind, however, that this solution is not compatible with Safe Search Enforcement on the firewall. Therefore, if you are using this option to force safe search on Google, the best practice is to block access to other search engines on the firewall by creating custom URL categories and adding them to the block list in the URL filtering profile.<br><br>If you plan to use the Google Lock SafeSearch solution, consider configuring DNS Proxy (**Network > DNS Proxy**) and setting the inheritance source as the Layer 3 interface on which the firewall receives DNS settings from service provider via DHCP. You would configure the DNS proxy with **Static Entries** for www.google.com and www.youtube.com, using the local IP address for the forcesafesearch.google.com server. |
| Yahoo | Offers safe search on individual computers only. The Yahoo Search Preferences includes three SafeSearch settings: **Strict**, **Moderate**, or **Off**. When enabled, the setting is stored in a browser cookie as `vm=` and passed to the server each time the user performs a Yahoo search.<br><br>Appending `vm=r` to a Yahoo search query URL also enables the strictest safe search settings.<br><br>When performing a search on Yahoo Japan (yahoo.co.jp) while logged into a Yahoo account, end users must also enable the **SafeSearch Lock** option. |
| Bing | Offers safe search on individual computers or through their Bing in the Classroom program. The Bing Settings include three SafeSearch settings: **Strict**, **Moderate**, or **Off**. When enabled, the setting is stored in a browser cookie as `adlt=` and passed to the server each time the user performs a Bing search.<br><br>Appending `adlt=strict` to a Bing search query URL also enables the strictest safe search settings.<br><br>The Bing SSL search engine does not enforce the safe search URL parameters and you should therefore consider blocking Bing over SSL for full safe search enforcement. |

## Container Pages

A container page is the main page that a user accesses when visiting a website, but additional websites may be loaded within the main page. If the **Log Container page only** option is enabled in the URL filtering profile, only the main container page will be logged, not subsequent pages that may be loaded within the container page. Because URL filtering can potentially generate a lot of log entries, you may want to turn on this option, so log entries will only contain those URIs where the requested page file name matches the specific mime-types. The default set includes the following mime-types:

- application/pdf
- application/soap+xml
- application/xhtml+xml
- text/html
- text/plain
- text/xml

If you have enabled the **Log container page only** option, there may not always be a correlated URL log entry for threats detected by antivirus or vulnerability protection.

 © Palo Alto Networks, Inc.

## HTTP Header Logging

URL filtering provides visibility and control over web traffic on your network. For improved visibility into web content, you can configure the URL Filtering profile to log HTTP header attributes included in a web request. When a client requests a web page, the HTTP header includes the user agent, referer, and x-forwarded-for fields as attribute-value pairs and forwards them to the web server. When enabled for logging HTTP headers, the firewall logs the following attribute-value pairs in the URL Filtering logs:

| Attribute | Description |
|---|---|
| User-Agent | The web browser that the user used to access the URL, for example, Internet Explorer. This information is sent in the HTTP request to the server. |
| Referer | The URL of the web page that linked the user to another web page; it is the source that redirected (referred) the user to the web page that is being requested. |
| X-Forwarded-For (XFF) | The option in the HTTP request header field that preserves the IP address of the user who requested the web page. If you have a proxy server on your network, the XFF allows you to identify the IP address of the user who requested the content, instead of only recording the proxy server's IP address as source IP address that requested the web page. |

## URL Filtering Response Pages

The firewall provides three predefined response pages that display by default when a user attempts to browse to a site in a category that is configured with one of the block actions in the URL Filtering Profile (block, continue, or override) or when Safe Search Enforcement is enabled:

- **URL Filtering and Category Match Block Page**—Access blocked by a URL Filtering Profile or because the URL category is blocked by a security policy.

- **URL Filtering Continue and Override Page**—Page with initial block policy that allows users to bypass the block by clicking **Continue**. With URL Admin Override enabled, (Configure URL Admin Override), after clicking **Continue**, the user must supply a password to override the policy that blocks the URL.

- **URL Filtering Safe Search Block Page**—Access blocked by a security policy with a URL filtering profile that has the Safe Search Enforcement option enabled (see Enable Safe Search Enforcement). The user will see this page if a search is performed using Google, Bing, Yahoo, or Yandex and their browser or search engine account setting for Safe Search is not set to strict.

You can either use the predefined pages, or you can Customize the URL Filtering Response Pages to communicate your specific acceptable use policies and/or corporate branding. In addition, you can use the URL Filtering Response Page Variables for substitution at the time of the block event or add one of the supported Response Page References to external images, sounds, or style sheets.

 © Palo Alto Networks, Inc.

**URL Filtering Response Page Variables**

| Variable | Usage |
|---|---|
| <user/> | The firewall replaces the variable with the username (if available via User-ID) or IP address of the user when displaying the response page. |
| <url/> | The firewall replaces the variable with the requested URL when displaying the response page. |
| <category/> | The firewall replaces the variable with the URL filtering category of the blocked request. |
| <pan_form/> | HTML code for displaying the **Continue** button on the URL Filtering Continue and Override page. |

You can also add code that triggers the firewall to display different messages depending on what URL category the user is attempting to access. For example, the following code snippet from a response page specifies to display Message 1 if the URL category is games, Message 2 if the category is travel, or Message 3 if the category is kids:

```
var cat = "<category/>";
switch(cat)
{
   case 'games':
      document.getElementById("warningText").innerHTML = "Message 1";
      break;
   case 'travel':
      document.getElementById("warningText").innerHTML = "Message 2";
      break;
   case 'kids':
      document.getElementById("warningText").innerHTML = "Message 3";
      break;
}
```

Only a single HTML page can be loaded into each virtual system for each type of block page. However, other resources such as images, sounds, and cascading style sheets (CSS files) can be loaded from other servers at the time the response page is displayed in the browser. All references must include a fully qualified URL.

**Response Page References**

| Reference Type | Example HTML Code |
|---|---|
| Image | `<img src="http://virginiadot.org/images/Stop-Sign-gif.gif">` |
| Sound | `<embed src="http://simplythebest.net/sounds/WAV/WAV_files/ movie_WAV_files/ do_not_go.wav" volume="100" hidden="true" autostart="true">` |
| Style Sheet | `<link href="http://example.com/style.css" rel="stylesheet" type="text/css" />` |
| Hyperlink | `<a href="http://en.wikipedia.org/wiki/Acceptable_use_policy">View Corporate Policy</a>` |

## URL Category as Policy Match Criteria

Use URL Categories as a match criteria in a policy rule for more granular enforcement. For example, suppose you have configured Decryption, but you want to exclude traffic to certain types of websites (for example, healthcare or financial services) from being decrypted. In this case you could create a decryption policy rule that matches those categories and set the action to no-decrypt. By placing this rule above the rule to decrypt all trafic, you can ensure that web traffic with URL categories that match the no-decrypt rule, and all other traffic would match the subsequent rule.

The following table describes the policy types that accept URL category as match criteria:

| Policy Type | Description |
|---|---|
| Captive Portal | To ensure that users authenticate before being allowed access to a specific category, you can attach a URL category as a match criterion for the Captive Portal policy. |
| Decryption | Decryption policies can use URL categories as match criteria to determine if specified websites should be decrypted or not. For example, if you have a decryption policy with the action decrypt for all traffic between two zones, there may be specific website categories, such as *financial-services* and/or *health-and-medicine*, that should not be decrypted. In this case, you would create a new decryption policy with the action of *no-decrypt* that precedes the decrypt policy and then defines a list of URL categories as match criteria for the policy. By doing this, each URL category that is part of the no-decrypt policy will not be decrypted. You could also configure a custom URL category to define your own list of URLs that can then be used in the no-decrypt policy. |
| QoS | QoS policies can use URL categories to allocate throughput levels for specific website categories. For example, you may want to allow the streaming-media category, but limit throughput by adding the URL category as match criteria to the QoS policy. |
| Security | In security policies you can use URL categories both as a match criteria in the **Service/URL Category** tab, and in URL filtering profiles that are attached in the **Actions** tab.<br>If for example, the IT-security group in your company needs access to the hacking category, while all other users are denied access to the category, you must create the following rules:<br>• A security rule that allows the IT-Security group to access content categorized as hacking. The security rule references the *hacking* category in the S**ervices/URL Category** tab and IT-Security group in the **Users** tab.<br>• Another security rule that allows general web access for all users. To this rule you attach a URL filtering profile that blocks the hacking category.<br>The policy that allows access to hacking must be listed before the policy that blocks hacking. This is because security policy rules are evaluated top down, so when a user who is part of the security group attempts to access a hacking site, the policy rule that allows access is evaluated first and will allow the user access to the hacking sites. Users from all other groups are evaluated against the general web access rule which blocks access to the hacking sites. |

# PAN-DB Categorization

▲ PAN-DB URL Categorization Components
▲ PAN-DB URL Categorization Workflow

## PAN-DB URL Categorization Components

The following table describes the PAN-DB components in detail. The BrightCloud system works similarly, but does not use an initial seed database.

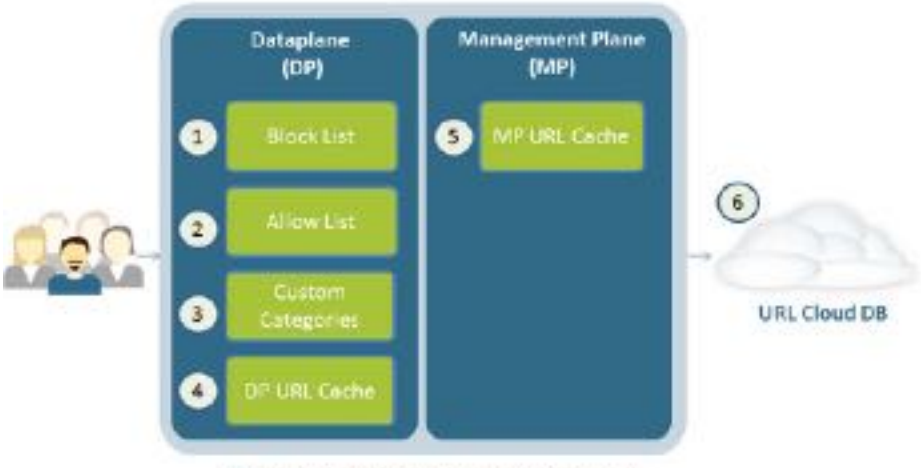
| Component | Description |
|---|---|
| URL Filtering Seed Database | The initial seed database downloaded to the firewall is a small subset of the database that is maintained on the Palo Alto Networks URL cloud servers. The reason this is done is because the full database contains millions of URLs and many of these URLs may never be accessed by your users. When downloading the initial seed database, you select a region (North America, Europe, APAC, Japan). Each region contains a subset of URLs most accessed for the given region. This allows the firewall to store a much smaller URL database for better URL lookup performance. If a user accesses a website that is not in the local URL database, the firewall queries the full cloud database and then adds the new URL to the local database. This way the local database on the firewall is continually populated/customized based on actual user activity.<br>Note that re-downloading the PAN-DB seed database or switching the URL database vendor from PAN-DB to BrightCloud will clear the local database. |
| Cloud Service<br>See Differences Between the PAN-DB Public Cloud and PAN-DB Private Cloud, for information on the private cloud. | The PAN-DB cloud service is implemented using Amazon Web Services (AWS). AWS provides a distributed, high-performance, and stable environment for seed database downloads and URL lookups for Palo Alto Networks firewalls and communication is performed over SSL. The AWS cloud systems hold the entire PAN-DB and is updated as new URLs are identified. The PAN-DB cloud service supports an automated mechanism to update the firewall's local URL database if the version does not match. Each time the firewall queries the cloud servers for URL lookups, it will also check for critical updates. If there have been no queries to the cloud servers for more than 30 minutes, the firewall will check for updates on the cloud systems.<br>The cloud system also provides a mechanism to submit URL category change requests. This is performed through the test-a-site service and is available directly from the device (URL filtering profile setup) and from the Palo Alto Networks Test A Site website. You can also submit a URL categorization change request directly from the URL filtering log on the firewall in the log details section. |

| Component | Description |
|---|---|
| Management Plane (MP) URL Cache | When you activate PAN-DB on the firewall, the firewall downloads a seed database from one of the PAN-DB cloud servers to initially populate the local cache for improved lookup performance. Each regional seed database contains the top URLs for the region and the size of the seed database (number of URL entries) also depends on the platform. The URL MP cache is automatically written to the firewall's local drive every eight hours, before the firewall is rebooted, or when the cloud upgrades the URL database version on the firewall. After rebooting the firewall, the file that was saved to the local drive will be loaded to the MP cache. A least recently used (LRU) mechanism is also implemented in the URL MP cache in case the cache is full. If the cache becomes full, the URLs that have been accessed the least will be replaced by the newer URLs. |
| Dataplane (DP) URL Cache | This is a subset of the MP cache and is a customized, dynamic URL database that is stored in the dataplane (DP) and is used to improve URL lookup performance. The URL DP cache is cleared at each firewall reboot. The number of URLs that are stored in the URL DP cache varies by hardware platform and the current URLs stored in the TRIE (data structure). A least recently used (LRU) mechanism is implemented in the DP cache in case the cache is full. If the cache becomes full, the URLs that have been accessed the least will be replaced by the newer URLs. Entries in the URL DP cache expire after a specified period of time and the expiration period cannot be changed by the administrator. |

 © Palo Alto Networks, Inc.

## PAN-DB URL Categorization Workflow

When a user attempts to access a URL and the URL category needs to be determined, the firewall will compare the URL with the following components (in order) until a match has been found:



URL Categorization Resolution Process Flow

If a URL query matches an expired entry in the URL DP cache, the cache responds with the expired category, but also sends a URL categorization query to the management plane. This is done to avoid unnecessary delays in the DP, assuming that the frequency of changing categories is low. Similarly, in the URL MP cache, if a URL query from the DP matches an expired entry in the MP, the MP responds to the DP with the expired category and will also send a URL categorization request to the cloud service. Upon getting the response from the cloud, the firewall will resend the updated response to the DP.

As new URLs and categories are defined or if critical updates are needed, the cloud database will be updated. Each time the firewall queries the cloud for a URL lookup or if no cloud lookups have occurred for 30 minutes, the database versions on the firewall be compared and if they do not match, an incremental update will be performed.

© Palo Alto Networks, Inc.

# Enable a URL Filtering Vendor

To enable URL filtering on a firewall, you must purchase and activate a URL Filtering license for one of the supported URL Filtering Vendors and then install the database for the vendor you selected.

Starting with PAN-OS 6.0, firewalls managed by Panorama do not need to be running the same URL filtering vendor that is configured on Panorama. For firewalls running PAN-OS 6.0 or later, when a mismatch is detected between the vendor enabled on the firewalls and what is enabled on Panorama, the firewalls can automatically migrate URL categories and/or URL profiles to (one or more) categories that align with that of the vendor enabled on it. For guidance on how to configure URL Filtering on Panorama if you are managing firewalls running different PAN-OS versions, refer to the Panorama Administrator's Guide.

If you have valid licenses for both PAN-DB and BrightCloud, activating the PAN-DB license automatically deactivates the BrightCloud license (and vice versa). At a time, only one URL filtering license can be active on a firewall.

- Enable PAN-DB URL Filtering
- Enable BrightCloud URL Filtering

© Palo Alto Networks, Inc.

# Enable PAN-DB URL Filtering

| Enable PAN-DB URL Filtering | |
|---|---|
| Step 1 Obtain and install a PAN-DB URL filtering license and confirm that it is installed.<br><br>If the license expires, PAN-DB URL Filtering continues to work based on the URL category information that exists in the dataplane and management plane caches. However, URL cloud lookups and other cloud-based updates will not function until you install a valid license. | 1. Select **Device > Licenses** and, in the License Management section, select the license installation method:<br>• **Retrieve license keys from license server**<br>• **Activate feature using authorization code**<br>• **Manually upload license key**<br>2. After installing the license, confirm that the PAN-DB URL Filtering section, **Date Expires** field, displays a valid date. |
| Step 2 Download the initial seed database and activate PAN-DB URL Filtering.<br><br>The firewall must have Internet access; you cannot manually upload the PAN-DB seed database. | 1. In the PAN-DB URL Filtering section, **Download Status** field, click **Download Now**.<br>2. Choose a region (North America, Europe, APAC, Japan) and then click **OK** to start the download.<br>3. After the download completes, click **Activate**.<br><br>If PAN-DB is already the active URL filtering vendor and you click **Re-Download**, this will reactivate PAN-DB by clearing the dataplane and management plane caches and replacing them with the contents of the new seed database. You should avoid doing this unless it is necessary, as you will lose your cache, which is customized based on the web traffic that has previously passed through the firewall based on user activity. |
| Step 3 Schedule the firewall to download dynamic updates for Applications and Threats.<br><br>A Threat Prevention license is required to receive content updates, which covers Antivirus and Applications and Threats. | 1. Select **Device > Dynamic Updates**.<br>2. In the Schedule field in the Applications and Threats section, click the **None** link to schedule periodic updates.<br><br>You can only schedule dynamic updates if the firewall has direct Internet access. If updates are already scheduled in a section, the link text displays the schedule settings.<br><br>The Applications and Threats updates might contain updates for URL filtering related to the **Safe Search Enforcement** option in the URL filtering profile (**Objects > Security Profiles > URL Filtering**). For example, if Palo Alto Networks adds support for a new search provider vendor or if the method used to detect the Safe Search setting for an existing vendor changes, the Application and Threats updates will include that update. |

# Enable BrightCloud URL Filtering

| Enable BrightCloud URL Filtering | | |
|---|---|---|
| Step 1 | Obtain and install a BrightCloud URL filtering license and confirm that it is installed.<br> BrightCloud has an option in the URL filtering profile (**Objects > Security Profiles > URL Filtering**) to either allow all categories or block all categories if the license expires. | 1. Select **Device > Licenses** and, in the **License Management** section, select the license installation method:<br>• **Activate feature using authorization code**<br>• **Retrieve license keys from license server**<br>• **Manually upload license key**<br>2. After installing the license, confirm that the BrightCloud URL Filtering section, **Date Expires** field, displays a valid date. |
| Step 2 | Install the BrightCloud database.<br>The way you do this depends on whether or not the firewall has direct Internet access. | **Firewall with Direct Internet Access**<br>Select **Device > Licenses** and in the BrightCloud URL Filtering section, Active field, click the **Activate** link to install the BrightCloud database. This operation automatically initiates a system reset.<br>**Firewall without Direct Internet Access**<br>1. Download the BrightCloud database to a host that has Internet access. The firewall must have access to the host:<br>a. On a host with Internet access, go to the Palo Alto Support website (https://support.paloaltonetworks.com) and log in.<br>b. In the Resources section, click **Dynamic Updates**.<br>c. In the BrightCloud Database section, click **Download** and save the file to the host.<br>2. Upload the database to the firewall:<br>a. Log in to the firewall, select **Device > Dynamic Updates** and click **Upload**.<br>b. For the **Type**, select **URL Filtering**.<br>c. Enter the path to the **File** on the host or click **Browse** to find it, then click **OK**. When the Status is **Completed**, click **Close**.<br>3. Install the database:<br>a. Select **Device > Dynamic Updates** and click **Install From File**.<br>b. For the **Type**, select **URL Filtering**. The firewall automatically selects the file you just uploaded.<br>c. Click **OK** and, when the Result is **Succeeded**, click **Close**. |
| Step 3 | Enable cloud lookups for dynamically categorizing a URL if the category is not available on the local BrightCloud database. | 1. Access the PAN-OS CLI.<br>2. Enter the following commands to enable dynamic URL filtering:<br>`configure`<br>`set deviceconfig setting url dynamic-url yes`<br>`commit` |

 © Palo Alto Networks, Inc.

| Enable BrightCloud URL Filtering (Continued) | |
|---|---|
| Step 4 Schedule the firewall to download dynamic updates for Applications and Threats signatures and URL filtering.<br><br>You can only schedule dynamic updates if the firewall has direct Internet access.<br><br>The Applications and Threats updates might contain updates for URL filtering related to the **Safe Search Enforcement** option in the URL filtering profile. For example, if Palo Alto Networks adds support for a new search provider vendor or if the method used to detect the Safe Search setting for an existing vendor changes, the Application and Threats updates will include that update.<br><br>BrightCloud updates include a database of approximately 20 million websites that are stored locally on the firewall. You must schedule URL filtering updates to receive BrightCloud database updates.<br><br> A Threat Prevention license is required to receive Antivirus and Applications and Threats updates. | 1. Select **Device > Dynamic Updates**.<br>2. In the Applications and Threats section, Schedule field, click the **None** link to schedule periodic updates.<br>3. In the URL Filtering section, Schedule field, click the **None** link to schedule periodic updates.<br><br> If updates are already scheduled in a section, the link text displays the schedule settings. |

# Determine URL Filtering Policy Requirements

The recommended practice for deploying URL filtering in your organization is to first start with a passive URL filtering profile that will alert on most categories. After setting the alert action, you can then monitor user web activity for a few days to determine patterns in web traffic. After doing so, you can then make decisions on the websites and website categories that should be controlled.

In the procedure that follows, threat-prone sites will be set to block and the other categories will be set to alert, which will cause all websites traffic to be logged. This may potentially create a large amount of log files, so it is best to do this for initial monitoring purposes to determine the types of websites your users are accessing. After determining the categories that your company approves of, those categories should then be set to allow, which will not generate logs. You can also reduce URL filtering logs by enabling the **Log container page only** option in the URL Filtering profile, so only the main page that matches the category will be logged, not subsequent pages/categories that may be loaded within the container page.

| **Configure and Apply a Passive URL Filtering Profile** | | |
|---|---|---|
| Step 1 | Create a new URL Filtering profile. | 1. Select **Objects > Security Profiles > URL Filtering**.<br>2. Select the default profile and then click **Clone**. The new profile will be named **default-1**.<br>3. Select the **default-1** profile and rename it. For example, rename it to URL-Monitoring. |
| Step 2 | Configure the action for all categories to **alert**, except for threat-prone categories, which should remain blocked.<br><br>To select all items in the category list from a Windows system, click the first category, then hold down the shift key and click the last category—this will select all categories. Hold the control key (ctrl) down and click items that should be deselected. On a Mac, do the same using the shift and command keys. You could also just set all categories to alert and manually change the recommended categories back to block. | 1. In the section that lists all URL categories, select all categories.<br>2. To the right of the *Action* column heading, mouse over and select the down arrow and then select **Set Selected Actions** and choose **alert**.<br>  <br>3. To ensure that you block access to threat-prone sites, select the following categories and then set the action to **block**: abused-drugs, adult, gambling, hacking, malware. phishing, questionable, weapons.<br>4. Click **OK** to save the profile. |
| Step 3 | Apply the URL Filtering profile to the security policy rule(s) that allows web traffic for users. | 1. Select **Policies > Security** and select the appropriate security policy to modify it.<br>2. Select the **Actions** tab and in the **Profile Setting** section, click the drop-down for **URL Filtering** and select the new profile.<br>3. Click **OK** to save. |
| Step 4 | Save the configuration. | Click **Commit**. |

 © Palo Alto Networks, Inc.

| Configure and Apply a Passive URL Filtering Profile (Continued) | | |
|---|---|---|
| Step 5 | View the URL filtering logs to determine all of the website categories that your users are accessing. In this example, some categories are set to block, so those categories will also appear in the logs.<br><br>For information on viewing the logs and generating reports, see Monitor Web Activity. | Select **Monitor > Logs > URL Filtering**. A log entry will be created for any website that exists in the URL filtering database that is in a category that is set to any action other than **allow**. |

# Monitor Web Activity

The ACC, URL filtering logs and reports show all user web activity for URL categories that are set to **alert**, **block**, **continue**, or **override**. By monitoring the logs, you can gain a better understanding of the web activity of your user base to determine a web access policy.

The following topics describe how to monitor web activity:

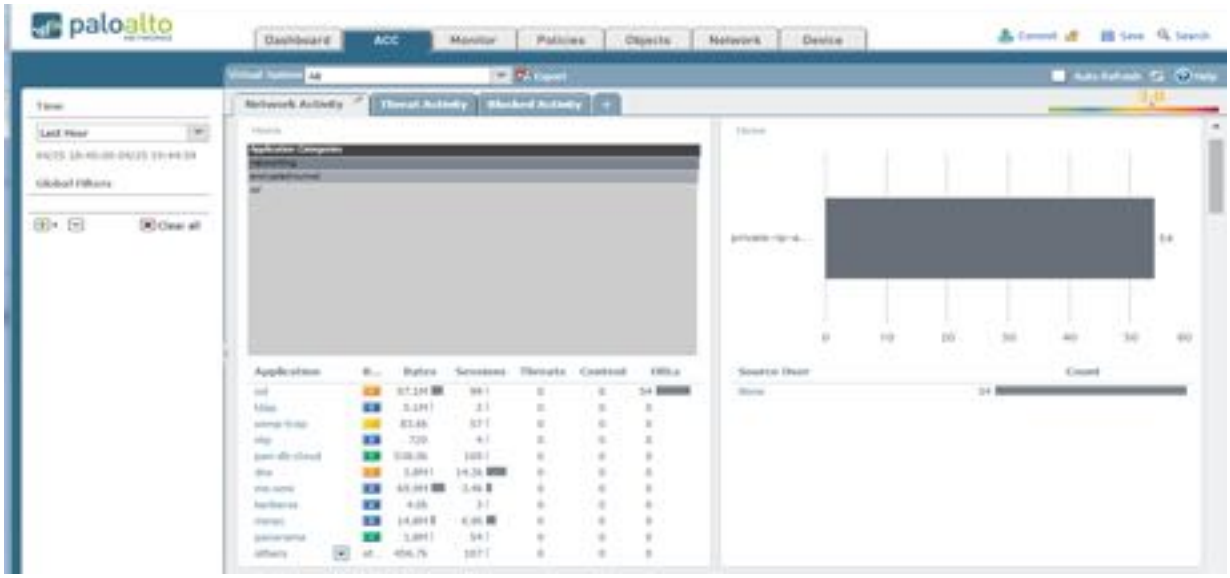
- Monitor Web Activity of Network Users
- View the User Activity Report
- Configure Custom URL Filtering Reports

© Palo Alto Networks, Inc.

## Monitor Web Activity of Network Users

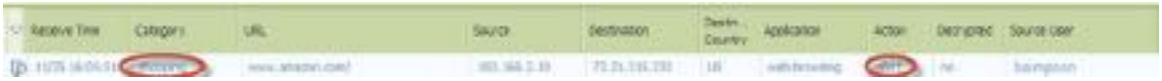
You can use the ACC, and the URL filtering reports and logs that are generated on the firewall to track user activity.

For a quick view of the most common categories users access in your environment, check the **ACC** widgets. Most widgets in the Network Activity tab, allows you to sort on URLs. For example, in the Application Usage widget, you can see that the networking category is the most accessed category, followed by encrypted tunnel, and ssl. You can also view the list of **Threat Activity** and **Blocked Activity** sorted on URLs.

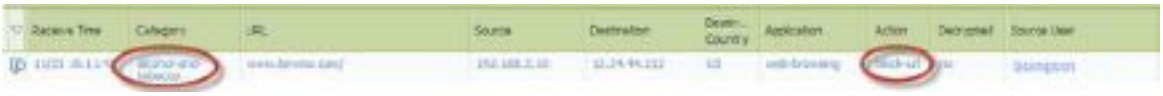


From the ACC, you can directly **Jump to the Logs** or you can navigate to **Monitor > Logs > URL filtering** to view the URL filtering logs. The following bullet points show examples of the URL filtering logs ().

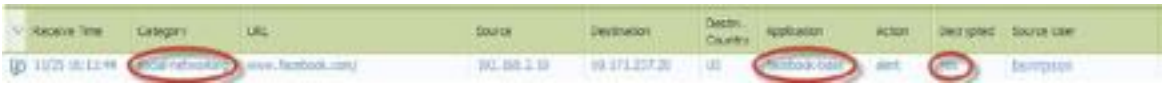
- **Alert log**—In this log, the category is shopping and the action is alert.



- **Block log**—In this log, the category alcohol-and-tobacco was set to block, so the action is block-url and the user will see a response page indicating that the website was blocked.



- **Alert log on encrypted website**—In this example, the category is social-networking and the application is facebook-base, which is required to access the Facebook website and other Facebook applications. Because faceboook.com is always encrypted using SSL, the traffic was decrypted by the firewall, which allows the website to be recognized and controlled if needed.



You can also add several other columns to your URL Filtering log view, such as: to and from zone, content type, and whether or not a packet capture was performed. To modify what columns to display, click the down arrow in any column and select the attribute to display.

To view the complete log details and/or request a category change for the given URL that was accessed, click the log details icon in the first column of the log.

To generate a predefined URL filtering reports on URL categories, URL users, Websites accessed, Blocked categories, and more, select **Monitor > Reports** and under the **URL Filtering Reports** section, select one of the reports. The reports are based on a 24-hour period and the day is selected by choosing a day in the calendar section. You can also export the report to PDF, CSV, or XML.

 © Palo Alto Networks, Inc.

Report shows computer-and-internet-info is the most popular category
Select a report
Select a date

## View the User Activity Report

This report provides a quick method of viewing user or group activity and also provides an option to view browse time activity.

| Generate a User Activity Report | |
|---|---|
| Step 1 Configure a User Activity Report | 1. Select **Monitor > PDF Reports > User Activity Report**.<br>2. Enter a report **Name** and select the report type. Select **User** to generate a report for one person, or select **Group** for a group of users.<br>You must Enable User-ID in order to be able to select user or group names. If User-ID is not configured, you can select the type **User** and enter the IP address of the user's computer.<br>3. Enter the Username/IP address for a user report or enter the group name for a user group report.<br>4. Select the time period. You can select an existing time period, or select **Custom**.<br>5. Select the **Include Detailed Browsing** check box, so browsing information is included in the report.<br> |
| Step 2 Run the user activity report and then download the report. | 1. Click **Run Now**.<br>2. After the report is generated, click the **Download User Activity Report** link.<br>  <br>3. After the report is downloaded, click **Cancel** and then click **OK** to save the report. |

 © Palo Alto Networks, Inc.

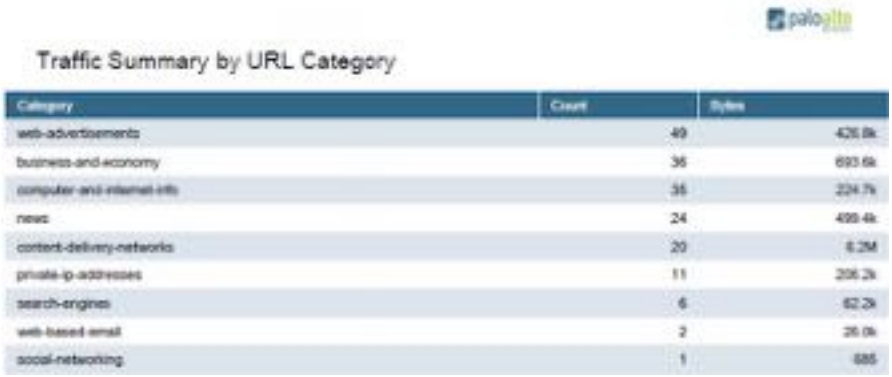
**Generate a User Activity Report (Continued)**

Step 3 View the user activity report by opening the PDF file that was downloaded. The top of the report will contain a table of contents similar to the following:

User Activity Report for 192.168.2.10
Tuesday, December 31, 2013 09:35:47 - 10:35:46

Application Usage 2
Traffic Summary by URL Category 3
Browsing Summary by URL Category 4
Browsing Summary by Website 5
Blocked Browsing Summary by Website 6
Detailed Web Browsing Activity 7

Step 4 Click an item in the table of contents to view details. For example, click *Traffic Summary by URL Category* to view statistics for the selected user or group.



Traffic Summary by URL Category

| Category | Count | Bytes |
|---|---|---|
| web-advertisements | 49 | 426.8k |
| business-and-economy | 36 | 693.6k |
| computer-and-internet-info | 35 | 224.7k |
| news | 24 | 499.4k |
| content-delivery-networks | 20 | 6.2M |
| private-ip-addresses | 11 | 206.2k |
| search-engines | 6 | 62.2k |
| web-based-email | 2 | 26.0k |
| social-networking | 1 | 686 |

## Configure Custom URL Filtering Reports

To generate a detailed report that can also be scheduled, you can configure a custom report and select from a list of all available URL filtering log fields.

| Configure a Custom URL Filtering Report | | |
|---|---|---|
| Step 1 | Add a new custom report. | 1. Select **Monitor > Manage Custom Reports** and click **Add**.<br>2. Enter a report **Name**, for example, My-URL-Custom-Report.<br>3. From the **Database** drop-down, select **URL Log**. |
| Step 2 | Configure report options. | 1. Select the **Time Frame** drop-down and select a range.<br>2. (Optional) To customize how the report is sorted and grouped, select **Sort By** and chose the number of items to display (top 25 for example) and then select **Group By** and select an option such as **Category**, and then select how many groups will be defined.<br>3. In the **Available Columns** list, select the fields to include the report. The following columns are typically used for a URL report:<br>• Action<br>• Category<br>• Destination Country<br>• Source User<br>• URL<br> |
| Step 3 | Run the report to check the results. If the results are satisfactory, set a schedule to run the report automatically. | 1. Click the **Run Now** icon to immediately generate the report that will appear in a new tab.<br>2. (Optional) Click the **Schedule** check box to run the report once per day. This will generate a daily report that details web activity over the last 24 hours. To access the report, select **Monitor > Report** and then expand **Custom Reports** on the right column and select the report. |
| Step 4 | Save the configuration. | Click **Commit**. |

© Palo Alto Networks, Inc.

# Configure URL Filtering

After you Determine URL Filtering Policy Requirements, you should have a basic understanding of what types of websites and website categories your users are accessing. With this information, you are now ready to create custom URL filtering profiles and attach them to the security policy rule(s) that allow web access.

| Configure Website Controls | | |
|---|---|---|
| Step 1 | Create a URL Filtering profile or select an existing one.<br> Because the default URL filtering profile blocks risky and threat-prone content, it is a best practice to clone this profile rather than creating a new profile to preserve these default settings. | 1. Select **Objects > Security Profiles > URL Filtering**.<br>Select the default profile and then click **Clone**. The new profile will be named default-1.<br>2. Select the new profile and rename it. |
| Step 2 | Define how to control access to web content. | In the **Categories** tab, for each category that you want visibility into or control over, select a value from the **Action** column as follows:<br>• If you do not care about traffic to a particular category (that is you neither want to block it nor log it), select **allow**.<br>• For visibility into traffic to sites in a category, select **alert**.<br>• To deny access to traffic that matches the category and to enable logging of the blocked traffic, select **block**.<br>• To require users to click Continue to proceed to a questionable site, select **continue**.<br>• To only allow access if users provide a configured password, select override. For more details on this setting, see Configure URL Admin Override. |
| Step 3 | Define websites that should always be blocked or allowed.<br>For example, to reduce URL filtering logs, you may want add you corporate websites in the allow list, so no logs will be generated for those sites. Or, if there is a website this is being overly used and is not work related in any way, you can add it to the block list.<br>Items in the block list will always be blocked regardless of the action for the associated category, and URLs in the allow list will always be allowed.<br>For more information on the proper format and wildcards usage, see Block and Allow Lists. | 1. In the URL filtering profile, enter URLs or IP addresses in the **Block List** and select an action:<br>• **block**—Block the URL.<br>• **continue**—Prompt users click **Continue** to proceed to the web page.<br>• **override**—The user will be a prompted for a password to continue to the website.<br>• **alert**—Allow the user to access the website and add an alert log entry in the URL log.<br>2. For the **Allow** list, enter IP addresses or URLs that should always be allowed. Each row must be separated by a new line.<br>3. (Optional) Enable Safe Search Enforcement. |

| Configure Website Controls | | |
|---|---|---|
| Step 4 | Modify the setting to log Container Pages only. | The **Log container page only** option is enabled by default so that only the main page that matches the category is logged, not subsequent pages/categories that may be loaded within the container page. To enable logging for all pages/categories, clear the **Log container page only** check box. |
| Step 5 | Enable HTTP Header Logging for one or more of the supported HTTP header fields. | To log an HTTP header field, select one or more of the following fields to log:<br>• **User-Agent**<br>• **Referer**<br>• **X-Forwarded-For** |
| Step 6 | Save the URL filtering profile. | 1. Click **OK**.<br> Optionally, you can Customize the URL Filtering Response Pages.<br>2. Click **Commit**.<br> To test the URL filtering configuration, simply access a website in a category that is set to block or continue to see if the appropriate action is performed. |

 © Palo Alto Networks, Inc.

# Customize the URL Filtering Response Pages

The firewall provides three predefined URL Filtering Response Pages that display by default when a user attempts to browse to a site in a category that is configured with one of the block actions in the URL Filtering Profile (block, continue, or override) or when Safe Search Enforcement blocks a search attempt. However, you can create your own custom response pages with your corporate branding, acceptable use policies, links to your internal resources as follows:

| **Customize the URL Filtering Response Pages** | | |
|---|---|---|
| Step 1 | Export the default response page(s). | 1. Select **Device > Response Pages**.<br>2. Select the link for the URL filtering response page you want to modify.<br>3. Click the response page (predefined or shared) and then click the **Export** link and save the file to your desktop. |
| Step 2 | Edit the exported page. | 1. Using the HTML text editor of your choice, edit the page:<br>• If you want the response page to display custom information about the specific user, URL, or category that was blocked, add one or more of the supported URL Filtering Response Page Variables.<br>• If you want to include custom images (such as your corporate logo), a sound, or style sheet, or link to another URL, for example to a document detailing your acceptable web use policy, include one or more of the supported Response Page References.<br>2. Save the edited page with a new filename. Make sure that the page retains its UTF-8 encoding. For example, in Notepad you would select **UTF-8** from the **Encoding** drop-down in the Save As dialog. |
| Step 3 | Import the customized response page. | 1. Select **Device > Response Pages**.<br>2. Select the link that corresponds to the URL Filtering response page you edited.<br>3. Click **Import** and then enter the path and filename in the **Import File** field or **Browse** to locate the file.<br>4. (Optional) Select the virtual system on which this login page will be used from the **Destination** drop-down or select **shared** to make it available to all virtual systems.<br>5. Click **OK** to import the file. |
| Step 4 | Save the new response page(s). | **Commit** the changes. |
| Step 5 | Verify that the new response page displays. | From a browser, go to the URL that will trigger the response page. For example, to see a modified URL Filtering and Category Match response page, browse to URL that your URL filtering policy is set to block. |

# Configure URL Admin Override

In some cases there may be URL categories that you want to block, but allow certain individuals to browse to on occasion. In this case, you would set the category action to **override** and define a URL admin override password in the firewall Content-ID configuration. When users attempt to browse to the category, they will be required to provide the override password before they are allowed access to the site. Use the following procedure to configure URL admin override:

| **Configure URL Admin Override** | |
|---|---|
| Step 1 Set the URL admin override password. | 1. Select **Device > Setup > Content ID**.<br>2. In the **URL Admin Override** section, click **Add**.<br>3. In the **Location** field, select the virtual system to which this password applies.<br>4. Enter the **Password** and **Confirm Password**.<br>5. Select an **SSL/TLS Service Profile**. The profile specifies the certificate that the firewall presents to the user if the site with the override is an HTTPS site. For details, see Configure an SSL/TLS Service Profile.<br>6. Select the **Mode** for prompting the user for the password:<br>• **Transparent**—The firewall intercepts the browser traffic destined for site in a URL category you have set to override and impersonates the original destination URL, issuing an HTTP 401 to prompt for the password. Note that the client browser will display certificate errors if it does not trust the certificate.<br>• **Redirect**—The firewall intercepts HTTP or HTTPS traffic to a URL category set to override and redirects the request to a Layer 3 interface on the firewall using an HTTP 302 redirect in order to prompt for the override password. If you select this option, you must provide the **Address** (IP address or DNS hostname) to which to redirect the traffic.<br>7. Click **OK**. |
| Step 2 (Optional) Set a custom override period. | 1. Edit the URL Filtering section.<br>2. To change the amount of time users can browse to a site in a category for which they have successfully entered the override password, enter a new value in the **URL Admin Override Timeout** field. By default, users can access sites within the category for 15 minutes without re-entering the password.<br>3. To change the amount of time users are blocked from accessing a site set to override after three failed attempts to enter the override password, enter a new value in the **URL Admin Lockout Timeout** field. By default, users are blocked for 30 minutes.<br>4. Click **OK**. |

© Palo Alto Networks, Inc.

| Configure URL Admin Override (Continued) | | |
|---|---|---|
| Step 3 | (Redirect mode only) Create a Layer 3 interface to which to redirect web requests to sites in a category configured for override. | 1. Create a management profile to enable the interface to display the URL Filtering Continue and Override Page response page:<br>a. Select **Network > Interface Mgmt** and click **Add**.<br>b. Enter a **Name** for the profile, select **Response Pages**, and then click **OK**.<br>2. Create the Layer 3 interface. Be sure to attach the management profile you just created (on the **Advanced > Other Info** tab of the Ethernet Interface dialog). |
| Step 4 | (Redirect mode only) To transparently redirect users without displaying certificate errors, install a certificate that matches the IP address of the interface to which you are redirecting web requests to a site in a URL category configured for override.You can either generate a self-signed certificate or import a certificate that is signed by an external CA. | To use a self-signed certificate, you must first create a root CA certificate and then use that CA to sign the certificate you will use for URL admin override as follows:<br>1. To create a root CA certificate, select **Device > Certificate Management > Certificates > Device Certificates** and then click **Generate**. Enter a **Certificate Name**, such as RootCA. Do not select a value in the **Signed By** field (this is what indicates that it is self-signed). Make sure you select the **Certificate Authority** check box and then click **Generate** the certificate.<br>2. To create the certificate to use for URL admin override, click **Generate**. Enter a **Certificate Name** and enter the DNS hostname or IP address of the interface as the **Common Name**. In the **Signed By** field, select the CA you created in the previous step. Add an IP address attribute and specify the IP address of the Layer 3 interface to which you will be redirecting web requests to URL categories that have the override action.<br>3. **Generate** the certificate.<br>4. To configure clients to trust the certificate, select the CA certificate on the **Device Certificates** tab and click **Export**. You must then import the certificate as a trusted root CA into all client browsers, either by manually configuring the browser or by adding the certificate to the trusted roots in an Active Directory Group Policy Object (GPO). |
| Step 5 | Specify which URL categories require an override password to enable access. | 1. Select **Objects > URL Filtering** and either select an existing URL filtering profile or **Add** a new one.<br>2. On the **Categories** tab, set the Action to **override** for each category that requires a password.<br>3. Complete any remaining sections on the URL filtering profile and then click **OK** to save the profile. |
| Step 6 | Apply the URL Filtering profile to the security policy rule(s) that allows access to the sites requiring password override for access. | 1. Select **Policies > Security** and select the appropriate security policy to modify it.<br>2. Select the **Actions** tab and in the **Profile Setting** section, click the drop-down for **URL Filtering** and select the profile.<br>3. Click **OK** to save. |
| Step 7 | Save the configuration. | Click **Commit**. |

# Enable Safe Search Enforcement

Many search engines have a safe search setting that filters out adult images and videos for search query return traffic. You can configure Safe Search Enforcement the Palo Alto Networks next-generation firewall to prevent search requests that do not have the strictest safe search settings enabled.

The Safe Search Enforcement for Google and YouTube Searches using a Virtual IP Address is not compatible with Safe Search Enforcement on the firewall.

There are two ways to enforce Safe Search on the firewall:

- Block Search Results that are not Using Strict Safe Search Settings
- Enable Transparent Safe Search Enforcement

## Block Search Results that are not Using Strict Safe Search Settings

By default, when you enable safe search enforcement, when a user attempts to perform a search without using the strictest safe search settings, the firewall will block the search query results and display the URL Filtering Safe Search Block Page. This page provides a link to the search settings page for the corresponding search provider so that the end user can enable the safe search settings. If you plan to use this default method for enforcing safe search, you should communicate the policy to your end users prior to deploying the policy. See Table: Search Provider Safe Search Settings for details on how each search provider implements safe search. The default URL Filtering Safe Search Block Page provides a link to the search settings for the corresponding search provider. You can optionally Customize the URL Filtering Response Pages.

Alternatively, to enable safe search enforcement so that it is transparent to your end users, configure the firewall to Enable Transparent Safe Search Enforcement.

 © Palo Alto Networks, Inc.

| Enable Safe Search Enforcement | | |
|---|---|---|
| Step 1 | Enable Safe Search Enforcement in the URL Filtering profile. | 1. Select **Objects > Security Profiles > URL Filtering**.<br>2. Select an existing profile to modify, or clone the default profile to create a new profile.<br>3. On the **Settings** tab, select the **Safe Search Enforcement** check box to enable it.<br>4. (Optional) Restrict users to specific search engines:<br>a. On the **Categories** tab, set the **search-engines** category to **block**.<br>b. For each search engine that you want end users to be able to access, enter the web address in the **Allow List** text box. For example, to allow users access to Google and Bing searches only, you would enter the following:<br>`www.google.com`<br>`www.bing.com`<br>5. Configure other settings as necessary to:<br>• Define how to control access to web content.<br>• Define websites that should always be blocked or allowed.<br>6. Click **OK** to save the profile. |
| Step 2 | Add the URL Filtering profile to the security policy rule that allows traffic from clients in the trust zone to the Internet. | 1. Select **Policies > Security** and select a rule to which to apply the URL filtering profile that you just enabled for Safe Search Enforcement.<br>2. On the **Actions** tab, select the **URL Filtering** profile.<br>3. Click **OK** to save the security policy rule. |
| Step 3 | Enable SSL Forward Proxy decryption.<br>Because most search engines encrypt their search results, you must enable SSL forward proxy decryption so that the firewall can inspect the search traffic and detect the safe search settings. | 1. Add a custom URL category for the search sites:<br>a. Select **Objects > Custom Objects > URL Category** and **Add** a custom category.<br>b. Enter a **Name** for the category, such as SearchEngineDecryption.<br>c. **Add** the following to the Sites list:<br>`www.bing.*`<br>`www.google.*`<br>`search.yahoo.*`<br>d. Click **OK** to save the custom URL category object.<br>2. Follow the steps to Configure SSL Forward Proxy.<br>3. On the **Service/URL Category** tab in the Decryption policy rule, **Add** the custom URL category you just created and then click **OK**. |

| Enable Safe Search Enforcement (Continued) | | |
|---|---|---|
| Step 4 | (Optional, but recommended) Block Bing search traffic running over SSL.<br><br>Because the Bing SSL search engine does not adhere to the safe search settings, for full safe search enforcement, you must deny all Bing sessions that run over SSL. | 1. Add a custom URL category for Bing:<br>a. Select **Objects > Custom Objects > URL Category** and **Add** a custom category.<br>b. Enter a **Name** for the category, such as EnableBingSafeSearch.<br>c. **Add** the following to the Sites list:<br>`www.bing.com/images/*`<br>`www.bing.com/videos/*`<br>d. Click **OK** to save the custom URL category object.<br>2. Create another URL filtering profile to block the custom category you just created:<br>a. Select **Objects > Security Profiles > URL Filtering**.<br>b. **Add** a new profile and give it a descriptive **Name**.<br>c. Locate the custom category in the Category list and set it to **block**.<br>d. Click **OK** to save the URL filtering profile.<br>3. Add a security policy rule to block Bing SSL traffic:<br>a. Select **Policies > Security** and **Add** a policy rule that allows traffic from your trust zone to the Internet.<br>b. On the **Actions** tab, attach the URL filtering profile you just created to block the custom Bing category.<br>c. On the **Service/URL Category** tab **Add** a **New Service** and give it a descriptive **Name**, such as bingssl.<br>d. Select **TCP** as the **Protocol** and set the **Destination Port** to `443`.<br>e. Click **OK** to save the rule.<br>f. Use the **Move** options to ensure that this rule is below the rule that has the URL filtering profile with safe search enforcement enabled. |
| Step 5 | Save the configuration. | Click **Commit**. |

© Palo Alto Networks, Inc.

| Enable Safe Search Enforcement (Continued) | |
|---|---|
| Step 6 Verify the Safe Search Enforcement configuration.<br><br>This verification step only works if you are using block pages to enforce safe search. If you are using transparent safe search enforcement, the firewall block page will invoke a URL rewrite with the safe search parameters in the query string. | 1. From a computer that is behind the firewall, disable the strict search settings for one of the supported search providers. For example, on bing.com, click the **Preferences** icon on the Bing menu bar.<br><br>  <br><br>2. Set the **SafeSearch** option to **Moderate** or **Off** and click **Save**.<br>3. Perform a Bing search and verify that the URL Filtering Safe Search Block page displays instead of the search results:<br><br> <br><br><br>4. Use the link in the block page to go to the search settings for the search provider and set the safe search setting back to the strictest setting (**Strict** in the case of Bing) and then click **Save**.<br>5. Perform a search again from Bing and verify that the filtered search results display instead of the block page. |

## Enable Transparent Safe Search Enforcement

If you want to enforce filtering of search query results with the strictest safe search filters, but you don't want your end users to have to manually configure the settings, you can enable transparent safe search enforcement as follows. This functionality is supported on Google, Yahoo, and Bing search engines only and requires Content Release version 475 or later.

| **Enable Transparent Safe Search Enforcement** | | |
|---|---|---|
| Step 1 | Make sure the firewall is running Content Release version 475 or later. | 1. Select **Device > Dynamic Updates**.<br>2. Check the **Applications and Threats** section to determine what update is currently running.<br>3. If the firewall is not running the required update or later, click **Check Now** to retrieve a list of available updates.<br>4. Locate the required update and click **Download**.<br>5. After the download completes, click **Install**. |
| Step 1 | Enable Safe Search Enforcement in the URL Filtering profile. | 1. Select **Objects > Security Profiles > URL Filtering**.<br>2. Select an existing profile to modify, or clone the default profile to create a new one.<br>3. On the **Settings** tab, select the **Safe Search Enforcement** check box to enable it.<br>4. (Optional) Allow access to specific search engines only:<br>a. On the **Categories** tab, set the **search-engines** category to **block**.<br>b. For each search engine that you want end users to be able to access, enter the web address in the **Allow List** text box. For example, to allow users access to Google and Bing searches only, you would enter the following:<br>`www.google.com`<br>`www.bing.com`<br>5. Configure other settings as necessary to:<br>• Define how to control access to web content.<br>• Define websites that should always be blocked or allowed.<br>6. Click **OK** to save the profile. |
| Step 2 | Add the URL Filtering profile to the security policy rule that allows traffic from clients in the trust zone to the Internet. | 1. Select **Policies > Security** and select a rule to which to apply the URL filtering profile that you just enabled for Safe Search Enforcement.<br>2. On the **Actions** tab, select the **URL Filtering** profile.<br>3. Click **OK** to save the security policy rule. |

© Palo Alto Networks, Inc.

| Enable Transparent Safe Search Enforcement (Continued) | | |
|---|---|---|
| Step 3 | (Optional, but recommended) Block Bing search traffic running over SSL.<br><br>Because the Bing SSL search engine does not adhere to the safe search settings, for full safe search enforcement, you must deny all Bing sessions that run over SSL. | 1. Add a custom URL category for Bing:<br>a. Select **Objects > Custom Objects > URL Category** and **Add** a custom category.<br>b. Enter a **Name** for the category, such as EnableBingSafeSearch.<br>c. **Add** the following to the Sites list:<br>`www.bing.com/images/*`<br>`www.bing.com/videos/*`<br>d. Click **OK** to save the custom URL category object.<br>2. Create another URL filtering profile to block the custom category you just created:<br>a. Select **Objects > Security Profiles > URL Filtering**.<br>b. **Add** a new profile and give it a descriptive **Name**.<br>c. Locate the custom category you just created in the Category list and set it to **block**.<br>d. Click **OK** to save the URL filtering profile.<br>3. **Add** a security policy rule to block Bing SSL traffic:<br>a. Select **Policies > Security** and **Add** a policy rule that allows traffic from your trust zone to the Internet.<br>b. On the **Actions** tab, attach the URL filtering profile you just created to block the custom Bing category.<br>c. On the **Service/URL Category** tab **Add** a **New Service** and give it a descriptive **Name**, such as bingssl.<br>d. Select **TCP** as the **Protocol**, set the **Destination Port** to `443`.<br>e. Click **OK** to save the rule.<br>f. Use the **Move** options to ensure that this rule is below the rule that has the URL filtering profile with safe search enforcement enabled. |
| Step 4 | Edit the URL Filtering Safe Search Block Page, replacing the existing code with the JavaScript for rewriting search query URLs to enforce safe search transparently.<br><br> For a script that you can copy and paste, go here. | 1. Select **Device > Response Pages > URL Filtering Safe Search Block Page**.<br>2. Select **Predefined** and then click **Export** to save the file locally.<br>3. Use an HTML editor and replace all of the existing block page text with the following text and then save the file: |

| Enable Transparent Safe Search Enforcement (Continued) | | |
|---|---|---|
| Step 5 | Import the edited URL Filtering Safe Search Block page onto the firewall. | 1. To import the edited block page, select **Device > Response Pages > URL Filtering Safe Search Block Page**.<br>2. Click **Import** and then enter the path and filename in the **Import File** field or **Browse** to locate the file.<br>3. (Optional) Select the virtual system on which this login page will be used from the **Destination** drop-down or select **shared** to make it available to all virtual systems.<br>4. Click **OK** to import the file. |
| Step 6 | Enable SSL Forward Proxy decryption.<br><br>Because most search engines encrypt their search results, you must enable SSL forward proxy decryption so that the firewall can inspect the search traffic and detect the safe search settings. | 1. Add a custom URL category for the search sites:<br>a. Select **Objects > Custom Objects > URL Category** and **Add** a custom category.<br>b. Enter a **Name** for the category, such as SearchEngineDecryption.<br>c. **Add** the following to the Sites list:<br>`www.bing.*`<br>`www.google.*`<br>`search.yahoo.*`<br>d. Click **OK** to save the custom URL category object.<br>2. Follow the steps to Configure SSL Forward Proxy.<br>3. On the **Service/URL Category** tab in the Decryption policy rule, **Add** the custom URL category you just created and then click **OK**. |
| Step 7 | Save the configuration. | Click **Commit**. |

# Set Up the PAN-DB Private Cloud

Use the following section to deploy one or more M-500 appliances as a PAN-DB private cloud within your network or data center and Configure the Firewalls to Access the PAN-DB Private Cloud.

| Set up the PAN-DB Private Cloud | | |
|---|---|---|
| Step 1 | Rack mount the M-500 appliance. | Refer to the M-500 Hardware Reference Guide for instructions. |
| Step 2 | Register the M-500 appliance. | For instruction on registering the M-500 appliance, see Register the Firewall. |
| Step 3 | Perform Initial Configuration of the M-500 Appliance.<br> <br>The M-500 appliance in PAN-DB mode uses two ports- MGT (Eth0) and Eth1; Eth2 is not used in PAN-DB mode. The management port is used for administrative access to the appliance and for obtaining the latest content updates from the PAN-DB public cloud. For communication between the appliance (PAN-DB server) and the firewalls on the network, you can use the MGT port or Eth1. | 1. Connect to the M-500 appliance in one of the following ways:<br>• Attach a serial cable from a computer to the Console port on the M-500 appliance and connect using a terminal emulation software (9600-8-N-1).<br>• Attach an RJ-45 Ethernet cable from a computer to the MGT port on the M-500 appliance. From a browser, go to https://192.168.1.1.Enabling access to this URL might require changing the IP address on the computer to an address in the 192.168.1.0 network (for example, 192.168.1.2).<br>2. When prompted, log in to the appliance. Log in using the default username and password (admin/admin). The appliance will begin to initialize.<br>3. Configure an network access settings including the IP address for the MGT interface:<br>**set deviceconfig system ip-address <server-IP> netmask <netmask> default-gateway <gateway-IP> dns-setting servers primary <DNS-IP>**<br>where <server-IP> is the IP address you want to assign to the management interface of the server, <netmask> is the subnet mask, <gateway-IP> is the IP address of the network gateway, and <DNS-IP> is the IP address of the primary DNS server.<br>4. Configure an network access settings including the IP address for the Eth1 interface:<br>**set deviceconfig system eth1 ip-address <server-IP> netmask <netmask> default-gateway <gateway-IP> dns-setting servers primary <DNS-IP>**<br>where <server-IP> is the IP address you want to assign to the data interface of the server, <netmask> is the subnet mask, <gateway-IP> is the IP address of the network gateway, and <DNS-IP> is the IP address of the DNS server.<br>5. Save your changes to the PAN-DB server.<br>**commit** |

 © Palo Alto Networks, Inc.

| Set up the PAN-DB Private Cloud | |
|---|---|
| Step 4 Switch to PAN-DB private cloud mode. | 1. To switch to PAN-DB mode, use the CLI command:<br>**request system system-mode pan-url-db**<br>You can switch from Panorama mode to PAN-DB mode and back; and from Panorama mode to Log Collector mode and back. Switching directly from PAN-DB mode to Log Collector mode or vice versa is not supported. When switching operational mode, a data reset is triggered. With the exception of management access settings, all existing configuration and logs will be deleted on restart.<br>2. Use the following command to verify that the mode is changed:<br>**show pan-url-cloud-status**<br>hostname: M-500<br>ip-address: 1.2.3.4<br>netmask: 255.255.255.0<br>default-gateway: 1.2.3.1<br>ipv6-address: unknown<br>ipv6-link-local-address: fe80:00/64<br>ipv6-default-gateway:<br>mac-address: 00:56:90:e7:f6:8e<br>time: Mon Apr 27 13:43:59 2015<br>uptime: 10 days, 1:51:28<br>family: m<br>model: M-500<br>serial: 0073010000xxx<br>sw-version: 7.0.0<br>app-version: 492-2638<br>app-release-date: 2015/03/19 20:05:33<br>av-version: 0<br>av-release-date: unknown<br>wf-private-version: 0<br>wf-private-release-date: unknown<br>logdb-version: 7.0.9<br>platform-family: m<br>pan-url-db: 20150417-220<br>**system-mode: Pan-URL-DB**<br>operational-mode: normal<br>3. Use the following command to check the version of the cloud database on the M-500 appliance:<br>**show pan-url-cloud-status**<br>Cloud status: Up<br>URL database version: 20150417-220 |

| Set up the PAN-DB Private Cloud | |
|---|---|
| Step 5 Install content and database updates.<br> The appliance only stores the currently running version of the content and one earlier version. | Pick one of the following methods of installing the content and database updates:<br>• If the PAN-DB server has direct Internet access use the following commands:<br>a. To check whether a new version is published use:<br>`request pan-url-db upgrade check`<br>b. To check the version that is currently installed on your server use:<br>`request pan-url-db upgrade info`<br>c. To download and install the latest version:<br>– `request pan-url-db upgrade download latest`<br>– `request pan-url-db upgrade install <version latest \| file>`<br>d. To schedule the M-500 appliance to automatically check for updates:<br>`set deviceconfig system update-schedule pan-url-db recurring weekly action download-and-install day-of-week <day of week> at <hr:min>`<br>• If the PAN-DB server is offline, access the Palo Alto Networks Support portal to download and save the content updates to an SCP server on your network. You can then import and install the updates using the following commands:<br>• `scp import pan-url-db remote-port <port-number> from username@host:path`<br>• `request pan-url-db upgrade install file <filename>` |

 © Palo Alto Networks, Inc.

| Set up the PAN-DB Private Cloud | |
|---|---|
| Step 6 Set up administrative access to the PAN-DB private cloud.<br> <br>The appliance has a default `admin` account. Any additional administrative users that you create can either be superusers (with full access) or superusers with read-only access.<br>PAN-DB private cloud does not support the use of RADIUS VSAs. If the VSAs used on the firewall or Panorama are used for enabling access to the PAN-DB private cloud, an authentication failure will occur. | • To set up a local administrative user on the PAN-DB server:<br>a. **configure**<br>b. **set mgt-config users <username> permissions role-based <superreader \| superuser> yes**<br>c. **set mgt-config users <username> password**<br>Enter password:**xxxxx**<br>Confirm password:**xxxxx**<br>d. **commit**<br>• To set up an administrative user with RADIUS authentication:<br>a. Create RADIUS server profile.<br>**set shared server-profile radius <server_profile_name> server <server_name> ip-address <ip_address> port <port_no> secret <shared_password>**<br>b. Create authentication-profile.<br>**set shared authentication-profile <auth_profile_name> user-domain <domain_name_for_authentication> allow-list <all> method radius server-profile <server_profile_name>**<br>c. Attach the authentication-profile to the user.<br>**set mgt-config users <username> authentication-profile <auth_profile_name>**<br>d. Commit the changes.<br>**commit**<br>• To view the list of users:.<br>**show mgt-config users**<br>`users { admin { phash fnRL/G5lXVMug; permissions { role-based { superuser yes; } } } admin_user_2 { permissions { role-based { superreader yes; } } authentication-profile RADIUS; } }` |
| Step 7 Configure the Firewalls to Access the PAN-DB Private Cloud. | |

## Configure the Firewalls to Access the PAN-DB Private Cloud

When using the PAN-DB public cloud, each firewall accesses the PAN-DB servers in the AWS cloud to download the list of eligible servers to which it can connect for URL lookups. With the PAN-DB private cloud, you must configure the firewalls with a (static) list of your PAN-DB private cloud servers that will be used for URL lookups. The list can contain up to 20 entries; IPv4 addresses, IPv6 addresses, and FQDNs are supported. Each entry on the list— IP address or FQDN—must be assigned to the management port and/or eth1 of the PAN-DB server.

**Configure the Firewalls to Access the PAN-DB Private Cloud.**

Step 1 Pick one of the following options based on the PAN-OS version on the firewall.

a. For firewalls running PAN-OS 7.0, Access the PAN-OS CLI or the web interface on the firewall.

- Use the following CLI command to configure access to the private cloud:

  **`set deviceconfig setting pan-url-db cloud-static-list <IP addresses> enable`**
- Or, in the web interface for each firewall,
  1. Select **Device > Setup >Content-ID,** edit the URL Filtering section.
  2. Enter the **PAN-DB Server** IP address(es) or FQDN(s). The list must be comma separated.

b. For firewalls running PAN-OS 5.0, 6.0, or 6.1, use the following CLI command to configure access to the private cloud:

**`debug device-server pan-url-db cloud-static-list-enable <IP addresses> enable`**

Step 2 **Commit** your changes.

Step 3 To verify that the change is effective, use the following CLI command on the firewall:

- **`show url-cloud status`**

```
Cloud status:            Up
URL database version:    20150417-220
```

To delete the entries for the private PAN-DB servers, and allow the firewalls to connect to the PAN-DB public cloud, use the command:

**`set deviceconfig setting pan-url-db cloud-static-list <IP addresses> disable`**

When you delete the list of private PAN-DB servers, a re-election process is triggered on the firewall. The firewall first checks for the list of PAN-DB private cloud servers and when it cannot find one, the firewall accesses the PAN-DB servers in the AWS cloud to download the list of eligible servers to which it can connect.

# URL Filtering Use Case Examples

The following use cases show how to use App-ID to control a specific set of web-based applications and how to use URL categories as match criteria in a policy. When working with App-ID, it is important to understand that each App-ID signature may have dependencies that are required to fully control an application. For example, with Facebook applications, the App-ID facebook-base is required to access the Facebook website and to control other Facebook applications. For example, to configure the firewall to control Facebook email, you would have to allow the App-IDs facebook-base and facebook-mail. As another example, if you search Applipedia (the App-ID database) for LinkedIn, you will see that in order to control LinkedIn mail, you need to apply the same action to both App-IDs: linkedin-base and linkedin-mail. To determine application dependencies for App-ID signatures, visit Applipedia, search for the given application, and then click the application for details.

The User-ID feature is required to implement policies based on users and groups and a Decryption policy is required to identify and control websites that are encrypted using SSL/TLS.

This section includes two uses cases:

- Use Case: Control Web Access
- Use Case: Use URL Categories for Policy Matching

## Use Case: Control Web Access

When using URL filtering to control user website access, there may be instances where granular control is required for a given website. In this use case, a URL filtering profile is applied to the security policy that allows web access for your users and the *social-networking* URL category is set to block, but the allow list in the URL profile is configured to allow the social networking site Facebook. To further control Facebook, the company policy also states that only marketing has full access to Facebook and all other users within the company can only read Facebook posts and cannot use any other Facebook applications, such as email, posting, chat, and file sharing. To accomplish this requirement, App-ID must be used to provide granular control over Facebook.

The first security rule will allow marketing to access the Facebook website as well as all Facebook applications. Because this allow rule will also allow access to the Internet, threat prevention profiles are applied to the rule, so traffic that matches the policy will be scanned for threats. This is important because the allow rule is terminal and will not continue to check other rules if there is a traffic match.

| **Control Web Access** | | |
|---|---|---|
| Step 1 | Confirm that URL filtering is licensed. | 1. Select **Device > Licenses** and confirm that a valid date appears for the URL filtering database that will used. This will either be PAN-DB or BrightCloud.<br>2. If a valid license is not installed, see Enable PAN-DB URL Filtering. |
| Step 2 | Confirm that User-ID is working. User-ID is required to create policies based on users and groups. | 1. To check Group Mapping from the CLI, enter the following command:<br>`show user group-mapping statistics`<br>2. To check User Mapping from the CLI, enter the following command:<br>`show user ip-user-mapping-mp all`<br>3. If statistics do not appear and/or IP address to user mapping information is not displayed, see User-ID. |
| Step 3 | Set up a URL filtering profile by cloning the default profile. | 1. Select **Objects > Security Profiles > URL Filtering** and select the **default** profile.<br>2. Click the **Clone** icon. A new profile should appear named **default-1**.<br>3. Select the new profile and rename it. |

 © Palo Alto Networks, Inc.

| Control Web Access (Continued) | | |
|---|---|---|
| Step 4 | Configure the URL filtering profile to block social-networking and allow Facebook. | 1. Modify the new URL filtering profile and in the **Category** list scroll to **social-networking** and in the **Action** column click on **allow** and change the action to **block**.<br>2. In the **Allow List**, enter `facebook.com`, press enter to start a new line and then type `*.facebook.com`. Both of these formats are required, so all URL variants a user may use will be identified, such as facebook.com, www.facebook.com, and https://facebook.com.<br>  <br>3. Click **OK** to save the profile. |
| Step 5 | Apply the new URL filtering profile to the security policy rule that allows web access from the user network to the Internet. | 1. Select **Policies > Security** and click on the policy rule that allows web access.<br>2. On the **Actions** tab, select the URL profile you just created from the **URL Filtering** drop-down.<br>  <br>3. Click **OK** to save. |

| Control Web Access (Continued) | |
|---|---|
| Step 6 Create the security policy rule that will allow marketing access the Facebook website and all Facebook applications.<br><br>This rule must precede other rules because:<br>• It is a specific rule. More specific rules must precede other rules.<br>• Allow rule will terminate when a traffic match occurs. | 1. Select **Policies > Security** and click **Add**.<br>2. Enter a **Name** and optionally a **Description** and **Tag**(s).<br>3. On the **Source** tab add the zone where the users are connected.<br>4. On the **User** tab in the **Source User** section click **Add**.<br>5. Select the directory group that contains your *marketing* users.<br>6. On the **Destination** tab, select the zone that is connected to the Internet.<br>7. On the **Applications** tab, click **Add** and add the *facebook* App-ID signature.<br>8. On the **Actions** tab, add the default profiles for **Antivirus**, **Vulnerability Protection**, and **Anti-Spyware**.<br> <br>9. Click **OK** to save the security profile.<br>The *facebook* App-ID signature used in this policy rule encompasses all Facebook applications, such as facebook-base, facebook-chat, and facebook-mail, so this is the only App-ID signature required in this rule.<br>With this rule in place, when a marketing employee attempts to access the Facebook website or any Facebook application, the rule matches based on the user being part of the marketing group. For traffic from any user outside of marketing, the rule will be skipped because there would not be a traffic match and rule processing would continue. |

© Palo Alto Networks, Inc.

**Control Web Access (Continued)**

Step 7 Configure the security policy to block all other users from using any Facebook applications other than simple web browsing. The easiest way to do this is to clone the marketing allow policy and then modify it.

1. From **Policies > Security** click the marketing Facebook allow policy you created earlier to highlight it and then click the **Clone** icon.
2. Enter a **Name** and optionally enter a **Description** and **Tag**('s).
3. On the **User** tab highlight the marketing group and delete it and in the drop-down select **any**.
4. On the **Applications** tab, click the *facebook* App-ID signature and delete it.
5. Click **Add** and add the following App-ID signatures:
   - facebook-apps
   - facebook-chat
   - facebook-file-sharing
   - facebook-mail
   - facebook-posting
   - facebook-social-plugin
6. On the **Actions** tab in the **Action Setting** section, select **Deny**. The profile settings should already be correct because this rule was cloned.

7. Click **OK** to save the security profile.
8. Ensure that this new deny rule is listed after the marketing allow rule, to ensure that rule processing occurs in the correct order to allow marketing users and then to deny/limit all other users.
9. Click **Commit** to save the configuration.

With these security policy rules in place, any user who is part of the marketing group will have full access to all Facebook applications and any user that is not part of the marketing group will only have read-only access to the Facebook website and will not be able to use Facebook applications such as post, chat, email, and file sharing.

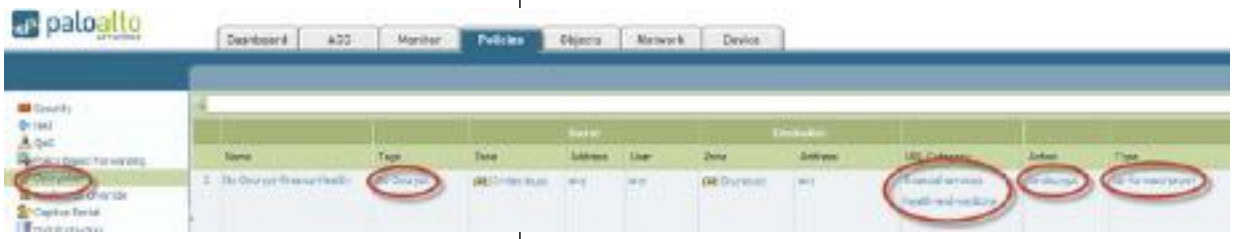
## Use Case: Use URL Categories for Policy Matching

URL categories can also be used as match criteria in the following policy types: Captive Portal, Decryption, Security, and QoS. In this use case, URL categories will be used in Decryption policy rules to control which web categories should be decrypted or not decrypted. The first rule is a no-decrypt rule that will not decrypt user traffic if the website category is *financial-services* or *health-and-medicine* and the second rule will decrypt all other traffic. The decryption policy type is *ssl-forward-proxy*, which is used for controlling decryption for all outbound connections performed by users.

**Configure a Decryption Policy Based on URL Category**

Step 1 Create the no-decrypt rule that will be listed first in the decryption policies list. This will prevent any website that is in the *financial-services* or *health-and-medicine* URL categories from being decrypted.

1. Select **Policies > Decryption** and click **Add**.
2. Enter a **Name** and optionally enter a **Description** and **Tag**(s).
3. On the **Source** tab, add the zone where the users are connected.
4. On the **Destination** tab, enter the zone that is connected to the Internet.
5. On the **URL Category** tab, click **Add** and select the *financial-services* and *health-and-medicine* URL categories.
6. On the **Options** tab, set the action to **No Decrypt**.
7. (Optional) Although the firewall does not decrypt and inspect the traffic for the session, you can attach a **Decryption profile** if you want to enforce the server certificates used during the session. The decryption profile allows you to configure the firewall to terminate the SSL connection either when the server certificates are expired or when the server certificates are issues by an untrusted issuer.



8. Click **OK** to save the policy rule.

 © Palo Alto Networks, Inc.

| Configure a Decryption Policy Based on URL Category (Continued) | | |
|---|---|---|
| Step 2 | Create the decryption policy rule that will decrypt all other traffic. | 1. Select the no-decrypt policy you created previously and then click **Clone**.<br>2. Enter a **Name** and optionally enter a **Description** and **Tag**(s).<br>3. On the **URL Category** tab, select *financial-services* and *health-and-medicine* and then click the **Delete** icon.<br>4. On the **Options** tab, set the action to **Decrypt** and the **Type** to **SSL Forward Proxy**.<br>5. (Optional) Attach a **Decryption profile** to specify the server certificate verification, unsupported mode checks and failure checks for the SSL traffic. See Configure SSL Forward Proxy for more details.<br>6. Ensure that this new decryption rule is listed after the no-decrypt rule to ensure that rule processing occurs in the correct order, so websites in the *financial-services* and *health-and-medicine* are not decrypted<br>7. Click **OK** to save the policy rule. |
| Step 3 | (BrightCloud only) Enable cloud lookups for dynamically categorizing a URL when the category is not available on the local database on the firewall. | 1. Access the CLI on the firewall.<br>2. Enter the following commands to enable Dynamic URL Filtering:<br>a. **configure**<br>b. **set deviceconfig setting url dynamic-url yes**<br>c. **commit** |
| Step 4 | Save the configuration. | Click **Commit**. |

With these two decrypt policies in place, any traffic destined for the *financial-services* or *health-and-medicine* URL categories will not be decrypted. All other traffic will be decrypted.

Now that you have a basic understanding of the powerful features of URL filtering, App-ID, and User-ID, you can apply similar policies to your firewall to control any application in the Palo Alto Networks App-ID signature database and control any website contained in the URL filtering database.

For help in troubleshooting URL filtering issues, see Troubleshoot URL Filtering.

# Troubleshoot URL Filtering

The following topics provide troubleshooting guidelines for diagnosing and resolving common URL filtering problems.

- Problems Activating PAN-DB
- PAN-DB Cloud Connectivity Issues
- URLs Classified as Not-Resolved
- Incorrect Categorization
- URL Database Out of Date

## Problems Activating PAN-DB

The following table describes procedures that you can use to resolve issues with activating PAN-DB.

| Troubleshoot PAN-DB Activation Issues |
|---|
| 1. Access the PAN-OS CLI. |
| 2. Verify whether PAN-DB has been activated by running the following command:<br>`admin@PA-200> show system setting url-database`<br>If the response is `paloaltonetworks`, then PAN-DB is the active vendor. |
| 3. Verify that the firewall has a valid PAN-DB license by running the following command:<br>`admin@PA-200> request license info`<br>You should see the license entry Feature: PAN_DB URL Filtering. If the license is not installed, you will need to obtain and install a license. See Configure URL Filtering. |
| 4. After the license is installed, download a new PAN-DB seed database by running the following command:<br>`admin@PA-200> request url-filtering download paloaltonetworks region` *<region>* |
| 5. Check the download status by running the following command:<br>`admin@PA-200> request url-filtering download status vendor paloaltonetworks`<br>• If the message is different from `PAN-DB download: Finished successfully`, stop here; there may be a problem connecting to the cloud. Attempt to solve the connectivity issue by performing basic network troubleshooting between the firewall and the Internet. For more information, see PAN-DB Cloud Connectivity Issues.<br>• If the message is `PAN-DB download: Finished successfully`, the firewall successfully downloaded the URL seed database. Try to enable PAN-DB again by running the following command:<br>`admin@PA-200> set system setting url-database paloaltonetworks` |
| 6. If the problems persists, contact Palo Alto Networks support. |

© Palo Alto Networks, Inc.

## PAN-DB Cloud Connectivity Issues

To check cloud connectivity, run the following command:

```
admin@pa-200> show url-cloud status
```

If the cloud is accessible, the expected response is similar to the following:

```
admin@PA-200> show url-cloud status
PAN-DB URL Filtering
License :                          valid
Current cloud server :             s0000.urlcloud.paloaltonetworks.com
Cloud connection :                 connected
URL database version - device :    2013.11.18.000
URL database version - cloud :     2013.11.18.000  ( last update time
2013/11/19
 13:20:51 )
URL database status :              good
URL protocol version - device :    pan/0.0.2
URL protocol version - cloud :     pan/0.0.2
Protocol compatibility status :    compatible
```

If the cloud is note accessible, the expected response is similar to the following:

```
admin@PA-200> show url-cloud status
PAN-DB URL Filtering
License :                          valid
Cloud connection :                 not connected
URL database version - device :    2013.11.18.000
URL database version - cloud :     2013.11.18.000  ( last update time
2013/11/19
 13:20:51 )
URL database status :              good
URL protocol version - device :    pan/0.0.2
URL protocol version - cloud :     pan/0.0.2
Protocol compatibility status :    compatible
```

The following table describes procedures that you can use to resolve issues based on the output of the `show url-cloud status` command, how to ping the URL cloud servers, and what to check if the firewall is in a High Availability (HA) configuration.

| Troubleshoot Cloud Connectivity Issues |
| --- |
| • PAN-DB URL Filtering license field shows invalid—Obtain and install a valid PAN-DB license.<br>• URL database status is out of date—Download a new seed database by running the following command:<br>`admin@pa-200> request url-filtering download paloaltonetworks region <region>`<br>• URL protocol version shows not compatible—Upgrade PAN-OS to the latest version.<br>• Attempt to ping the PAN-DB cloud server from the firewall by running the following command:<br>`admin@pa-200> ping source <ip-address> host s0000.urlcloud.paloaltonetworks.com`<br>For example, if your management interface IP address is 10.1.1.5, run the following command:<br>`admin@pa-200> ping source 10.1.1.5 host s0000.urlcloud.paloaltonetworks.com`<br>• If the firewall is in an HA configuration, verify that the HA state of the devices supports connectivity to the cloud systems. You can determine the HA state by running the following command:<br>`admin@pa-200> show high-availability state`<br>Connection to the cloud will be blocked if the firewall is not in one of the following states:<br>  • active<br>  • active-primary<br>  • active-secondary<br>If the problem persists, contact Palo Alto Networks support. |

## URLs Classified as Not-Resolved

The following table describes procedures you can use to resolve issues where some or all of the URLs being identified by PAN-DB are classified as *Not-resolved*:

| Troubleshoot URLs Classified as Not-Resolved |
| --- |
| 1. Check the PAN-DB cloud connection by running the following command:<br>`admin@PA-200> show url-cloud status`<br>The Cloud connection: field should show *connected*. If you see anything other than *connected*, any URL that do not exist in the management plane cache will be categorized as *not-resolved*. To resolve this issue, see PAN-DB Cloud Connectivity Issues. |
| 2. If the cloud connection status shows *connected*, check the current utilization of the firewall. If the firewall's performance is spiking, URL requests may be dropped (may not reach the management plane), and will be categorized as *not-resolved*.<br>To view system resources, run the following command and view the *%CPU* and *%MEM* columns:<br>`admin@PA-200> show system resources`<br>You can also view system resources from the firewall's web interfaces by clicking the **Dashboard** tab and viewing the **System Resources** section. |
| 3. If the problem persist, contact Palo Alto Networks support. |

 © Palo Alto Networks, Inc.

## Incorrect Categorization

The following steps describe the procedures you can use if you identify a URL that does not have the correct categorization. For example, if the URL *paloaltonetworks.com* was categorized as *alcohol-and-tobacco*, the categorization is not correct; the category should be *computer-and-internet-info*.

**Troubleshoot Incorrect Categorization Issues**

1. Verify the category in the dataplane by running the following command:

   `admin@PA-200>` show running url <*URL*>

   For example, to view the category for the Palo Alto Networks website, run the following command:

   ```
   admin@PA-200> show running url paloaltonetworks.com
   ```

   If the URL stored in the dataplane cache has the correct category (computer-and-internet-info in this example), then the categorization is correct and no further action is required. If the category is not correct, continue to the next step.

2. Verify if the category in the management plane by running the command:

   `admin@PA-200> test url-info-host` <*URL*>

   For example:

   ```
   admin@PA-200> test url-info-host paloaltonetworks.com
   ```

   If the URL stored in the management plane cache has the correct category, remove the URL from the dataplane cache by running the following command:

   `admin@PA-200> clear url-cache url` <*URL*>

   The next time the device requests the category for this URL, the request will be forwarded to the management plane. This will resolve the issue and no further action is required. If this does not solve the issue, go to the next step to check the URL category on the cloud systems.

3. Verify the category in the cloud by running the following command:

   `admin@PA-200> test url-info-cloud <URL>`

4. If the URL stored in the cloud has the correct category, remove the URL from the dataplane and the management plane caches.

   Run the following command to delete a URL from the dataplane cache:

   ```
   admin@PA-200> clear url-cache url <URL>
   ```

   Run the following command to delete a URL from the management plane cache:

   ```
   admin@PA-200> delete url-database url <URL>
   ```

   The next time the device queries for the category of the given URL, the request will be forwarded to the management plane and then to the cloud. This should resolve the category lookup issue. If problems persist, see the next step to submit a categorization change request.

5. To submit a change request from the web interface, go to the URL log and select the log entry for the URL you would like to have changed.

**Troubleshoot Incorrect Categorization Issues**

6. Click the **Request Categorization** change link and follow instructions. You can also request a category change from the Palo Alto Networks Test A Site website by searching for the URL and then clicking the **Request Change** icon. To view a list of all available categories with descriptions of each category, refer to https://urlfiltering.paloaltonetworks.com/CategoryList.aspx.

   If your change request is approved, you will receive an email notification. You then have two options to ensure that the URL category is updated on the firewall:

   - Wait until the URL in the cache expires and the next time the URL is accessed by a user, the new categorization update will be put in the cache.
   - Run the following command to force an update in the cache:

     ```
     admin@PA-200> request url-filtering update url <URL>
     ```

## URL Database Out of Date

If you have observed through the syslog or the CLI that PAN-DB is out-of-date, it means that the connection from the firewall to the URL Cloud is blocked. This usually occurs when the URL database on the firewall is too old (version difference is more than three months) and the cloud cannot update the firewall automatically. In order to resolve this issue, you will need to re-download an initial seed database from the cloud (this operation is not blocked). This will result in an automatic re-activation of PAN-DB.

To manually update the database, perform one of the following steps:

- From the web interface, select **Device > Licenses** and in the **PAN-DB URL Filtering** section click the **Re-Download** link.
- From the CLI, run the following command:

  ```
  admin@PA-200> request url-filtering download paloaltonetworks region <region_name>
  ```

When the seed database is re-download, the URL cache in the management plane and dataplane will be purged. The management plane cache will then be re-populated with the contents of the new seed database.

 © Palo Alto Networks, Inc.

# Quality of Service

Quality of Service (QoS) is a set of technologies that work on a network to guarantee its ability to dependably run high-priority applications and traffic under limited network capacity. QoS technologies accomplish this by providing differentiated handling and capacity allocation to specific flows in network traffic. This enables the network administrator to assign the order in which traffic is handled, and the amount of bandwidth afforded to traffic.

Palo Alto Networks Application Quality of Service (QoS) provides basic QoS applied to networks and extends it to provide QoS to applications and users.

Use the following topics to learn about and configure Palo Alto Networks Application QoS:

- QoS Overview
- QoS Concepts
- Configure QoS
- Configure QoS for a Virtual System
- Enforce QoS Based on DSCP Classification
- QoS Use Cases

- Use the Palo Alto Networks product comparison tool to view the QoS features supported on your firewall platform. Select two or more product platforms and click **Compare Now** to view QoS feature support for each platform (for example, you can check if your firewall platform supports QoS on subinterfaces and if so, the maximum number of subinterfaces on which QoS can be enabled).
- QoS on Aggregate Ethernet (AE) interfaces is supported on PA-7000 Series, PA-5000 Series, PA-3000 Series, and PA-2000 Series firewalls running PAN-OS 7.0 or later release versions.

# QoS Overview

Use QoS to prioritize and adjust quality aspects of network traffic. You can assign the order in which packets are handled and allot bandwidth, ensuring preferred treatment and optimal levels of performance are afforded to selected traffic, applications, and users.

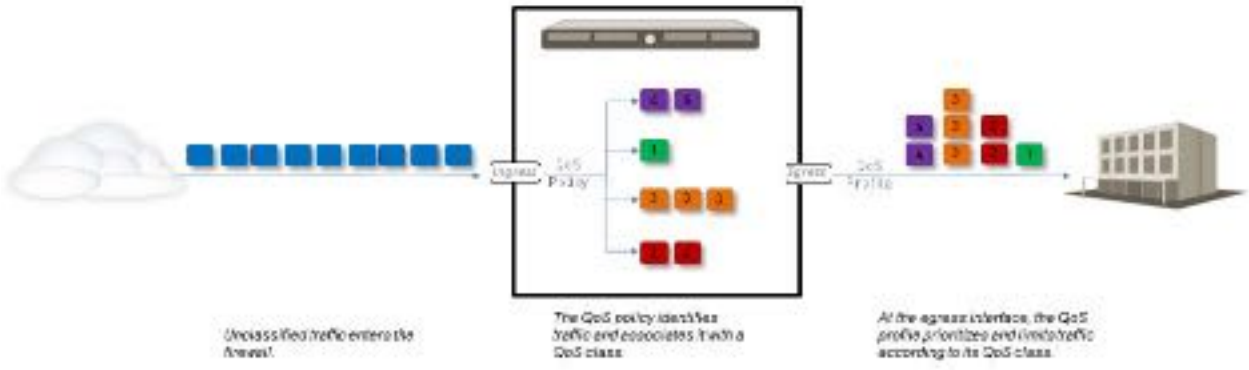
Service quality measurements subject to a QoS implementation are bandwidth (maximum rate of transfer), throughput (actual rate of transfer), latency (delay), and jitter (variance in latency). The capability to shape and control these service quality measurements makes QoS of particular importance to high-bandwidth, real-time traffic such as voice over IP (VoIP), video conferencing, and video-on-demand that has a high sensitivity to latency and jitter. Additionally, use QoS to achieve outcomes such as the following:

- Prioritize network and application traffic, guaranteeing high priority to important traffic or limiting non-essential traffic.
- Achieve equal bandwidth sharing among different subnets, classes, or users in a network.
- Allocate bandwidth externally or internally or both, applying QoS to both upload and download traffic or to only upload or download traffic.
- Ensure low latency for customer and revenue-generating traffic in an enterprise environment.
- Perform traffic profiling of applications to ensure bandwidth usage.

QoS implementation on a Palo Alto Networks firewall begins with three primary configuration components that support a full QoS solution: a QoS Profile, a QoS Policy, and setting up the QoS Egress Interface. Each of these options in the QoS configuration task facilitate a broader process that optimizes and prioritizes the traffic flow and allocates and ensures bandwidth according to configurable parameters.

The figure QoS Traffic Flow shows traffic as it flows from the source, is shaped by the firewall with QoS enabled, and is ultimately prioritized and delivered to its destination.

**QoS Traffic Flow**



The QoS configuration options allow you to control the traffic flow and define it at different points in the flow. The QoS Traffic Flow indicates where the configurable options define the traffic flow. Use the QoS Profile to define QoS classes and use the QoS Policy to associate QoS classes with selected traffic. Enable the QoS Profile on an interface to shape traffic according to the QoS configuration as it flows through the network.

 © Palo Alto Networks, Inc.

You can configure a QoS Profile and QoS Policy individually or in any order, according to your preference. Each of the QoS configuration options has components that influence the definition of the other options and the QoS configuration options can be used to create a full and granular QoS policy or can be used sparingly with minimal administrator action.

Each firewall model supports a maximum number of ports that can be configured with QoS. Refer to the spec sheet for your firewall model or use the product comparison tool to view QoS feature support for two or more firewalls on a single page.

# QoS Concepts

Use the following topics to learn about the different components and mechanisms of a QoS configuration on a Palo Alto Networks firewall:

- QoS for Applications and Users
- QoS Profile
- QoS Classes
- QoS Policy
- QoS Egress Interface
- QoS Clear Text and Tunneled Traffic

## QoS for Applications and Users

A Palo Alto Networks firewall provides basic QoS, controlling traffic leaving the firewall according to network or subnet, and extends the power of QoS to also classify and shape traffic according to application and user. The Palo Alto Networks firewall provides this capability by integrating the features App-ID and User-ID with the QoS configuration. App-ID and User-ID entries that exist to identify specific applications and users in your network are available in the QoS configuration so that you can easily specify applications and users to apply QoS to.

You can use a QoS Policy in the web interface (**Policies** > **QoS**) to apply QoS specifically to an application's traffic:

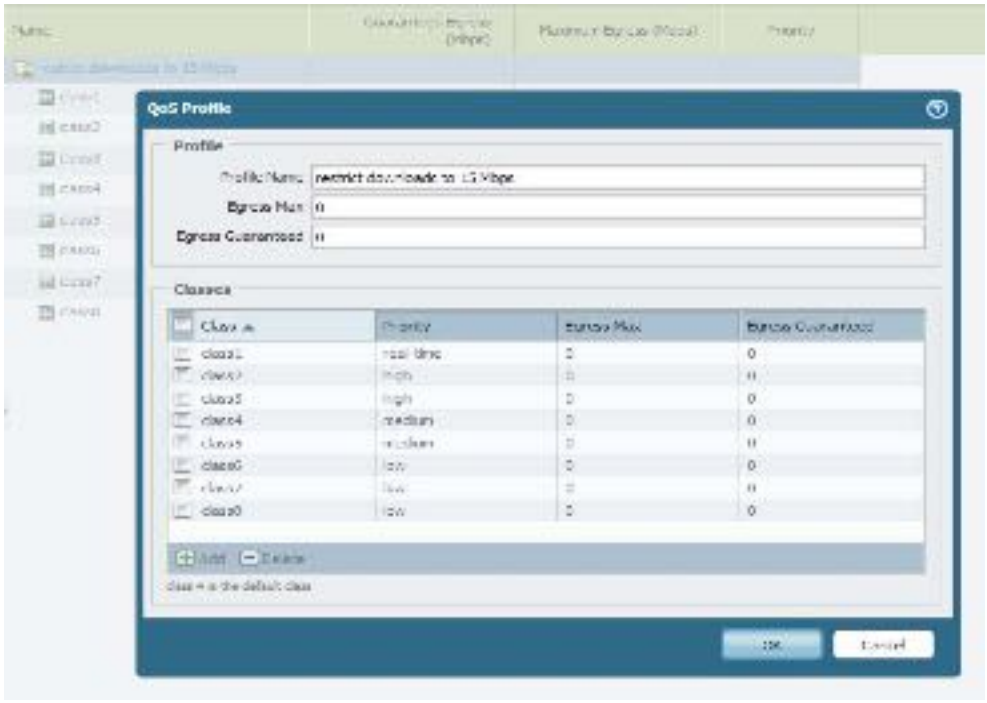
Or to a user's traffic:

See App-ID and User-ID for more information on these features.

© Palo Alto Networks, Inc.

## QoS Profile

Use a QoS profile to define values of up to eight QoS classes contained within that single profile (**Network** > **Network Profiles** > **QoS Profile**):



You enable QoS by applying a QoS profile to the egress interface for network, application, and user traffic, and for clear text or tunneled traffic. An interface configured with QoS shapes traffic according to the QoS profile class definitions and the traffic associated with those classes in the QoS policy.

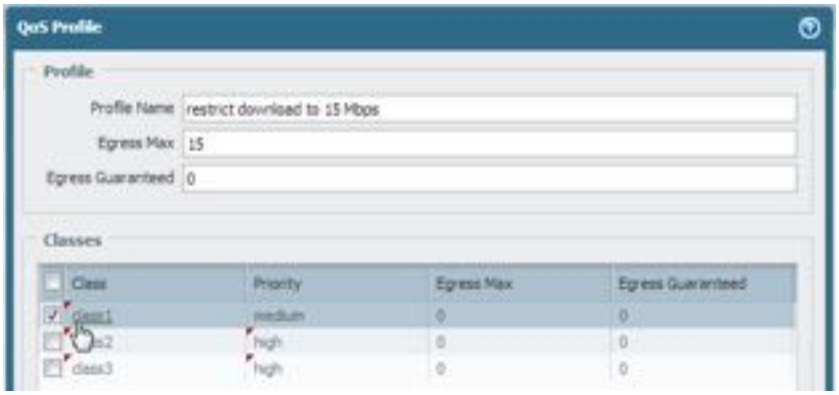
A default QoS Profile is available on the firewall. The default profile and the classes defined in the profile do not have predefined maximum or guaranteed bandwidth limits.

You can set bandwidth limits for a QoS profile and/or set limits for individual QoS classes within the QoS profile. The total guaranteed bandwidth limits of all eight QoS classes in a QoS Profile cannot exceed the total bandwidth allocated to that QoS Profile. Enabling QoS on a physical interface includes setting the maximum bandwidth for traffic leaving the firewall through this interface. A QoS profile's guaranteed bandwidth (the **Egress Guaranteed** field) should not exceed the bandwidth allocated to the physical interface that QoS is enabled on.

For details, see Add a QoS profile.

## QoS Classes

A QoS class determines the priority and bandwidth for traffic it is assigned to. In the web interface, use the QoS profile to define QoS classes (**Network** > **Network Profiles** > **QoS Profile**):



Defining a QoS class includes setting the class's Priority, maximum bandwidth (Egress Max), and guaranteed bandwidth (Egress Guaranteed).

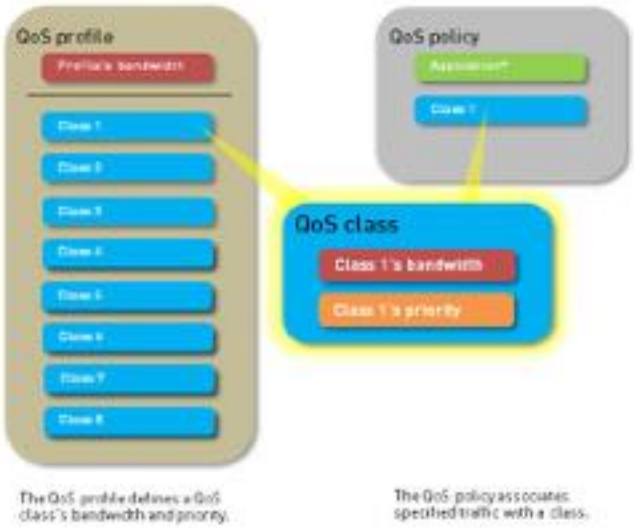
Real-time priority is typically used for applications that are particularly sensitive to latency, such as voice and video applications.

Use the QoS policy to assign a QoS class to specified traffic (**Policies** > **QoS**):

There are up to eight definable QoS classes in a single QoS profile. Unless otherwise configured, traffic that does not match a QoS class is assigned a class of 4.

QoS priority queuing and bandwidth management, the fundamental mechanisms of a QoS configuration, are configured within the QoS class definition (see Step 3). Queuing priority is determined by the priority set for a QoS class. Bandwidth management is determined according to the maximum and guaranteed bandwidths set for a QoS class.

 © Palo Alto Networks, Inc.



The queuing and bandwidth management mechanisms determine the order of traffic and how traffic is handled upon entering or leaving a network:

- **QoS Priority:** One of four QoS priorities can be defined in a QoS class: real-time, high, medium, and low. When a QoS class is associated with specific traffic, the priority defined in that QoS class is assigned to the traffic. Packets in the traffic flow are then queued according to their priority until the network is ready to process them. This method of priority queuing provides the capability to ensure that important traffic, applications, or users takes precedence.
- **QoS Class Bandwidth Management:** QoS class bandwidth management provides the capability to control traffic flows on a network so that traffic does not exceed network capacity, resulting in network congestion, or to allocate specific bandwidth limits to traffic, applications, or users. You can set overall limits on bandwidth using the QoS profile or set limits for individual QoS classes. A QoS profile and QoS classes in the profile have guaranteed and maximum bandwidth limits. The guaranteed bandwidth limit (Egress Guaranteed) ensures that any amount of traffic up to that set bandwidth limit is processed. The maximum bandwidth limit (Egress Max) sets the total limit of bandwidth allocated to either the QoS Profile or QoS Class. Traffic in excess of the Maximum Bandwidth limit is dropped. The total bandwidth limits and guaranteed bandwidth limits of QoS classes in a QoS profile cannot exceed the bandwidth limit of the QoS profile.

## QoS Policy

Use a QoS policy rule to define traffic to receive QoS treatment (either preferential treatment or bandwidth-limiting) and assigns such traffic a QoS class of service.

Define a QoS policy rule to match to traffic based on:

- Applications and application groups.
- Source zones, source addresses, and source users.
- Destination zones and destination addresses.

- Services and service groups limited to specific TCP and/or UDP port numbers.
- URL categories, including custom URL categories.
- Differentiated Services Code Point (DSCP) and Type of Service (ToS) values, which are used to indicate the level of service requested for traffic, such as high priority or best effort delivery.

Set up multiple QoS policy rules (**Policies** > **QoS**) to associate different types of traffic with different QoS Classes of service.

## QoS Egress Interface

Enabling a QoS profile on the egress interface of the traffic identified for QoS treatment completes a QoS configuration. The ingress interface for QoS traffic is the interface on which the traffic enters the firewall. The egress interface for QoS traffic is the interface that traffic leaves the firewall from. QoS is always enabled and enforced on a traffic flow's egress interface. The egress interface in a QoS configuration can either be the external- or internal-facing interface of the firewall, depending on the flow of the traffic receiving QoS treatment.

For example, in an enterprise network, if you are limiting employees' download traffic from a specific website, the egress interface in the QoS configuration is the firewall's internal interface, as the traffic flow is from the Internet, through the firewall, and to your company network. Alternatively, when limiting employees' upload traffic to the same website, the egress interface in the QoS configuration is the firewall's external interface, as the traffic you are limiting flows from your company network, through the firewall, and then to the Internet.

See Step 3 to learn how to Identify the egress interface for applications that you identified as needing QoS treatment.

 © Palo Alto Networks, Inc.

## QoS Clear Text and Tunneled Traffic

At the minimum, enabling a QoS interfaces requires you to select a default QoS profile to be used to shape all clear text traffic egressing the interface. However, when setting up or modifying a QoS interface, granular QoS settings can be applied to outgoing clear text traffic and tunneled traffic. QoS preferential treatment and bandwidth limiting can be enforced for individual tunnel interfaces and/or for clear text traffic originating from different source interfaces and source subnets.

On Palo Alto Networks firewalls, *tunneled traffic* refers to tunnel interface traffic, specifically IPSec traffic in tunnel mode.

# Configure QoS

Follow these steps to configure Quality of Service (QoS), which includes creating a QoS profile, creating a QoS policy, and enabling QoS on an interface.

| Configure QoS | | |
|---|---|---|
| Step 1 | Identify the traffic to which to apply QoS.<br><br>This example shows how to use QoS to limit web browsing. | Select **ACC** to view the **Application Command Center** page. Use the settings and charts on the **ACC** page to view trends and traffic related to Applications, URL filtering, Threat Prevention, Data Filtering, and HIP Matches.<br><br>Click any application name to display detailed application information. |
| Step 2 | Identify the egress interface for applications that you identified as needing QoS treatment.<br><br>The egress interface for traffic depends on the traffic flow. If you are shaping incoming traffic, the egress interface is the internal-facing interface. If you are shaping outgoing traffic, the egress interface is the external-facing interface. | Select **Monitor > Logs > Traffic** to view the device's traffic logs.<br><br>To filter and only show logs for a specific application:<br>• If an entry is displayed for the application, click the underlined link in the Application column then click the Submit icon.<br>• If an entry is not displayed for the application, click the Add Log icon and search for the application.<br><br>The **Egress I/F** in the traffic logs displays each application's egress interface. To display the **Egress I/F** column if it is not displayed by default:<br>• Click any column header to add a column to the log:<br>  <br>• Click the spyglass icon to the left of any entry to display a detailed log that includes the application's egress interface listed in the Destination section:<br> <br>In this example, the egress interface for web-browsing traffic is ethernet 1/1. |

 © Palo Alto Networks, Inc.

**Configure QoS (Continued)**

Step 3 Add a QoS profile.

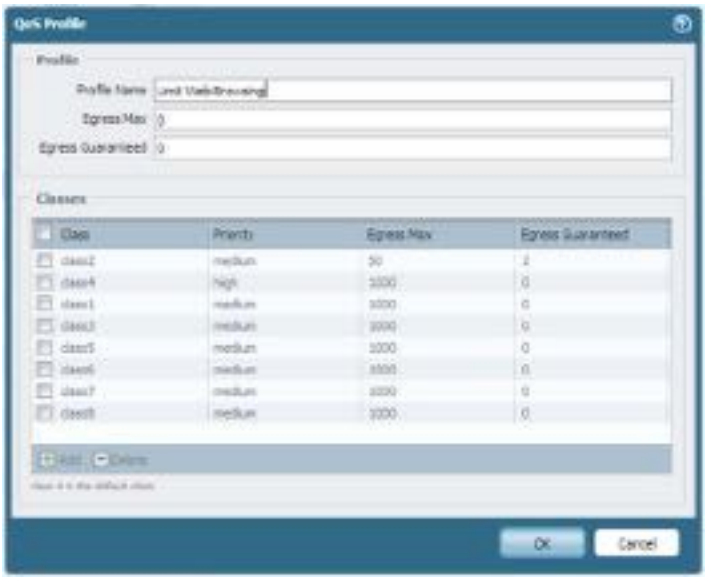
A QoS profile allows you to define the eight classes of service that traffic can receive, including the priority and bandwidth for each class, as well as the total, combined bandwidth for all eight classes.

You can edit any existing QoS profile, including the default, by clicking the QoS profile name.

1. Select **Network > Network Profiles > QoS Profile** and click **Add** to open the **QoS Profile** dialog.
2. Enter a descriptive **Profile Name**.
3. Enter an **Egress Max** to set the overall bandwidth allocation for the QoS Profile.
4. Enter an **Egress Guaranteed** to set the guaranteed bandwidth for the QoS Profile.

   Any traffic that exceeds the **Egress Guaranteed** value is best effort and not guaranteed.
5. In the Classes section, specify how to treat up to eight individual QoS classes:
   a. Click **Add** to add a class to the QoS Profile.
   b. Select the **Priority** for the class.
   c. Enter an **Egress Max** for a class to set the overall bandwidth limit for that individual class.
   d. Enter an **Egress Guaranteed** for the class to set the guaranteed bandwidth for that individual class.
6. Click **OK** to save the QoS Profile.

In the following example, the QoS Profile named Limit Web Browsing limits traffic identified as Class 2 traffic to maximum bandwidth of 50Mbps and a guaranteed bandwidth of 2Mbps. Any traffic that is associated with class 2 in a the QoS policy (Step 4) is subject to these limits.



| Configure QoS (Continued) | |
|---|---|
| Step 4 Add a QoS policy rule.<br><br>A QoS policy allows define traffic to receive QoS treatment, and to assign traffic matched to the policy rule a QoS class of service. | 1. Select **Policies > QoS** and click **Add** to open the QoS Policy Rule dialog.<br>2. On the **General** tab, give the QoS Policy Rule a descriptive **Name**.<br>3. Specify the traffic to which the QoS Policy Rule will apply. Use the **Source**, **Destination**, **Application**, **Service/URL Category**, and **DSCP/ToS** tabs to define matching parameters for identifying traffic (use the **DSCP/ToS** tab to Enforce QoS Based on DSCP Classification).<br>For example, select the **Application** tab, click **Add**, and select web-browsing to apply the QoS Policy Rule to that application:<br>  <br>(Optional) Define additional parameters. For example, on the **Source** tab, click **Add** to limit web-browsing for a specific user, in this case, user1:<br> <br>4. On the **Other Settings** tab, select a QoS Class to assign to the QoS Policy Rule. For example, assign Class 2 to the user1's web-browsing traffic:<br> <br>5. Click **OK** to save the QoS Policy Rule. |

© Palo Alto Networks, Inc.

**Configure QoS (Continued)**

Step 5 Enable the QoS Profile on a physical interface.

You can configure settings to select clear text and tunneled traffic for unique QoS treatment, in addition to the QoS configuration on the physical interface:

- To define QoS treatment for clear text traffic based on source interface and subnet, perform step 4.
- To define QoS treatment for a specific tunnel interface(s), perform step 5.

See QoS Clear Text and Tunneled Traffic for details on enforcing QoS for clear text and tunneled traffic.

Check if the platform you're using supports enabling QoS on a subinterface by reviewing a summary of the Product Specifications.

It is a best practice to always define the **Egress Max** value for a QoS interface.

1. Select **Network > QoS** and click **Add** to open the QoS Interface dialog.
2. Enable QoS on the physical interface:
   a. On the **Physical Interface** tab, select the **Interface Name** of the interface to which to enable QoS.

      In the example, Ethernet 1/1 is the egress interface for web-browsing traffic (see Step 2).

   b. Select **Turn on QoS feature on this interface**.
3. On the **Physical Interface** tab, select a QoS profile to apply by default to all **Clear Text** traffic.

   (Optional) Use the Tunnel Interface field to apply a QoS profile by default to all tunneled traffic.

For example, enable QoS on ethernet 1/1 and apply the QoS Profile named Limit Web Browsing as the default QoS Profile for clear text traffic.

4. (Optional) Select **Clear Text Traffic** and configure more granular QoS settings for clear text traffic:
   - Set the **Egress Guaranteed** and **Egress Max** bandwidths for clear text traffic.
   - Click **Add** to further specify QoS treatment for clear text traffic, based on source interface and source subnet.
5. (Optional) Select **Tunneled Traffic** and configure more granular QoS settings for tunnel interfaces:
   - Set the **Egress Guaranteed** and **Egress Max** bandwidths for tunneled traffic.
   - Click **Add** and attach a QoS profile to a single tunnel interface.
6. Click **OK** and **Commit** the changes to enable QoS on the interface.

| Configure QoS (Continued) | |
|---|---|
| Step 6 Verify QoS configuration. | Select **Network > QoS** and then **Statistics** to view QoS bandwidth, active sessions of a selected QoS class, and active applications for the selected QoS class.<br>For example, see the statistics for ethernet 1/1 with QoS enabled:<br>  <br>Class 2 traffic limited to 2Mbps of guaranteed bandwidth and a maximum bandwidth of 50Mbps.<br>Continue to click the tabs to display further information regarding applications, source users, destination users, security rules and QoS rules.<br>Bandwidth limits shown on the **QoS Statistics** window include a hardware adjustment factor. |

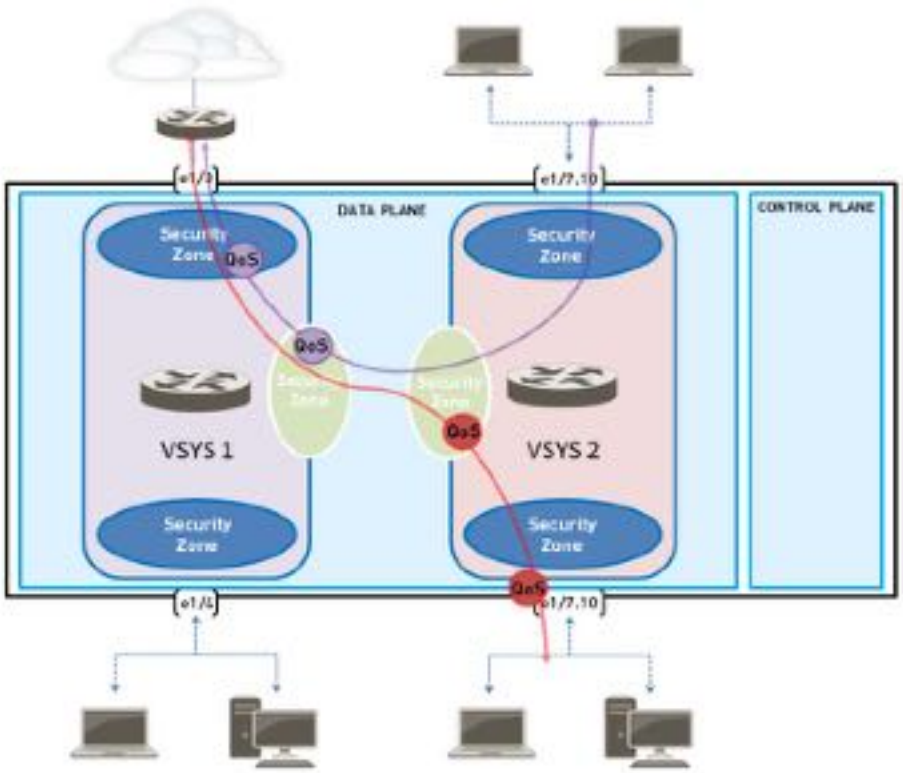
# Configure QoS for a Virtual System

QoS can be configured for a single or several virtual systems configured on a Palo Alto Networks firewall. Because a virtual system is an independent firewall, QoS must be configured independently for a single virtual system.

Configuring QoS for a virtual system is similar to configuring QoS on a physical firewall, with the exception that configuring QoS for a virtual system requires specifying the source and destination of traffic. Because a virtual system exists without set physical boundaries and because traffic in a virtual environment spans more than one virtual system, specifying source and destination zones and interfaces for traffic is necessary to control and shape traffic for a single virtual system.

The example below shows two virtual systems configured on firewall. VSYS 1 (purple) and VSYS 2 (red) each have QoS configured to prioritize or limit two distinct traffic flows, indicated by their corresponding purple (VSYS 1) and red (VSYS 2) lines. The QoS nodes indicate the points at traffic is matched to a QoS policy and assigned a QoS class of service, and then later indicate the point at which traffic is shaped as it egresses the firewall.



Refer to the Virtual Systems (VSYS) tech note for information on Virtual Systems and how to configure them.

| Configure QoS in a Virtual System Environment | | |
|---|---|---|
| Step 1 | Confirm that the appropriate interfaces, virtual routers, and security zones are associated with each virtual system. | • To view configured interfaces, select **Network > Interface**.<br>• To view configured zones, select **Network > Zones**.<br>• To view information on defined virtual routers, select **Network > Virtual Routers**. |

| Configure QoS in a Virtual System Environment | |
|---|---|
| Step 2 Identify traffic to apply QoS to. | Select **ACC** to view the **Application Command Center** page. Use the settings and charts on the **ACC** page to view trends and traffic related to Applications, URL filtering, Threat Prevention, Data Filtering, and HIP Matches.<br>To view information for a specific virtual system, select the virtual system from the **Virtual System** drop-down:<br>  <br><br>Click any application name to display detailed application information. |

 © Palo Alto Networks, Inc.

**Configure QoS in a Virtual System Environment**

Step 3 Identify the egress interface for applications that you identified as needing QoS treatment.

In a virtual system environment, QoS is applied to traffic on the traffic's egress point on the virtual system. Depending the configuration and QoS policy for a virtual system, the egress point of QoS traffic could be associated with a physical interface or could be a zone.

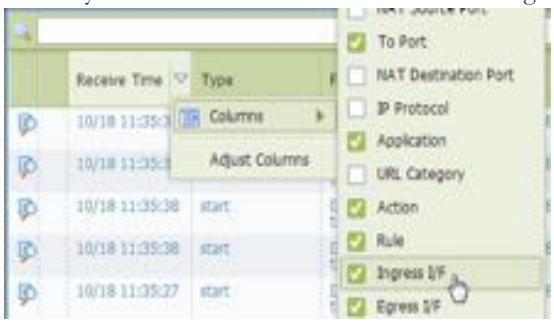
This example shows how to limit web-browsing traffic on vsys 1.

Select **Monitor > Logs > Traffic** to view traffic logs. Each entry has the option to display columns with information necessary to configure QoS in a virtual system environment:

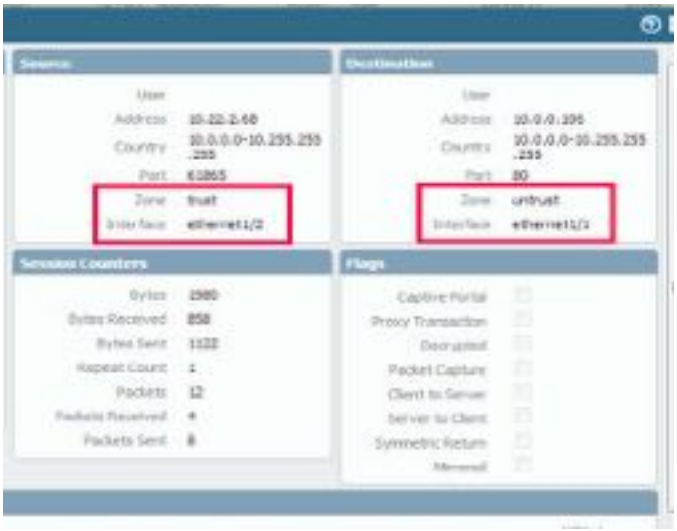
- virtual system
- egress interface
- ingress interface
- source zone
- destination zone

To display a column if it is not displayed by default:

- Click any column header to add a column to the log:



- Click the spyglass icon to the left of any entry to display a detailed log that includes the application's egress interface, as well as source and destination zones, in the **Source** and **Destination** sections:



For example, for web-browsing traffic from VSYS 1, the ingress interface is ethernet 1/2, the egress interface is ethernet 1/1, the source zone is *trust* and the destination zone is *untrust*.

| Configure QoS in a Virtual System Environment | |
|---|---|
| Step 4 Create a QoS Profile.<br><br>You can edit any existing QoS Profile, including the default, by clicking the profile name. | 1. Select **Network > Network Profiles > QoS Profile** and click **Add** to open the QoS Profile dialog.<br>2. Enter a descriptive **Profile Name**.<br>3. Enter an **Egress Max** to set the overall bandwidth allocation for the QoS profile.<br>4. Enter an **Egress Guaranteed** to set the guaranteed bandwidth for the QoS profile.<br><br> Any traffic that exceeds the QoS profile's egress guaranteed limit is best effort but is not guaranteed.<br>5. In the Classes section of the **QoS Profile**, specify how to treat up to eight individual QoS classes:<br>a. Click **Add** to add a class to the QoS Profile.<br>b. Select the **Priority** for the class.<br>c. Enter an **Egress Max** for a class to set the overall bandwidth limit for that individual class.<br>d. Enter an **Egress Guaranteed** for the class to set the guaranteed bandwidth for that individual class.<br>6. Click **OK** to save the QoS profile. |

 © Palo Alto Networks, Inc.

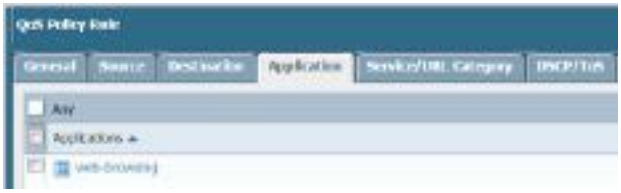
**Configure QoS in a Virtual System Environment**

Step 5 Create a QoS policy.

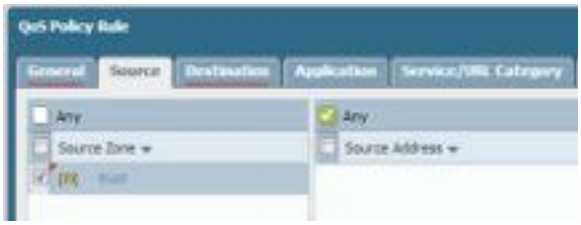
In an environment with multiple virtual systems, traffic spans more than one virtual system. Because of this, when you are enabling QoS for a virtual system, you must define traffic to receive QoS treatment based on source and destination zones. This ensures that the traffic is prioritized and shaped only for that virtual system (and not for other virtual systems through which the traffic might flow).

1. Select **Policies > QoS** and **Add** a QoS Policy Rule.
2. Select **General** and give the QoS Policy Rule a descriptive **Name**.
3. Specify the traffic to which the QoS policy rule will apply. Use the **Source**, **Destination**, **Application**, and **Service/URL Category** tabs to define matching parameters for identifying traffic.

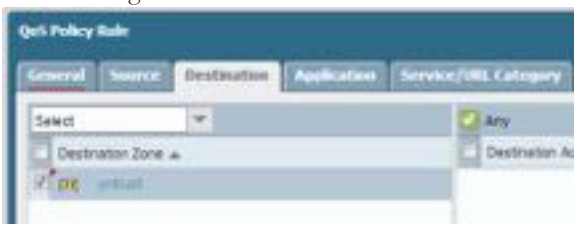
   For example, select **Application** and **Add** web-browsing to apply the QoS policy rule to that application:



4. Select **Source** and **Add** the source zone of vsys 1 web-browsing traffic.



5. Select **Destination** and **Add** the destination zone of vsys 1 web-browsing traffic.



6. Select **Other Settings** and select a **QoS Class** to assign to the QoS policy rule. For example, assign Class 2 to web-browsing traffic on vsys 1:

7. Click **OK** to save the QoS policy rule.

| Configure QoS in a Virtual System Environment | |
|---|---|
| Step 6 Enable the QoS Profile on a physical interface.<br><br>It is a best practice to always define the **Egress Max** value for a QoS interface. | 1. Select **Network > QoS** and click **Add** to open the QoS Interface dialog.<br>2. Enable QoS on the physical interface:<br>a. On the **Physical Interface** tab, select the **Interface Name** of the interface to apply the QoS Profile to.<br>In this example, ethernet 1/1 is the egress interface for web-browsing traffic on vsys 1 (see Step 2).<br> <br>b. Select **Turn on QoS feature on this interface**.<br>3. On the **Physical Interface** tab, select the default QoS profile to apply to all **Clear Text** traffic.<br>(Optional) Use the **Tunnel Interface** field to apply a default QoS profile to all tunneled traffic.<br>4. (Optional) On the **Clear Text Traffic** tab, configure additional QoS settings for clear text traffic:<br>• Set the **Egress Guaranteed** and **Egress Max** bandwidths for clear text traffic.<br>• Click **Add** to apply a QoS Profile to selected clear text traffic, further selecting the traffic for QoS treatment according to source interface and source subnet (creating a QoS node).<br>5. (Optional) On the **Tunneled Traffic** tab, configure additional QoS settings for tunnel interfaces:<br>• Set the **Egress Guaranteed** and **Egress Max** bandwidths for tunneled traffic.<br>• Click **Add** to associate a selected tunnel interface with a QoS Profile.<br>6. Click **OK** to save changes.<br>7. **Commit** the changes. |

© Palo Alto Networks, Inc.

| Configure QoS in a Virtual System Environment | |
|---|---|
| Step 7 Verify QoS configuration. | • Select **Network > QoS** to view the QoS Policies page. The **QoS Policies** page verifies that QoS is enabled and includes a **Statistics** link. Click the Statistics link to view QoS bandwidth, active sessions of a selected QoS node or class, and active applications for the selected QoS node or class.<br>• In a multi-vsys environment, sessions cannot span multiple systems. Multiple sessions are created for one traffic flow if the traffic passes through more than one virtual system. To browse sessions running on the firewall and view applied QoS Rules and QoS Classes, select **Monitor > Session Browser**. |

# Enforce QoS Based on DSCP Classification

A Differentiated Services Code Point (DSCP) is a packet header value that can be used to indicate the level of service requested for traffic, such as high priority or best effort delivery. Session-Based DSCP Classification allows you to both honor the service class requested for traffic and to mark a session to receive continued QoS treatment. Session-based DSCP extends the power of Quality of Service (QoS), which polices traffic as it passes through the firewall, by allowing all network devices between the firewall and the client to also police traffic. All inbound and outbound traffic for a session can receive continuous QoS/DSCP treatment as it flows through your network. For example, inbound return traffic from an external server can now be treated with the same QoS/DSCP priority that the firewall initially enforced for the outbound flow. Network devices between the firewall and end user will also then enforce the same priority for the return traffic (and any other outbound or inbound traffic for the session).

Use the following steps to enable Session-Based DSCP Classification. Start by configuring QoS based on DSCP marking detected at the beginning of a session. You can then continue to enable the firewall to mark the return flow for a session with the same DSCP value used to enforce QoS for the initial outbound flow.

| **Provide QoS Based on DSCP/ToS Marking** | |
|---|---|
| Before you set up or modify a QoS policy to control traffic based on DSCP/ToS code point values, make sure that you have performed the preliminary steps for configuring QoS. | The following steps are useful before setting up a QoS policy:<br>❑ Identify the traffic to which to apply QoS.<br>❑ Identify the egress interface for traffic to be enforced with QoS.<br>See Configure QoS for details on performing these steps. |

 © Palo Alto Networks, Inc.

**Provide QoS Based on DSCP/ToS Marking (Continued)**

Step 1 Apply QoS to traffic based on the DSCP value detected at the beginning of the session.

1. Select **Policies > QoS** and **Add** or modify an existing QoS rule and populate required fields.
2. **Add** a **DSCP/ToS** rule and give the rule a descriptive **Name**. You can choose to add multiple DSCP/ToS rules to a single QoS rule to enforce the same QoS priority for sessions with different DSCP values.
3. Select the **Type** of DSCP/ToS marking for the QoS rule to match to traffic:

   It is a best practice to use a single DSCP type to manage and prioritize your network traffic.

   - **Expedited Forwarding (EF)**: Can be used to request low loss, low latency and guaranteed bandwidth for traffic. Packets with EF codepoints are typically guaranteed highest priority delivery.
   - **Assured Forwarding (AF)**: Can be used to provide reliable delivery for applications. Packets with AF codepoint indicate a request for the traffic to receive higher priority treatment than best effort service provides (though packets with an EF codepoint will continue to take precedence over those with an AF codepoint).
   - **Class Selector (CS)**: Can be used to provide backward compatibility with network devices that use the IP precedence field to mark priority traffic.
   - **IP Precedence (ToS)**: Can be used by legacy network devices to mark priority traffic (the IP Precedence header field was used to indicate the priority for a packet before the introduction of the DSCP classification).
   - **Custom Codepoint**: Create a custom codepoint to match to traffic by entering a **Codepoint Name** and **Binary Value**.

   For example, select the **Assured Forwarding (AF)** to ensure traffic marked with an **AF** codepoint value has higher priority for reliable delivery over applications marked to receive lower priority.
4. Match the QoS policy to traffic on a more granular scale by specifying the **Codepoint** value. For example, with Assured Forwarding (AF) selected as the **Type** of DSCP value for the policy to match, further specify an AF **Codepoint** value such as AF11.

   When Expedited Forwarding (EF) is selected as the **Type** of DSCP marking, a granular **Codepoint** value cannot be specified. The QoS policy will match to traffic marked with any EF codepoint value.
5. Select **Other Settings** and a **QoS Class** to assign to traffic matched to the QoS rule. For example, assign Class 1 to sessions where a DSCP marking of AF11 is detected for the first packet in the session.
6. Click **OK** to save the QoS rule.

| | | |
|---|---|---|
| Step 2 | Define the QoS priority for traffic to receive when it is matched to a QoS rule based the DSCP marking detected at the beginning of a session. | 1. Select **Network > Network Profiles > QoS Profile** and **Add** or modify an existing QoS profile. For details on profile options to set priority and bandwidth for traffic, see QoS Concepts and Configure QoS.<br>2. **Add** or modify a profile class. For example, because Step 1 showed steps to classify AF11 traffic as Class 1 traffic, you could add or modify a **class1** entry.<br>3. Select a **Priority** for the class of traffic, such as **high**.<br>4. Click **OK** to save the QoS Profile. |

| Provide QoS Based on DSCP/ToS Marking (Continued) | | |
|---|---|---|
| Step 3 | Enable QoS on an interface. | Select **Network > QoS** and **Add** or modify an existing interface and **Turn on QoS feature on this interface**.<br>In this example, traffic with an AF11 DSCP marking is matched to the QoS rule and assigned Class 1. The QoS profile enabled on the interface enforces high priority treatment for Class 1 traffic as it egresses the firewall (the session *outbound* traffic). |
| Step 4 | Enable DSCP Marking.<br>Mark return traffic with a DSCP value, enabling the inbound flow for a session to be marked with the same DSCP value detected for the outbound flow. | 1. Select **Policies > Security** and **Add** or modify a security policy.<br>2. Select **Actions** and in the **QoS Marking** drop-down, choose **Follow-Client-to-Server-Flow**.<br>3. Click **OK** to save your changes.<br>Completing this step enables the firewall to mark traffic with the same DSCP value that was detected at the beginning of a session (in this example, the firewall would mark return traffic with the DSCP AF11 value). While configuring QoS allows you to shape traffic as it egresses the firewall, enabling this option in a security rule allows the other network devices intermediate to the firewall and the client to continue to enforce priority for DSCP marked traffic. |
| Step 5 | Save the configuration. | **Commit** your changes. |

 © Palo Alto Networks, Inc.

# QoS Use Cases

The following use cases demonstrate how to use QoS in common scenarios:

- Use Case: QoS for a Single User
- Use Case: QoS for Voice and Video Applications

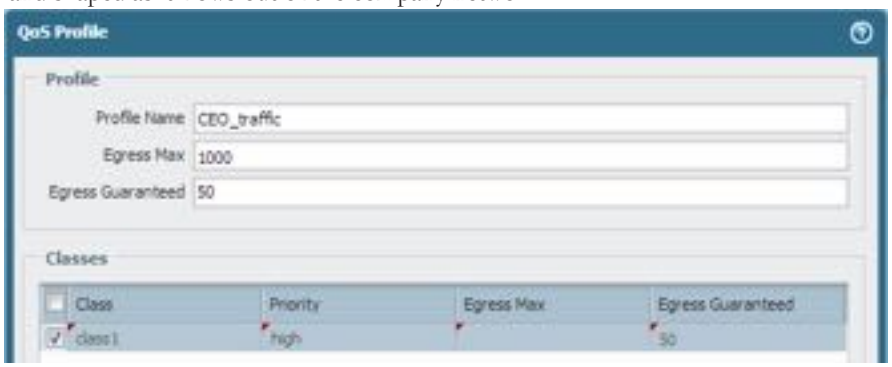
© Palo Alto Networks, Inc.

## Use Case: QoS for a Single User

A CEO finds that during periods of high network usage, she is unable to access enterprise applications to respond effectively to critical business communications. The IT admin wants to ensure that all traffic to and from the CEO receives preferential treatment over other employee traffic so that she is guaranteed not only access to, but high performance of, critical network resources.

### Apply QoS to a Single User

Step 1 The admin creates the QoS profile *CEO_traffic* to define how traffic originating from the CEO will be treated and shaped as it flows out of the company network:



The admin assigns a guaranteed bandwidth (**Egress Guaranteed**) of 50 Mbps to ensure that the CEO will have that amount that bandwidth guaranteed to her at all times (more than she would need to use), regardless of network congestion.

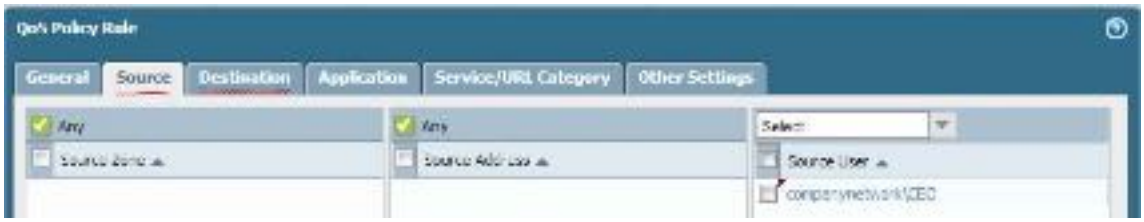
The admin continues by designating Class 1 traffic as high priority and sets the profile's maximum bandwidth usage (**Egress Max**) to 1000 Mbps, the same maximum bandwidth for the interface that the admin will enable QoS on. The admin is choosing to not restrict the CEO's bandwidth usage in any way.

It is a best practice to populate the **Egress Max** field for a QoS profile, even if the max bandwidth of the profile matches the max bandwidth of the interface. The QoS profile's max bandwidth should never exceed the max bandwidth of the interface you are planning to enable QoS on.

 © Palo Alto Networks, Inc.

**Apply QoS to a Single User (Continued)**

Step 2 The admin creates a QoS policy to identify the CEO's traffic (**Policies** > **QoS**) and assigns it the class that he defined in the QoS profile (see Step 1). Because User-ID is configured, the admin uses the **Source** tab in the QoS policy to singularly identify the CEO's traffic by her company network username. (If User-ID is not configured, the administrator could **Add** the CEO's IP address under **Source Address**. See User-ID.):



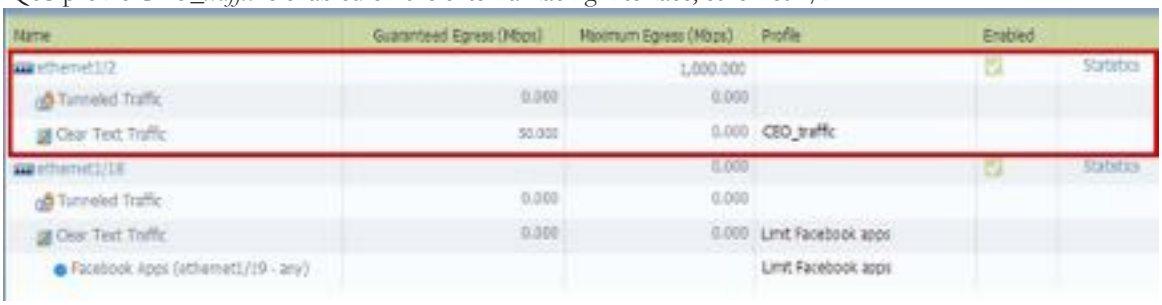
The admin associates the CEO's traffic with Class 1 (**Other Settings** tab) and then continues to populate the remaining required policy fields; the admin gives the policy a descriptive **Name** (**General** tab) and selects **Any** for the **Source Zone** (**Source** tab) and **Destination Zone** (**Destination** tab):

Step 3 Now that Class 1 is associated with the CEO's traffic, the admin enables QoS by checking **Turn on QoS feature on interface** and selecting the traffic flow's egress interface. The egress interface for the CEO's traffic flow is the external-facing interface, in this case, ethernet 1/2:

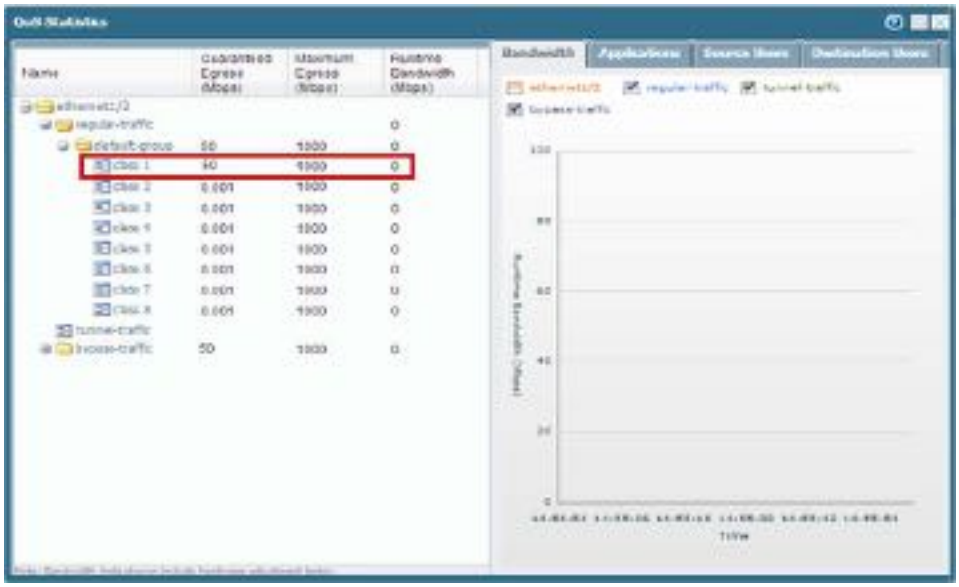
Because the admin wants to ensure that all traffic originating from the CEO is guaranteed by the QoS profile and associated QoS policy he created, he selects the *CEO_traffic* to apply to **Clear Text** traffic flowing from ethernet 1/2.

**Apply QoS to a Single User (Continued)**

Step 4 After committing the QoS configuration, the admin navigates to the **Network > QoS** page to confirm that the QoS profile *CEO_traffic* is enabled on the external-facing interface, ethernet 1/2:



He clicks **Statistics** to view how traffic originating with the CEO (Class 1) is being shaped as it flows from ethernet 1/2:



This case demonstrates how to apply QoS to traffic originating from a single source user. However, if you also wanted to guarantee or shape traffic to a destination user, you could configure a similar QoS setup. Instead of, or in addition to this work flow, create a QoS policy that specifies the user's IP address as the **Destination Address** on the **Policies > QoS** page (instead of specifying the user's source information, as shown in Step 2) and then enable QoS on the network's internal-facing interface on the **Network > QoS** page (instead of the external-facing interface, as shown in Step 3.)

© Palo Alto Networks, Inc.

## Use Case: QoS for Voice and Video Applications

Voice and video traffic is particularly sensitive to measurements that the QoS feature shapes and controls, especially latency and jitter. For voice and video transmissions to be audible and clear, voice and video packets cannot be dropped, delayed, or delivered inconsistently. A best practice for voice and video applications, in addition to guaranteeing bandwidth, is to guarantee priority to voice and video traffic.

In this example, employees at a company branch office are experiencing difficulties and unreliability in using video conferencing and Voice over IP (VoIP) technologies to conduct business communications with other branch offices, with partners, and with customers. An IT admin intends to implement QoS in order to address these issues and ensure effective and reliable business communication for the branch employees. Because the admin wants to guarantee QoS to both incoming and outgoing network traffic, he will enable QoS on both the firewall's internal- and external-facing interfaces.

**Ensure Quality for Voice and Video Applications**

Step 1 The admin creates a QoS profile, defining Class 2 so that any traffic associated with Class 2 receives real-time priority and on an interface with a maximum bandwidth of 1000 Mbps, is guaranteed a bandwidth of 250 Mbps at all times, including peak periods of network usage.

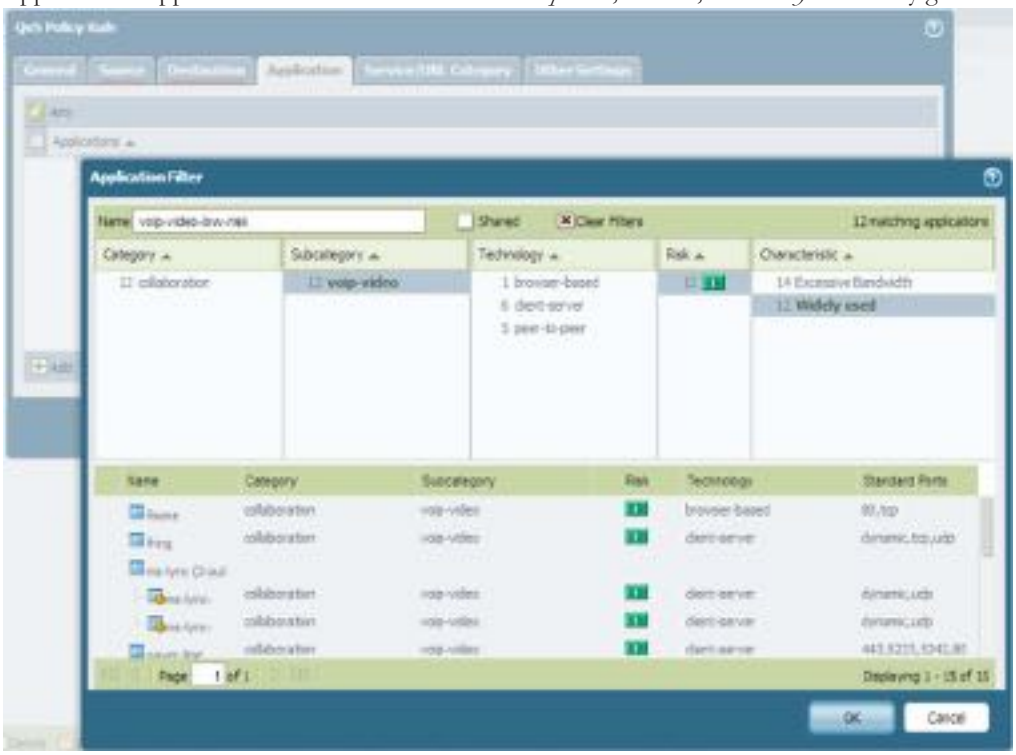
Real-time priority is typically recommended for applications affected by latency, and is particularly useful in guaranteeing performance and quality of voice and video applications.

On the **Network > Network Profiles > Qos Profile** page, the admin clicks **Add**, enters the **Profile Name** *ensure voip-video traffic* and defines Class 2 traffic.

**Ensure Quality for Voice and Video Applications (Continued)**

Step 2 The admin creates a QoS policy to identify voice and video traffic. Because the company does not have one standard voice and video application, the admin wants to ensure QoS is applied to a few applications that are widely and regularly used by employees to communicate with other offices, with partners, and with customers. On the **Policies > QoS > QoS Policy Rule > Applications** tab, the admin clicks **Add** and opens the **Application Filter** window. The admin continues by selecting criteria to filter the applications he wants to apply QoS to, choosing the Subcategory *voip-video*, and narrowing that down by specifying only voip-video applications that are both low-risk and widely-used.

The application filter is a dynamic tool that, when used to filter applications in the QoS policy, allows QoS to be applied to all applications that meet the criteria of *voip-video*, *low risk*, and *widely used* at any given time.



The admin names the **Application Filter** *voip-video-low-risk* and includes it in the QoS policy:

The admin names the QoS policy *Voice-Video* and associates the *voip-video-low-risk* application filter with Class 2 traffic (as he defined it in Step 1). He is going to use the *Voice-Video* QoS policy for both incoming and outgoing QoS traffic, so he sets **Source** and **Destination** information to **Any**:

 © Palo Alto Networks, Inc.

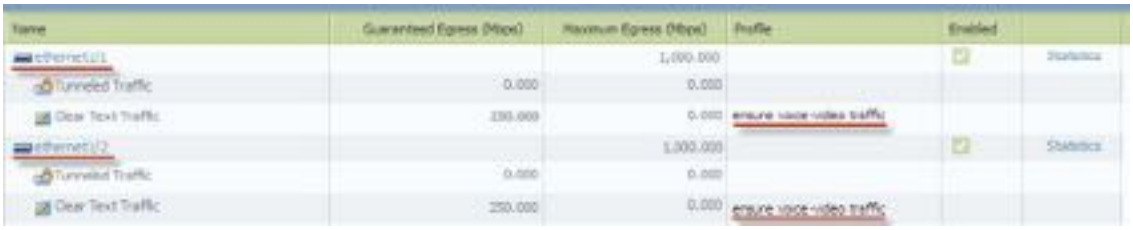
**Ensure Quality for Voice and Video Applications (Continued)**

Step 3 Because the admin wants to ensure QoS for both incoming and outgoing voice and video communications, he enables QoS on the network's external-facing interface (to apply QoS to outgoing communications) and to the internal-facing interface (to apply QoS to incoming communications).

The admin begins by enabling the QoS profile he created in Step 1, *ensure voice-video traffic* (Class 1 in this profile is associated with policy created in Step 2, *Voice-Video*) on the external-facing interface, in this case, ethernet 1/2.

He then enables the same QoS profile *ensure voip-video traffic* on the internal-facing interface, in this case, ethernet 1/1.

Step 4 The admin confirms that QoS is enabled for both incoming and outgoing voice and video traffic:



The admin has successfully enabled QoS on both the network's internal- and external-facing interfaces. Real-time priority is now ensured for voice and video application traffic as it flows both into and out of the network, ensuring that these communications, which are particularly sensitive to latency and jitter, can be used reliably and effectively to perform both internal and external business communications.

 © Palo Alto Networks, Inc.

# VPNs

Virtual private networks (VPNs) create tunnels that allow users/systems to connect securely over a public network, as if they were connecting over a local area network (LAN). To set up a VPN tunnel, you need a pair of devices that can authenticate each other and encrypt the flow of information between them. The devices can be a pair of Palo Alto Networks firewalls, or a Palo Alto Networks firewall along with a VPN-capable device from another vendor.

- VPN Deployments
- Site-to-Site VPN Overview
- Site-to-Site VPN Concepts
- Set Up Site-to-Site VPN
- Site-to-Site VPN Quick Configs

© Palo Alto Networks, Inc.

# VPN Deployments

The Palo Alto Networks firewall supports the following VPN deployments:

- **Site-to-Site VPN**— A simple VPN that connects a central site and a remote site, or a hub and spoke VPN that connects a central site with multiple remote sites. The firewall uses the IP Security (IPSec) set of protocols to set up a secure tunnel for the traffic between the two sites. See Site-to-Site VPN Overview.
- **Remote User-to-Site VPN**—A solution that uses the GlobalProtect agent to allow a remote user to establish a secure connection through the firewall. This solution uses SSL and IPSec to establish a secure connection between the user and the site. Refer to the GlobalProtect Administrator's Guide.
- **Large Scale VPN**— The Palo Alto Networks GlobalProtect Large Scale VPN (LSVPN) provides a simplified mechanism to roll out a scalable hub and spoke VPN with up to 1024 satellite offices. The solution requires Palo Alto Networks firewalls to be deployed at the hub and at every spoke. It uses certificates for device authentication, SSL for securing communication between all components, and IPSec to secure data. See Large Scale VPN (LSVPN).

**Figure: VPN Deployments**

 © Palo Alto Networks, Inc.

# Site-to-Site VPN Overview

A VPN connection that allows you to connect two Local Area Networks (LANs) is called a site-to-site VPN. You can configure route-based VPNs to connect Palo Alto Networks firewalls located at two sites or to connect a Palo Alto Networks firewall with a third-party security device at another location. The firewall can also interoperate with third-party policy-based VPN devices; the Palo Alto Networks firewall supports route-based VPN.

The Palo Alto Networks firewall sets up a route-based VPN, where the firewall makes a routing decision based on the destination IP address. If traffic is routed to a specific destination through a VPN tunnel, then it is handled as VPN traffic.

The IP Security (IPSec) set of protocols is used to set up a secure tunnel for the VPN traffic, and the information in the TCP/IP packet is secured (and encrypted if the tunnel type is ESP). The IP packet (header and payload) is embedded in another IP payload, and a new header is applied and then sent through the IPSec tunnel. The source IP address in the new header is that of the local VPN peer and the destination IP address is that of the VPN peer on the far end of the tunnel. When the packet reaches the remote VPN peer (the firewall at the far end of the tunnel), the outer header is removed and the original packet is sent to its destination.

In order to set up the VPN tunnel, first the peers need to be authenticated. After successful authentication, the peers negotiate the encryption mechanism and algorithms to secure the communication. The Internet Key Exchange (IKE) process is used to authenticate the VPN peers, and IPSec Security Associations (SAs) are defined at each end of the tunnel to secure the VPN communication. IKE uses digital certificates or preshared keys, and the Diffie Hellman keys to set up the SAs for the IPSec tunnel.The SAs specify all of the parameters that are required for secure transmission— including the security parameter index (SPI), security protocol, cryptographic keys, and the destination IP address—encryption, data authentication, data integrity, and endpoint authentication.

The following figure shows a VPN tunnel between two sites. When a client that is secured by VPN Peer A needs content from a server located at the other site, VPN Peer A initiates a connection request to VPN Peer B. If the security policy permits the connection, VPN Peer A uses the IKE Crypto profile parameters (IKE phase 1) to establish a secure connection and authenticate VPN Peer B. Then, VPN Peer A establishes the VPN tunnel using the IPSec Crypto profile, which defines the IKE phase 2 parameters to allow the secure transfer of data between the two sites.

**Figure: Site-to-Site VPN**

# Site-to-Site VPN Concepts

A VPN connection provides secure access to information between two or more sites. In order to provide secure access to resources and reliable connectivity, a VPN connection needs the following components:

- IKE Gateway
- Tunnel Interface
- Tunnel Monitoring
- Internet Key Exchange (IKE) for VPN
- IKEv2

## IKE Gateway

The Palo Alto Networks firewalls or a firewall and another security device that initiate and terminate VPN connections across the two networks are called the IKE Gateways. To set up the VPN tunnel and send traffic between the IKE Gateways, each peer must have an IP address—static or dynamic—or FQDN. The VPN peers use preshared keys or certificates to mutually authenticate each other.

The peers must also negotiate the mode—main or aggressive—for setting up the VPN tunnel and the SA lifetime in IKE Phase 1. Main mode protects the identity of the peers and is more secure because more packets are exchanged when setting up the tunnel. Main mode is the recommended mode for IKE negotiation if both peers support it. Aggressive mode uses fewer packets to set up the VPN tunnel and is hence faster but a less secure option for setting up the VPN tunnel.

See Set Up an IKE Gateway for configuration details.

## Tunnel Interface

To set up a VPN tunnel, the Layer 3 interface at each end must have a logical *tunnel* interface for the firewall to connect to and establish a VPN tunnel. A tunnel interface is a logical (virtual) interface that is used to deliver traffic between two endpoints. Each tunnel interface can have a maximum of 10 IPSec tunnels; this means that up to 10 networks can be associated with the same tunnel interface on the firewall.

The tunnel interface must belong to a security zone to apply policy and it must be assigned to a virtual router in order to use the existing routing infrastructure. Ensure that the tunnel interface and the physical interface are assigned to the same virtual router so that the firewall can perform a route lookup and determine the appropriate tunnel to use.

Typically, the Layer 3 interface that the tunnel interface is attached to belongs to an external zone, for example the untrust zone. While the tunnel interface can be in the same security zone as the physical interface, for added security and better visibility, you can create a separate zone for the tunnel interface. If you create a separate zone for the tunnel interface, say a VPN zone, you will need to create security policies to enable traffic to flow between the VPN zone and the trust zone.

 © Palo Alto Networks, Inc.

To route traffic between the sites, a tunnel interface does not require an IP address. An IP address is only required if you want to enable tunnel monitoring or if you are using a dynamic routing protocol to route traffic across the tunnel. With dynamic routing, the tunnel IP address serves as the next hop IP address for routing traffic to the VPN tunnel.

If you are configuring the Palo Alto Networks firewall with a VPN peer that performs policy-based VPN, you must configure a local and remote Proxy ID when setting up the IPSec tunnel. Each peer compares the Proxy-IDs configured on it with what is actually received in the packet in order to allow a successful IKE phase 2 negotiation. If multiple tunnels are required, configure unique Proxy IDs for each tunnel interface; a tunnel interface can have a maximum of 250 Proxy IDs. Each Proxy ID counts towards the IPSec VPN tunnel capacity of the firewall, and the tunnel capacity varies by the firewall model.

See Set Up an IPSec Tunnel for configuration details.

## Tunnel Monitoring

For a VPN tunnel, you can check connectivity to a destination IP address across the tunnel. The network monitoring profile on the firewall allows you to verify connectivity (using ICMP) to a destination IP address or a next hop at a specified polling interval, and to specify an action on failure to access the monitored IP address.

If the destination IP is unreachable, you either configure the firewall to wait for the tunnel to recover or configure automatic failover to another tunnel. In either case, the firewall generates a system log that alerts you to a tunnel failure and renegotiates the IPSec keys to accelerate recovery.

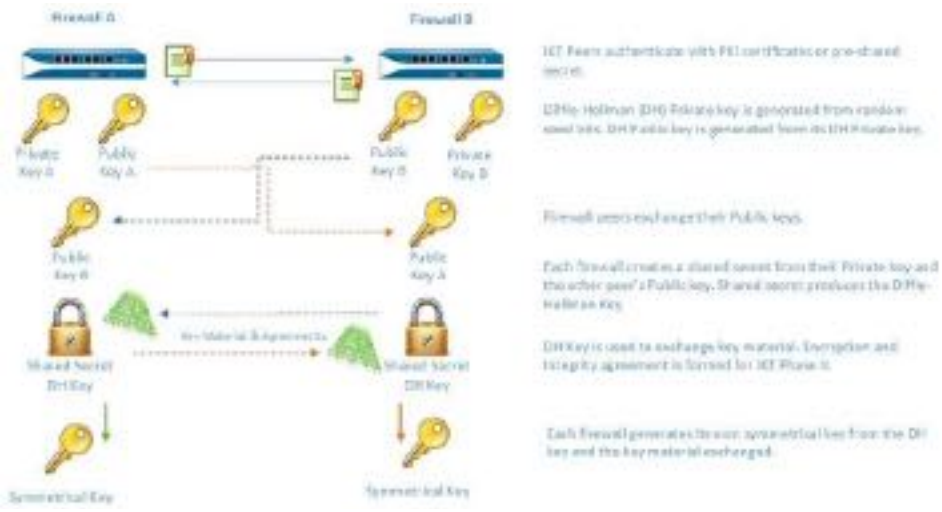
The default monitoring profile is configured to wait for the tunnel to recover; the polling interval is 3 seconds and the failure threshold is 5.

See Set Up Tunnel Monitoring for configuration details.

## Internet Key Exchange (IKE) for VPN

The IKE process allows the VPN peers at both ends of the tunnel to encrypt and decrypt packets using mutually agreed-upon keys or certificate and method of encryption. The IKE process occurs in two phases: IKE Phase 1 and IKE Phase 2. Each of these phases use keys and encryption algorithms that are defined using cryptographic profiles— IKE crypto profile and IPSec crypto profile—and the result of the IKE negotiation is a Security Association (SA). An SA is a set of mutually agreed-upon keys and algorithms that are used by both VPN peers to allow the flow of data across the VPN tunnel. The following illustration depicts the key exchange process for setting up the VPN tunnel:

© Palo Alto Networks, Inc.



## IKE Phase 1

In this phase, the firewalls use the parameters defined in the IKE Gateway configuration and the IKE Crypto profile to authenticate each other and set up a secure control channel. IKE Phase supports the use of preshared keys or digital certificates (which use public key infrastructure, PKI) for mutual authentication of the VPN peers. Preshared keys are a simple solution for securing smaller networks because they do not require the support of a PKI infrastructure. Digital certificates can be more convenient for larger networks or implementations that require stronger authentication security.

When using certificates, make sure that the CA issuing the certificate is trusted by both gateway peers and that the maximum length of certificates in the certificate chain is 5 or less. With IKE fragmentation enabled, the firewall can reassemble IKE messages with up to 5 certificates in the certificate chain and successfully establish a VPN tunnel.

The IKE Crypto profile defines the following options that are used in the IKE SA negotiation:

- Diffie-Hellman (DH) group for generating symmetrical keys for IKE.

  The Diffie-Hellman algorithm uses the private key of one party and the public key of the other to create a shared secret, which is an encrypted key that both VPN tunnel peers share. The DH groups supported on the firewall are: Group 1—768 bits, Group 2—1024 bits (default), Group 5—1536 bits, Group 14—2048 bits, Group 19—256-bit elliptic curve group, and Group 20—384-bit elliptic curve group.

- Authentication algorithms—sha1, sha 256, sha 384, sha 512, or md5

- Encryption algorithms—3des, aes-128-cbc, aes-192-cbc, or aes-256-cbc

## IKE Phase 2

After the tunnel is secured and authenticated, in Phase 2 the channel is further secured for the transfer of data between the networks. IKE Phase 2 uses the keys that were established in Phase 1 of the process and the IPSec Crypto profile, which defines the IPSec protocols and keys used for the SA in IKE Phase 2.

 © Palo Alto Networks, Inc.

The IPSEC uses the following protocols to enable secure communication:

- Encapsulating Security Payload (ESP)—Allows you to encrypt the entire IP packet, and authenticate the source and verify integrity of the data. While ESP requires that you encrypt and authenticate the packet, you can choose to only encrypt or only authenticate by setting the encryption option to Null; using encryption without authentication is discouraged.
- Authentication Header (AH)—Authenticates the source of the packet and verifies data integrity. AH does not encrypt the data payload and is unsuited for deployments where data privacy is important. AH is commonly used when the main concern is to verify the legitimacy of the peer, and data privacy is not required.

**Table: Algorithms Supported for IPSEC Authentication and Encryption**

| ESP | AH |
|---|---|
| Diffie Hellman (DH) exchange options supported | |
| • Group 1—768 bits<br>• Group 2—1024 bits (the default)<br>• Group 5—1536 bits<br>• Group 14—2048 bits.<br>• Group 19— 256-bit elliptic curve group<br>• Group 20—384-bit elliptic curve group<br>• no-pfs—By default, perfect forward secrecy (PFS) is enabled, which means a new DH key is generated in IKE phase 2 using one of the groups listed above. This key is independent of the keys exchanged in IKE phase1 and provides better data transfer security. If you select no-pfs, the DH key created at phase 1 is not renewed and a single key is used for the IPSec SA negotiations. Both VPN peers must be enabled or disabled for PFS. | |
| Encryption algorithms supported | |
| • 3des | Triple Data Encryption Standard (3DES) with a security strength of 112 bits |
| • aes-128-cbc | Advanced Encryption Standard (AES) using cipher block chaining (CBC) with a security strength of 128 bits |
| • aes-192-cbc | AES using CBC with a security strength of 192 bits |
| • aes-256-cbc | AES using CBC with a security strength of 256 bits |
| • aes-128-ccm | AES using Counter with CBC-MAC (CCM) with a security strength of 128 bits |
| • aes-128-gcm | AES using Galois/Counter Mode (GCM) with a security strength of 128 bits |
| • aes-256-gcm | AES using GCM with a security strength of 256 bits |
| Authentication algorithms supported | |
| • md5 | • md5 |

| ESP | AH |
|---|---|
| • sha 1 | • sha 1 |
| • sha 256 | • sha 256 |
| • sha 384 | • sha 384 |
| • sha512 | • sha 512 |

## Methods of Securing IPSec VPN Tunnels (IKE Phase 2)

IPSec VPN tunnels can be secured using manual keys or auto keys. In addition, IPSec configuration options include Diffie-Hellman Group for key agreement, and/or an encryption algorithm and a hash for message authentication.

- **Manual Key**—Manual key is typically used if the Palo Alto Networks firewall is establishing a VPN tunnel with a legacy device, or if you want to reduce the overhead of generating session keys. If using manual keys, the same key must be configured on both peers.

  Manual keys are not recommended for establishing a VPN tunnel because the session keys can be compromised when relaying the key information between the peers; if the keys are compromised, the data transfer is no longer secure.

- **Auto Key**— Auto Key allows you to automatically generate keys for setting up and maintaining the IPSec tunnel based on the algorithms defined in the IPSec Crypto profile.

# IKEv2

An IPSec VPN gateway uses IKEv1 or IKEv2 to negotiate the IKE security association (SA) and IPSec tunnel. IKEv2 is defined in RFC 5996.

Unlike IKEv1, which uses Phase 1 SA and Phase 2 SA, IKEv2 uses a child SA for Encapsulating Security Payload (ESP) or Authentication Header (AH), which is set up with an IKE SA.

NAT traversal (NAT-T) must be enabled on both gateways if you have NAT occurring on a device that sits between the two gateways. A gateway can see only the public (globally routable) IP address of the NAT device.

IKEv2 provides the following benefits over IKEv1:

- Tunnel endpoints exchange fewer messages to establish a tunnel. IKEv2 uses four messages; IKEv1 uses either nine messages (in main mode) or six messages (in aggressive mode).
- Built-in NAT-T functionality improves compatibility between vendors.
- Built-in health check automatically re-establishes a tunnel if it goes down. The liveness check replaces the Dead Peer Detection used in IKEv1.
- Supports traffic selectors (one per exchange). The traffic selectors are used in IKE negotiations to control what traffic can access the tunnel.

 © Palo Alto Networks, Inc.

- Supports Hash and URL certificate exchange to reduce fragmentation.
- Resiliency against DoS attacks with improved peer validation. An excessive number of half-open SAs can trigger cookie validation.

Before configuring IKEv2, you should be familiar with the following concepts:

- Liveness Check
- Cookie Activation Threshold and Strict Cookie Validation
- Traffic Selectors
- Hash and URL Certificate Exchange
- SA Key Lifetime and Re-Authentication Interval

After you Set Up an IKE Gateway, if you chose IKEv2, perform the following optional tasks related to IKEv2 as required by your environment:

- Export a Certificate for a Peer to Access Using Hash and URL
- Import a Certificate for IKEv2 Gateway Authentication
- Change the Key Lifetime or Authentication Interval for IKEv2
- Change the Cookie Activation Threshold for IKEv2
- Configure IKEv2 Traffic Selectors

## Liveness Check

The liveness check for IKEv2 is similar to Dead Peer Detection (DPD), which IKEv1 uses as the way to determine whether a peer is still available.

In IKEv2, the liveness check is achieved by any IKEv2 packet transmission or an empty informational message that the gateway sends to the peer at a configurable interval, five seconds by default. If necessary, the sender attempts the retransmission up to ten times. If it doesn't get a response, the sender closes and deletes the IKE_SA and corresponding CHILD_SAs. The sender will start over by sending out another IKE_SA_INIT message.

## Cookie Activation Threshold and Strict Cookie Validation

Cookie validation is always enabled for IKEv2; it helps protect against half-SA DoS attacks. You can configure the global threshold number of half-open SAs that will trigger cookie validation. You can also configure individual IKE gateways to enforce cookie validation for every new IKEv2 SA.

- The **Cookie Activation Threshold** is a global VPN session setting that limits the number of simultaneous half-opened IKE SAs (default is 500). When the number of half-opened IKE SAs exceeds the **Cookie Activation Threshold**, the Responder will request a cookie, and the Initiator must respond with an IKE_SA_INIT containing a cookie to validate the connection. If the cookie validation is successful, another SA can be initiated. A value of 0 means that cookie validation is always on.

The Responder does not maintain a state of the Initiator, nor does it perform a Diffie-Hellman key exchange, until the Initiator returns the cookie. IKEv2 cookie validation mitigates a DoS attack that would try to leave numerous connections half open.

The **Cookie Activation Threshold** must be lower than the **Maximum Half Opened SA** setting. If you Change the Cookie Activation Threshold for IKEv2 to a very high number (for example, 65534) and the **Maximum Half Opened SA** setting remained at the default value of 65535, cookie validation is essentially disabled.

- You can enable **Strict Cookie Validation** if you want cookie validation performed for every new IKEv2 SA a gateway receives, regardless of the global threshold. **Strict Cookie Validation** affects only the IKE gateway being configured and is disabled by default. If **Strict Cookie Validation** is disabled, the system uses the **Cookie Activation Threshold** to determine whether a cookie is needed or not.

## Traffic Selectors

In IKEv1, a firewall that has a route-based VPN needs to use a local and remote Proxy ID in order to set up an IPSec tunnel. Each peer compares its Proxy IDs with what it received in the packet in order to successfully negotiate IKE Phase 2. IKE Phase 2 is about negotiating the SAs to set up an IPSec tunnel. (For more information on Proxy IDs, see Tunnel Interface.)

In IKEv2, you can Configure IKEv2 Traffic Selectors, which are components of network traffic that are used during IKE negotiation. Traffic selectors are used during the CHILD_SA (tunnel creation) Phase 2 to set up the tunnel and to determine what traffic is allowed through the tunnel. The two IKE gateway peers must negotiate and agree on their traffic selectors; otherwise, one side narrows its address range to reach agreement. One IKE connection can have multiple tunnels; for example, you can assign different tunnels to each department to isolate their traffic. Separation of traffic also allows features such as QoS to be implemented.

The IPv4 and IPv6 traffic selectors are:

- **Source IP address**—A network prefix, address range, specific host, or wildcard.
- **Destination IP address**—A network prefix, address range, specific host, or wildcard.
- **Protocol**—A transport protocol, such as TCP or UDP.
- **Source port**—The port where the packet originated.
- **Destination port**—The port the packet is destined for.

During IKE negotiation, there can be multiple traffic selectors for different networks and protocols. For example, the Initiator might indicate that it wants to send TCP packets from 172.168.0.0/16 through the tunnel to its peer, destined for 198.5.0.0/16. It also wants to send UDP packets from 172.17.0.0/16 through the same tunnel to the same gateway, destined for 0.0.0.0 (any network). The peer gateway must agree to these traffic selectors so that it knows what to expect.

It is possible that one gateway will start negotiation using a traffic selector that is a more specific IP address than the IP address of the other gateway.

 © Palo Alto Networks, Inc.

- For example, gateway A offers a source IP address of 172.16.0.0/16 and a destination IP address of 192.16.0.0/16. But gateway B is configured with 0.0.0.0 (any source) as the source IP address and 0.0.0.0 (any destination) as the destination IP address. Therefore, gateway B narrows down its source IP address to 192.16.0.0/16 and its destination address to 172.16.0.0/16. Thus, the narrowing down accommodates the addresses of gateway A and the traffic selectors of the two gateways are in agreement.
- If gateway B (configured with source IP address 0.0.0.0) is the Initiator instead of the Responder, gateway A will respond with its more specific IP addresses, and gateway B will narrow down its addresses to reach agreement.

## Hash and URL Certificate Exchange

IKEv2 supports Hash and URL Certificate Exchange, which is used during an IKEv2 negotiation of an SA. You store the certificate on an HTTP server, which is specified by a URL. The peer fetches the certificate from the server based on receiving the URL to the server. The hash is used to check whether the content of the certificate is valid or not. Thus, the two peers exchange certificates with the HTTP CA rather than with each other.

The hash part of Hash and URL reduces the message size and thus Hash and URL is a way to reduce the likelihood of packet fragmentation during IKE negotiation. The peer receives the certificate and hash that it expects, and thus IKE Phase 1 has validated the peer. Reducing fragmentation occurrences helps protect against DoS attacks.

You can enable the Hash and URL certificate exchange when configuring an IKE gateway by selecting **HTTP Certificate Exchange** and entering the **Certificate URL**. The peer must also use Hash and URL certificate exchange in order for the exchange to be successful. If the peer cannot use Hash and URL, X.509 certificates are exchanged similarly to how they are exchanged in IKEv1.

If you enable the Hash and URL certificate exchange, you must export your certificate to the certificate server if it is not already there. When you export the certificate, the file format should be **Binary Encoded Certificate (DER)**. See Export a Certificate for a Peer to Access Using Hash and URL.

## SA Key Lifetime and Re-Authentication Interval

In IKEv2, two IKE crypto profile values, **Key Lifetime** and **IKEv2 Authentication Multiple**, control the establishment of IKEv2 IKE SAs. The key lifetime is the length of time that a negotiated IKE SA key is effective. Before the key lifetime expires, the SA must be re-keyed; otherwise, upon expiration, the SA must begin a new IKEv2 IKE SA re-key. The default value is 8 hours.

The re-authentication interval is derived by multiplying the **Key Lifetime** by the **IKEv2 Authentication Multiple**. The authentication multiple defaults to 0, which disables the re-authentication feature.

The range of the authentication multiple is 0-50. So, if you were to configure an authentication multiple of 20, for example, the system would perform re-authentication every 20 re-keys, which is every 160 hours. That means the gateway could perform Child SA creation for 160 hours before the gateway must re-authenticate with IKE to recreate the IKE SA from scratch.

In IKEv2, the Initiator and Responder gateways have their own key lifetime value, and the gateway with the shorter key lifetime is the one that will request that the SA be re-keyed.

© Palo Alto Networks, Inc.

# Set Up Site-to-Site VPN

To set up site-to-site VPN:

- Make sure that your Ethernet interfaces, virtual routers, and zones are configured properly. For more information, see Configure Interfaces and Zones.
- Create your tunnel interfaces. Ideally, put the tunnel interfaces in a separate zone, so that tunneled traffic can use different policies.
- Set up static routes or assign routing protocols to redirect traffic to the VPN tunnels. To support dynamic routing (OSPF, BGP, RIP are supported), you must assign an IP address to the tunnel interface.
- Define IKE gateways for establishing communication between the peers across each end of the VPN tunnel; also define the cryptographic profile that specifies the protocols and algorithms for identification, authentication, and encryption to be used for setting up VPN tunnels in IKEv1 Phase 1. See Set Up an IKE Gateway and Define IKE Crypto Profiles.
- Configure the parameters that are needed to establish the IPSec connection for transfer of data across the VPN tunnel; See Set Up an IPSec Tunnel. For IKEv1 Phase-2, see Define IPSec Crypto Profiles.
- (Optional) Specify how the firewall will monitor the IPSec tunnels. See Set Up Tunnel Monitoring.
- Define security policies to filter and inspect the traffic.

If there is a deny rule at the end of the security rulebase, intra-zone traffic is blocked unless otherwise allowed. Rules to allow IKE and IPSec applications must be explicitly included above the deny rule.

When these tasks are complete, the tunnel is ready for use. Traffic destined for the zones/addresses defined in policy is automatically routed properly based on the destination route in the routing table, and handled as VPN traffic. For a few examples on site-to-site VPN, see Site-to-Site VPN Quick Configs.

For troubleshooting purposes, you can Enable/Disable, Refresh or Restart an IKE Gateway or IPSec Tunnel.

 © Palo Alto Networks, Inc.

## Set Up an IKE Gateway

To set up a VPN tunnel, the VPN peers or gateways must authenticate each other using preshared keys or digital certificates and establish a secure channel in which to negotiate the IPSec security association (SA) that will be used to secure traffic between the hosts on each side.

| Set Up an IKE Gateway | | |
|---|---|---|
| Step 1 | Define the IKE Gateway. | 1. Select **Network > Network Profiles > IKE Gateways**, click **Add**, and on the **General** tab, enter the **Name** of the gateway.<br>2. For **Version**, select **IKEv1 only mode**, **IKEv2 only mode**, or **IKEv2 preferred mode**. The IKE gateway begins its negotiation with its peer in the mode specified here. If you select **IKEv2 preferred mode**, the two peers will use IKEv2 if the remote peer supports it; otherwise they will use IKEv1.<br>(The **Version** selection also determines which options are available on the **Advanced Options** tab.) |
| Step 2 | Establish the local endpoint of the tunnel (gateway). | 1. For **Address Type**, click **IPv4** or **IPv6**.<br>2. Select the physical, outgoing **Interface** on the firewall where the local gateway resides.<br>3. From the **Local IP Address** drop-down, select the IP address that will be used as the endpoint for the VPN connection. This is the external-facing interface with a publicly routable IP address on the firewall. |
| Step 3 | Establish the peer at the far end of the tunnel (gateway). | 1. Select the **Peer IP Type** to be a **Static** or **Dynamic** address assignment.<br>2. If the **Peer IP Address** is static, enter the IP address of the peer. |
| Step 4 | Specify how the peer is authenticated. | Select the **Authentication** method: **Pre-Shared Key** or **Certificate**. If you choose Pre-Shared Key, proceed to Step 5. If you choose Certificate, proceed to Step 6. |

| Set Up an IKE Gateway | |
|---|---|
| Step 5 Configure a pre-shared key. | 1. Enter a **Pre-shared Key**, which is the security key to use for authentication across the tunnel. Re-enter the value to **Confirm Pre-shared Key**.<br> Generate a key that is difficult to crack with dictionary attacks; use a pre-shared key generator, if necessary.<br>2. For **Local Identification**, choose from the following types and enter a value that you determine: **FQDN (hostname)**, **IP address**, **KEYID (binary format ID string in HEX)**, **User FQDN (email address)**. Local identification defines the format and identification of the local gateway. If no value is specified, the local IP address will be used as the local identification value.<br>3. For **Peer Identification**, choose from the following types and enter the value: **FQDN (hostname)**, **IP address**, **KEYID (binary format ID string in HEX)**, **User FQDN (email address)**. Peer identification defines the format and identification of the peer gateway. If no value is specified, the peer IP address will be used as the peer identification value.<br>4. Proceed to Step 7 and continue from there. |

 © Palo Alto Networks, Inc.

| Set Up an IKE Gateway | |
|---|---|
| Step 6 Configure certificate-based authentication. Perform the remaining steps in this procedure if you selected **Certificate** as the method of authenticating the peer gateway at the opposite end of the tunnel. | 1. Select a **Local Certificate** that is already on the firewall from the drop-down, or **Import** a certificate, or **Generate** to create a new certificate.<br>• If you want to **Import** a certificate, Import a Certificate for IKEv2 Gateway Authentication and then return to this task.<br>• If you want to **Generate** a new certificate, Generate a Certificate on the Device and then return to this task.<br>2. Click the **HTTP Certificate Exchange** check box if you want to configure Hash and URL (IKEv2 only). For an HTTP certificate exchange, enter the **Certificate URL**. For more information, see Hash and URL Certificate Exchange.<br>3. Select the **Local Identification** type from the following: **Distinguished Name (Subject)**, **FQDN (hostname)**, **IP address**, **User FQDN (email address)**, and enter the value. Local identification defines the format and identification of the local gateway.<br>4. Select the **Peer Identification** type from the following: **Distinguished Name (Subject)**, **FQDN (hostname)**, **IP address**, **User FQDN (email address)**, and enter the value. Peer identification defines the format and identification of the peer gateway.<br>5. Select one type of **Peer ID Check**:<br>• **Exact**—Check this to ensure that the local setting and peer IKE ID payload match exactly.<br>• **Wildcard**—Check this to allow the peer identification to match as long as every character before the wildcard (*) matches. The characters after the wildcard need not match.<br>6. Click **Permit peer identification and certificate payload identification mismatch** if you want to allow a successful IKE SA even when the peer identification does not match the peer identification in the certificate.<br>7. Choose a **Certificate Profile** from the drop-down. A certificate profile contains information about how to authenticate the peer gateway.<br>8. Click **Enable strict validation of peer's extended key use** if you want to strictly control how the key can be used. |

© Palo Alto Networks, Inc.

| Set Up an IKE Gateway | |
|---|---|
| Step 7 Configure advanced options for the gateway. | 1. Select the **Advanced Options** tab.<br>2. In the Common Options section, **Enable Passive Mode** if you want the firewall to only respond to IKE connection requests and never initiate them.<br>3. **Enable NAT Traversal** if you have a device performing NAT between the gateways, to have UDP encapsulation used on IKE and UDP protocols, enabling them to pass through intermediate NAT devices.<br>4. If you chose **IKEv1 only mode** earlier, on the IKEv1 tab:<br>• Choose **auto**, **aggressive**, or **main** for the **Exchange Mode**. When a device is set to use **auto** exchange mode, it can accept both **main** mode and **aggressive** mode negotiation requests; however, whenever possible, it initiates negotiation and allows exchanges in **main** mode.<br>If the exchange mode is not set to **auto**, you must configure both peers with the same exchange mode to allow each peer to accept negotiation requests.<br>• Select an existing profile or keep the default profile from **IKE Crypto Profile** drop-down. For details on defining an IKE Crypto profile, see Define IKE Crypto Profiles.<br>• (Only if using certificate-based authentication and the exchange mode is not set to **aggressive** mode) Click **Enable Fragmentation** to enable the firewall to operate with IKE Fragmentation.<br>• Click **Dead Peer Detection** and enter an **Interval** (range is 2-100 seconds). For **Retry,** define the time to delay (range is 2-100 seconds) before attempting to re-check availability. Dead peer detection identifies inactive or unavailable IKE peers by sending an IKE phase 1 notification payload to the peer and waiting for an acknowledgment.<br>5. If you chose **IKEv2 only mode** or **IKEv2 preferred mode** in Step 1, on the IKEv2 tab:<br>• Select an **IKE Crypto Profile** from the drop-down, which configures IKE Phase 1 options such as the DH group, hash algorithm, and ESP authentication. For information about IKE crypto profiles, see IKE Phase 1.<br>• Enable **Strict Cookie Validation** if you want to always enforce cookie validation on IKEv2 SAs for this gateway. See Cookie Activation Threshold and Strict Cookie Validation.<br>• **Enable Liveness Check** and enter an **Interval (sec)** (default is 5) if you want to have the gateway send a message request to its gateway peer, requesting a response. If necessary, the Initiator attempts the liveness check up to 10 times. If it doesn't get a response, the Initiator closes and deletes the IKE_SA and CHILD_SA. The Initiator will start over by sending out another IKE_SA_INIT. |

© Palo Alto Networks, Inc.

| Set Up an IKE Gateway | |
|---|---|
| Step 8 Save the changes. | Click **OK** and **Commit**. |

## Export a Certificate for a Peer to Access Using Hash and URL

IKEv2 supports Hash and URL Certificate Exchange as a method of having the peer at the remote end of the tunnel fetch the certificate from a server where you have exported the certificate. Perform this task to export your certificate to that server.

❒ You must have already created a certificate using **Device > Certificate Management**.

| Export a Certificate for Hash and URL | |
|---|---|
| Export a certificate for a peer to access using Hash and URL certificate exchange. | 1. Select **Device > Certificates**, and if your platform supports multiple virtual systems, for **Location**, select the appropriate virtual system.<br>2. On the **Device Certificates** tab, select the certificate to **Export** to the server.<br>The status of the certificate should be valid, not expired. The firewall will not stop you from exporting an invalid certificate.<br>3. For **File Format**, select **Binary Encoded Certificate (DER)**.<br>4. Leave **Export private key** clear. Exporting the private key is unnecessary for Hash and URL.<br>5. Click **OK**. |

## Import a Certificate for IKEv2 Gateway Authentication

Perform this task if you are authenticating a peer for an IKEv2 gateway and you did not use a local certificate already on the firewall; you want to import a certificate from elsewhere.

This task presumes that you selected **Network > IKE Gateways**, added a gateway, and for **Local Certificate**, you clicked **Import**.

| Import a Certificate for IKEv2 Gateway Authentication | |
|---|---|
| Step 1 Import a certificate. | 1. Select **Network > IKE Gateways**, **Add** a gateway, and on the **General** tab, for **Authentication**, select **Certificate**. For **Local Certificate**, click **Import**.<br>2. In the Import Certificate window, enter a **Certificate Name** for the certificate you are importing.<br>3. Select **Shared** if this certificate is to be shared among multiple virtual systems.<br>4. For **Certificate File**, **Browse** to the certificate file. Click on the file name and click **Open**, which populates the **Certificate File** field.<br>5. For **File Format**, select one of the following:<br>• **Base64 Encoded Certificate (PEM)**—Contains the certificate, but not the key. It is cleartext.<br>• **Encrypted Private Key and Certificate (PKCS12)**—Contains both the certificate and the key.<br>6. Select **Import private key** if the key is in a different file from the certificate file. The key is optional, with the following exception:<br>• You must import a key if you set the **File Format** to **PEM**. Enter a **Key file** by clicking **Browse** and navigating to the key file to import.<br>• Enter a **Passphrase** and **Confirm Passphrase**.<br>7. Click **OK**. |
| Step 2 After you perform this task, return to Configure an IKEv2 Gateway and resume Step 6. | |

## Change the Key Lifetime or Authentication Interval for IKEv2

This task is optional; the default setting of the IKEv2 IKE SA re-key lifetime is 8 hours. The default setting of the IKEv2 Authentication Multiple is 0, meaning the re-authentication feature is disabled. For more information, see SA Key Lifetime and Re-Authentication Interval.

To change the default values, perform the following task. A prerequisite is that an IKE crypto profile already exists.

 © Palo Alto Networks, Inc.

| Change the SA Key Lifetime or Authentication Interval | | |
|---|---|---|
| Step 1 | Change the SA key lifetime or authentication interval for an IKE Crypto profile. | 1. Select **Network > Network Profiles > IKE Crypto** and select the IKE Crypto profile that applies to the local gateway.<br>2. For the **Key Lifetime**, select a unit (**Seconds**, **Minutes**, **Hours**, or **Days**) and enter a value. The minimum is three minutes.<br>3. For **IKE Authentication Multiple**, enter a value, which is multiplied by the lifetime to determine the re-authentication interval. |
| Step 2 | Save the configuration. | Click **OK** and **Commit**. |

## Change the Cookie Activation Threshold for IKEv2

Perform the following task if you want a firewall to have a threshold different from the default setting of 500 half-opened SA sessions before cookie validation is required. For more information about cookie validation, see Cookie Activation Threshold and Strict Cookie Validation.

| Change the Cookie Activation Threshold | | |
|---|---|---|
| Step 1 | Change the Cookie Activation Threshold. | 1. Select **Device > Setup > Session** and edit the VPN Session Settings. For **Cookie Activation Threshold**, enter the maximum number of half-opened SAs that are allowed before the responder requests a cookie from the initiator (range is 0-65535; default: is 500).<br>2. Click **OK**. |
| Step 2 | Save the configuration | Click **OK** and **Commit**. |

## Configure IKEv2 Traffic Selectors

| Configure Traffic Selectors for IKEv2 | | |
|---|---|---|
| Step 1 | Configure Traffic Selectors. | 1. Select **Network > IPSec Tunnels > Proxy IDs**.<br>2. Select the **IPv4** or **IPv6** tab.<br>3. Click **Add** and enter the **Name** in the **Proxy ID** field.<br>4. In the **Local** field, enter the **Source IP Address**.<br>5. In the **Remote** field, enter the **Destination IP Address**.<br>6. In the **Protocol** field, select the transport protocol (**TCP** or **UDP**) from the drop-down.<br>7. Click **OK**. |

# Define Cryptographic Profiles

A cryptographic profile specifies the ciphers used for authentication and/or encryption between two IKE peers, and the lifetime of the key. The time period between each renegotiation is known as the lifetime; when the specified time expires, the firewall renegotiates a new set of keys.

For securing communication across the VPN tunnel, the firewall requires IKE and IPSec cryptographic profiles for completing IKE phase 1 and phase 2 negotiations, respectively. The firewall includes a default IKE crypto profile and a default IPSec crypto profile that is ready for use.

- Define IKE Crypto Profiles
- Define IPSec Crypto Profiles

## Define IKE Crypto Profiles

The IKE crypto profile is used to set up the encryption and authentication algorithms used for the key exchange process in IKE Phase 1, and lifetime of the keys, which specifies how long the keys are valid. To invoke the profile, you must attach it to the IKE Gateway configuration.

All IKE gateways configured on the same interface or local IP address must use the same crypto profile.

| **Define an IKE Crypto Profile** | | |
|---|---|---|
| Step 1 | Create a new IKE profile. | 1. Select **Network > Network Profiles > IKE Crypto** and select **Add**.<br>2. Enter a **Name** for the new profile. |
| Step 2 | Specify the DH Group (Diffie–Hellman group) for key exchange, and the Authentication and Encryption algorithms. | Click **Add** in the corresponding sections (DH Group, Authentication, and Encryption) and select from the drop-downs.<br>If you are not certain of what the VPN peers support, add multiple groups or algorithms in the order of most-to-least secure as follows; the peers negotiate the strongest supported group or algorithm to establish the tunnel:<br>• DH Group—**group20**, **group19**, **group14**, **group5**, **group2**, and **group1**.<br>• Authentication—**sha512**, **sha384**, **sha256**, **sha1**, **md5**.<br>• Encryption—**aes-256-cbc**, **aes-192-cbc**, **aes-128-cbc**, **3des**. |
| Step 3 | Specify the duration for which the key is valid and the re-authentication interval.<br>For details, see SA Key Lifetime and Re-Authentication Interval. | 1. In the **Key Lifetime** fields, specify the period (in seconds, minutes, hours, or days) for which the key is valid. (Range is 3 minutes to 365 days; default is 8 hours.) When the key expires, the firewall renegotiates a new key. A lifetime is the period between each renegotiation.<br>2. For the **IKEv2 Authentication Multiple**, specify a value (range is 0-50) that is multiplied by the **Key Lifetime** to determine the authentication count. The default value of 0 disables the re-authentication feature. |

 © Palo Alto Networks, Inc.

| Define an IKE Crypto Profile | | |
|---|---|---|
| Step 4 | Save your IKE Crypto profile. | Click **OK** and click **Commit**. |
| Step 5 | Attach the IKE Crypto profile to the IKE Gateway configuration. | See Step 7 in Set Up an IKE Gateway. |

## Define IPSec Crypto Profiles

The IPSec crypto profile is invoked in IKE Phase 2. It specifies how the data is secured within the tunnel when Auto Key IKE is used to automatically generate keys for the IKE SAs.

| Define the IPSec Crypto Profile | | |
|---|---|---|
| Step 1 | Create a new IPSec profile. | 1. Select **Network > Network Profiles > IPSec Crypto** and select **Add**.<br>2. Enter a **Name** for the new profile.<br>3. Select the **IPSec Protocol**—ESP or AH—that you want to apply to secure the data as it traverses across the tunnel.<br>4. Click **Add** and select the **Authentication** and **Encryption** algorithms for ESP, and **Authentication** algorithms for AH, so that the IKE peers can negotiate the keys for the secure transfer of data across the tunnel.<br>If you are not certain of what the IKE peers support, add multiple algorithms in the order of most-to-least secure as follows; the peers negotiate the strongest supported algorithm to establish the tunnel:<br>• Encryption—**aes-256-gcm**, **aes-256-cbc**, **aes-192-cbc**, **aes-128-gcm**, **aes-128-ccm** (the VM-Series firewall doesn't support this option), **aes-128-cbc**, **3des**.<br>• Authentication—**sha512**, **sha384**, **sha256**, **sha1**, **md5**. |
| Step 2 | Select the DH Group to use for the IPSec SA negotiations in IKE phase 2. | Select the key strength that you want to use from the **DH Group** drop-down.<br>If you are not certain of what the VPN peers support, add multiple groups in the order of most-to-least secure as follows; the peers negotiate the strongest supported group to establish the tunnel: **group20**, **group19**, **group14**, **group5**, **group2**, and **group1**.<br>Select **no-pfs** if you do not want to renew the key that was created at phase 1; the current key is reused for the IPSEC SA negotiations. |

| Define the IPSec Crypto Profile | | |
|---|---|---|
| Step 3 | Specify the duration of the key—time and volume of traffic. | Using a combination of time and traffic volume allows you to ensure safety of data.<br>Select the **Lifetime** or time period for which the key is valid in seconds, minutes, hours, or days (range is 3 minutes to 365 days). When the specified time expires, the firewall will renegotiate a new set of keys.<br>Select the **Lifesize** or volume of data after which the keys must be renegotiated. |
| Step 4 | Save your IPSec profile. | Click **OK** and click **Commit**. |
| Step 5 | Attach the IPSec Profile to an IPSec tunnel configuration. | See Step 4 in Set Up an IPSec Tunnel. |

© Palo Alto Networks, Inc.

## Set Up an IPSec Tunnel

The IPSec tunnel configuration allows you to authenticate and/or encrypt the data (IP packet) as it traverses across the tunnel.

If you are setting up the Palo Alto Networks firewall to work with a peer that supports policy-based VPN, you must define Proxy IDs. Devices that support policy-based VPN use specific security rules/policies or access-lists (source addresses, destination addresses and ports) for permitting interesting traffic through an IPSec tunnel. These rules are referenced during quick mode/IKE phase 2 negotiation, and are exchanged as Proxy-IDs in the first or the second message of the process. So, if you are configuring the Palo Alto Networks firewall to work with a policy-based VPN peer, for a successful phase 2 negotiation you must define the Proxy-ID so that the setting on both peers is identical. If the Proxy-ID is not configured, because the Palo Alto Networks firewall supports route-based VPN, the default values used as Proxy-ID are source ip: 0.0.0.0/0, destination ip: 0.0.0.0/0 and application: any; and when these values are exchanged with the peer, it results in a failure to set up the VPN connection.

**Set Up an IPSec Tunnel**

Step 1 Select **Network > IPSec Tunnels> General** and enter a **Name** for the new tunnel.

Step 2 Select the **Tunnel interface** that will be used to set up the IPSec tunnel.

To create a new tunnel interface:

1. Select **Network > Interfaces > Tunnel** and click **Add**.
2. In the **Interface Name** field, specify a numeric suffix, such as **.2**.
3. On the **Config** tab, expand the **Security Zone** drop-down to define the zone as follows:
   - To use your trust zone as the termination point for the tunnel, select the zone from the drop-down. Associating the tunnel interface with the same zone (and virtual router) as the external-facing interface on which the packets enter the firewall, mitigates the need to create inter-zone routing.
   - (Recommended) To create a separate zone for VPN tunnel termination, click **New Zone**. In the Zone dialog, define a **Name** for new zone (for example vpn-corp), and click **OK**.
4. In the **Virtual Router** drop-down, select **default**.
5. (Optional) If you want to assign an IPv4 address to the tunnel interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 10.31.32.1/32.
6. If you want to assign an IPv6 address to the tunnel interface, see Step 3.
7. To save the interface configuration, click **OK**.

| Set Up an IPSec Tunnel | |
|---|---|
| Step 3 (Optional) Enable IPv6 on the tunnel interface. | 1. Select the IPv6 tab on **Network > Interfaces > Tunnel > IPv6**.<br>2. Select the check box to **Enable IPv6 on the interface**.<br>This option allows you to route IPv6 traffic over an IPv4 IPSec tunnel and will provide confidentiality between IPv6 networks. The IPv6 traffic is encapsulated by IPv4 and then ESP. To route IPv6 traffic to the tunnel, you can use a static route to the tunnel, or use OSPFv3, or use a Policy-Based Forwarding (PBF) rule to direct traffic to the tunnel.<br>3. Enter the 64-bit extended unique **Interface ID** in hexadecimal format, for example, 00:26:08:FF:FE:DE:4E:29. By default, the firewall will use the EUI-64 generated from the physical interface's MAC address.<br>4. To enter an IPv6 **Address**, click **Add** and enter an IPv6 address and prefix length, for example 2001:400:f00::1/64. If Prefix is not selected, the IPv6 address assigned to the interface will be wholly specified in the address text box.<br>a. Select **Use interface ID as host portion** to assign an IPv6 address to the interface that will use the interface ID as the host portion of the address.<br>b. Select **Anycast** to include routing through the nearest node. |
| Step 4 Select the type of key that will be used to secure the IPSec tunnel. | Continue to one of the following steps, depending on what type of key exchange you are using:<br>• Set up Auto Key exchange.<br>• Set up a Manual Key exchange. |
| • Set up Auto Key exchange. | 1. Select the IKE Gateway. To set up an IKE gateway, see Set Up an IKE Gateway.<br>2. (Optional) Select the default IPSec Crypto Profile. To create a new IPSec Profile, see Define IPSec Crypto Profiles. |

© Palo Alto Networks, Inc.

| Set Up an IPSec Tunnel | |
|---|---|
| • Set up a Manual Key exchange. | 1. Set up the parameters for the local firewall:<br>a. Specify the **SPI** for the local firewall. SPI is a 32-bit hexadecimal index that is added to the header for IPSec tunneling to assist in differentiating between IPSec traffic flows; it is used to create the SA required for establishing a VPN tunnel.<br>b. Select the **Interface** that will be the tunnel endpoint, and optionally select the IP address for the local interface that is the endpoint of the tunnel.<br>c. Select the protocol to be used—**AH** or **ESP**.<br>d. For AH, select the **Authentication** method from the drop-down and enter a **Key** and then **Confirm Key**.<br>e. For ESP, select the **Authentication** method from the drop-down and enter a **Key** and then **Confirm Key**. Then, select the **Encryption** method and enter a **Key** and then **Confirm Key**, if needed.<br>2. Set up the parameters that pertain to the remote VPN peer.<br>a. Specify the **SPI** for the remote peer.<br>b. Enter the **Remote Address**, the IP address of the remote peer. |
| Step 5 Protect against a replay attack.<br>A replay attack occurs when a packet is maliciously intercepted and retransmitted by the interceptor. | Select the **Show Advanced Options** check box, select **Enable Replay Protection** to detect and neutralize against replay attacks. |
| Step 6 Preserve the Type of Service header for the priority or treatment of IP packets. | In the **Show Advanced Options** section, select **Copy TOS Header**. This copies the Type of Service (TOS) header from the inner IP header to the outer IP header of the encapsulated packets in order to preserve the original TOS information. |
| Step 7 Enable Tunnel Monitoring.<br>You need to assign an IP address to the tunnel interface for monitoring. | To alert the device administrator to tunnel failures and to provide automatic failover to another tunnel interface:<br>1. Specify a **Destination IP** address on the other side of the tunnel to determine if the tunnel is working properly.<br>2. Select a **Profile** to determine the action on tunnel failure. To create a new profile, see Define a Tunnel Monitoring Profile. |

| Set Up an IPSec Tunnel | | |
|---|---|---|
| Step 8 | (Required only if the VPN peer uses policy-based VPN). Create a Proxy ID to identify the VPN peers. | 1. Select **Network > IPSec Tunnels** and click **Add**.<br>2. Select the **Proxy IDs** tab.<br>3. Select the **IPv4** or **IPv6** tab.<br>4. Click **Add** and enter the **Proxy ID** name.<br>5. Enter the **Local** IP address or subnet for the VPN gateway.<br>6. Enter the **Remote** address for the VPN gateway.<br>7. Select the **Protocol** from the drop-down:<br>• **Number**—Specify the protocol number (used for interoperability with third-party devices).<br>• **Any**—Allows TCP and/or UDP traffic.<br>• **TCP**—Specify the Local Port and Remote Port numbers.<br>• **UDP**—Specify the Local Port and Remote Port numbers.<br>8. Click **OK**. |
| Step 9 | Save your changes. | Click **OK** and **Commit**. |

 © Palo Alto Networks, Inc.

# Set Up Tunnel Monitoring

To provide uninterrupted VPN service, you can use the Dead Peer Detection capability along with the tunnel monitoring capability on the firewall. You can also monitor the status of the tunnel. These monitoring tasks are described in the following sections:

- Define a Tunnel Monitoring Profile
- View the Status of the Tunnels

## Define a Tunnel Monitoring Profile

A tunnel monitoring profile allows you to verify connectivity between the VPN peers; you can configure the tunnel interface to ping a destination IP address at a specified interval and specify the action if the communication across the tunnel is broken.

| Define a Tunnel Monitoring Profile |
|---|
| 1. Select **Network > Network Profiles > Monitor**. A default tunnel monitoring profile is available for use. |
| 2. Click **Add**, and enter a **Name** for the profile. |
| 3. Select the **Action** if the destination IP address is unreachable.<br>• **Wait Recover**—the firewall waits for the tunnel to recover. It continues to use the tunnel interface in routing decisions as if the tunnel were still active.<br>• **Fail Over**—forces traffic to a back-up path if one is available. The firewall disables the tunnel interface, and thereby disables any routes in the routing table that use the interface.<br>In either case, the firewall attempts to accelerate the recovery by negotiating new IPSec keys. |
| 4. Specify the **Interval** and **Threshold** to trigger the specified action.<br>The threshold specifies the number of heartbeats to wait before taking the specified action. The range is 2-100 and the default is 5.<br>The Interval measures the time between heartbeats. The range is 2-10 and the default is 3 seconds. |
| 5. Attach the monitoring profile to the IPsec Tunnel configuration. See Enable Tunnel Monitoring. |

## View the Status of the Tunnels

The status of the tunnel informs you about whether or not valid IKE phase-1 and phase-2 SAs have been established, and whether the tunnel interface is up and available for passing traffic.

Because the tunnel interface is a logical interface, it cannot indicate a physical link status. Therefore, you must enable tunnel monitoring so that the tunnel interface can verify connectivity to an IP address and determine if the path is still usable. If the IP address is unreachable, the firewall will either wait for the tunnel to recover or failover. When a failover occurs, the existing tunnel is torn down and routing changes are triggered to set up a new tunnel and redirect traffic.

© Palo Alto Networks, Inc.

| View Tunnel Status |
|---|
| 1. Select **Network > IPSec Tunnels**. |
| 2. View the **Tunnel Status**.<br>• Green indicates a valid IPSec SA tunnel.<br>• Red indicates that IPSec SA is not available or has expired. |
| 3. View the **IKE Gateway Status**.<br>• Green indicates a valid IKE phase-1 SA.<br>• Red indicates that IKE phase-1 SA is not available or has expired. |
| 4. View the **Tunnel Interface Status**.<br>• Green indicates that the tunnel interface is up.<br>• Red indicates that the tunnel interface is down, because tunnel monitoring is enabled and the status is down. |

To troubleshoot a VPN tunnel that is not yet up, see Interpret VPN Error Messages.

## Enable/Disable, Refresh or Restart an IKE Gateway or IPSec Tunnel

You can enable, disable, refresh or restart an IKE gateway or VPN tunnel to make troubleshooting easier.

| Enable or Disable an IKE Gateway or Tunnel | |
|---|---|
| Enable or disable an IKE gateway. | 1. Select **Network > Network Profiles > IKE Gateways** and select the gateway you want to enable or disable.<br>2. At the bottom of the screen, click **Enable** or **Disable**. |
| Enable or disable an IPSec tunnel. | 1. Select **Network > IPSec Tunnels** and select the tunnel you want to enable or disable.<br>2. At the bottom of the screen, click **Enable** or **Disable**. |

The refresh and restart behaviors for an IKE gateway and IPSec tunnel are as follows:

| | Refresh | Restart |
|---|---|---|
| IKE Gateway (IKE Phase 1) | Updates the onscreen statistics for the selected IKE gateway.<br>Equivalent to issuing a second `show` command in the CLI (after an initial `show` command). | Restarts the selected IKE gateway.<br>**IKEv2**: Also restarts any associated child IPSec security associations (SAs).<br>**IKEv1**: Does not restart the associated IPSec SAs.<br>A restart is disruptive to all existing sessions.<br>Equivalent to issuing a `clear, test, show` command sequence in the CLI. |

© Palo Alto Networks, Inc.

| | Refresh | Restart |
|---|---|---|
| IPSec Tunnel (IKE Phase 2) | Updates the onscreen statistics for the selected IPSec tunnel.<br>Equivalent to issuing a second `show` command in the CLI (after an initial `show` command). | Restarts the IPSec tunnel.<br>A restart is disruptive to all existing sessions.<br>Equivalent to issuing a `clear, test, show` command sequence in the CLI. |

As the table above indicates, restarting an IKEv2 gateway has a result different from restarting an IKEv1 gateway.

| Refresh or Restart an IKE Gateway or IPSec Tunnel | |
|---|---|
| Refresh or restart an IKE gateway. | 1. Select **Network > IPSec Tunnels** and select the tunnel for the gateway you want to refresh or restart.<br>2. In the row for that tunnel, under the Status column, click **IKE Info**.<br>3. At the bottom of the IKE Info screen, click the action you want:<br>• **Refresh**—Updates the statistics on the screen.<br>• **Restart**—Clears the SAs, so traffic is dropped until the IKE negotiation starts over and the tunnel is recreated. |
| Refresh or restart an IPSec tunnel.<br>You might determine that the tunnel needs to be refreshed or restarted because you use the tunnel monitor to monitor the tunnel status, or you use an external network monitor to monitor network connectivity through the IPSec tunnel | 1. Select **Network > IPSec Tunnels** and select the tunnel you want to refresh or restart.<br>2. In the row for that tunnel, under the Status column, click **Tunnel Info**.<br>3. At the bottom of the Tunnel Info screen, click the action you want:<br>• **Refresh**—Updates the onscreen statistics.<br>• **Restart**—Clears the SAs, so traffic is dropped until the IKE negotiation starts over and the tunnel is recreated. |

# Test VPN Connectivity

## Test Connectivity

- Initiate IKE phase 1 by either pinging a host across the tunnel or using the following CLI command:

  **test vpn ike-sa gateway** *gateway_name*

- Then enter the following command to test if IKE phase 1 is set up:

  **show vpn ike-sa gateway** *gateway_name*
  In the output, check if the Security Association displays. If it does not, review the system log messages to interpret the reason for failure.

- Initiate IKE phase 2 by either pinging a host from across the tunnel or using the following CLI command:

  **test vpn ipsec-sa tunnel** *tunnel_name*

- Then enter the following command to test if IKE phase 1 is set up:

  **show vpn ipsec-sa tunnel** *tunnel_name*
  In the output, check if the Security Association displays. If it does not, review the system log messages to interpret the reason for failure.

- To view the VPN traffic flow information, use the following command:

  **show vpn-flow**

```
admin@PA-500> show vpn flow
total tunnels configured:             1
filter - type IPSec, state any

total IPSec tunnel configured:        1
total IPSec tunnel shown:             1

name               id      state    local-ip       peer-ip       tunnel-i/f
------------------------------------------------------------------------------
vpn-to-siteB       5       active    100.1.1.1     200.1.1.1      tunnel.41
```

 © Palo Alto Networks, Inc.

## Interpret VPN Error Messages

The following table lists some of the common VPN error messages that are logged in the system log.

**Table: Syslog Error Messages for VPN Issues**

| If error is this: | Try this: |
|---|---|
| `IKE phase-1 negotiation is failed as initiator, main mode. Failed SA: x.x.x.x[500]-y.y.y.y[500] cookie:84222f276c2fa2e9:0000000000000000 due to timeout.`<br>or<br>`IKE phase 1 negotiation is failed. Couldn't find configuration for IKE phase-1 request for peer IP x.x.x.x[1929]` | • Verify that the public IP address for each VPN peer is accurate in the IKE Gateway configuration.<br>• Verify that the IP addresses can be pinged and that routing issues are not causing the connection failure. |
| `Received unencrypted notify payload (no proposal chosen) from IP x.x.x.x[500] to y.y.y.y[500], ignored...`<br>or<br>`IKE phase-1 negotiation is failed. Unable to process peer's SA payload.` | Check the IKE Crypto profile configuration to verify that the proposals on both sides have a common encryption, authentication, and DH Group proposal. |
| `pfs group mismatched:my: 2peer: 0`<br>or<br>`IKE phase-2 negotiation failed when processing SA payload. No suitable proposal found in peer's SA payload.` | Check the IPSec Crypto profile configuration to verify that:<br>• pfs is either enabled or disabled on both VPN peers<br>• the DH Groups proposed by each peer has at least one DH Group in common |
| `IKE phase-2 negotiation failed when processing Proxy ID. Received local id x.x.x.x/x type IPv4 address protocol 0 port 0, received remote id y.y.y.y/y type IPv4 address protocol 0 port 0.` | The VPN peer on one end is using policy-based VPN. You must configure a Proxy ID on the Palo Alto Networks firewall. See Step 8. |

# Site-to-Site VPN Quick Configs

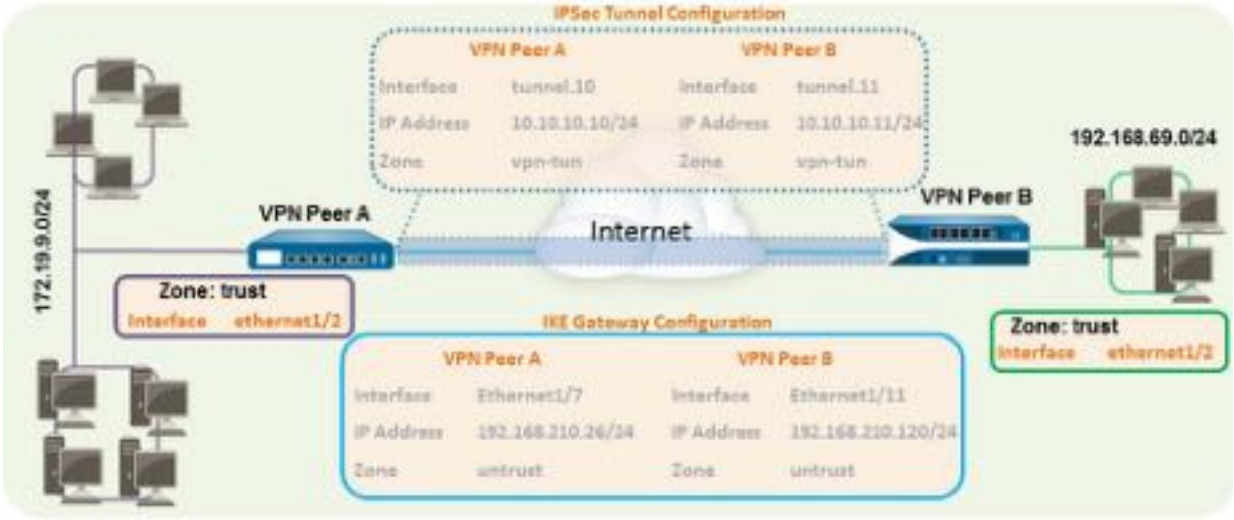
The following sections provide instructions for configuring some common VPN deployments:

- Site-to-Site VPN with Static Routing
- Site-to-Site VPN with OSPF
- Site-to-Site VPN with Static and Dynamic Routing

© Palo Alto Networks, Inc.

## Site-to-Site VPN with Static Routing

The following example shows a VPN connection between two sites that use static routes. Without dynamic routing, the tunnel interfaces on VPN Peer A and VPN Peer B do not require an IP address because the firewall automatically uses the tunnel interface as the next hop for routing traffic across the sites. However, to enable tunnel monitoring, a static IP address has been assigned to each tunnel interface.

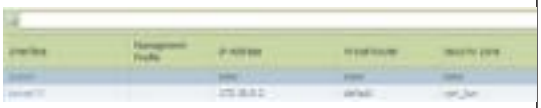


| Quick Config: Site-to-Site VPN with Static Routing | |
|---|---|
| Step 1 Configure a Layer 3 interface.<br><br>This interface is used for the IKE phase-1 tunnel. | 1. Select **Network > Interfaces > Ethernet** and then select the interface you want to configure for VPN.<br>2. Select **Layer3** from the **Interface Type** drop-down.<br>3. On the **Config** tab, select the **Security Zone** to which the interface belongs:<br>• The interface must be accessible from a zone outside of your trust network. Consider creating a dedicated VPN zone for visibility and control over your VPN traffic.<br>• If you have not yet created the zone, select **New Zone** from the **Security Zone** drop-down, define a **Name** for the new zone and then click **OK**.<br>4. Select the **Virtual Router** to use.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 192.168.210.26/24.<br>6. To save the interface configuration, click **OK**.<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—ethernet1/7<br>• **Security Zone**—untrust<br>• **Virtual Router**—default<br>• **IPv4**—192.168.210.26/24<br>The configuration for VPN Peer B is:<br>• **Interface**—ethernet1/11<br>• **Security Zone**—untrust<br>• **Virtual Router**—default<br>• **IPv4**—192.168.210.120/24 |

 © Palo Alto Networks, Inc.

**Quick Config: Site-to-Site VPN with Static Routing**

Step 2 Create a tunnel interface and attach it to a virtual router and security zone.



1. Select **Network > Interfaces > Tunnel** and click **Add**.
2. In the **Interface Name** field, specify a numeric suffix, such as **.1**.
3. On the **Config** tab, expand the **Security Zone** drop-down to define the zone as follows:
   - To use your trust zone as the termination point for the tunnel, select the zone from the drop-down.
   - (Recommended) To create a separate zone for VPN tunnel termination, click **New Zone**. In the Zone dialog, define a **Name** for new zone (for example *vpn-tun*), and then click **OK**.
4. Select the **Virtual Router**.
5. (Optional) Assign an IP address to the tunnel interface, select the **IPv4** or **IPv6** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface.

   With static routes, the tunnel interface does not require an IP address. For traffic that is destined to a specified subnet/IP address, the tunnel interface will automatically become the next hop. Consider adding an IP address if you want to enable tunnel monitoring.
6. To save the interface configuration, click **OK**.

   In this example, the configuration for VPN Peer A is:
   - **Interface**—tunnel.11
   - **Security Zone**—vpn_tun
   - **Virtual Router**—default
   - **IPv4**—172.19.9.2/24

   The configuration for VPN Peer B is:
   - **Interface**—tunnel.12
   - **Security Zone**—vpn_tun
   - **Virtual Router**—default
   - **IPv4**—192.168.69.2/24

Step 3 Configure a static route, on the virtual router, to the destination subnet.

1. Select **Network > Virtual Router** and click the router you defined in the prior step.
2. Select **Static Route**, click **Add**, and enter a new route to access the subnet that is at the other end of the tunnel.

   In this example, the configuration for VPN Peer A is:
   - **Destination**—192.168.69.0/24
   - **Interface**—tunnel.11

   The configuration for VPN Peer B is:
   - **Destination**—172.19.9.0/24
   - **Interface**—tunnel.12

| Quick Config: Site-to-Site VPN with Static Routing | | |
|---|---|---|
| Step 4 | Set up the Crypto profiles (IKE Crypto profile for phase 1 and IPSec Crypto profile for phase 2).<br><br>Complete this task on both peers and make sure to set identical values. | 1. Select **Network > Network Profiles > IKE Crypto**. In this example, we use the default profile.<br><br> <br><br>2. Select **Network > Network Profiles > IPSec Crypto**. In this example, we use the default profile.<br><br> |
| Step 5 | Set up the IKE Gateway. | 1. Select **Network > Network Profiles > IKE Gateway.**<br>2. Click **Add** and configure the options in the **General** tab**.**<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—ethernet1/7<br>• **Local IP address**—192.168.210.26/24<br>• **Peer IP type/address**—static/192.168.210.120<br>• **Preshared keys**—enter a value<br>• **Local identification**—None; this means that the local IP address will be used as the local identification value.<br>The configuration for VPN Peer B is:<br>• **Interface**—ethernet1/11<br>• **Local IP address**—192.168.210.120/24<br>• **Peer IP type/address**—static/192.168.210.26<br>• **Preshared keys**—enter same value as on Peer A<br>• **Local identification**—None<br>3. Select **Advanced Phase 1 Options** and select the IKE Crypto profile you created earlier to use for IKE phase 1. |

 © Palo Alto Networks, Inc.

| Quick Config: Site-to-Site VPN with Static Routing | | |
|---|---|---|
| Step 6 | Set up the IPSec Tunnel.<br>  | 1. Select **Network > IPSec Tunnels**.<br>2. Click **Add** and configure the options in the **General** tab.<br>In this example, the configuration for VPN Peer A is:<br>• **Tunnel Interface**—tunnel.11<br>• **Type**—Auto Key<br>• **IKE Gateway**—Select the IKE Gateway defined above.<br>• **IPSec Crypto Profile**—Select the IPSec Crypto profile defined in Step 4.<br>The configuration for VPN Peer B is:<br>• **Tunnel Interface**—tunnel.12<br>• **Type**—Auto Key<br>• **IKE Gateway**—Select the IKE Gateway defined above.<br>• **IPSec Crypto Profile**—Select the IPSec Crypto defined in Step 4.<br>3. (Optional) Select **Show Advanced Options**, select **Tunnel Monitor**, and specify a Destination IP address to ping for verifying connectivity. Typically, the tunnel interface IP address for the VPN Peer is used.<br>4. (Optional) To define the action on failure to establish connectivity, see Define a Tunnel Monitoring Profile. |
| Step 7 | Create policies to allow traffic between the sites (subnets). | 1. Select **Policies > Security**.<br>2. Create rules to allow traffic between the untrust and the vpn-tun zone and the vpn-tun and the untrust zone for traffic originating from specified source and destination IP addresses. |
| Step 8 | Save any pending configuration changes. | Click **Commit**. |
| Step 9 | Test VPN connectivity. | See View the Status of the Tunnels. |

## Site-to-Site VPN with OSPF

In this example, each site uses OSPF for dynamic routing of traffic. The tunnel IP address on each VPN peer is statically assigned and serves as the next hop for routing traffic between the two sites.

 © Palo Alto Networks, Inc.

| Quick Config: Site-to-Site VPN with Dynamic Routing using OSPF | |
|---|---|
| Step 1 Configure the Layer 3 interfaces on each firewall. | 1. Select **Network > Interfaces > Ethernet** and then select the interface you want to configure for VPN.<br>2. Select **Layer3** from the **Interface Type** drop-down.<br>3. On the **Config** tab, select the **Security Zone** to which the interface belongs:<br>• The interface must be accessible from a zone outside of your trust network. Consider creating a dedicated VPN zone for visibility and control over your VPN traffic.<br>• If you have not yet created the zone, select **New Zone** from the **Security Zone** drop-down, define a **Name** for the new zone and then click **OK**.<br>4. Select the **Virtual Router** to use.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 192.168.210.26/24.<br>6. To save the interface configuration, click **OK**.<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—ethernet1/7<br>• **Security Zone**—untrust<br>• **Virtual Router**—default<br>• **IPv4**—100.1.1.1/24<br>The configuration for VPN Peer B is:<br>• **Interface**—ethernet1/11<br>• **Security Zone**—untrust<br>• **Virtual Router**—default<br>• **IPv4**—200.1.1.1/24 |

| Quick Config: Site-to-Site VPN with Dynamic Routing using OSPF | |
|---|---|
| Step 2 Create a tunnel interface and attach it to a virtual router and security zone.<br> | 1. Select **Network > Interfaces > Tunnel** and click **Add**.<br>2. In the **Interface Name** field, specify a numeric suffix, say, **.11**.<br>3. On the **Config** tab, expand the **Security Zone** drop-down to define the zone as follows:<br>• To use your trust zone as the termination point for the tunnel, select the zone from the drop-down.<br>• (Recommended) To create a separate zone for VPN tunnel termination, click **New Zone**. In the Zone dialog, define a **Name** for new zone (for example *vpn-tun*), and then click **OK**.<br>4. Select the **Virtual Router**.<br>5. Assign an IP address to the tunnel interface, select the **IPv4** or **IPv6** tab, click **Add** in the IP section, and enter the IP address and network mask/prefix to assign to the interface, for example, 172.19.9.2/24.<br>This IP address will be used as the next hop IP address to route traffic to the tunnel and can also be used to monitor the status of the tunnel.<br>6. To save the interface configuration, click **OK**.<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—tunnel.41<br>• **Security Zone**—vpn_tun<br>• **Virtual Router**—default<br>• **IPv4**—2.1.1.141/24<br>The configuration for VPN Peer B is:<br>• **Interface**—tunnel.40<br>• **Security Zone**—vpn_tun<br>• **Virtual Router**—default<br>• **IPv4**—2.1.1.140/24 |
| Step 3 Set up the Crypto profiles (IKE Crypto profile for phase 1 and IPSec Crypto profile for phase 2).<br>Complete this task on both peers and make sure to set identical values. | 1. Select **Network > Network Profiles > IKE Crypto**. In this example, we use the default profile.<br> <br>2. Select **Network > Network Profiles > IPSec Crypto**. In this example, we use the default profile.<br> |

© Palo Alto Networks, Inc.

| Quick Config: Site-to-Site VPN with Dynamic Routing using OSPF | | |
|---|---|---|
| Step 4 | Set up the OSPF configuration on the virtual router and attach the OSPF areas with the appropriate interfaces on the firewall.<br><br>For more information on the OSPF options that are available on the firewall, see Configure OSPF.<br><br>Use Broadcast as the link type when there are more than two OSPF routers that need to exchange routing information. | 1. Select **Network > Virtual Routers**, and select the default router or add a new router.<br>2. Select **OSPF** (for IPv4) or **OSPFv3** (for IPv6) and select **Enable**.<br>3. In this example, the OSPF configuration for VPN Peer A is:<br>– **Router ID**: 192.168.100.141<br>– **Area ID**: 0.0.0.0 that is assigned to the tunnel.1 interface with Link type: p2p<br>– **Area ID**: 0.0.0.10 that is assigned to the interface Ethernet1/1 and Link Type: Broadcast<br>The OSPF configuration for VPN Peer B is:<br>– **Router ID**: 192.168.100.140<br>– **Area ID**: 0.0.0.0 that is assigned to the tunnel.1 interface with Link type: p2p<br>– **Area ID**: 0.0.0.20 that is assigned to the interface Ethernet1/15 and Link Type: Broadcast |
| Step 5 | Set up the IKE Gateway.<br><br>This examples uses static IP addresses for both VPN peers. Typically, the corporate office uses a statically configured IP address, and the branch side can be a dynamic IP address; dynamic IP addresses are not best suited for configuring stable services such as VPN. | 1. Select **Network > Network Profiles > IKE Gateway.**<br>2. Click **Add** and configure the options in the **General** tab**.**<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—ethernet1/7<br>• **Local IP address**—100.1.1.1/24<br>• **Peer IP address**—200.1.1.1/24<br>• **Preshared keys**—enter a value<br>The configuration for VPN Peer B is:<br>• **Interface**—ethernet1/11<br>• **Local IP address**—200.1.1.1/24<br>• **Peer IP address**—100.1.1.1/24<br>• **Preshared keys**—enter same value as on Peer A<br>3. Select the IKE Crypto profile you created earlier to use for IKE phase 1. |

| Quick Config: Site-to-Site VPN with Dynamic Routing using OSPF | |
|---|---|
| Step 6 Set up the IPSec Tunnel. | 1. Select **Network > IPSec Tunnels**.<br>2. Click **Add** and configure the options in the **General** tab.<br>In this example, the configuration for VPN Peer A is:<br>• **Tunnel Interface**—tunnel.41<br>• **Type**—Auto Key<br>• **IKE Gateway**—Select the IKE Gateway defined above.<br>• **IPSec Crypto Profile**—Select the IKE Gateway defined above.<br>The configuration for VPN Peer B is:<br>• **Tunnel Interface**—tunnel.40<br>• **Type**—Auto Key<br>• **IKE Gateway**—Select the IKE Gateway defined above.<br>• **IPSec Crypto Profile**—Select the IKE Gateway defined above.<br>3. Select **Show Advanced Options**, select **Tunnel Monitor**, and specify a Destination IP address to ping for verifying connectivity.<br>4. To define the action on failure to establish connectivity, see Define a Tunnel Monitoring Profile. |
| Step 7 Create policies to allow traffic between the sites (subnets). | 1. Select **Policies > Security**.<br>2. Create rules to allow traffic between the untrust and the vpn-tun zone and the vpn-tun and the untrust zone for traffic originating from specified source and destination IP addresses. |

| Quick Config: Site-to-Site VPN with Dynamic Routing using OSPF | | |
|---|---|---|
| Step 8 | Verify OSPF adjacencies and routes from the CLI. | Verify that both the firewalls can see each other as neighbors with full status. Also confirm that the IP address of the VPN peer's tunnel interface and the OSPF Router ID. Use the following CLI commands on each VPN peer.<br>• **show routing protocol ospf neighbor**<br>  |
| | | • **show routing route type ospf**<br>  |
| Step 9 | Test VPN connectivity. | See Set Up Tunnel Monitoring and View the Status of the Tunnels. |

## Site-to-Site VPN with Static and Dynamic Routing

In this example, one site uses static routes and the other site uses OSPF. When the routing protocol is not the same between the locations, the tunnel interface on each firewall must be configured with a static IP address. Then, to allow the exchange of routing information, the firewall that participates in both the static and dynamic routing process must be configured with a *Redistribution profile*. Configuring the redistribution profile enables the virtual router to redistribute and filter routes between protocols—static routes, connected routes, and hosts—from the static autonomous system to the OSPF autonomous system. Without this redistribution profile, each protocol functions on its own and does not exchange any route information with other protocols running on the same virtual router.

In this example, the satellite office has static routes and all traffic destined to the 192.168.x.x network is routed to tunnel.41. The virtual router on VPN Peer B participates in both the static and the dynamic routing process and is configured with a redistribution profile in order to propagate (*export*) the static routes to the OSPF autonomous system.

 © Palo Alto Networks, Inc.

| Quick Config: Site-to-Site VPN with Static and Dynamic Routing | | |
|---|---|---|
| Step 1 | Configure the Layer 3 interfaces on each firewall. | 1. Select **Network > Interfaces > Ethernet** and then select the interface you want to configure for VPN.<br>2. Select **Layer3** from the **Interface Type** drop-down.<br>3. On the **Config** tab, select the **Security Zone** to which the interface belongs:<br>• The interface must be accessible from a zone outside of your trust network. Consider creating a dedicated VPN zone for visibility and control over your VPN traffic.<br>• If you have not yet created the zone, select **New Zone** from the **Security Zone** drop-down, define a **Name** for the new zone and then click **OK**.<br>4. Select the **Virtual Router** to use.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 192.168.210.26/24.<br>6. To save the interface configuration, click **OK**.<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—ethernet1/7<br>• **Security Zone**—untrust<br>• **Virtual Router**—default<br>• **IPv4**—100.1.1.1/24<br>The configuration for VPN Peer B is:<br>• **Interface**—ethernet1/11<br>• **Security Zone**—untrust<br>• **Virtual Router**—default<br>• **IPv4**—200.1.1.1/24 |
| Step 2 | Set up the Crypto profiles (IKE Crypto profile for phase 1 and IPSec Crypto profile for phase 2).<br>Complete this task on both peers and make sure to set identical values. | 1. Select **Network > Network Profiles > IKE Crypto**. In this example, we use the default profile.<br> <br>2. Select **Network > Network Profiles > IPSec Crypto**. In this example, we use the default profile.<br> |

| Quick Config: Site-to-Site VPN with Static and Dynamic Routing | |
|---|---|
| Step 3 Set up the IKE Gateway.<br><br>With pre-shared keys, to add authentication scrutiny when setting up the IKE phase-1 tunnel, you can set up Local and Peer Identification attributes and a corresponding value that is matched in the IKE negotiation process. | 1. Select **Network > Network Profiles > IKE Gateway.**<br>2. Click **Add** and configure the options in the **General** tab.<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—ethernet1/7<br>• **Local IP address**—100.1.1.1/24<br>• **Peer IP type**—dynamic<br>• **Preshared keys**—enter a value<br>• **Local identification**—select **FQDN(hostname)** and enter the value for VPN Peer A.<br>• **Peer identification**—select **FQDN(hostname)** and enter the value for VPN Peer B<br>The configuration for VPN Peer B is:<br>• **Interface**—ethernet1/11<br>• **Local IP address**—200.1.1.1/24<br>• **Peer IP address**—dynamic<br>• **Preshared keys**—enter same value as on Peer A<br>• **Local identification**—select **FQDN(hostname)** and enter the value for VPN Peer B<br>• **Peer identification**—select **FQDN(hostname)** and enter the value for VPN Peer A<br>3. Select the IKE Crypto profile you created earlier to use for IKE phase 1. |

 © Palo Alto Networks, Inc.

| Quick Config: Site-to-Site VPN with Static and Dynamic Routing | | |
|---|---|---|
| Step 4 | Create a tunnel interface and attach it to a virtual router and security zone.<br> | 1. Select **Network > Interfaces > Tunnel** and click **Add**.<br>2. In the **Interface Name** field, specify a numeric suffix, say, **.41**.<br>3. On the **Config** tab, expand the **Security Zone** drop-down to define the zone as follows:<br>• To use your trust zone as the termination point for the tunnel, select the zone from the drop-down.<br>• (Recommended) To create a separate zone for VPN tunnel termination, click **New Zone**. In the Zone dialog, define a **Name** for new zone (for example *vpn-tun*), and then click **OK**.<br>4. Select the **Virtual Router**.<br>5. Assign an IP address to the tunnel interface, select the **IPv4** or **IPv6** tab, click **Add** in the IP section, and enter the IP address and network mask/prefix to assign to the interface, for example, 172.19.9.2/24.<br>This IP address will be used to route traffic to the tunnel and to monitor the status of the tunnel.<br>6. To save the interface configuration, click **OK**.<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—tunnel.41<br>• **Security Zone**—vpn_tun<br>• **Virtual Router**—default<br>• **IPv4**—2.1.1.141/24<br>The configuration for VPN Peer B is:<br>• **Interface**—tunnel.42<br>• **Security Zone**—vpn_tun<br>• **Virtual Router**—default<br>• **IPv4**—2.1.1.140/24 |
| Step 5 | Specify the interface to route traffic to a destination on the 192.168.x.x network. | 1. On VPN Peer A, select the virtual router.<br>2. Select **Static Routes**, and **Add** tunnel.41 as the **Interface** for routing traffic with a **Destination** in the 192.168.x.x network. |

| Quick Config: Site-to-Site VPN with Static and Dynamic Routing | |
|---|---|
| Step 6 Set up the static route and the OSPF configuration on the virtual router and attach the OSPF areas with the appropriate interfaces on the firewall. | 1. On VPN Peer B, select **Network > Virtual Routers**, and select the default router or add a new router.<br>2. Select **Static Routes** and **Add** the tunnel IP address as the next hop for traffic in the 172.168.x.x. network.<br>Assign the desired route metric; using a lower the value makes the a higher priority for route selection in the forwarding table.<br>3. Select **OSPF** (for IPv4) or **OSPFv3** (for IPv6) and select **Enable**.<br>4. In this example, the OSPF configuration for VPN Peer B is:<br>• Router ID: 192.168.100.140<br>• Area ID: 0.0.0.0 is assigned to the interface Ethernet 1/12 Link type: Broadcast<br>• Area ID: 0.0.0.10 that is assigned to the interface Ethernet1/1 and Link Type: Broadcast<br>• Area ID: 0.0.0.20 is assigned to the interface Ethernet1/15 and Link Type: Broadcast |
| Step 7 Create a redistribution profile to inject the static routes into the OSPF autonomous system.<br> <br> | 1. Create a redistribution profile on VPN Peer B.<br>a. Select **Network > Virtual Routers**, and select the router you used above.<br>b. Select **Redistribution Profiles,** and click **Add**.<br>c. Enter a Name for the profile and select **Redist** and assign a **Priority** value. If you have configured multiple profiles, the profile with the lowest priority value is matched first.<br>d. Set **Source Type** as **static**, and click **OK**. The static route defined in Step 6-2 will be used for the redistribution.<br>2. Inject the static routes in to the OSPF system.<br>a. Select **OSPF> Export Rules** (for IPv4) or **OSPFv3> Export Rules** (for IPv6).<br>b. Click **Add**, and select the redistribution profile that you just created.<br>c. Select how the external routes are brought into the OSPF system. The default option, **Ext2** calculates the total cost of the route using only the external metrics. To use both internal and external OSPF metrics, use **Ext1.**<br>d. Assign a **Metric** (cost value) for the routes injected into the OSPF system. This option allows you to change the metric for the injected route as it comes into the OSPF system.<br>e. Click **OK** to save the changes. |

 © Palo Alto Networks, Inc.

| Quick Config: Site-to-Site VPN with Static and Dynamic Routing | | |
|---|---|---|
| Step 8 | Set up the IPSec Tunnel. | 1. Select **Network > IPSec Tunnels**.<br>2. Click **Add** and configure the options in the **General** tab.<br>In this example, the configuration for VPN Peer A is:<br>• **Tunnel Interface**—tunnel.41<br>• **Type**—Auto Key<br>• **IKE Gateway**—Select the IKE Gateway defined above.<br>• **IPSec Crypto Profile**—Select the IKE Gateway defined above.<br>The configuration for VPN Peer B is:<br>• **Tunnel Interface**—tunnel.40<br>• **Type**—Auto Key<br>• **IKE Gateway**—Select the IKE Gateway defined above.<br>• **IPSec Crypto Profile**—Select the IKE Gateway defined above.<br>3. Select **Show Advanced Options**, select **Tunnel Monitor**, and specify a Destination IP address to ping for verifying connectivity.<br>4. To define the action on failure to establish connectivity, see Define a Tunnel Monitoring Profile. |
| Step 9 | Create policies to allow traffic between the sites (subnets). | 1. Select **Policies > Security**.<br>2. Create rules to allow traffic between the untrust and the vpn-tun zone and the vpn-tun and the untrust zone for traffic originating from specified source and destination IP addresses. |

| Quick Config: Site-to-Site VPN with Static and Dynamic Routing | |
|---|---|
| Step 10 Verify OSPF adjacencies and routes from the CLI. | Verify that both the firewalls can see each other as neighbors with full status. Also confirm that the IP address of the VPN peer's tunnel interface and the OSPF Router ID. Use the following CLI commands on each VPN peer.<br>• **`show routing protocol ospf neighbor`**<br>  |
| | • **show routing route**<br>The following is an example of the output on each VPN peer.<br> |
| Step 11 Test VPN connectivity. | See Set Up Tunnel Monitoring and View the Status of the Tunnels. |

# Large Scale VPN (LSVPN)

The GlobalProtect Large Scale VPN (LSVPN) feature on the Palo Alto Networks next-generation firewall simplifies the deployment of traditional hub and spoke VPNs, enabling you to quickly deploy enterprise networks with several branch offices with a minimum amount of configuration required on the remote *satellite* devices. This solution uses certificates for device authentication and IPSec to secure data.

LSVPN enables site-to-site VPNs between Palo Alto Networks firewalls. To set up a site-to-site VPN between a Palo Alto Networks firewall and another device, see VPNs.

The following topics describe the LSVPN components and how to set them up to enable site-to-site VPN services between Palo Alto Networks firewalls:

- LSVPN Overview
- Create Interfaces and Zones for the LSVPN
- Enable SSL Between GlobalProtect LSVPN Components
- Configure the Portal to Authenticate Satellites
- Configure GlobalProtect Gateways for LSVPN
- Configure the GlobalProtect Portal for LSVPN
- Prepare the Satellite Device to Join the LSVPN
- Verify the LSVPN Configuration
- LSVPN Quick Configs

# LSVPN Overview

GlobalProtect provides a complete infrastructure for managing secure access to corporate resources from your remote sites. This infrastructure includes the following components:

- **GlobalProtect Portal**—Provides the management functions for your GlobalProtect LSVPN infrastructure. Every satellite that participates in the GlobalProtect LSVPN receives configuration information from the portal, including configuration information to enable the satellites (the spokes) to connect to the gateways (the hubs). You configure the portal on an interface on any Palo Alto Networks next-generation firewall.
- **GlobalProtect Gateways**—A Palo Alto Networks firewall that provides the tunnel end point for satellite connections. The resources that the satellites access is protected by security policy on the gateway. It is not required to have a separate portal and gateway; a single firewall can function both as portal and gateway.
- **GlobalProtect Satellite**—A Palo Alto Networks firewall at a remote site that establishes IPSec tunnels with the gateway(s) at your corporate office(s) for secure access to centralized resources. Configuration on the satellite firewall is minimal, enabling you to quickly and easily scale your VPN as you add new sites.

The following diagram illustrates how the GlobalProtect LSVPN components work together.

 © Palo Alto Networks, Inc.

# Create Interfaces and Zones for the LSVPN

You must configure the following interfaces and zones for your LSVPN infrastructure:

- **GlobalProtect portal**—Requires a Layer 3 interface for GlobalProtect satellites to connect to. If the portal and gateway are on the same firewall, they can use the same interface. The portal must be in a zone that is accessible from your branch offices.
- **GlobalProtect gateways**—Requires three interfaces: a Layer 3 interface in the zone that is reachable by the remote satellites, an internal interface in the trust zone that connects to the protected resources, and a logical tunnel interface for terminating the VPN tunnels from the satellites. Unlike other site-to-site VPN solutions, the GlobalProtect gateway only requires a single tunnel interface, which it will use for tunnel connections with all of your remote satellites (point-to-multi-point). If you plan to use dynamic routing, you must assign an IP address to the tunnel interface.
- **GlobalProtect satellites**—Requires a single tunnel interface for establishing a VPN with the remote gateways (up to a maximum of 25 gateways). If you plan to use dynamic routing, you must assign an IP address to the tunnel interface.

For more information about portals, gateways, and satellites see LSVPN Overview.

| Set Up Interfaces and Zones for the GlobalProtect LSVPN | |
|---|---|
| Step 1 Configure a Layer 3 interface.<br><br>The portal and each gateway and satellite all require a Layer 3 interface to enable traffic to be routed between sites.<br><br>If the gateway and portal are on the same firewall, you can use a single interface for both components.<br><br>IPv6 addresses are not supported with LSVPN. | 1. Select **Network > Interfaces > Ethernet** and then select the interface you want to configure for GlobalProtect LSVPN.<br>2. Select **Layer3** from the **Interface Type** drop-down.<br>3. On the **Config** tab, select the **Security Zone** to which the interface belongs:<br>• The interface must be accessible from a zone outside of your trust network. Consider creating a dedicated VPN zone for visibility and control over your VPN traffic.<br>• If you have not yet created the zone, select **New Zone** from the **Security Zone** drop-down, define a **Name** for the new zone and then click **OK**.<br>4. Select the **Virtual Router** to use.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 203.0.11.100/24.<br>6. To save the interface configuration, click **OK**. |

| Set Up Interfaces and Zones for the GlobalProtect LSVPN (Continued) | | |
|---|---|---|
| Step 2 | On the firewall(s) hosting GlobalProtect gateway(s), configure the logical tunnel interface that will terminate VPN tunnels established by the GlobalProtect satellites.<br><br>IP addresses are not required on the tunnel interface unless plan to use dynamic routing. However, assigning an IP address to the tunnel interface can be useful for troubleshooting connectivity issues.<br><br>Make sure to enable User-ID in the zone where the VPN tunnels terminate. | 1. Select **Network > Interfaces > Tunnel** and click **Add**.<br>2. In the **Interface Name** field, specify a numeric suffix, such as **.2**.<br>3. On the **Config** tab, expand the **Security Zone** drop-down to define the zone as follows:<br>• To use your trust zone as the termination point for the tunnel, select the zone from the drop-down.<br>• (Recommended) To create a separate zone for VPN tunnel termination, click **New Zone**. In the Zone dialog, define a **Name** for new zone (for example *lsvpn-tun*), select the **Enable User Identification** check box, and then click **OK**.<br>4. Select the **Virtual Router**.<br>5. (Optional) If you want to assign an IP address to the tunnel interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 203.0.11.33/24.<br>6. To save the interface configuration, click **OK**. |
| Step 3 | If you created a separate zone for tunnel termination of VPN connections, create a security policy to enable traffic flow between the VPN zone and your trust zone. | For example, the following policy rule enables traffic between the *lsvpn-tun* zone and the *L3-Trust* zone.<br>  |
| Step 4 | Save the configuration. | Click **Commit**. |

# Enable SSL Between GlobalProtect LSVPN Components

All interaction between the GlobalProtect components occurs over an SSL/TLS connection. Therefore, you must generate and/or install the required certificates before configuring each component so that you can reference the appropriate certificate(s) and/or certificate profiles in the configurations for each component. The following sections describe the supported methods of certificate deployment, descriptions and best practice guidelines for the various GlobalProtect certificates, and provide instructions for generating and deploying the required certificates:

- About Certificate Deployment
- Deploy Server Certificates to the GlobalProtect LSVPN Components

## About Certificate Deployment

There are two basic approaches to deploying certificates for GlobalProtect LSVPN:

- **Enterprise Certificate Authority**—If you already have your own enterprise certificate authority, you can use this internal CA to issue an intermediate CA certificate for the GlobalProtect portal to enable it to issue certificates to the GlobalProtect gateways and satellites.
- **Self-Signed Certificates**—You can generate a self-signed root CA certificate on the firewall and use it to issue server certificates for the portal, gateway(s), and satellite(s). As a best practice, create a self-signed root CA certificate on the portal and use it to issue server certificates for the gateways and satellites. This way, the private key used for certificate signing stays on the portal.

## Deploy Server Certificates to the GlobalProtect LSVPN Components

The GlobalProtect LSVPN components use SSL/TLS to mutually authenticate. Before deploying the LSVPN, you must assign an SSL/TLS service profile to each portal and gateway. The profile specifies the server certificate and allowed TLS versions for communication with satellite devices. You don't need to create SSL/TLS service profiles for the satellite devices because the portal will issue a server certificate for each device during the first connection as part of the device registration process.

In addition, you must import the root certificate authority (CA) certificate used to issue the server certificates onto each firewall that you plan to host as a gateway or satellite device. Finally, on each gateway and satellite device participating in the LSVPN, you must configure a certificate profile that will enable them to establish an SSL/TLS connection using mutual authentication.

The following workflow shows the best practice steps for deploying SSL certificates to the GlobalProtect LSVPN components:

© Palo Alto Networks, Inc.

| Deploy SSL Server Certificates to the GlobalProtect Components | | |
|---|---|---|
| Step 1 | On the firewall hosting the GlobalProtect portal, create the root CA certificate for signing the certificates of the GlobalProtect components. | Create a Self-Signed Root CA Certificate:<br>1. Select **Device > Certificate Management > Certificates > Device Certificates** and click **Generate**.<br>2. Enter a **Certificate Name**, such as `LSVPN_CA`.<br>3. Do not select a value in the **Signed By** field (this is what indicates that it is self-signed).<br>4. Select the **Certificate Authority** check box and then click **OK** to generate the certificate. |
| Step 2 | Create SSL/TLS service profiles for the GlobalProtect portal and gateways.<br><br>For the portal and each gateway, you must assign an SSL/TLS service profile that references a unique self-signed server certificate.<br><br> The best practice is to issue all of the required certificates on the portal, so that the signing certificate (with the private key) doesn't have to be exported.<br><br> If the GlobalProtect portal and gateway are on the same firewall interface, you can use the same server certificate for both components. | 1. Use the root CA on the portal to Generate a Certificate on the Device for each gateway you will deploy:<br>a. Select **Device > Certificate Management > Certificates > Device Certificates** and click **Generate**.<br>b. Enter a **Certificate Name**.<br>c. Enter the FQDN (recommended) or IP address of the interface where you plan to configure the gateway in the **Common Name** field.<br>d. In the **Signed By** field, select the `LSVPN_CA` certificate you just created.<br>e. In the Certificate Attributes section, click **Add** and define the attributes to uniquely identify the gateway. If you add a **Host Name** attribute (which populates the SAN field of the certificate), it must exactly match the value you defined for the **Common Name**.<br>f. **Generate** the certificate.<br>2. Configure an SSL/TLS Service Profile for the portal and each gateway:<br>a. Select **Device > Certificate Management > SSL/TLS Service Profile** and click **Add**.<br>b. Enter a **Name** to identify the profile and select the server **Certificate** you just created for the portal or gateway.<br>c. Define the range of TLS versions (**Min Version** to **Max Version**) allowed for communicating with satellite devices and click **OK**. |

 © Palo Alto Networks, Inc.

| Deploy SSL Server Certificates to the GlobalProtect Components (Continued) | |
|---|---|
| Step 3 Deploy the self-signed server certificates to the gateways.<br><br>**Best Practices:**<br>•Export the self-signed server certificates issued by the root CA from the portal and import them onto the gateways.<br>•Be sure to issue a unique server certificate for each gateway.<br>•The Common Name (CN) and, if applicable, the Subject Alternative Name (SAN) fields of the certificate must match the IP address or fully qualified domain name (FQDN) of the interface where you configure the gateway. | 1. On the portal, select **Device > Certificate Management > Certificates > Device Certificates**, select the gateway certificate you want to deploy, and click **Export**.<br>2. Select **Encrypted Private Key and Certificate (PKCS12)** from the **File Format** drop-down.<br>3. Enter (and re-enter) a **Passphrase** to encrypt the private key associated with the certificate and then click **OK** to download the PKCS12 file to your computer.<br>4. On the gateway, select **Device > Certificate Management > Certificates > Device Certificates** and click **Import**.<br>5. Enter a **Certificate Name**.<br>6. Enter the path and name to the **Certificate File** you just downloaded from the portal, or **Browse** to find the file.<br>7. Select **Encrypted Private Key and Certificate (PKCS12)** as the **File Format**.<br>8. Enter the path and name to the PKCS12 file in the **Key File** field or **Browse** to find it.<br>9. Enter and re-enter the **Passphrase** you used to encrypt the private key when you exported it from the portal and then click **OK** to import the certificate and key. |
| Step 4 Import the root CA certificate used to issue server certificates for the LSVPN components.<br><br>You must import the root CA certificate onto all gateways and satellites. For security reasons, make sure you export the certificate only, and not the associated private key. | 1. Download the root CA certificate from the portal.<br>a. Select **Device > Certificate Management > Certificates > Device Certificates**.<br>b. Select the root CA certificate used to issue certificates for the LSVPN components and click **Export**.<br>c. Select **Base64 Encoded Certificate (PEM)** from the **File Format** drop-down and click **OK** to download the certificate. (Do not export the private key.)<br>2. On the firewalls hosting the gateways and satellites, import the root CA certificate.<br>a. Select **Device > Certificate Management > Certificates > Device Certificates** and click **Import**.<br>b. Enter a **Certificate Name** that identifies the certificate as your client CA certificate.<br>c. **Browse** to the **Certificate File** you downloaded from the CA.<br>d. Select **Base64 Encoded Certificate (PEM)** as the **File Format** and then click **OK**.<br>e. Select the certificate you just imported on the **Device Certificates** tab to open it.<br>f. Select **Trusted Root CA** and then click **OK**.<br>g. **Commit** the changes. |

| Deploy SSL Server Certificates to the GlobalProtect Components (Continued) | | |
|---|---|---|
| Step 5 | Create a certificate profile.<br>The GlobalProtect LSVPN portal and each gateway require a certificate profile that specifies which certificate to use to authenticate the satellite devices. | 1. Select **Device > Certificate Management > Certificate Profile** and click **Add** and enter a profile **Name**.<br>2. Make sure **Username Field** is set to **None**.<br>3. In the **CA Certificates** field, click **Add**, select the Trusted Root CA certificate you imported in Step 4.<br>4. (Optional, but recommended) Enable use of CRL and/or OCSP to enable certificate status verification.<br>5. Click **OK** to save the profile. |
| Step 6 | Save the configuration. | Click **Commit**. |

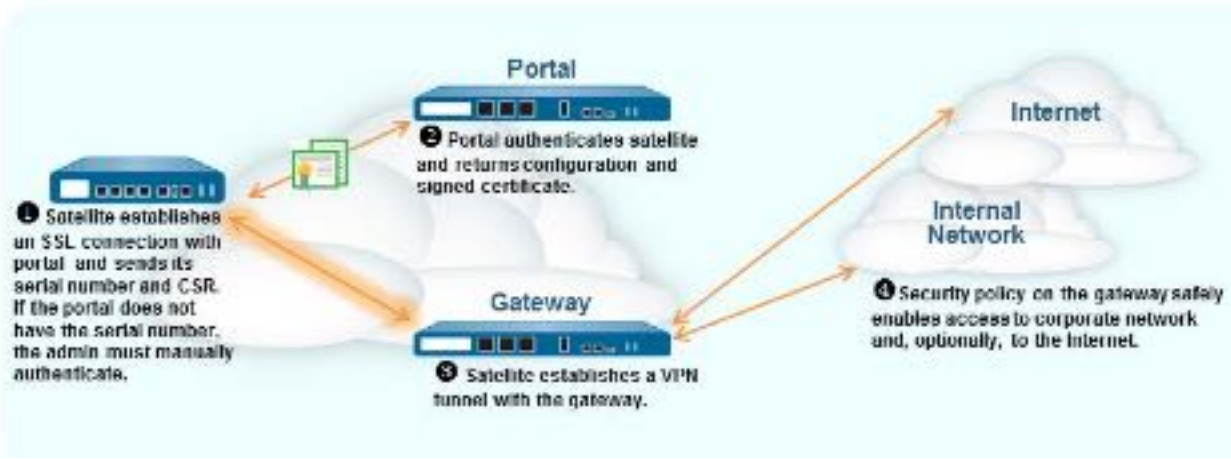
© Palo Alto Networks, Inc.

# Configure the Portal to Authenticate Satellites

In order to register with the LSVPN, each satellite must establish an SSL/TLS connection with the portal. After establishing the connection, the portal authenticates the satellite device to ensure that is authorized to join the LSVPN. After successfully authenticating the satellite, the portal will issue a server certificate for the satellite and push the LSVPN configuration specifying the gateways to which the satellite can connect and the root CA certificate required to establish an SSL connection with the gateways.

There are two ways that the satellite can authenticate to the portal during its initial connection:

- **Serial number**—You can configure the portal with the serial number of the satellite firewalls that are authorized to join the LSVPN. During the initial satellite connection to the portal, the satellite presents its serial number to the portal and if the portal has the serial number in its configuration, the satellite will be successfully authenticated. You add the serial numbers of authorized satellites when you configure the portal. See Configure the Portal.
- **Username and password**—If you would rather provision your satellites without manually entering the serial numbers of the satellite devices into the portal configuration, you can instead require the satellite administrator to authenticate when establishing the initial connection to the portal. Although the portal will always look for the serial number in the initial request from the satellite, if it cannot identify the serial number, the satellite administrator must provide a username and password to authenticate to the portal. Because the portal will always fall back to this form of authentication, you must create an authentication profile in order to commit the portal configuration. This requires that you set up an authentication profile for the portal LSVPN configuration even if you plan to authenticate satellites using the serial number.



The following workflow describes how to set up the portal to authenticate satellites against an existing authentication service. GlobalProtect LSVPN supports external authentication using a local database, LDAP (including Active Directory), Kerberos, TACACS+, or RADIUS.

| Set Up Satellite Authentication | | |
|---|---|---|
| Step 1 | (External authentication only) Create a server profile on the portal.<br><br>The server profile defines how the firewall connects to an external authentication service to validate the authentication credentials that the satellite device administrator enters.<br><br> If you use local authentication, skip this step and instead add a local user for the satellite device administrator: see Create the local database. | Configure a server profile for the authentication service type:<br>• Configure a RADIUS Server Profile.<br>• Configure a TACACS+ Server Profile.<br>• Configure an LDAP Server Profile. If you use LDAP to connect to Active Directory (AD), create a separate LDAP server profile for every AD domain.<br>• Configure a Kerberos Server Profile. |
| Step 2 | Configure an authentication profile.<br><br>The authentication profile defines which server profile to use to authenticate satellite devices. | 1. Select **Device > Authentication Profile** and click **Add**.<br>2. Enter a **Name** for the profile and then select the authentication **Type**. If the **Type** is an external service, select the **Server Profile** you created in Step 1. If you added a local user instead, set the **Type** to **Local Database**.<br>3. Click **OK** and **Commit**. |

 © Palo Alto Networks, Inc.

# Configure GlobalProtect Gateways for LSVPN

Because the GlobalProtect configuration that the portal delivers to the satellites includes the list of gateways the satellite can connect to, it is a good idea to configure the gateways before configuring the portal.

- ▲ Prerequisite Tasks
- ▲ Configure the Gateway

## Prerequisite Tasks

Before you can configure the GlobalProtect gateway, you must complete the following tasks:

- ❒ Create Interfaces and Zones for the LSVPN on the interface where you will configure each gateway. You must configure both the physical interface and the virtual tunnel interface.
- ❒ Enable SSL Between GlobalProtect LSVPN Components by configuring the gateway server certificates, SSL/TLS service profiles, and certificate profile required to establish a mutual SSL/TLS connection from the GlobalProtect satellite devices to the gateway.

## Configure the Gateway

After you have completed the Prerequisite Tasks, configure each GlobalProtect gateway to participate in the LSVPN as follows:

| Configure the Gateway for LSVPN | | |
|---|---|---|
| Step 1 | Add a gateway. | 1. Select **Network > GlobalProtect > Gateways** and click **Add**.<br>2. On the **General** tab, enter a **Name** for the gateway. The gateway name should not contain any spaces and as a best practice it should include the location or other descriptive information that will help identify the gateway.<br>3. (Optional) Select the virtual system to which this gateway belongs from the **Location** field. |
| Step 2 | Specify the network information to enable satellite devices to connect to the gateway.<br><br>If you haven't yet created the network interface for the gateway, see Create Interfaces and Zones for the LSVPN for instructions. If you haven't yet created an SSL/TLS Service profile for the gateway, see Deploy Server Certificates to the GlobalProtect LSVPN Components. | 1. Select the **Interface** that satellite devices will use for ingress access to the gateway.<br>2. Select the **IP Address** for gateway access.<br>3. Select the **SSL/TLS Service Profile** for the gateway. |

© Palo Alto Networks, Inc.

| Configure the Gateway for LSVPN (Continued) | | |
|---|---|---|
| Step 3 | Select the certificate profile for the gateway to use to authenticate satellite devices attempting to establish tunnels.<br><br>If you have not yet set up the certificate profile, see Enable SSL Between GlobalProtect LSVPN Components for instructions. | Select the **Certificate Profile** to you created for SSL communication between the LSVPN components. |
| Step 4 | Configure the tunnel parameters and enable tunneling. | 1. On the GlobalProtect Gateway dialog, select **Satellite Configuration > Tunnel Settings**.<br>2. Select the **Tunnel Configuration** check box to enable tunneling.<br>3. Select the **Tunnel Interface** you defined in Step 2 in Create Interfaces and Zones for the LSVPN.<br>4. (Optional) If you want to preserve the Type of Service (ToS) information in the encapsulated packets, select the **Copy TOS** check box. |
| Step 5 | (Optional) Enable tunnel monitoring.<br><br>Tunnel monitoring enables satellite devices to monitor its gateway tunnel connection, allowing it to failover to a backup gateway if the connection fails. Failover to another gateway is the only type of tunnel monitoring profile supported with LSVPN. | 1. Select the **Tunnel Monitoring** check box.<br>2. Specify the **Destination IP** address the satellite devices should use to determine if the gateway is active. Alternatively, if you configured an IP address for the tunnel interface, you can leave this field blank and the tunnel monitor will instead use the tunnel interface to determine if the connection is active.<br>3. Select **Failover** from the **Tunnel Monitor Profile** drop-down (this is the only supported tunnel monitor profile for LSVPN). |
| Step 6 | Select the IPSec Crypto profile to use when establishing tunnel connections.<br><br>The profile specifies the type of IPSec encryption and the authentication method for securing the data that will traverse the tunnel. Because both tunnel endpoints in an LSVPN are trusted firewalls within your organization, you can typically use the default (predefined) profile, which uses ESP as the IPSec protocol, group2 for the DH group, AES-128-CBC for encryption, and SHA-1 for authentication. | In the **IPSec Crypto Profile** drop-down, select **default** to use the predefined profile or select **New IPSec Crypto Profile** to define a new profile. For details on the authentication and encryption options, see Define IPSec Crypto Profiles. |

 © Palo Alto Networks, Inc.

| Configure the Gateway for LSVPN (Continued) | | |
|---|---|---|
| Step 7 | Configure the network settings to assign the satellite devices during establishment of the IPSec tunnel.<br><br>You can also configure the satellite device to push the DNS settings to its local clients by configuring a DHCP server on the firewall hosting the satellite. In this configuration, the satellite will push DNS settings it learns from the gateway to the DHCP clients. | 1. On the GlobalProtect Gateway dialog, select **Satellite Configuration > Network Settings**.<br>2. (Optional) If clients local to the satellite device need to resolve FQDNs on the corporate network, configure the gateway to push DNS settings to the satellites in one of the following ways:<br>• Manually define the **Primary DNS**, **Secondary DNS**, and **DNS Suffix** settings to push to the satellites.<br>• If the gateway has an interface that is configured as a DHCP client, you can set the **Inheritance Source** to that interface and the GlobalProtect satellites will be assigned the same settings received by the DHCP client.<br>3. To specify the **IP Pool** of addresses to assign the tunnel interface on the satellite devices when the VPN is established, click **Add** and then specify the IP address range(s) to use.<br>4. To define what destination subnets to route through the tunnel click **Add** in the **Access Route** area and then enter the routes as follows:<br>• If you want to route all traffic from the satellites through the tunnel, leave this field blank. Note that in this case, all traffic except traffic destined for the local subnet will be tunneled to the gateway.<br>• To route only some traffic through the gateway (called *split tunneling*), specify the destination subnets that must be tunneled. In this case, the satellite will route traffic that is not destined for a specified access route using its own routing table. For example, you may choose to only tunnel traffic destined for your corporate network, and use the local satellite to safely enable Internet access.<br>• If you want to enable routing between satellites, enter the summary route for the network protected by each satellite. |
| Step 8 | (Optional) Define what routes, if any, the gateway will accept from satellites.<br><br>By default, the gateway will not add any routes satellites advertise to its routing table. If you do not want the gateway to accept routes from satellites, you do not need to complete this step. | 1. To enable the gateway to accept routes advertised by satellites, select **Satellite Configuration > Route Filter**.<br>2. Select the **Accept published routes** check box.<br>3. To filter which of the routes advertised by the satellites to add to the gateway routing table, click **Add** and then define the subnets to include. For example, if all the satellites are configured with subnet 192.168.x.0/24 on the LAN side, configuring a permitted route of 192.168.0.0/16 to enable the gateway to only accept routes from the satellite if it is in the 192.168.0.0/16 subnet. |
| Step 9 | Save the gateway configuration. | 1. Click **OK** to save the settings and close the GlobalProtect Gateway dialog.<br>2. **Commit** the configuration. |

# Configure the GlobalProtect Portal for LSVPN

The GlobalProtect portal provides the management functions for your GlobalProtect LSVPN. Every satellite system that participates in the LSVPN receives configuration information from the portal, including information about available gateways as well as the certificate it needs in order to connect to the gateways.

The following sections provide procedures for setting up the portal:

- Prerequisite Tasks
- Configure the Portal
- Define the Satellite Configurations

## Prerequisite Tasks

Before configuring the GlobalProtect portal, you must complete the following tasks:

- Create Interfaces and Zones for the LSVPN on the interface where you will configure the portal.
- Enable SSL Between GlobalProtect LSVPN Components by creating an SSL/TLS service profile for the portal server certificate, issuing gateway server certificates, and configuring the portal to issue server certificates for the GlobalProtect satellite devices.
- Configure the Portal to Authenticate Satellites by defining the authentication profile that the portal will use to authenticate satellite devices if the serial number is not available.
- Configure GlobalProtect Gateways for LSVPN.

## Configure the Portal

After you have completed the Prerequisite Tasks, configure the GlobalProtect portal as follows:

| **Configure the Portal for LSVPN** | |
|---|---|
| Step 1 Add the portal. | 1. Select **Network > GlobalProtect > Portals** and click **Add**.<br>2. On the **Portal Configuration** tab, enter a **Name** for the portal. The portal name should not contain any spaces.<br>3. (Optional) Select the virtual system to which this portal belongs from the **Location** field. |

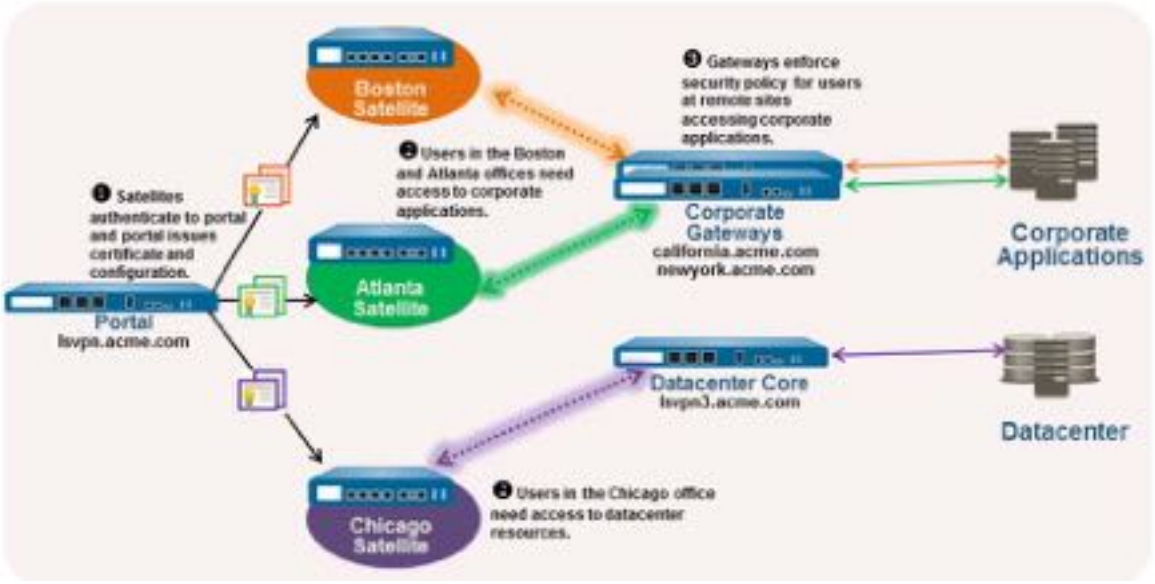
© Palo Alto Networks, Inc.

| Configure the Portal for LSVPN (Continued) | | |
|---|---|---|
| Step 2 | Specify the network information to enable satellite devices to connect to the portal.<br><br>If you haven't yet created the network interface for the portal, see Create Interfaces and Zones for the LSVPN for instructions. If you haven't yet created an SSL/TLS service profile for the portal and issued gateway certificates, see Deploy Server Certificates to the GlobalProtect LSVPN Components. | 1. Select the **Interface** that satellite devices will use for ingress access to the portal.<br>2. Select the **IP Address** for satellite device access to the portal.<br>3. Select the **SSL/TLS Service Profile** to enable the satellite device to establish an SSL/TLS connection to the portal. |
| Step 3 | Specify an authentication profile for authenticating satellite devices.<br><br>If the portal can't validate the serial numbers of connecting satellite devices, it will fall back to the authentication profile. Therefore, you must configure an authentication profile before you can save the portal configuration (by clicking **OK**). | • Select the **Authentication Profile** you defined for authenticating satellite devices.<br>• If you haven't yet configured the authentication profile, select **New Authentication Profile** to Configure an authentication profile. |
| Step 4 | Continue with defining the configurations to push to the satellite devices or, if you have already created the satellite device configurations, save the portal configuration. | Click **OK** to save the portal configuration or continue to Define the Satellite Configurations. |

## Define the Satellite Configurations

When a GlobalProtect satellite connects and successfully authenticates to the GlobalProtect portal, the portal delivers a satellite configuration, which specifies what gateways the satellite can connect to. If all your satellites will use the same gateway and certificate configurations, you can create a single satellite configuration to deliver to all satellites upon successful authentication. However, if you require different satellite configurations—for example if you want one group of satellites to connect to one gateway and another group of satellites to connect to a different gateway—you can create a separate satellite configuration for each. The portal will then use the enrollment username/group name or the serial number of the satellite device to determine which satellite configuration to deploy. As with security rule evaluation, the portal looks for a match starting from the top of the list. When it finds a match, it delivers the corresponding configuration to the satellite.

For example, the following figure shows a network in which some branch offices require VPN access to the corporate applications protected by your perimeter firewalls and another site needs VPN access to the datacenter.



Use the following procedure to create one or more satellite configurations.

| Create a GlobalProtect Satellite Configuration | |
|---|---|
| Step 1 Specify the certificates required to enable satellites to participate in the LSVPN. | 1. Select **Network > GlobalProtect > Portals** and select the portal configuration for which you want to add a satellite configuration and then select the **Satellite Configuration** tab.<br>2. In the **Trusted Root CA** field, click **Add** and then select the CA certificate used to issue the gateway server certificates. The portal will deploy the root CA certificate you add here to all satellites as part of the configuration to enable the satellite to establish an SSL connection with the gateways. As a best practice, all of your gateways should use the same issuer.<br>If the root CA certificate used to issue your gateway server certificates is not on the portal, you can **Import** it now. See Enable SSL Between GlobalProtect LSVPN Components for details on how to import a root CA certificate.<br>3. Select the Root CA certificate that the portal will use to issue certificates to satellites upon successfully authenticating them from the **Issuing Certificate** drop-down. |
| Step 2 Add a satellite configuration.<br>The satellite configuration specifies the GlobalProtect LSVPN configuration settings to deploy to the connecting satellites. You must define at least one satellite configuration. | In the Satellite Configuration section, click **Add** and enter a **Name** for the configuration.<br>If you plan to create multiple configurations, make sure the name you define for each is descriptive enough to allow you to distinguish them. |

 © Palo Alto Networks, Inc.

| Create a GlobalProtect Satellite Configuration (Continued) | | |
|---|---|---|
| Step 3 | Specify which satellites to deploy this configuration to.<br><br>The portal uses the **Enrollment User/User Group** settings and/or **Devices** serial numbers to match a satellite to a configuration. Therefore, if you have multiple configurations, be sure to order them properly. As soon as the portal finds a match, it will deliver the configuration. Therefore, more specific configurations must precede more general ones. See Step 6 for instructions on ordering the list of satellite configurations. | Specify the match criteria for the satellite configuration as follows:<br>• To restrict this configuration to satellite devices with specific serial numbers, select the **Devices** tab, click **Add**, and enter serial number (you do not need to enter the satellite hostname; it will be automatically added when the satellite connects). Repeat this step for each satellite you want to receive this configuration.<br>• Select the **Enrollment User/User Group** tab, click **Add**, and then select the user or group you want to receive this configuration. Satellites that do not match on serial number will be required to authenticate as a user specified here (either an individual user or group member).<br><br>Before you can restrict the configuration to specific groups, you must Map Users to Groups. |
| Step 4 | Specify the gateways that satellites with this configuration can establish VPN tunnels with.<br><br>Routes published by the gateway are installed on the satellite as static routes. The metric for the static route is 10x the routing priority. If you have more than one gateway, make sure to also set the routing priority to ensure that routes advertised by backup gateways have higher metrics compared to the same routes advertised by primary gateways. For example, if you set the routing priority for the primary gateway and backup gateway to 1 and 10 respectively, the satellite will use 10 as the metric for the primary gateway and 100 as the metric for the backup gateway. | 1. On the **Gateways** tab, click **Add**.<br>2. Enter a descriptive **Name** for the gateway. The name you enter here should match the name you defined when you configured the gateway and should be descriptive enough identify the location of the gateway.<br>3. Enter the FQDN or IP address of the interface where the gateway is configured in the **Gateways** field. The address you specify must exactly match the Common Name (CN) in the gateway server certificate.<br>4. (Optional) If you are adding two or more gateways to the configuration, the **Routing Priority** helps the satellite pick the preferred gateway. Enter a value in the range of 1-25, with lower numbers having the higher priority (that is, the gateway the satellite will connect to if all gateways are available). The satellite will multiply the routing priority by 10 to determine the routing metric. |
| Step 5 | Save the satellite configuration. | 1. Click **OK** to save the satellite configuration.<br>2. If you want to add another satellite configuration, repeat Step 2 through Step 5. |
| Step 6 | Arrange the satellite configurations so that the proper configuration is deployed to each satellite. | • To move a satellite configuration up on the list of configurations, select the configuration and click **Move Up**.<br>• To move a satellite configuration down on the list of configurations, select the configuration and click **Move Down**. |
| Step 7 | Save the portal configuration. | 1. Click **OK** to save the settings and close the GlobalProtect Portal dialog.<br>2. **Commit** your changes. |

# Prepare the Satellite Device to Join the LSVPN

In order to participate in the LSVPN, the satellite devices require a minimal amount of configuration. Because the required configuration is minimal, you can pre-configure the devices before shipping them to your branch offices for installation.

| Prepare the Satellite Device to Join the GlobalProtect LSVPN | | |
|---|---|---|
| Step 1 | Configure a Layer 3 interface. | This is the physical interface the satellite will use to connect to the portal and the gateway. This interface must be in a zone that allows access outside of the local trust network. As a best practice, create a dedicated zone for VPN connections for visibility and control over traffic destined for the corporate gateways. |
| Step 2 | Configure the logical tunnel interface for the tunnel to use to establish VPN tunnels with the GlobalProtect gateways.<br> IP addresses are not required on the tunnel interface unless you plan to use dynamic routing. However, assigning an IP address to the tunnel interface can be useful for troubleshooting connectivity issues. | 1. Select **Network > Interfaces > Tunnel** and click **Add**.<br>2. In the **Interface Name** field, specify a numeric suffix, such as **.2**.<br>3. On the **Config** tab, expand the **Security Zone** drop-down and select an existing zone or create a separate zone for VPN tunnel traffic by clicking **New Zone** and defining a **Name** for new zone (for example *lsvpnsat*).<br>4. In the **Virtual Router** drop-down, select **default**.<br>5. (Optional) If you want to assign an IP address to the tunnel interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 2.2.2.11/24.<br>6. To save the interface configuration, click **OK**. |

 © Palo Alto Networks, Inc.

| Prepare the Satellite Device to Join the GlobalProtect LSVPN (Continued) | | |
|---|---|---|
| Step 3 | If you generated the portal server certificate using a Root CA that is not trusted by the satellite devices (for example, if you used self-signed certificates), import the root CA certificate used to issue the portal server certificate.<br><br>The root CA certificate is required to enable the satellite device to establish the initial connection with the portal to obtain the LSVPN configuration. | 1. Download the CA certificate that was used to generate the portal server certificates. If you are using self-signed certificates, export the root CA certificate from the portal as follows:<br>a. Select **Device > Certificate Management > Certificates > Device Certificates**.<br>b. Select the CA certificate, and click **Export**.<br>c. Select **Base64 Encoded Certificate (PEM)** from the **File Format** drop-down and click **OK** to download the certificate. (You do not need to export the private key.)<br>2. Import the root CA certificate you just exported onto each satellite device as follows.<br>a. Select **Device > Certificate Management > Certificates > Device Certificates** and click **Import**.<br>b. Enter a **Certificate Name** that identifies the certificate as your client CA certificate.<br>c. **Browse** to the **Certificate File** you downloaded from the CA.<br>d. Select **Base64 Encoded Certificate (PEM)** as the **File Format** and then click **OK**.<br>e. Select the certificate you just imported on the **Device Certificates** tab to open it.<br>f. Select **Trusted Root CA** and then click **OK**. |
| Step 4 | Configure the IPSec tunnel configuration. | 1. Select **Network > IPSec Tunnels** and click **Add**.<br>2. On the **General** tab, enter a descriptive **Name** for the IPSec configuration.<br>3. Select the **Tunnel Interface** you created for the satellite device.<br>4. Select **GlobalProtect Satellite** as the **Type**.<br>5. Enter the IP address or FQDN of the portal as the **Portal Address**.<br>6. Select the Layer 3 **Interface** you configured for the satellite device.<br>7. Select the **Local IP Address** to use on the selected interface. |

| Prepare the Satellite Device to Join the GlobalProtect LSVPN (Continued) | |
|---|---|
| Step 5 (Optional) Configure the satellite to publish local routes to the gateway.<br><br>Pushing routes to the gateway enables traffic to the subnets local to the satellite via the gateway. However, you must also configure the gateway to accept the routes as detailed in Step 8 in Configure the Gateway. | 1. To enable the satellite to push routes to the gateway, on the **Advanced** tab select **Publish all static and connected routes to Gateway**.<br><br>If you select this check box, the firewall will forward all static and connected routes from the satellite to the gateway. However, to prevent the creation of routing loops, the firewall will apply some route filters, such as the following:<br>• Default routes<br>• Routes within a virtual router other than the virtual router associated with the tunnel interface<br>• Routes using the tunnel interface<br>• Routes using the physical interface associated with the tunnel interface<br>2. (Optional) If you only want to push routes for specific subnets rather than all routes, click **Add** in the Subnet section and specify which subnet routes to publish. |
| Step 6 Save the satellite configuration. | 1. Click **OK** to save the IPSec tunnel settings.<br>2. Click **Commit**. |
| Step 7 If required, provide the credentials to allow the satellite to authenticate to the portal.<br><br>This step is only required if the portal was unable to find a serial number match in its configuration or if the serial number didn't work. In this case, the satellite will not be able to establish the tunnel with the gateway(s). | 1. Select **Network > IPSec Tunnels** and click the **Gateway Info** link in the Status column of the tunnel configuration you created for the LSVPN.<br>2. Click the **enter credentials** link in the **Portal Status** field and username and password required to authenticate the satellite to the portal.<br><br>After the portal successfully authenticates to the portal, it will receive its signed certificate and configuration, which it will use to connect to the gateway(s). You should see the tunnel establish and the **Status** change to **Active**.<br><br> |

© Palo Alto Networks, Inc.

# Verify the LSVPN Configuration

After configuring the portal, gateways, and satellite devices, verify that the satellites are able to connect to the portal and gateway and establish VPN tunnels with the gateway(s).

| Verify the LSVPN Configuration | | |
|---|---|---|
| Step 1 | Verify satellite connectivity with portal. | From the firewall hosting the portal, verify that satellites are successfully connecting by selecting **Network > GlobalProtect > Portal** and clicking **Satellite Info** in the Info column of the portal configuration entry.<br> |
| Step 1 | Verify satellite connectivity with the gateway(s). | On each firewall hosting a gateway, verify that satellites are able to establish VPN tunnels by selecting **Network > GlobalProtect > Gateways** and click **Satellite Info** in the Info column of the gateway configuration entry. Satellites that have successfully established tunnels with the gateway will display on the **Active Satellites** tab.<br> |
| Step 1 | Verify LSVPN tunnel status on the satellite. | On each firewall hosting a satellite, verify the tunnel status by selecting **Network > IPSec Tunnels** and verify active Status as indicated by a green icon.<br> |

# LSVPN Quick Configs

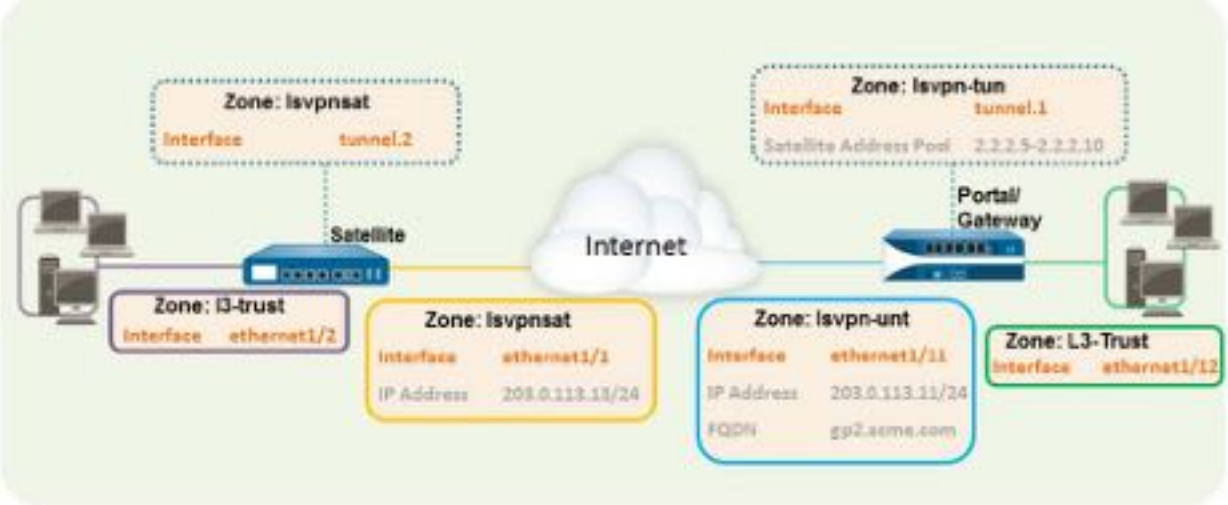
The following sections provide step-by-step instructions for configuring some common GlobalProtect LSVPN deployments:

- Basic LSVPN Configuration with Static Routing
- Advanced LSVPN Configuration with Dynamic Routing

© Palo Alto Networks, Inc.

# Basic LSVPN Configuration with Static Routing

This quick config shows the fastest way to get up and running with LSVPN. In this example, a single firewall at the corporate headquarters site is configured as both a portal and a gateway. Satellite devices can be quickly and easily deployed with minimal configuration for optimized scalability.



The following workflow shows the steps for setting up this basic configuration:

| Quick Config: Basic LSVPN with Static Routing | | |
|---|---|---|
| Step 1 | Configure a Layer 3 interface. | In this example, the Layer 3 interface on the portal/gateway requires the following configuration:<br>• **Interface**—ethernet1/11<br>• **Security Zone**—lsvpn-unt<br>• **IPv4**—203.0.113.11/24 |
| Step 2 | On the firewall(s) hosting GlobalProtect gateway(s), configure the logical tunnel interface that will terminate VPN tunnels established by the GlobalProtect satellites.<br>To enable visibility into users and groups connecting over the VPN, enable User-ID in the zone where the VPN tunnels terminate. | In this example, the Tunnel interface on the portal/gateway requires the following configuration:<br>• **Interface**—tunnel.1<br>• **Security Zone**—lsvpn-tun |

© Palo Alto Networks, Inc.

| Quick Config: Basic LSVPN with Static Routing (Continued) | | |
|---|---|---|
| Step 3 | Create the security policy rule to enable traffic flow between the VPN zone where the tunnel terminates (lsvpn-tun) and the trust zone where the corporate applications reside (L3-Trust). | The following is an example of a policy rule for allowing traffic to flow between the VPN zone and the trust zone:<br>  |
| Step 4 | Assign an SSL/TLS Service profile to the portal/gateway. The profile must reference a self-signed server certificate.<br>The certificate subject name must match the FQDN or IP address of the Layer 3 interface you create for the portal/gateway. | 1. On the firewall hosting the GlobalProtect portal, create the root CA certificate for signing the certificates of the GlobalProtect components. In this example, the root CA certificate, `lsvpn-CA`, will be used to issue the server certificate for the portal/gateway. In addition, the portal will use this root CA certificate to sign the CSRs from the satellite devices.<br>2. Create SSL/TLS service profiles for the GlobalProtect portal and gateways.<br>Because the portal and gateway are on the same interface in this example, they can share an SSL/TLS Service profile that uses the same server certificate. In this example, the profile is named `lsvpnserver`. |
| Step 5 | Create a certificate profile. | In this example, the certificate profile `lsvpn-profile`, references the root CA certificate `lsvpn-CA`. The gateway will use this certificate profile to authenticate satellite devices attempting to establish VPN tunnels. |
| Step 6 | Configure an authentication profile for the portal to use if the satellite device serial number is not available. | 1. Create one type of server profile on the portal:<br>• Configure a RADIUS Server Profile.<br>• Configure a TACACS+ Server Profile.<br>• Configure an LDAP Server Profile. If you use LDAP to connect to Active Directory (AD), create a separate LDAP server profile for every AD domain.<br>• Configure a Kerberos Server Profile.<br>2. Configure an authentication profile. In this example, the profile `lsvpn-sat` is used to authenticate satellite devices. |

 © Palo Alto Networks, Inc.

| Quick Config: Basic LSVPN with Static Routing (Continued) | |
|---|---|
| Step 7 Configure the Gateway for LSVPN. | Select **Network > GlobalProtect > Gateways** and **Add** a configuration. This example requires the following gateway configuration:<br>• **Interface**—ethernet1/11<br>• **IP Address**—203.0.113.11/24<br>• **SSL/TLS Server Profile**—lsvpnserver<br>• **Certificate Profile**—lsvpn-profile<br>• **Tunnel Interface**—tunnel.1<br>• **Primary DNS**/**Secondary DNS**—4.2.2.1/4.2.2.2<br>• **IP Pool**—2.2.2.111-2.2.2.120<br>• **Access Route**—10.2.10.0/24 |
| Step 8 Configure the Portal for LSVPN. | Select **Network > GlobalProtect > Portal** and **Add** a configuration. This example requires the following portal configuration:<br>• **Interface**—ethernet1/11<br>• **IP Address**—203.0.113.11/24<br>• **SSL/TLS Server Profile**—lsvpnserver<br>• **Authentication Profile**—lsvpn-sat |
| Step 9 Create a GlobalProtect Satellite Configuration. | On the **Satellite Configuration** tab in the portal configuration, **Add** a Satellite Configuration and a Trusted Root CA and specify the CA the portal will use to issue certificates for the satellites. In this example the required settings are as following:<br>• **Gateway**—203.0.113.11<br>• **Issuing Certificate**—lsvpn-CA<br>• **Trusted Root CA**—lsvpn-CA |

| Quick Config: Basic LSVPN with Static Routing (Continued) | |
|---|---|
| Step 10 Prepare the Satellite Device to Join the LSVPN. | The satellite configuration in this example requires the following settings:<br>Interface Configuration<br>• Layer 3 interface—ethernet1/1, 203.0.113.13/24<br>• Tunnel interface—tunnel.2<br>• Zone—lsvpnsat<br>Root CA Certificate from Portal<br>• lsvpn-CA<br>IPSec Tunnel Configuration<br>• **Tunnel Interface**—tunnel.2<br>• **Portal Address**—203.0.113.11<br>• **Interface**—ethernet1/1<br>• **Local IP Address**—203.0.113.13/24<br>• **Publish all static and connected routes to Gateway**—enabled |

# Advanced LSVPN Configuration with Dynamic Routing

In larger LSVPN deployments with multiple gateways and many satellites, investing a little more time in the initial configuration to set up dynamic routing will simplify the maintenance of gateway configurations because access routes will update dynamically. The following example configuration shows how to extend the basic LSVPN configuration to configure OSPF as the dynamic routing protocol.

Setting up an LSVPN to use OSPF for dynamic routing requires the following additional steps on the gateways and the satellites:

- Manual assignment of IP addresses to tunnel interfaces on all gateways and satellites.
- Configuration of OSPF point-to-multipoint (P2MP) on the virtual router on all gateways and satellites. In addition, as part of the OSPF configuration on each gateway, you must manually define the tunnel IP address of each satellite as an OSPF neighbor. Similarly, on each satellite, you must manually define the tunnel IP address of each gateway as an OSPF neighbor.

Although dynamic routing requires additional setup during the initial configuration of the LSVPN, it reduces the maintenance tasks associated with keeping routes up to date as topology changes occur on your network.

The following figure shows an LSVPN dynamic routing configuration. This example shows how to configure OSPF as the dynamic routing protocol for the VPN.

For a basic setup of a LSVPN, follow the steps in Basic LSVPN Configuration with Static Routing. You can then complete the steps in the following workflow to extend the configuration to use dynamic routing rather than static routing.

| Quick Config: LSVPN with Dynamic Routing | |
|---|---|
| Step 1 Add an IP address to the tunnel interface configuration on each gateway and each satellite. | Complete the following steps on each gateway and each satellite:<br>1. Select **Network > Interfaces > Tunnel** and select the tunnel configuration you created for the LSVPN to open the Tunnel Interface dialog.<br>If you have not yet created the tunnel interface, see Step 2 in Quick Config: Basic LSVPN with Static Routing.<br>2. On the **IPv4** tab, click **Add** and then enter an IP address and subnet mask. For example, to add an IP address for the gateway tunnel interface you would enter 2.2.2.100/24.<br>3. Click **OK** to save the configuration. |
| Step 2 Configure the dynamic routing protocol on the gateway.<br>  | To configure OSPF on the gateway:<br>1. Select **Network > Virtual Routers** and select the virtual router associated with your VPN interfaces.<br>2. On the **Areas** tab, click **Add** to create the backbone area, or, if it is already configured, click on the area ID to edit it.<br>3. If you are creating a new area, enter an **Area ID** on the **Type** tab.<br>4. On the **Interface** tab, click **Add** and select the tunnel **Interface** you created for the LSVPN.<br>5. Select **p2mp** as the **Link Type**.<br>6. Click **Add** in the Neighbors section and enter the IP address of the tunnel interface of each satellite device, for example 2.2.2.111.<br>7. Click **OK** twice to save the virtual router configuration and then **Commit** the changes on the gateway.<br>8. Repeat this step each time you add a new satellite to the LSVPN. |
| Step 3 Configure the dynamic routing protocol on the satellite.<br>  | To configure OSPF on the satellite:<br>1. Select **Network > Virtual Routers** and select the virtual router associated with your VPN interfaces.<br>2. On the **Areas** tab, click **Add** to create the backbone area, or, if it is already configured, click on the area ID to edit it.<br>3. If you are creating a new area, enter an **Area ID** on the **Type** tab.<br>4. On the **Interface** tab, click **Add** and select the tunnel **Interface** you created for the LSVPN.<br>5. Select **p2mp** as the **Link Type**.<br>6. Click **Add** in the Neighbors section and enter the IP address of the tunnel interface of each GlobalProtect gateway, for example 2.2.2.100.<br>7. Click **OK** twice to save the virtual router configuration and then **Commit** the changes on the gateway.<br>8. Repeat this step each time you add a new gateway. |

 © Palo Alto Networks, Inc.

| Quick Config: LSVPN with Dynamic Routing (Continued) | |
|---|---|
| Step 4 Verify that the gateways and satellites are able to form router adjacencies. | • On each satellite and each gateway, confirm that peer adjacencies have formed and that routing table entries have been created for the peers (that is, the satellites have routes to the gateways and the gateways have routes to the satellites). Select **Network > Virtual Router** and click the **More Runtime Stats** link for the virtual router you are using for the LSVPN. On the Routing tab, verify that the LSVPN peer has a route.<br> <br>• On the **OSPF > Interface** tab, verify that the **Type** is **p2mp**.<br> <br>• On the **OSPF > Neighbor** tab, verify that the firewalls hosting your gateways have established router adjacencies with the firewalls hosting your satellites and vice versa. Also verify that the **Status** is **Full**, indicating that full adjacencies have been established.<br>  |

# Networking

All Palo Alto Networks® next-generation firewalls provide a flexible networking architecture that includes support for dynamic routing, switching, and VPN connectivity, and enables you to deploy the firewall into nearly any networking environment. When configuring the Ethernet ports on your firewall, you can choose from virtual wire, Layer 2, or Layer 3 interface deployments. In addition, to allow you to integrate into a variety of network segments, you can configure different types of interfaces on different ports. The Interface Deployments section provides basic information on each type of deployment. For more detailed deployment information, refer to Designing Networks with Palo Alto Networks Firewalls.

The following topics describe networking concepts and how to integrate Palo Alto Networks next-generation firewalls into your network.

- Interface Deployments
- Virtual Routers
- Static Routes
- RIP
- OSPF
- BGP
- Session Settings and Timeouts
- DHCP
- NAT
- NPTv6
- LACP
- ECMP
- LLDP

For information on route distribution, refer to Understanding Route Redistribution and Filtering.

# Interface Deployments

A Palo Alto Networks firewall can operate in multiple deployments at once because the deployments occur at the interface level. The following sections describe the deployments.

- Virtual Wire Deployments
- Layer 2 Deployments
- Layer 3 Deployments
- Tap Mode Deployments

## Virtual Wire Deployments

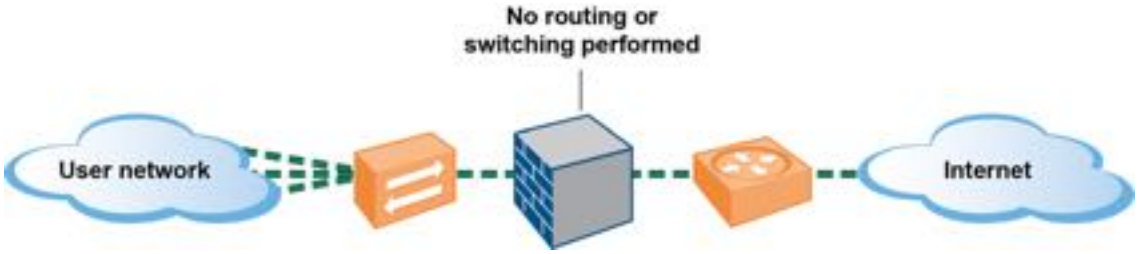
In a virtual wire deployment, the firewall is installed transparently on a network segment by binding two ports together and should be used only when no switching or routing is needed.

A virtual wire deployment allows the following conveniences:

- Simplifies installation and configuration.
- Does not require any configuration changes to surrounding or adjacent network devices.

The virtual wire deployment shipped as the factory default configuration (default-vwire) binds together Ethernet ports 1 and 2 and allows all untagged traffic. You can, however, use a virtual wire to connect any two ports and configure it to block or allow traffic based on the virtual LAN (VLAN) tags; the VLAN tag "0" indicates untagged traffic. You can also create multiple subinterfaces, add them into different zones and then classify traffic according to a VLAN tag, or a combination of a VLAN tag with IP classifiers (address, range, or subnet) to apply granular policy control for specific VLAN tags or for VLAN tags from a specific source IP address, range, or subnet.

**Figure: Virtual Wire Deployment**



### Virtual Wire Subinterfaces

Virtual wire subinterfaces provide flexibility in enforcing distinct policies when you need to manage traffic from multiple customer networks. It allows you to separate and classify traffic into different zones (the zones can belong to separate virtual systems, if required) using the following criteria:

 © Palo Alto Networks, Inc.

- **VLAN tags** —The example in Figure: Virtual Wire Deployment with Subinterfaces (VLAN Tags only), shows an Internet Service Provider (ISP) using virtual wire subinterfaces with VLAN tags to separate traffic for two different customers.
- **VLAN tags in conjunction with IP classifiers (address, range, or subnet)**— The following example shows an ISP with two separate virtual systems on a firewall that manages traffic from two different customers. On each virtual system, the example illustrates how virtual wire subinterfaces with VLAN tags and IP classifiers are used to classify traffic into separate zones and apply relevant policy for customers from each network.

| Virtual Wire Subinterface Workflow |
|---|
| 1. Configure two Ethernet interfaces as type virtual wire, and assign these interfaces to a virtual wire. |
| 2. Create subinterfaces on the parent Virtual Wire to separate CustomerA and CustomerB traffic. Make sure that the VLAN tags defined on each pair of subinterfaces that are configured as virtual wire(s) are identical. This is essential because a virtual wire does not switch VLAN tags. |
| 3. Create new subinterfaces and define IP classifiers. This task is optional and only required if you wish to add additional subinterfaces with IP classifiers for further managing traffic from a customer based on the combination of VLAN tags and a specific source IP address, range or subnet.<br>You can also use IP classifiers for managing untagged traffic. To do so, you must create a sub-interface with the vlan tag "0", and define sub-interface(s) with IP classifiers for managing untagged traffic using IP classifiers |

IP classification may only be used on the subinterfaces associated with one side of the virtual wire. The subinterfaces defined on the corresponding side of the virtual wire must use the same VLAN tag, but must not include an IP classifier.

**Figure: Virtual Wire Deployment with Subinterfaces (VLAN Tags only)**

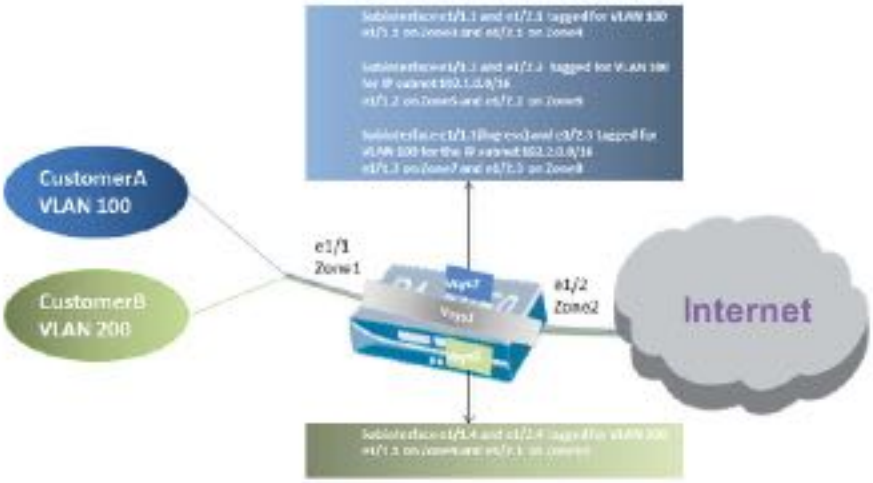
Figure: Virtual Wire Deployment with Subinterfaces (VLAN Tags only) depicts CustomerA and CustomerB connected to the firewall through one physical interface, ethernet1/1, configured as a Virtual Wire; it is the ingress interface. A second physical interface, ethernet1/2, is also part of the Virtual Wire; it is the egress interface that provides access to the Internet. For CustomerA, you also have subinterfaces ethernet1/1.1 (ingress) and ethernet1/2.1 (egress). For CustomerB, you have the subinterface ethernet1/1.2 (ingress) and ethernet1/2.2 (egress). When configuring the subinterfaces, you must assign the appropriate VLAN tag and zone in order to apply policies for each customer. In this example, the policies for CustomerA are created between Zone1 and Zone2, and policies for CustomerB are created between Zone3 and Zone4.

When traffic enters the firewall from CustomerA or CustomerB, the VLAN tag on the incoming packet is first matched against the VLAN tag defined on the ingress subinterfaces. In this example, a single subinterface matches the VLAN tag on the incoming packet, hence that subinterface is selected. The policies defined for the zone are evaluated and applied before the packet exits from the corresponding subinterface.

The same VLAN tag must not be defined on the parent virtual wire interface and the subinterface. Verify that the VLAN tags defined on the Tag Allowed list of the parent virtual wire interface (**Network > Virtual Wires**) are not included on a subinterface.

Figure: Virtual Wire Deployment with Subinterfaces (VLAN Tags and IP Classifiers) depicts CustomerA and CustomerB connected to one physical firewall that has two virtual systems (vsys), in addition to the default virtual system (vsys1). Each virtual system is an independent virtual firewall that is managed separately for each customer. Each vsys has attached interfaces/subinterfaces and security zones that are managed independently.

**Figure: Virtual Wire Deployment with Subinterfaces (VLAN Tags and IP Classifiers)**



Vsys1 is set up to use the physical interfaces ethernet1/1 and ethernet1/2 as a virtual wire; ethernet1/1 is the ingress interface and ethernet1/2 is the egress interface that provides access to the Internet. This virtual wire is configured to accept all tagged and untagged traffic with the exception of VLAN tags 100 and 200 that are assigned to the subinterfaces.

CustomerA is managed on vsys2 and CustomerB is managed on vsys3. On vsys2 and vsys3, the following vwire subinterfaces are created with the appropriate VLAN tags and zones to enforce policy measures.

| Customer | Vsys | Vwire Subinterfaces | Zone | VLAN Tag | IP Classifier |
|---|---|---|---|---|---|
| A | 2 | e1/1.1 (ingress)<br>e1/2.1 (egress) | Zone3<br>Zone4 | 100<br>100 | None |
| | 2 | e1/1.2 (ingress)<br>e1/2.2 (egress) | Zone5<br>Zone6 | 100<br>100 | IP subnet<br>192.1.0.0/16 |
| | 2 | e1/1.3 (ingress)<br>e1/2.3 (egress) | Zone7<br>Zone8 | 100<br>100 | IP subnet<br>192.2.0.0/16 |
| B | 3 | e1/1.4 (ingress)<br>e1/2.4 (egress) | Zone9<br>Zone10 | 200<br>200 | None |

 © Palo Alto Networks, Inc.

When traffic enters the firewall from CustomerA or CustomerB, the VLAN tag on the incoming packet is first matched against the VLAN tag defined on the ingress subinterfaces. In this case, for CustomerA, there are multiple subinterfaces that use the same VLAN tag. Hence, the firewall first narrows the classification to a subinterface based on the source IP address in the packet. The policies defined for the zone are evaluated and applied before the packet exits from the corresponding subinterface.

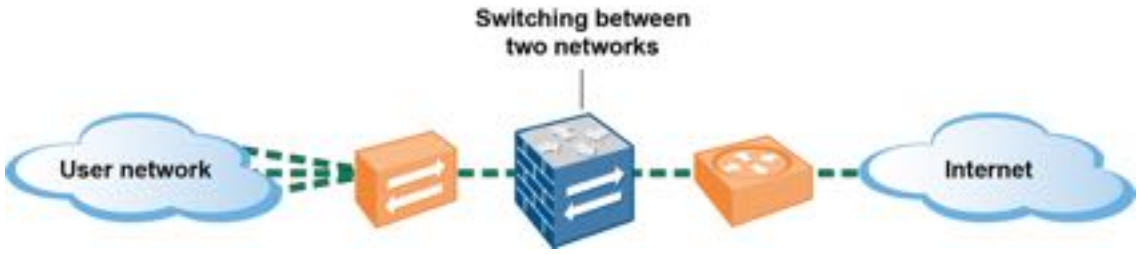
For return-path traffic, the firewall compares the destination IP address as defined in the IP classifier on the customer-facing subinterface and selects the appropriate virtual wire to route traffic through the accurate subinterface.

The same VLAN tag must not be defined on the parent virtual wire interface and the subinterface. Verify that the VLAN tags defined on the Tag Allowed list of the parent virtual wire interface (**Network > Virtual Wires**) are not included on a subinterface.

## Layer 2 Deployments

In a Layer 2 deployment, the firewall provides switching between two or more networks. Each group of interfaces must be assigned to a VLAN object in order for the firewall to switch between them. The firewall will perform VLAN tag switching when layer 2 subinterfaces are attached to a common VLAN object. Choose this option when switching is required.

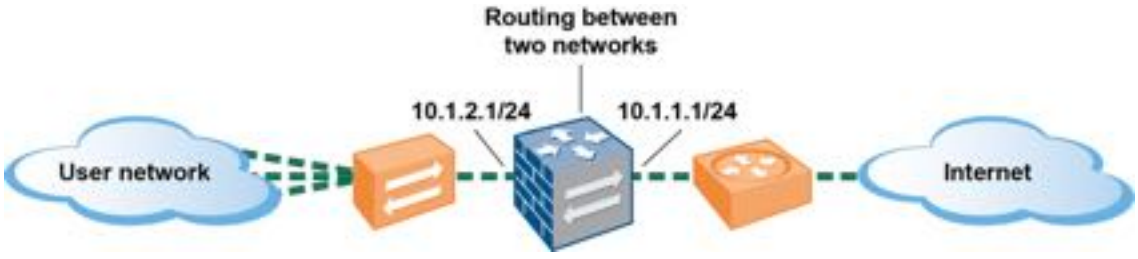
**Figure: Layer 2 Deployment**



## Layer 3 Deployments

In a Layer 3 deployment, the firewall routes traffic between multiple ports. An IP address must be assigned to each interface and a virtual router must be defined to route the traffic. Choose this option when routing is required.

**Figure: Layer 3 Deployment**



In addition, because the firewall must route traffic in a Layer 3 deployment, you must configure a virtual router. See Virtual Routers.

### Point-to-Point Protocol over Ethernet Support

You can configure the firewall to be a Point-to-Point Protocol over Ethernet (PPPoE) termination point to support connectivity in a Digital Subscriber Line (DSL) environment where there is a DSL modem but no other PPPoE device to terminate the connection.

You can choose the PPPoE option and configure the associated settings when an interface is defined as a Layer 3 interface.

PPPoE is not supported in HA active/active mode.

### DHCP Client

You can configure the firewall interface to act as a DHCP client and receive a dynamically assigned IP address. The firewall also provides the capability to propagate settings received by the DHCP client interface into a DHCP server operating on the firewall. This is most commonly used to propagate DNS server settings from an Internet service provider to client machines operating on the network protected by the firewall.

DHCP client is not supported in HA active/active mode.

For more information, see DHCP.

## Tap Mode Deployments

A network tap is a device that provides a way to access data flowing across a computer network. Tap mode deployment allows you to passively monitor traffic flows across a network by way of a switch SPAN or mirror port.

The SPAN or mirror port permits the copying of traffic from other ports on the switch. By dedicating an interface on the firewall as a tap mode interface and connecting it with a switch SPAN port, the switch SPAN port provides the firewall with the mirrored traffic. This provides application visibility within the network without being in the flow of network traffic.

When deployed in tap mode, the firewall is not able to take action, such as block traffic or apply QoS traffic control.

 © Palo Alto Networks, Inc.

# Virtual Routers

The firewall uses virtual routers to obtain routes to other subnets by manually defining a route (static routes) or through participation in Layer 3 routing protocols (dynamic routes). The best routes obtained through these methods are used to populate the firewall's IP route table. When a packet is destined for a different subnet, the Virtual Router obtains the best route from this IP route table and forwards the packet to the next hop router defined in the table.

The Ethernet interfaces and VLAN interfaces defined on the firewall receive and forward the Layer 3 traffic. The destination zone is derived from the outgoing interface based on the forwarding criteria, and policy rules are consulted to identify the security policies to be applied. In addition to routing to other network devices, virtual routers can route to other virtual routers within the same firewall if a next hop is specified to point to another virtual router.

You can configure the virtual router to participate with dynamic routing protocols (BGP, OSPF, or RIP) as well as adding static routes. You can also create multiple virtual routers, each maintaining a separate set of routes that are not shared between virtual routers, enabling you to configure different routing behaviors for different interfaces.

Each Layer 3 interface, loopback interface, and VLAN interface defined on the firewall must be associated with a virtual router. While each interface can belong to only one virtual router, multiple routing protocols and static routes can be configured for a virtual router. Regardless of the static routes and dynamic routing protocols configured for a virtual router, a common general configuration is required. The firewall uses Ethernet switching to reach other devices on the same IP subnet.

The following Layer 3 routing protocols are supported from Virtual Routers:

- RIP
- OSPF
- OSPFv3
- BGP

| **Define a Virtual Router General Configuration** | | |
|---|---|---|
| Step 1 | Gather the required information from your network administrator. | • Interfaces that you want to route<br>• Administrative distances for static, OSFP internal, OSPF external, IBGP, EBGP and RIP |
| Step 2 | Create the virtual router and name it. | 1. Select **Network > Virtual Routers**.<br>2. Click **Add** and enter a name for the virtual router.<br>3. Select interfaces to apply to the virtual router.<br>4. Click **OK**. |
| Step 3 | Select interfaces to apply to the virtual router. | 1. Click **Add** in the Interfaces box.<br>2. Select an already defined interface from the drop-down.<br>3. Repeat Step 2 for all interfaces that you want to add to the virtual router. |

© Palo Alto Networks, Inc.

| Define a Virtual Router General Configuration (Continued) | | |
|---|---|---|
| Step 4 | Set Administrative Distances for static and dynamic routing. | Set Administrative Distances as required.<br>• **Static**—Range is 10-240; default is 10.<br>• **OSPF Internal**—Range is 10-240; default is 30.<br>• **OSPF External**—Range is 10-240; default is 110.<br>• **IBGP**—Range is 10-240; default is 200.<br>• **EBGP**—Range is 10-240; default is 20.<br>• **RIP**—Range is 10-240; default is 120. |
| Step 5 | Save virtual router general settings. | Click **OK** to save your settings. |
| Step 6 | Commit your changes. | Click **Commit**. The device may take up to 90 seconds to save your changes. |

 © Palo Alto Networks, Inc.

# Static Routes

The following procedure shows how to integrate the firewall into the network using static routing.

| Set Up Interfaces and Zones | | |
|---|---|---|
| Step 1 | Configure a default route to your Internet router. | 1. Select **Network > Virtual Router** and then select the **default** link to open the Virtual Router dialog.<br>2. Select the **Static Routes** tab and click **Add**. Enter a **Name** for the route and enter the route in the **Destination** field (for example, 0.0.0.0/0).<br>3. Select the **IP Address** radio button in the **Next Hop** field and then enter the IP address and netmask for your Internet gateway (for example, 208.80.56.1).<br>4. Click **OK** twice to save the virtual router configuration. |
| Step 2 | Configure the external interface (the interface that connects to the Internet). | 1. Select **Network > Interfaces** and then select the interface you want to configure. In this example, we are configuring Ethernet1/3 as the external interface.<br>2. Select the **Interface Type**. Although your choice here depends on your network topology, this example shows the steps for **Layer3**.<br>3. In the **Virtual Router** drop-down, select **default**.<br>4. On the **Config** tab, select **New Zone** from the **Security Zone** drop-down. In the Zone dialog, define a **Name** for new zone, for example Untrust, and then click **OK**.<br>5. To assign an IP address to the interface, select the **IPv4** tab and **Static** radio button. Click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 208.80.56.100/24.<br>6. To enable you to ping the interface, select **Advanced > Other Info**, expand the **Management Profile** drop-down, and select **New Management Profile**. Enter a **Name** for the profile, select **Ping** and then click **OK**.<br>7. To save the interface configuration, click **OK**. |

| Set Up Interfaces and Zones (Continued) | | |
|---|---|---|
| Step 3 | Configure the interface that connects to your internal network.<br><br>In this example, the interface connects to a network segment that uses private IP addresses. Because private IP addresses cannot be routed externally, you will have to configure NAT. See Configure NAT for details. | 1. Select **Network > Interfaces** and select the interface you want to configure. In this example, we are configuring Ethernet1/4 as the internal interface.<br>2. Select **Layer3** from the **Interface Type** drop-down.<br>3. On the **Config** tab, expand the **Security Zone** drop-down and select **New Zone**. In the Zone dialog, define a **Name** for new zone, for example Trust, and then click **OK**.<br>4. Select the same Virtual Router you used in Step 2, default in this example.<br>5. To assign an IP address to the interface, select the **IPv4** tab and the **Static** radio button, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 192.168.1.4/24.<br>6. To enable you to ping the interface, select the management profile that you created in Step 2-6.<br>7. To save the interface configuration, click **OK**. |
| Step 4 | Configure the interface that connects to the DMZ. | 1. Select the interface you want to configure.<br>2. Select **Layer3** from the **Interface Type** drop-down. In this example, we are configuring Ethernet1/13 as the DMZ interface.<br>3. On the **Config** tab, expand the **Security Zone** drop-down and select **New Zone**. In the Zone dialog, define a **Name** for new zone, for example DMZ, and then click **OK**.<br>4. Select the Virtual Router you used in Step 2, default in this example.<br>5. To assign an IP address to the interface, select the **IPv4** tab and the **Static** radio button, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 10.1.1.1/24.<br>6. To enable you to ping the interface, select the management profile that you created in Step 2-6.<br>7. To save the interface configuration, click **OK**. |
| Step 5 | Save the interface configuration. | Click **Commit**. |
| Step 6 | Cable the firewall. | Attach straight through cables from the interfaces you configured to the corresponding switch or router on each network segment. |
| Step 7 | Verify that the interfaces are active. | From the web interface, select **Network > Interfaces** and verify that icon in the Link State column is green. You can also monitor link state from the **Interfaces** widget on the **Dashboard**.<br><br>  |

 © Palo Alto Networks, Inc.

# RIP

Routing Information Protocol (RIP) is an interior gateway protocol (IGP) that was designed for small IP networks. RIP relies on hop count to determine routes; the best routes have the fewest number of hops. RIP is based on UDP and uses port 520 for route updates. By limiting routes to a maximum of 15 hops, the protocol helps prevent the development of routing loops, but also limits the supported network size. If more than 15 hops are required, traffic is not routed. RIP also can take longer to converge than OSPF and other routing protocols. The firewall supports RIP v2.

Perform the following procedure to configure RIP.

| **Configure RIP** | | |
|---|---|---|
| Step 1 | Configure general virtual router configuration settings. | See Virtual Routers for details. |
| Step 2 | Configure general RIP configuration settings. | 1. Select the **RIP** tab.<br>2. Select the **Enable** check box to enable the RIP protocol.<br>3. Select the **Reject Default Route** check box if you do not want to learn any default routes through RIP. This is the recommended default setting.<br>4. De-select the **Reject Default Route** check box if you want to permit redistribution of default routes through RIP. |
| Step 3 | Configure interfaces for the RIP protocol. | 1. On **Interfaces** tab, select an interface from the drop-down in the Interface configuration section.<br>2. Select an already defined interface from the drop-down.<br>3. Select the **Enable** check box.<br>4. Select the **Advertise** check box to advertise a default route to RIP peers with the specified metric value.<br>5. You can optionally select a profile from the **Auth Profile** drop-down. See Step 5 for details.<br>6. Select normal, passive or send-only from the **Mode** drop-down.<br>7. Click **OK**. |
| Step 4 | Configure RIP timers. | 1. On the **Timers** tab, enter a value in the **Interval Seconds (sec)** box. This setting defines the length of the timer interval in seconds (range is 1-60; default is 1). This duration is used for the remaining RIP timing fields.<br>2. Enter an **Update Intervals** value to define the number of intervals between route update announcements (range is 1-3600; default is 30).<br>3. Specify the **Delete Intervals** to define the number of intervals between the time that the route expires to its deletion (range is 1-3600; default is 180).<br>4. Specify the **Expire Intervals** to define the number of intervals between the time that the route was last updated to its expiration (range is 1-3600; default is 120). |

© Palo Alto Networks, Inc.

| Configure RIP | |
|---|---|
| Step 5 (Optional) Configure Auth Profiles. | By default, the firewall does not use RIP authentication for the exchange between RIP neighbors. Optionally, you can configure RIP authentication between RIP neighbors by either a simple password or using MD5 authentication.<br>**Simple Password RIP authentication**<br>1. Select **Auth Profiles** and click **Add**.<br>2. Enter a name for the authentication profile to authenticate RIP messages.<br>3. Select **Simple Password** as the **Password Type**.<br>4. Enter a simple password and then confirm.<br>**MD5 RIP authentication**<br>1. Select **Auth Profiles** and click **Add**.<br>2. Enter a name for the authentication profile to authenticate RIP messages.<br>3. Select **MD5** as the **Password Type**.<br>4. Click **Add**.<br>5. Enter one or more password entries, including:<br>• Key-ID (range is 0-255)<br>• Key<br>6. You can optionally select **Preferred** status.<br>7. Click **OK** to specify the key to be used to authenticate outgoing message.<br>8. Click **OK** again in the Virtual Router - RIP Auth Profile dialog box. |

 © Palo Alto Networks, Inc.

# OSPF

Open Shortest Path First (OSPF) is an interior gateway protocol (IGP) that is most often used to dynamically manage network routes in large enterprise network. It determines routes dynamically by obtaining information from other routers and advertising routes to other routers by way of Link State Advertisements (LSAs). The information gathered from the LSAs is used to construct a topology map of the network. This topology map is shared across routers in the network and used to populate the IP routing table with available routes.

Changes in the network topology are detected dynamically and used to generate a new topology map within seconds. A shortest path tree is computed of each route. Metrics associated with each routing interface are used to calculate the best route. These can include distance, network throughput, link availability etc. Additionally, these metrics can be configured statically to direct the outcome of the OSPF topology map.

Palo Alto networks implementation of OSPF fully supports the following RFCs:

- RFC 2328 (for IPv4)
- RFC 5340 (for IPv6)

The following topics provide more information about the OSPF and procedures for configuring OSPF on the firewall:

- OSPF Concepts
- Configure OSPF
- Configure OSPFv3
- Configure OSPF Graceful Restart
- Confirm OSPF Operation

Also refer to How to Configure OSPF Tech Note.

## OSPF Concepts

The following topics introduce the OSPF concepts you will need to understand in order to configure the firewall to participate in an OSPF network:

- OSPFv3
- OSPF Neighbors
- OSPF Areas
- OSPF Router Types

## OSPFv3

OSPFv3 provides support for the OSPF routing protocol within an IPv6 network. As such, it provides support for IPv6 addresses and prefixes. It retains most of the structure and functions in OSPFv2 (for IPv4) with some minor changes. The following are some of the additions and changes to OSPFv3:

- **Support for multiple instances per link**—With OSPFv3, you can run multiple instances of the OSPF protocol over a single link. This is accomplished by assigning an OSPFv3 instance ID number. An interface that is assigned to an instance ID drops packets that contain a different ID.
- **Protocol Processing Per-link**—OSPFv3 operates per-link instead of per-IP-subnet as on OSPFv2.
- **Changes to Addressing**—IPv6 addresses are not present in OSPFv3 packets, except for LSA payloads within link state update packets. Neighboring routers are identified by the Router ID.
- **Authentication Changes**—OSPFv3 doesn't include any authentication capabilities. Configuring OSPFv3 on a firewall requires an authentication profile that specifies Encapsulating Security Payload (ESP) or IPv6 Authentication Header (AH).The re-keying procedure specified in RFC 4552 is not supported in this release.
- **Support for multiple instances per-link**—Each instance corresponds to an instance ID contained in the OSPFv3 packet header.
- **New LSA Types**—OSPFv3 supports two new LSA types: Link LSA and Intra Area Prefix LSA.

All additional changes are described in detail in RFC 5340.

## OSPF Neighbors

Two OSPF-enabled routers connected by a common network and in the same OSPF area that form a relationship are OSPF neighbors. The connection between these routers can be through a common broadcast domain or by a point-to-point connection. This connection is made through the exchange of hello OSPF protocol packets. These neighbor relationships are used to exchange routing updates between routers.

 © Palo Alto Networks, Inc.

## OSPF Areas

OSPF operates within a single autonomous system (AS). Networks within this single AS, however, can be divided into a number of areas. By default, Area 0 is created. Area 0 can either function alone or act as the OSPF backbone for a larger number of areas. Each OSPF area is named using a 32-bit identifier which in most cases is written in the same dotted-decimal notation as an IP4 address. For example, Area 0 is usually written as 0.0.0.0.

The topology of an area is maintained in its own link state database and is hidden from other areas, which reduces the amount of traffic routing required by OSPF. The topology is then shared in a summarized form between areas by a connecting router.

**Table: OSPF Area Types**

| Area Type | Description |
|---|---|
| Backbone Area | The backbone area (Area 0) is the core of an OSPF network. All other areas are connected to it and all traffic between areas must traverse it. All routing between areas is distributed through the backbone area. While all other OSPF areas must connect to the backbone area, this connection doesn't need to be direct and can be made through a virtual link. |
| Normal OSPF Area | In a normal OSPF area there are no restrictions; the area can carry all types of routes. |
| Stub OSPF Area | A stub area does not receive routes from other autonomous systems. Routing from the stub area is performed through the default route to the backbone area. |
| NSSA Area | The Not So Stubby Area (NSSA) is a type of stub area that can import external routes, with some limited exceptions. |

## OSPF Router Types

Within an OSPF area, routers are divided into the following categories.

- **Internal Router**—A router with that has OSPF neighbor relationships only with devices in the same area.
- **Area Border Router (ABR)**—A router that has OSPF neighbor relationships with devices in multiple areas. ABRs gather topology information from their attached areas and distribute it to the backbone area.
- **Backbone Router**—A backbone router is any OSPF router that is attached to the OSPF backbone. Since ABRs are always connected to the backbone, they are always classified as backbone routers.
- **Autonomous System Boundary Router (ASBR)**—An ASBR is a router that attaches to more than one routing protocol and exchanges routing information between them.

© Palo Alto Networks, Inc.

## Configure OSPF

OSPF determines routes dynamically by obtaining information from other routers and advertising routes to other routers by way of Link State Advertisements (LSAs). The router keeps information about the links between it and the destination and can make highly efficient routing decisions. A cost is assigned to each router interface, and the best routes are determined to be those with the lowest costs, when summed over all the encountered outbound router interfaces and the interface receiving the LSA.

Hierarchical techniques are used to limit the number of routes that must be advertised and the associated LSAs. Because OSPF dynamically processes a considerable amount of route information, it has greater processor and memory requirements than does RIP.

| **Configure OSPF** | | |
|---|---|---|
| Step 1 | Configure general virtual router configuration settings. | See Virtual Routers for details. |
| Step 2 | Configure general OSPF configuration settings. | 1. Select the **OSPF** tab.<br>2. Select the **Enable** check box to enable the OSPF protocol.<br>3. Optionally enter the **Router ID**.<br>4. Select the **Reject Default Route** check box if you do not want to learn any default routes through OSPF. This is the recommended default setting.<br>De-select the **Reject Default Route** check box if you want to permit redistribution of default routes through OSPF. |

© Palo Alto Networks, Inc.

**Configure OSPF (Continued)**

| | |
|---|---|
| Step 3 Configure Areas - Type for the OSFP protocol. | 1. On the **Areas** tab, click **Add**.<br>2. Enter an Area ID for the area in *x.x.x.x* format. This is the identifier that each neighbor must accept to be part of the same area.<br>3. On the **Type** tab, select one of the following from the area **Type** drop-down:<br>• **Normal**—There are no restrictions; the area can carry all types of routes.<br>• **Stub**—There is no outlet from the area. To reach a destination outside of the area, it is necessary to go through the border, which connects to other areas. If you select this option, configure the following:<br>– **Accept Summary**—Link state advertisements (LSA) are accepted from other areas. If this option on a stub area Area Border Router (ABR) interface is disabled, the OSPF area will behave as a Totally Stubby Area (TSA) and the ABR will not propagate any summary LSAs.<br>– **Advertise Default Route**—Default route LSAs will be included in advertisements to the stub area along with a configured metric value in the configured range 1-255.<br>• **NSSA** (Not-So-Stubby Area)—The firewall can only leave the area by routes other than OSPF routes. If selected, configure **Accept Summary** and **Advertise Default Route** as described for **Stub**. If you select this option, configure the following:<br>– **Type**—Select either **Ext 1** or **Ext 2** route type to advertise the default LSA.<br>– **Ext Ranges**—Click **Add** in the section to enter ranges of external routes that you want to enable or suppress advertising for.<br>4. **Priority**—Enter the OSPF priority for this interface (0-255). This is the priority for the router to be elected as a designated router (DR) or as a backup DR (BDR) according to the OSPF protocol. When the value is zero, the router will not be elected as a DR or BDR.<br>• **Auth Profile**—Select a previously-defined authentication profile.<br>• **Timing**—It is recommended that you keep the default timing settings.<br>• **Neighbors**—For p2pmp interfaces, enter the neighbor IP address for all neighbors that are reachable through this interface.<br>5. Select **normal**, **passive** or **send-only** as the **Mode**.<br>6. Click **OK**. |

| Configure OSPF (Continued) | | |
|---|---|---|
| Step 4 | Configure Areas - Range for the OSFP protocol | 1. On the **Range** tab, click **Add** to aggregate LSA destination addresses in the area into subnets.<br>2. **Advertise** or **Suppress** advertising LSAs that match the subnet, and click **OK**. Repeat to add additional ranges. |
| Step 5 | Configure Areas - Interfaces for the OSFP protocol | 1. On the **Interface** tab, click **Add** and enter the following information for each interface to be included in the area:<br>• **Interface**—Select an interface from the drop-down box.<br>• **Enable**—Selecting this option causes the OSPF interface settings to take effect.<br>• **Passive**—Select the check box to if you do not want the OSPF interface to send or receive OSPF packets. Although OSPF packets are not sent or received if you choose this option, the interface is included in the LSA database.<br>• **Link type**—Choose **Broadcast** if you want all neighbors that are accessible through the interface to be discovered automatically by multicasting OSPF hello messages, such as an Ethernet interface. Choose **p2p** (point-to-point) to automatically discover the neighbor. Choose **p2mp** (point-to-multipoint) when neighbors must be defined manually. Defining neighbors manually is allowed only for **p2mp** mode.<br>• **Metric**—Enter an OSPF metric for this interface (range is 0-65535; default is 10).<br>• **Priority**—Enter an OSPF priority for this interface. This is the priority for the router to be elected as a designated router (DR) or as a backup DR (BDR) (range is 0-255; default is 1). If zero is configured, the router will not be elected as a DR or BDR.<br>• **Auth Profile**—Select a previously-defined authentication profile.<br>• **Timing**—The following OSPF timing settings can be set. Palo Alto Networks recommends that you retain the default timing settings.<br>– **Hello Interval (sec)**—Interval (in seconds) at which the OSPF process sends hello packets to its directly connected neighbors (range is 0-3600; default is 10).<br>– **Dead Counts—**Number of times the hello interval can occur for a neighbor without OSPF receiving a hello packet from the neighbor, before OSPF considers that neighbor down (range is 3-20; default is 4). The **Hello Interval** multiplied by the **Dead Counts** equals the value of the dead timer. |

© Palo Alto Networks, Inc.

| Configure OSPF (Continued) | |
|---|---|
| | – **Retransmit Interval (sec)**—Length of time (in seconds) that OSPF waits to receive a link state advertisement (LSA) from a neighbor before OSPF retransmits the LSA (range is 0-3600; default is 10).<br>– **Transit Delay (sec)**—Length of time (in seconds) that an LSA is delayed before it is sent out of an interface (range is 0-3600; default is 1).<br>– **Graceful Restart Hello Delay (sec)**—Applies to an OSPF interface when Active/Passive High Availability is configured. **Graceful Restart Hello Delay** is the length of time (in seconds) during which the firewall sends Grace LSA packets at 1-second intervals (range is 1-10; default is 10). During this time, no hello packets are sent from the restarting firewall. During the restart, the dead timer (which is the **Hello Interval** multiplied by the **Dead Counts**) is also counting down. If the dead timer is too short, the adjacency will go down during the graceful restart because of the hello delay. Therefore, it is recommended that the dead timer be at least four times the value of the **Graceful Restart Hello Delay**. For example, a **Hello Interval** of 10 seconds and a **Dead Counts** of 4 yield a dead timer of 40 seconds. If the **Graceful Restart Hello Delay** is set to 10 seconds, that 10-second delay of hello packets is comfortably within the 40-second dead timer, so the adjacency will not time out during a graceful restart.<br>• If **p2mp** is selected for **Link Type** interfaces, enter the neighbor IP addresses for all neighbors that are reachable through this interface.<br>2. Click **OK** |
| Step 6 Configure Areas - Virtual Links. | 1. On the **Virtual Link** tab, click **Add** and enter the following information for each virtual link to be included in the backbone area:<br>• **Name**—Enter a name for the virtual link.<br>• **Neighbor ID**—Enter the router ID of the router (neighbor) on the other side of the virtual link.<br>• **Transit Area**—Enter the area ID of the transit area that physically contains the virtual link.<br>• **Enable**—Select to enable the virtual link.<br>• **Timing**—It is recommended that you keep the default timing settings.<br>• **Auth Profile**—Select a previously-defined authentication profile.<br>2. Click **OK**. |

| Configure OSPF (Continued) | |
|---|---|
| Step 7 (Optional) Configure Auth Profiles. | By default, the firewall does not use OSPF authentication for the exchange between OSPF neighbors. Optionally, you can configure OSPF authentication between OSPF neighbors by either a simple password or using MD5 authentication.<br>**Simple Password OSPF authentication**<br>1. On the **Auth Profiles** tab, click **Add**.<br>2. Enter a name for the authentication profile to authenticate OSPF messages.<br>3. Select **Simple Password** as the **Password Type**.<br>4. Enter a simple password and then confirm.<br>**MD5 OSPF authentication**<br>1. On the **Auth Profiles** tab, click **Add**.<br>2. Enter a name for the authentication profile to authenticate OSPF messages.<br>3. Select **MD5** as the **Password Type**.<br>4. Click **Add**.<br>5. Enter one or more password entries, including:<br>• Key-ID (range is 0-255)<br>• Key<br>• Select the **Preferred** option to specify that the key be used to authenticate outgoing messages.<br>6. Click **OK**.<br>7. Click **OK** again in the Virtual Router - OSPF Auth Profile dialog box. |
| Step 8 Configure Advanced OSPF options. | 1. On the **Advanced** tab, select the **RFC 1583 Compatibility** check box to ensure compatibility with RFC 1583.<br>2. Configure a value for the **SPF Calculation Delay** (sec) timer.<br>This timer allows you to tune the delay time between receiving new topology information and performing an SPF calculation. Lower values enable faster OSPF re-convergence. Routers peering with the firewall should be tuned in a similar manner to optimize convergence times.<br>3. Configure a value for the **LSA Interval (sec)** time. This timer specifies the minimum time between transmissions of two instances of the same LSA (same router, same type, same LSA ID). This is equivalent to MinLSInterval in RFC 2328. Lower values can be used to reduce re-convergence times when topology changes occur. |

# Configure OSPFv3

| Configure OSPFv3 | | |
|---|---|---|
| Step 1 | Configure general virtual router configuration settings. | See Virtual Routers for details. |
| Step 2 | Configure general OSPF configuration settings. | 1. Select the **OSPF** tab.<br>2. Select the **Enable** check box to enable the OSPF protocol.<br>3. Select the **Reject Default Route** check box if you do not want to learn any default routes through OSPF. This is the recommended default setting.<br>4. Clear the **Reject Default Route** check box if you want to permit redistribution of default routes through OSPF. |
| Step 3 | Configure general OSPFv3 configuration settings. | 1. Select the **OSPFv3** tab.<br>2. Select the **Enable** check box to enable the OSPF protocol.<br>3. Select the **Reject Default Route** check box if you do not want to learn any default routes through OSPFv3 This is the recommended default setting.<br>De-select the **Reject Default Route** check box if you want to permit redistribution of default routes through OSPFv3. |
| Step 4 | Configure Auth Profile for the OSFPv3 protocol.<br>While OSPFv3 doesn't include any authentication capabilities of its own, it relies entirely on IPsec to secure communications between neighbors. | When configuring an authentication profile, you must use Encapsulating Security Payload (ESP) or IPv6 Authentication Header (AH).<br>**ESP OSPFv3 authentication**<br>1. On the **Auth Profiles** tab, click **Add**.<br>2. Enter a name for the authentication profile to authenticate OSPFv3 messages.<br>3. Specify a Security Policy Index (**SPI**). The SPI must match between both ends of the OSPFv3 adjacency. The SPI number must be a hexadecimal value between 00000000 and FFFFFFFF.<br>4. Select **ESP** for **Protocol**.<br>5. Select a **Crypto Algorithm** from the drop-down.<br>You can enter none or one of the following algorithms: SHA1, SHA256, SHA384, SHA512 or MD5.<br>6. If a **Crypto Algorithm** other than none was selected, enter a value for **Key** and then confirm. |

| Configure OSPFv3 (Continued) | |
|---|---|
| | **AH OSPFv3 authentication**<br>1. On the **Auth Profiles** tab, click **Add**.<br>2. Enter a name for the authentication profile to authenticate OSPFv3 messages.<br>3. Specify a Security Policy Index (**SPI**). The SPI must match between both ends of the OSPFv3 adjacency. The SPI number must be a hexadecimal value between 00000000 and FFFFFFFF.<br>4. Select **AH** for **Protocol**.<br>5. Select a **Crypto Algorithm** from the drop-down.<br>You must enter one of the following algorithms: SHA1, SHA256, SHA384, SHA512 or MD5.<br>6. Enter a value for **Key** and then confirm.<br>7. Click **OK**.<br>8. Click **OK** again in the Virtual Router - OSPF Auth Profile dialog. |
| Step 5 Configure Areas - Type for the OSFP protocol. | 1. On the **Areas** tab, click **Add**.<br>2. Enter an Area ID. This is the identifier that each neighbor must accept to be part of the same area.<br>3. On the **General** tab, select one of the following from the area **Type** drop-down:<br>• **Normal**—There are no restrictions; the area can carry all types of routes.<br>• **Stub**—There is no outlet from the area. To reach a destination outside of the area, it is necessary to go through the border, which connects to other areas. If you select this option, configure the following:<br>– **Accept Summary**—Link state advertisements (LSA) are accepted from other areas. If this option on a stub area Area Border Router (ABR) interface is disabled, the OSPF area will behave as a Totally Stubby Area (TSA) and the ABR will not propagate any summary LSAs.<br>– **Advertise Default Route**—Default route LSAs will be included in advertisements to the stub area along with a configured metric value in the configured range 1-255. |

 © Palo Alto Networks, Inc.

| Configure OSPFv3 (Continued) | | |
|---|---|---|
| | | • **NSSA** (Not-So-Stubby Area)—The firewall can only leave the area by routes other than OSPF routes. If selected, configure **Accept Summary** and **Advertise Default Route** as described for **Stub**. If you select this option, configure the following:<br>– **Type**—Select either **Ext 1** or **Ext 2** route type to advertise the default LSA.<br>– **Ext Ranges**—Click **Add** in the section to enter ranges of external routes that you want to enable or suppress advertising for. |
| Step 6 | Associate an OSPFv3 authentication profile to an area or an interface. | **To an Area**<br>1. On the **Areas** tab, select an existing area from the table.<br>2. On the **General** tab, select a previously defined **Authentication Profile** from the **Authentication** drop-down.<br>3. Click **OK**.<br>**To an Interface**<br>1. On the **Areas** tab, select an existing area from the table.<br>2. Select the **Interface** tab and click **Add**.<br>3. Select the authentication profile you want to associate with the OSPF interface from the **Auth Profile** drop-down. |
| Step 7 | (Optional) Configure Export Rules | 1. On the **Export** tab, click **Add**.<br>2. Select the **Allow Redistribute Default Route** check box to permit redistribution of default routes through OSPFv3.<br>3. Select the name of a redistribution profile. The value must be an IP subnet or valid redistribution profile name.<br>4. Select a metric to apply for **New Path Type**.<br>5. Specify a **New Tag** for the matched route that has a 32-bit value.<br>6. Assign a metric for the new rule (range is 1 - 65535).<br>7. Click **OK**. |

| Configure OSPFv3 (Continued) | |
|---|---|
| Step 8 Configure Advanced OSPFv3 options. | 1. On the **Advanced** tab, select the **Disable Transit Routing for SPF Calculation** check box if you want the firewall to participate in OSPF topology distribution without being used to forward transit traffic.<br>2. Configure a value for the **SPF Calculation Delay** (sec) timer.<br>This timer allows you to tune the delay time between receiving new topology information and performing an SPF calculation. Lower values enable faster OSPF re-convergence. Routers peering with the firewall should be tuned in a similar manner to optimize convergence times.<br>3. Configure a value for the **LSA Interval (sec) time**, This timer specifies the minimum time between transmissions of two instances of the same LSA (same router, same type, same LSA ID). This is equivalent to MinLSInterval in RFC 2328. Lower values can be used to reduce re-convergence times when topology changes occur.<br>4. Optionally, Configure OSPF Graceful Restart. |

## Configure OSPF Graceful Restart

OSPF Graceful Restart directs OSPF neighbors to continue using routes through a device during a short transition when it is out of service. This behavior increases network stability by reducing the frequency of routing table reconfiguration and the related route flapping that can occur during short periodic down times.

For a Palo Alto Networks firewall, OSPF Graceful Restart involves the following operations:

- **Firewall as a restarting device**—In a situation where the firewall will be down for a short period of time or is unavailable for short intervals, it sends Grace LSAs to its OSPF neighbors. The neighbors must be configured to run in Graceful Restart Helper mode. In Helper Mode, the neighbors receive the Grace LSAs that inform it that the firewall will perform a graceful restart within a specified period of time defined as the **Grace Period**. During the grace period, the neighbor continues to forward routes through the firewall and to send LSAs that announce routes through the firewall. If the firewall resumes operation before expiration of the grace period, traffic forwarding will continue as before without network disruption. If the firewall does not resume operation after the grace period has expired, the neighbors will exit helper mode and resume normal operation, which will involve reconfiguring the routing table to bypass the firewall.
- **Firewall as a Graceful Restart Helper**—In a situation where neighboring routers may be down for a short periods of time, the firewall can be configured to operate in Graceful Restart Helper mode. If configured in this mode, the firewall will be configured with a **Max Neighbor Restart Time**. When the firewall receives the Grace LSAs from its OSFP neighbor, it will continue to route traffic to the neighbor and advertise routes through the neighbor until either the grace period or max neighbor restart time expires. If neither expires before the neighbor returns to service, traffic forwarding continues as before without network disruption. If either period expires before the neighbor returns to service, the firewall will exit helper mode and resume normal operation, which will involve reconfiguring the routing table to bypass the neighbor.

 © Palo Alto Networks, Inc.

| Configure OSPF Graceful Restart |
|---|
| 1. Select **Network > Virtual Routers** and select the virtual router you want to configure. |
| 2. Select **OSPF > Advanced**. |
| 3. Verify that the following check boxes are selected (they are enabled by default):<br>• **Enable Graceful Restart**<br>• **Enable Helper Mode**<br>• **Enable Strict LSA checking**<br>These check boxes should remain selected unless required by your topology. |
| 4. Configure a **Grace Period** in seconds. |
| 5. Configure a **Max Neighbor Restart Time** in seconds. |

## Confirm OSPF Operation

Once an OSPF configuration has been committed, you can use any of the following operations to confirm that OSPF is operating:

- View the Routing Table
- Confirm OSPF Adjacencies
- Confirm that OSPF Connections are Established

### View the Routing Table

By viewing the routing table, you can see whether OSPF routes have been established. The routing table is accessible from either the web interface or the CLI. If you are using the CLI, use the following commands:

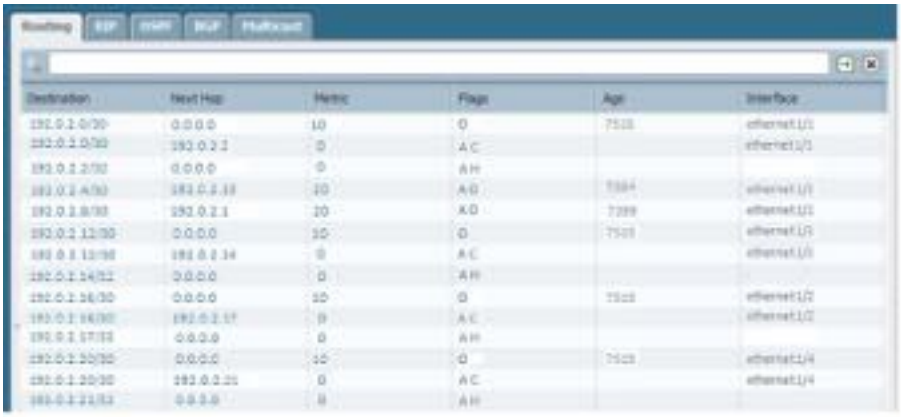
- `show routing route`
- `show routing fib`

The following procedure describes how to use the web interface to view the routing table.

| View the Routing Table |
|---|
| 1. Select **Network > Virtual Routers**. |
|  |

**View the Routing Table**

2. Select the **Routing** tab and examine the **Flags** column of the routing table for routes that were learned by OSPF.

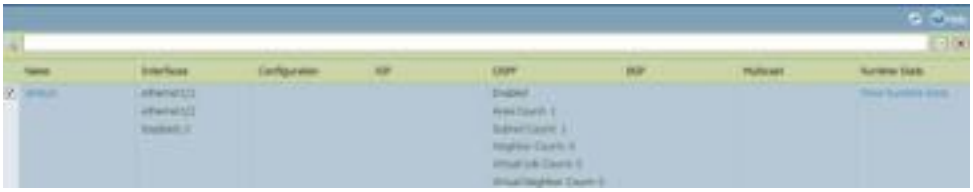


## Confirm OSPF Adjacencies

By viewing the **Neighbor** tab as described in the following procedure, you can confirm that OSPF adjacencies have been established.

**View the Neighbor Tab to Confirm OSPF Adjacencies**

1. Select **Network > Virtual Routers**.



2. Select **OSPF > Neighbor** and examine the **Status** column to determine if OSPF adjacencies have been established.

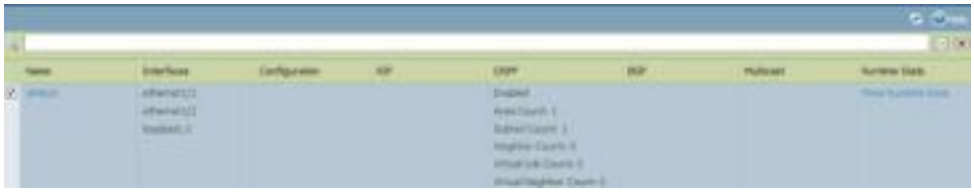
 © Palo Alto Networks, Inc.

## Confirm that OSPF Connections are Established

By viewing the system log, you can confirm that OSPF connections have been established, as described in the following procedure:

**Examine the System Log**

1. Select **Monitor> System** and look for messages to confirm that OSPF adjacencies have been established.



2. Select **OSPF > Neighbor** and examine the **Status** column to determine if OSPF adjacencies have been established.

# BGP

Border Gateway Protocol (BGP) is the primary Internet routing protocol. BGP determines network reachability based on IP prefixes that are available within autonomous systems (AS), where an AS is a set of IP prefixes that a network provider has designated to be part of a single routing policy.

In the routing process, connections are established between BGP peers (or neighbors). If a route is permitted by the policy, it is stored in the routing information base (RIB). Each time the local firewall RIB is updated, the firewall determines the optimal routes and sends an update to the external RIB, if export is enabled.

Conditional advertisement is used to control how BGP routes are advertised. The BGP routes must satisfy conditional advertisement rules before being advertised to peers.

BGP supports the specification of aggregates, which combine multiple routes into a single route. During the aggregation process, the first step is to find the corresponding aggregation rule by performing a longest match that compares the incoming route with the prefix values for other aggregation rules.

For more information on BGP, refer to How to Configure BGP Tech Note.

The firewall provides a complete BGP implementation, which includes the following features:

- Specification of one BGP routing instance per virtual router.
- Routing policies based on route-map to control import, export and advertisement, prefix-based filtering, and address aggregation.
- Advanced BGP features that include route reflector, AS confederation, route flap dampening, and graceful restart.
- IGP-BGP interaction to inject routes to BGP using redistribution profiles.

BGP configuration consists of the following elements:

- Per-routing-instance settings, which include basic parameters such as local route ID and local AS and advanced options such as path selection, route reflector, AS confederation, route flap, and dampening profiles.
- Authentication profiles, which specify the MD5 authentication key for BGP connections.
- Peer group and neighbor settings, which include neighbor address and remote AS and advanced options such as neighbor attributes and connections.
- Routing policy, which specifies rule sets that peer groups and peers use to implement imports, exports, conditional advertisements, and address aggregation controls.

Perform the following procedure to configure BGP.

| **Configure BGP** | | |
|---|---|---|
| Step 1 | Configure general virtual router configuration settings. | See Virtual Routers for details. |

 © Palo Alto Networks, Inc.

| Configure BGP (Continued) | | |
|---|---|---|
| Step 2 | Configure standard BGP configuration settings. | 1. Select the **BGP** tab.<br>2. Select the **Enable** check box to enable the BGP protocol.<br>3. Assign an IP address to the virtual router in the **Router ID** box.<br>4. Enter the number of the AS to which the virtual router belongs in the **AS Number** box, based on the router ID. Range is 1-4294967295. |
| Step 3 | Configure general BGP configuration settings. | 1. Select **BGP > General**.<br>2. Select the **Reject Default Route** check box to ignore any default routes that are advertised by BGP peers.<br>3. Select the **Install Route** check box to install BGP routes in the global routing table.<br>4. Select the **Aggregate MED** check box to enable route aggregation even when routes have different Multi-Exit Discriminator (MED) values.<br>5. Enter a value for the **Default Local Preference** that specifies a value than can be used to determine preferences among different paths.<br>6. Select one of the following values for the AS format for interoperability purposes:<br>• 2 Byte (default value)<br>• 4 Byte<br>7. Enable or disable each of the following values for **Path Selection**:<br>• **Always Compare MED**—Enable this comparison to choose paths from neighbors in different autonomous systems.<br>• **Deterministic MED Comparison**—Enable this comparison to choose between routes that are advertised by IBGP peers (BGP peers in the same autonomous system).<br>8. Click **Add** to include a new authentication profile and configure the following settings:<br>• **Profile Name**—Enter a name to identify the profile.<br>• **Secret/Confirm Secret**—Enter and confirm a passphrase for BGP peer communications. |

| Configure BGP (Continued) | |
|---|---|
| Step 4 Configure BGP Advanced settings (Optional) | 1. On the **Advanced** tab, select **Graceful Restart** and configure the following timers:<br>• **Stale Route Time (sec)**—Specifies the length of time in seconds that a route can say in the stale state (range is 1- 3600; default is 120).<br>• **Local Restart Time (sec)**—Specifies the length of time in seconds that the local device waits to restart. This value is advertised to peers (range is 1-3600' default is 120).<br>• **Max Peer Restart Time (sec)**—Specifies the maximum length of time in seconds that the local device accepts as a grave period restart time for peer devices (range is 1-3600; default is 120).<br>2. Specify an IPv4 identifier to represent the reflector cluster in the **Reflector Cluster ID** box.<br>3. Specify the identifier for the AS confederation to be presented as a single AS to external BGP peers in the **Confederation Member AS** box.<br>4. Click **Add** and enter the following information for each Dampening Profile that you want to configure, select **Enable**, and click **OK**:<br>• **Profile Name**—Enter a name to identify the profile.<br>• **Cutoff**—Specify a route withdrawal threshold above which a route advertisement is suppressed (range is 0.0-1000.0; default: is 1.25).<br>• **Reuse**—Specify a route withdrawal threshold below which a suppressed route is used again (range is 0.0-1000.0; default is 5).<br>• **Max Hold Time (sec)**—Specify the maximum length of time in seconds that a route can be suppressed, regardless of how unstable it has been (range is 0-3600 seconds; default is 900).<br>• **Decay Half Life Reachable (sec)**—Specify the length of time in seconds after which a route's stability metric is halved if the route is considered reachable (range is 0-3600 seconds; default: is 300).<br>• **Decay Half Life Unreachable (sec)**—Specify the length of time in seconds after which a route's stability metric is halved if the route is considered unreachable (range is 0-3600; default is 300).<br>5. Click **OK**. |

© Palo Alto Networks, Inc.

| Configure BGP (Continued) | | |
|---|---|---|
| Step 5 | Configure the BGP peer group. | 1. Select the **Peer Group** tab and click **Add**.<br>2. Enter a **Name** for the peer group and select **Enable**.<br>3. Select the **Aggregated Confed AS Path** check box to include a path to the configured aggregated confederation AS.<br>4. Select the **Soft Reset with Stored Info** check box to perform a soft reset of the firewall after updating the peer settings.<br>5. Specify the type of peer or group from the **Type** drop-down and configure the associated settings (see below in this table for descriptions of Import Next Hop and Export Next Hop).<br>• **IBGP—Export Next Hop:** Specify **Original** or **Use self**<br>• **EBGP Confed—Export Next Hop:** Specify **Original** or **Use self**<br>• **EBGP Confed—Export Next Hop:** Specify **Original** or **Use self**<br>• **EBGP—Import Next Hop:** Specify **Original** or **Use self**, **Export Next Hop:** Specify **Resolve** or **Use self**. Select **Remove Private AS** if you want to force BGP to remove private AS numbers.<br>6. Click **OK** to save. |
| Step 6 | Configure Import and Export rules.<br>The import/export rules are used to import/export routes from/to other routers. For example, importing the default route from your Internet Service Provider. | 1. Select the **Import** tab and then click **Add** and enter a name in the **Rules** field and select the **Enable** check box.<br>2. Click **Add** and select the **Peer Group** to which the routes will be imported from.<br>3. Click the **Match** tab and define the options used to filter routing information. You can also define the Multi-Exit Discriminator (MED) value and a next hop value to routers or subnets for route filtering. The MED option is an external metric that lets neighbors know about the preferred path into an AS. A lower value is preferred over a higher value.<br>4. Click the **Action** tab and define the action that should occur (allow/deny) based on the filtering options defined in the **Match** tab. If **Deny** is selected, no further options need to be defined. If the **Allow** action is selected, define the other attributes.<br>5. Click the **Export** tab and define export attributes, which are similar to the **Import** settings, but are used to control route information that is exported from the firewall to neighbors.<br>6. Click **OK** to save. |

| Configure BGP (Continued) | | |
|---|---|---|
| Step 7 | Configure conditional advertising, which allows you to control what route to advertise in the event that a different route is not available in the local BGP routing table (LocRIB), indicating a peering or reachability failure. This is useful in cases where you want to try to force routes to one AS over another, for example if you have links to the Internet through multiple ISPs and you want traffic to be routed to one provider instead of the other unless there is a loss of connectivity to the preferred provider. | 1. Select the **Conditional Adv** tab, click **Add** and enter a name in the **Policy** field.<br>2. Select the **Enable** check box.<br>3. Click **Add** and in the **Used By** section enter the peer group(s) that will use the conditional advertisement policy.<br>4. Select the **Non Exist Filter** tab and define the network prefix(es) of the preferred route. This specifies the route that you want to advertise, if it is available in the local BGP routing table. If a prefix is going to be advertised and matches a Non Exist filter, the advertisement will be suppressed.<br>5. Select the **Advertise Filters** tab and define the prefix(es) of the route in the Local-RIB routing table that should be advertised in the event that the route in the non-exist filter is not available in the local routing table. If a prefix is going to be advertised and does not match a Non Exist filter, the advertisement will occur. |
| Step 8 | Configure aggregate options to summaries routes in the BGP configuration.<br><br>BGP route aggregation is used to control how BGP aggregates addresses. Each entry in the table results in one aggregate address being created. This will result in an aggregate entry in the routing table when at least one or more specific route matching the address specified is learned. | 1. Select the **Aggregate** tab, click **Add** and enter a name for the aggregate address.<br>2. In the **Prefix** field, enter the network prefix that will be the primary prefix for the aggregated prefixes.<br>3. Select the **Suppress Filters** tab and define the attributes that will cause the matched routes to be suppressed.<br>4. Select the **Advertise Filters** tab and define the attributes that will cause the matched routes to always be advertised to peers. |
| Step 9 | Configure redistribution rules.<br><br>This rule is used to redistribute host routes and unknown routes that are not on the local RIB to the peers routers. | 1. Select the **Redist Rules** tab and click **Add**.<br>2. In the **Name** field, enter an IP subnet or select a redistribution profile. You can also configure a new redistribution profile from the drop-down if needed.<br>3. Click the **Enable** check box to enable the rule.<br>4. In the **Metric** field, enter the route metric that will be used for the rule.<br>5. In the **Set Origin** drop-down, select **incomplete**, **igp**, or **egp**.<br>6. Optionally set MED, local preference, AS path limit and community values. |

# Session Settings and Timeouts

This section describes the global settings that affect TCP, UDP, and ICMPv6 sessions, in addition to IPv6, NAT64, NAT oversubscription, jumbo frame size, MTU, accelerated aging, and captive portal authentication. There is also a setting (Rematch Sessions) that allows you to apply newly configured security policies to sessions that are already in progress.

The **Device > Setup > Session** tab is where these session settings and timeouts are configured.

The first few topics below provide brief summaries of the Transport Layer of the OSI model, TCP, UDP, and ICMP. For more information about the protocols, refer to their respective RFCs. The remaining topics describe the session timeouts and settings.

- Transport Layer Sessions
- TCP
- UDP
- ICMP
- Configure Session Timeouts
- Configure Session Settings
- Prevent TCP Split Handshake Session Establishment

© Palo Alto Networks, Inc.

## Transport Layer Sessions

A network session is an exchange of messages that occurs between two or more communication devices, lasting for some period of time. A session is established and is torn down when the session ends. Different types of sessions occur at three layers of the OSI model: the Transport layer, the Session layer, and the Application layer.

The Transport Layer operates at Layer 4 of the OSI model, providing reliable or unreliable, end-to-end delivery and flow control of data. Internet protocols that implement sessions at the Transport layer include Transmission Control Protocol (TCP) and User Datagram Protocol (UDP).

 © Palo Alto Networks, Inc.

# TCP

Transmission Control Protocol (TCP) (RFC 793) is one of the main protocols in the Internet Protocol (IP) suite, and is so prevalent that it is frequently referenced together with IP as *TCP/IP*. TCP is considered a reliable transport protocol because it provides error-checking while transmitting and receiving segments, acknowledges segments received, and reorders segments that arrive in the wrong order. TCP also requests and provides retransmission of segments that were dropped. TCP is stateful and connection-oriented, meaning a connection between the sender and receiver is established for the duration of the session. TCP provides flow control of packets, so it can handle congestion over networks.

TCP performs a handshake during session setup to initiate and acknowledge a session. After the data is transferred, the session is closed in an orderly manner, where each side transmits a FIN packet and acknowledges it with an ACK packet. The handshake that initiates the TCP session is often a three-way handshake (an exchange of three messages) between the initiator and the listener, or it could be a variation, such as a four-way or five-way split handshake or a simultaneous open. The TCP Split Handshake Drop explains how to Prevent TCP Split Handshake Session Establishment.

Applications that use TCP as their transport protocol include Hypertext Transfer Protocol (HTTP), HTTP Secure (HTTPS), File Transfer Protocol (FTP), Simple Mail Transfer Protocol (SMTP), Telnet, Post Office Protocol version 3 (POP3), Internet Message Access Protocol (IMAP), and Secure Shell (SSH).

The following topics describe details of the PAN-OS implementation of TCP.

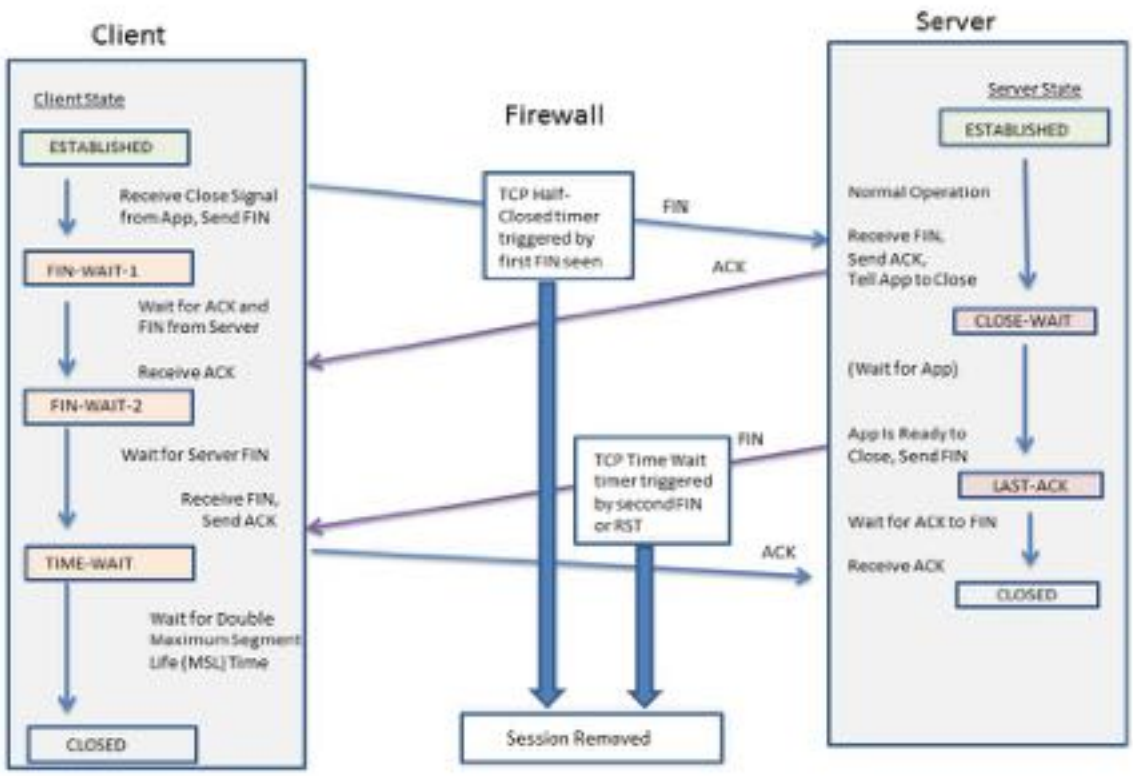
- TCP Half Closed and TCP Time Wait Timers
- Unverified RST Timer
- TCP Split Handshake Drop

## TCP Half Closed and TCP Time Wait Timers

The TCP connection termination procedure uses a TCP Half Closed timer, which is triggered by the first FIN the firewall sees for a session. The timer is named TCP Half Closed because only one side of the connection has sent a FIN. A second timer, TCP Time Wait, is triggered by the second FIN or a RST.

If the firewall were to have only one timer triggered by the first FIN, a setting that was too short could prematurely close the half-closed sessions. Conversely, a setting that was too long would make the session table grow too much and possibly use up all of the sessions. Two timers allow you to have a relatively long TCP Half Closed timer and a short TCP Time Wait timer, thereby quickly aging fully closed sessions and controlling the size of the session table.

The following figure illustrates when the firewall's two timers are triggered during the TCP connection termination procedure.



The TCP Time Wait timer should be set to a value less than the TCP Half Closed timer for the following reasons:

- The longer time allowed after the first FIN is seen gives the opposite side of the connection time to fully close the session.
- The shorter Time Wait time is because there is no need for the session to remain open for a long time after the second FIN or a RST is seen. A shorter Time Wait time frees up resources sooner, yet still allows time for the firewall to see the final ACK and possible retransmission of other datagrams.

If you configure a TCP Time Wait timer to a value greater than the TCP Half Closed timer, the commit will be accepted, but in practice the TCP Time Wait timer will not exceed the TCP Half Closed value.

The timers can be set globally or per application. The global settings are used for all applications by default. If you configure TCP wait timers at the application level, they override the global settings.

## Unverified RST Timer

If the firewall receives a Reset (RST) packet that cannot be verified (because it has an unexpected sequence number within the TCP window or it is from an asymmetric path), the Unverified RST timer controls the aging out of the session. It defaults to 30 seconds; the range is 1-600 seconds. The Unverified RST timer provides an additional security measure, explained in the second bullet below.

A RST packet will have one of three possible outcomes:

- A RST packet that falls outside the TCP window is dropped.

 © Palo Alto Networks, Inc.

- A RST packet that falls inside the TCP window but does not have the exact expected sequence number is unverified and subject to the Unverified RST timer setting. This behavior helps prevent denial of service (DoS) attacks where the attack tries to disrupt existing sessions by sending random RST packets to the firewall.
- A RST packet that falls within the TCP window and has the exact expected sequence number is subject to the TCP Time Wait timer setting.

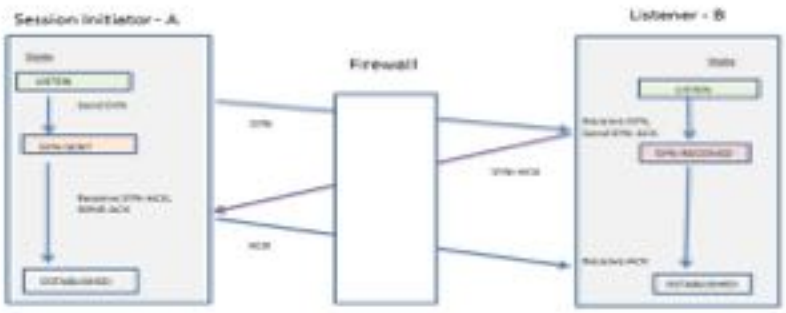
## TCP Split Handshake Drop

The **Split Handshake** option in a Zone Protection profile will prevent a TCP session from being established if the session establishment procedure does not use the well-known three-way handshake, but instead uses a variation, such as a four-way or five-way split handshake or a simultaneous open.

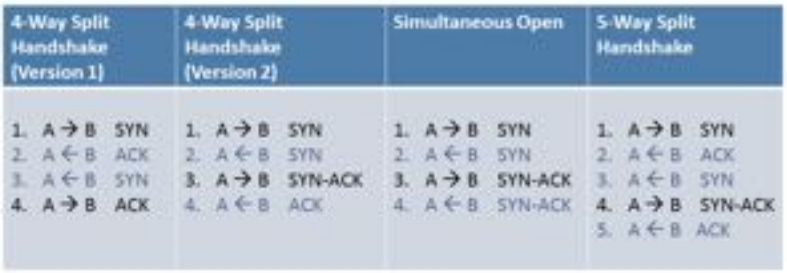
The Palo Alto Networks next-generation firewall correctly handles sessions and all Layer 7 processes for split handshake and simultaneous open session establishment without enabling the **Split Handshake** option. Nevertheless, the **Split Handshake** option (which causes a TCP split handshake drop) is made available. When the **Split Handshake** option is configured for a Zone Protection profile and that profile is applied to a zone, TCP sessions for interfaces in that zone must be established using the standard three-way handshake; variations are not allowed.

The **Split Handshake** option is disabled by default.

The following illustrates the standard three-way handshake used to establish a TCP session with a PAN-OS firewall between the initiator (typically a client) and the listener (typically a server).



The **Split Handshake** option is configured for a Zone Protection profile that is assigned to a zone. An interface that is a member of the zone drops any synchronization (SYN) packets sent from the server, preventing the following variations of handshakes. The letter A in the figure indicates the session initiator and B indicates the listener. Each numbered segment of the handshake has an arrow indicating the direction of the segment from the sender to the receiver, and each segment indicates the control bit(s) setting.



| 4-Way Split Handshake (Version 1) | 4-Way Split Handshake (Version 2) | Simultaneous Open | 5-Way Split Handshake |
|---|---|---|---|
| 1. A → B SYN | 1. A → B SYN | 1. A → B SYN | 1. A → B SYN |
| 2. A ← B ACK | 2. A ← B SYN | 2. A ← B SYN | 2. A ← B ACK |
| 3. A ← B SYN | 3. A → B SYN-ACK | 3. A → B SYN-ACK | 3. A ← B SYN |
| 4. A → B ACK | 4. A ← B ACK | 4. A ← B SYN-ACK | 4. A → B SYN-ACK |
| | | | 5. A ← B ACK |

You can Prevent TCP Split Handshake Session Establishment.

 © Palo Alto Networks, Inc.

## UDP

User Datagram Protocol (UDP) (RFC 768) is another main protocol of the IP suite, and is an alternative to TCP. UDP is stateless and connectionless in that there is no handshake to set up a session, and no connection between the sender and receiver; the packets may take different routes to get to a single destination. UDP is considered an unreliable protocol because it does not provide acknowledgments, error-checking, retransmission, or reordering of datagrams. Without the overhead required to provide those features, UDP has reduced latency and is faster than TCP. UDP is referred to as a best-effort protocol because there is no mechanism or guarantee to ensure that the data will arrive at its destination.

Although UDP uses a checksum for data integrity, it performs no error checking at the network interface level. Error checking is assumed to be unnecessary or is performed by the application rather than UDP itself. UDP has no mechanism to handle flow control of packets.

UDP is often used for applications that require faster speeds and time-sensitive, real-time delivery, such as Voice over IP (VoIP), streaming audio and video, and online games. UDP is transaction-oriented, so it is also used for applications that respond to small queries from many clients, such as Domain Name System (DNS) and Trivial File Transfer Protocol (TFTP).

© Palo Alto Networks, Inc.

# ICMP

Internet Control Message Protocol (ICMP) (RFC 792) is another one of the main protocols of the Internet Protocol suite; it operates at the Network layer of the OSI model. ICMP is used for diagnostic and control purposes, to send error messages about IP operations, or messages about requested services or the reachability of a host or router. Network utilities such as traceroute and ping are implemented by using various ICMP messages.

ICMP is a connectionless protocol that does not open or maintain actual sessions. However, the ICMP messages between two devices can be considered a session.

Palo Alto Networks firewalls support ICMPv4 and ICMPv6. ICMPv4 and ICMPv6 error packets can be controlled by configuring a security policy for a zone, and selecting the **icmp** or **ipv6-icmp** application in the policy. Additionally, the ICMPv6 error packet rate can be controlled through the session settings, as described in the section Configure Session Settings.

## ICMPv6 Rate Limiting

ICMPv6 rate limiting is a throttling mechanism to prevent flooding and DDoS attempts. The implementation employs an error packet rate and a token bucket, which work together to enable throttling and ensure that ICMP packets do not flood the network segments protected by the firewall.

First the global ICMPv6 error packet rate controls the rate at which ICMP error packets are allowed through the firewall; the default is 100 packets per second; the range is 10 to 65535 packets per second. If the firewall reaches the ICMP error packet rate, then the token bucket comes into play and throttling occurs, as follows.

The concept of a logical token bucket controls the rate at which ICMP messages can be transmitted. The number of tokens in the bucket is configurable, and each token represents an ICMP message that can be sent. The token count is decremented each time an ICMP message is sent; when the bucket reaches zero tokens, no more ICMP messages can be sent until another token is added to the bucket. The default size of the token bucket is 100 tokens (packets); the range is 10 to 65535 tokens.

To change the default token bucket size or error packet rate, see the section Configure Session Settings.

 © Palo Alto Networks, Inc.

## Configure Session Timeouts

A session timeout defines the duration of time for which PAN-OS maintains a session on the firewall after inactivity in the session. By default, when the session timeout for the protocol expires, PAN-OS closes the session.

On the firewall, you can define a number of timeouts for TCP, UDP, and ICMP sessions in particular. The Default timeout applies to any other type of session. All of these timeouts are global, meaning they apply to all of the sessions of that type on the firewall.

In addition to the global settings, you have the flexibility to define timeouts for an individual application in the **Objects > Applications** tab. The firewall applies application timeouts to an application that is in established state. When configured, timeouts for an application override the global TCP or UDP session timeouts.

Returning to the global settings, perform the optional tasks below if you need to change default values of the global session timeout settings for TCP, UDP, ICMP, Captive Portal authentication, or other types of sessions. All values are in seconds.

The defaults are optimal values. However, you can modify these according to your network needs. Setting a value too low could cause sensitivity to minor network delays and could result in a failure to establish connections with the firewall. Setting a value too high could delay failure detection.

| **Change Session Timeouts** | | |
|---|---|---|
| Step 1 | Access the Session Settings. | 1. Select **Device > Setup > Session**.<br>2. In the Session Timeouts section, click the Edit icon. |
| Step 2 | (Optional) Change miscellaneous timeouts. | • **Default**—Maximum length of time that a non-TCP/UDP or non-ICMP session can be open without a response (range is 1-1599999; default is 30).<br>• **Discard Default**—Maximum length of time that a non-TCP/UDP session remains open after PAN-OS denies a session based on security policies configured on the firewall (range is 1-1599999; default is 60).<br>• **Scan**—Maximum length of time that any session remains open after it is considered inactive; an application is regarded as inactive when it exceeds the application trickling threshold defined for the application (range is 5-30; default is 10).<br>• **Captive Portal**—Authentication session timeout for the Captive Portal web form. To access the requested content, the user must enter the authentication credentials in this form and be successfully authenticated (range is 1-1599999; default is 30).<br>To define other Captive Portal timeouts, such as the idle timer and the expiration time before the user must be re-authenticated, select **Device > User Identification > Captive Portal Settings**. See Configure Captive Portal in User-ID. |

| Change Session Timeouts (Continued) | |
|---|---|
| Step 3 (Optional) Change TCP timeouts. | • **Discard TCP**—Maximum length of time that a TCP session remains open after it is denied based on a security policy configured on the firewall. Default: 90. Range: 1-1599999.<br>• **TCP**—Maximum length of time that a TCP session remains open without a response, after a TCP session is in the Established state (after the handshake is complete and/or data is being transmitted). Default: 3600. Range: 1-1599999.<br>• **TCP Handshake**—Maximum length of time permitted between receiving the SYN-ACK and the subsequent ACK to fully establish the session. Default: 10. Range: 1-60.<br>• **TCP init**—Maximum length of time permitted between receiving the SYN and SYN-ACK prior to starting the TCP handshake timer. Default: 5. Range: 1-60.<br>• **TCP Half Closed**—Maximum length of time between receiving the first FIN and receiving the second FIN or a RST. Default: 120. Range: 1-604800.<br>• **TCP Time Wait**—Maximum length of time after receiving the second FIN or a RST. Default: 15. Range: 1-600.<br>• **Unverified RST**—Maximum length of time after receiving a RST that cannot be verified (the RST is within the TCP window but has an unexpected sequence number, or the RST is from an asymmetric path). Default: 30. Range: 1-600.<br>• See also the **Scan** timeout in the section (Optional) Change miscellaneous timeouts. |
| Step 4 (Optional) Change UDP timeouts. | • **Discard UDP**—Maximum length of time that a UDP session remains open after it is denied based on a security policy configured on the firewall. Default: 60. Range: 1-1599999.<br>• **UDP**—Maximum length of time that a UDP session remains open without a UDP response. Default: 30. Range: 1-1599999.<br>• See also the **Scan** timeout in the section (Optional) Change miscellaneous timeouts. |
| Step 5 (Optional) Change ICMP timeouts. | • **ICMP**—Maximum length of time that an ICMP session can be open without an ICMP response. Default: 6. Range: 1-1599999.<br>• See also the **Discard Default** and **Scan** timeout in the section (Optional) Change miscellaneous timeouts. |
| Step 6 Commit the changes. | Click **OK** and **Commit** the changes. |

 © Palo Alto Networks, Inc.

## Configure Session Settings

This topic describes various settings for sessions other than timeouts values. Perform these optional tasks if you need to change the default settings.

| Change Session Settings | | |
|---|---|---|
| Step 1 | Access the Session Settings. | 1. Select **Device > Setup > Session.**<br>2. In the **Session Settings** section, click the **Edit** icon. |
| Step 2 | (Optional) Change session settings. | • **Rematch Sessions**—Causes the firewall to apply newly configured security policies to sessions that are already in progress. This capability is enabled by default. If this setting is disabled, any policy change applies only to sessions initiated after the policy change was committed.<br>For example, if a Telnet session started while an associated policy was configured that allowed Telnet, and you subsequently committed a policy change to deny Telnet, the firewall applies the revised policy to the current session and blocks it.<br>• **ICMPv6 Token Bucket Size**—Default: 100 tokens. See the section ICMPv6 Rate Limiting.<br>• **ICMPv6 Error Packet Rate (per sec)**—Default: 100. See the section ICMPv6 Rate Limiting.<br>• **Enable IPv6 Firewalling**—Enables firewall capabilities for IPv6. All IPv6-based configurations are ignored if IPv6 is not enabled. Even if IPv6 is enabled for an interface, the **IPv6 Firewalling** setting must also be enabled for IPv6 to function.<br>• **Enable Jumbo Frame**—Enables jumbo frame support on Ethernet interfaces. Jumbo frames have a maximum transmission unit (MTU) of 9216 bytes and are available on certain platforms.<br>**Global MTU**—Establishes the maximum transmission unit (MTU) available globally; this field is tied to the **Enable Jumbo Frame** field.<br>  • If you do not check **Enable Jumbo Frame**, the **Global MTU** defaults to 1500 bytes; the range is 576 to 1500 bytes.<br>  • If you check **Enable Jumbo Frame**, the **Global MTU** defaults to 9192 bytes; the range is 9192 to 9216 bytes.<br> If you enable jumbo frames and you have interfaces where the MTU is not specifically configured, those interfaces will automatically inherit the jumbo frame size. Therefore, before you enable jumbo frames, if you have any interface that you do not want to have jumbo frames, you must set the MTU for that interface to 1500 bytes or another value.<br>• **NAT64 IPv6 Minimum Network MTU**—Sets the global MTU for IPv6 translated traffic. The default of 1280 bytes is based on the standard minimum MTU for IPv6 traffic. |

| Change Session Settings (Continued) | |
|---|---|
| | • **NAT Oversubscription Rate**—If NAT is configured to be Dynamic IP and Port (DIPP) translation, an oversubscription rate can be configured to multiply the number of times that the same translated IP address and port pair can be used concurrently. The rate is 1, 2, 4, or 8. The default setting is based on the firewall platform.<br>  • A rate of 1 means no oversubscription; each translated IP address and port pair can be used only once at a time.<br>  • If the setting is **Platform Default**, user configuration of the rate is disabled and the default oversubscription rate for the platform applies.<br>Reducing the oversubscription rate decreases the number of source device translations, but provides higher NAT rule capacities.<br>• **Accelerated Aging**—Enables faster aging-out of idle sessions. Select the check box to enable accelerated aging, and, if necessary, change the threshold (%) and scaling factor.<br>  • **Accelerated Aging Threshold**—Percentage of the session table that is full when accelerated aging begins. The default is 80%. When the session table reaches this threshold (% full), PAN-OS applies the **Accelerated Aging Scaling Factor** to the aging calculations for all sessions.<br>  • **Accelerated Aging Scaling Factor**—Scaling factor used in the accelerated aging calculations. The default scaling factor is 2, meaning that the accelerated aging occurs at a rate twice as fast as the configured idle time. The configured idle time divided by 2 results in a faster timeout of one-half the time. To calculate the session's accelerated aging, PAN-OS divides the configured idle time (for that type of session) by the scaling factor to determine a shorter timeout.<br>For example, if the scaling factor is 10, a session that would normally time out after 3600 seconds would time out 10 times faster (in 1/10 of the time), which is 360 seconds. |
| Step 3 Commit the changes. | Click **OK** and **Commit** the changes. |

 © Palo Alto Networks, Inc.

## Prevent TCP Split Handshake Session Establishment

You can configure a TCP Split Handshake Drop in a Zone Protection profile to prevent TCP sessions from being established unless they use the standard three-way handshake. This task assumes that the interface where this feature is desired is already assigned to a security zone.

| Configure a Zone Protection Profile to Prevent TCP Split Handshake Sessions | | |
|---|---|---|
| Step 1 | Configure a Zone Protection profile to prevent TCP sessions that use anything other than a three-way handshake to establish a session. | 1. Select **Network > Network Profiles > Zone Protection** and click **Add** to create a new profile (or select an existing profile).<br>2. If creating a new profile, enter a **Name** for the profile and an optional **Description**.<br>3. Select **Packet Based Attack Protection > TCP Drop** and select the **Split Handshake** check box.<br>4. Click **OK**. |
| Step 2 | Apply the profile to one or more security zones. | 1. Select **Network > Zones** and select the zone where you want to assign the zone protection profile.<br>2. In the Zone window, from the **Zone Protection Profile** drop-down, select the profile you configured in Step 1.<br>Alternatively, you could start creating a new profile here by clicking **Zone Protection Profile**, in which case you would continue accordingly.<br>3. Click **OK**.<br>4. (Optional) Repeat steps 1-3 to apply the profile to additional zones. |
| Step 3 | Save the configuration. | Click **OK** and **Commit**. |

# DHCP

This section describes Dynamic Host Configuration Protocol (DHCP) and the tasks required to configure an interface on a Palo Alto Networks firewall to act as a DHCP server, client, or relay agent. By assigning these roles to different interfaces, the firewall can perform multiple roles.

- DHCP Overview
- DHCP Messages
- DHCP Addressing
- DHCP Options
- Firewall as a DHCP Server and Client
- Configure an Interface as a DHCP Server
- Configure an Interface as a DHCP Client
- Configure an Interface as a DHCP Relay Agent
- Monitor and Troubleshoot DHCP

 © Palo Alto Networks, Inc.

## DHCP Overview

DHCP is a standardized protocol defined in RFC 2131, Dynamic Host Configuration Protocol. DHCP has two main purposes: to provide TCP/IP and link-layer configuration parameters and to provide network addresses to dynamically configured hosts on a TCP/IP network.

DHCP uses a client-server model of communication. This model consists of three roles that the device can fulfill: DHCP client, DHCP server, and DHCP relay agent.

- A device acting as a DHCP client (host) can request an IP address and other configuration settings from a DHCP server. Users on client devices save configuration time and effort, and need not know the network's addressing plan or other resources and options they are inheriting from the DHCP server.
- A device acting as a DHCP server can service clients. By using any of three DHCP Addressing mechanisms, the network administrator saves configuration time and has the benefit of reusing a limited number of IP addresses when a client no longer needs network connectivity. The server can deliver IP addressing and many DHCP options to many clients.
- A device acting as a DHCP relay agent transmits DHCP messages between DHCP clients and servers.

DHCP uses User Datagram Protocol (UDP), RFC 768, as its transport protocol. DHCP messages that a client sends to a server are sent to well-known port 67 (UDP—Bootstrap Protocol and DHCP). DHCP Messages that a server sends to a client are sent to port 68.

An interface on a Palo Alto Networks firewall can perform the role of a DHCP server, client, or relay agent. The interface of a DHCP server or relay agent must be a Layer 3 Ethernet, Aggregated Ethernet, or Layer 3 VLAN interface. You configure the firewall's interfaces with the appropriate settings for any combination of roles. The behavior of each role is summarized in Firewall as a DHCP Server and Client.

The firewall supports DHCPv4 Server and DHCPv6 Relay. However, a single interface cannot support both DHCPv4 Server and DHCPv6 Relay.

The DHCP standard, RFC 2131, is designed to support IPv4 and IPv6 addresses. The Palo Alto Networks implementations of DHCP server and DHCP client support IPv4 addresses only. Its DHCP relay implementation supports IPv4 and IPv6.

DHCP client is not supported in High Availability active/active mode.

## DHCP Messages

DHCP uses eight standard message types, which are identified by an option type number in the DHCP message. For example, when a client wants to find a DHCP server, it broadcasts a DHCPDISCOVER message on its local physical subnetwork. If there is no DHCP server on its subnet and if DHCP Helper or DHCP Relay is configured properly, the message is forwarded to DHCP servers on a different physical subnet. Otherwise, the message will go no further than the subnet on which it originated. One or more DHCP servers will respond with a DHCPOFFER message that contains an available network address and other configuration parameters.

When the client needs an IP address, it sends a DHCPREQUEST to one or more servers. Of course if the client is requesting an IP address, it doesn't have one yet, so RFC 2131 requires that the broadcast message the client sends out have a source address of 0 in its IP header.

When a client requests configuration parameters from a server, it might receive responses from more than one server. Once a client has received its IP address, it is said that the client has at least an IP address and possibly other configuration parameters *bound* to it. DHCP servers manage such binding of configuration parameters to clients.

The following table lists the DHCP messages.

| DHCP Message | Description |
|---|---|
| DHCPDISCOVER | Client broadcast to find available DHCP servers. |
| DHCPOFFER | Server response to client's DHCPDISCOVER, offering configuration parameters. |
| DHCPREQUEST | Client message to one or more servers to do any of the following:<br>• Request parameters from one server and implicitly decline offers from other servers.<br>• Confirm that a previously allocated address is correct after, for example, a system reboot.<br>• Extend the lease of a network address. |
| DHCPACK | Server to client acknowledgment message containing configuration parameters, including a confirmed network address. |
| DHCPNAK | Server to client negative acknowledgment indicating the client's understanding of the network address is incorrect (for example, if the client has moved to a new subnet), or a client's lease has expired. |
| DHCPDECLINE | Client to server message indicating the network address is already being used. |
| DHCPRELEASE | Client to server message giving up the user of the network address and canceling the remaining time on the lease. |
| DHCPINFORM | Client to server message requesting only local configuration parameters; client has an externally configured network address. |

 © Palo Alto Networks, Inc.

# DHCP Addressing

▲ DHCP Address Allocation Methods
▲ DHCP Leases

## DHCP Address Allocation Methods

There are three ways that a DHCP server either assigns or sends an IP address to a client:

- **Automatic allocation**—The DHCP server assigns a permanent IP address to a client from its **IP Pools**. On the firewall, a **Lease** specified as **Unlimited** means the allocation is permanent.
- **Dynamic allocation**—The DHCP server assigns a reusable IP address from **IP Pools** of addresses to a client for a maximum period of time, known as a *lease*. This method of address allocation is useful when the customer has a limited number of IP addresses; they can be assigned to clients who need only temporary access to the network. See the DHCP Leases section.
- **Static allocation**—The network administrator chooses the IP address to assign to the client and the DHCP server sends it to the client. A static DHCP allocation is permanent; it is done by configuring a DHCP server and choosing a **Reserved Address** to correspond to the **MAC Address** of the client device. The DHCP assignment remains in place even if the client logs off, reboots, has a power outage, etc.

  Static allocation of an IP address is useful, for example, if you have a printer on a LAN and you do not want its IP address to keep changing, because it is associated with a printer name through DNS. Another example is if a client device is used for something crucial and must keep the same IP address, even if the device is turned off, unplugged, rebooted, or a power outage occurs, etc.

  Keep these points in mind when configuring a **Reserved Address**:

  - It is an address from the **IP Pools**. You may configure multiple reserved addresses.
  - If you configure no **Reserved Address**, the clients of the server will receive new DHCP assignments from the pool when their leases expire or if they reboot, etc. (unless you specified that a **Lease** is **Unlimited**).
  - If you allocate all of the addresses in the **IP Pools** as a **Reserved Address,** there are no dynamic addresses free to assign to the next DHCP client requesting an address.
  - You may configure a **Reserved Address** without configuring a **MAC Address**. In this case, the DHCP server will not assign the **Reserved Address** to any device. You might reserve a few addresses from the pool and statically assign them to a fax and printer, for example, without using DHCP.

## DHCP Leases

A lease is defined as the time period for which a DHCP server allocates a network address to a client. The lease might be extended (renewed) upon subsequent requests. If the client no longer needs the address, it can release the address back to the server before the lease is up. The server is then free to assign that address to a different client if it has run out of unassigned addresses.

© Palo Alto Networks, Inc.

The lease period configured for a DHCP server applies to all of the addresses that a single DHCP server (interface) dynamically assigns to its clients. That is, all of that interface's addresses assigned dynamically are of **Unlimited** duration or have the same **Timeout** value. A different DHCP server configured on the firewall may have a different lease term for its clients. A **Reserved Address** is a static address allocation and is not subject to the lease terms.

Per the DHCP standard, RFC 2131, a DHCP client does not wait for its lease to expire, because it risks getting a new address assigned to it. Instead, when a DHCP client reaches the halfway point of its lease period, it attempts to extend its lease so that it retains the same IP address. Thus, the lease duration is like a sliding window.

Typically if an IP address was assigned to a device, the device was subsequently taken off the network and its lease was not extended, the DHCP server will let that lease run out. Because the client is gone from the network and no longer needs the address, the lease duration in the server is reached and the lease is in "Expired" state.

The firewall has a hold timer that prevents the expired IP address from being reassigned immediately. This behavior temporarily reserves the address for the device in case it comes back onto the network. But if the address pool runs out of addresses, the server re-allocates this expired address before the hold timer expires. Expired addresses are cleared automatically as the systems needs more addresses or when the hold timer releases them.

In the CLI, use the `show dhcp server lease` operational command to view lease information about the allocated IP addresses. If you do not want to wait for expired leases to be released automatically, you can use the `clear dhcp lease interface` *`value`* `expired-only` command to clear expired leases, making those addresses available in the pool again. You can use the `clear dhcp lease interface` *`value`* `ip` *`ip`* command to release a particular IP address. Use the `clear dhcp lease interface` *`value`* `mac` *`mac_address`* command to release a particular MAC address.

# DHCP Options

The history of DHCP and DHCP options traces back to the Bootstrap Protocol (BOOTP). BOOTP was used by a host to configure itself dynamically during its booting procedure. A host could receive an IP address and a file from which to download a boot program from a server, along with the server's address and the address of an Internet gateway.

Included in the BOOTP packet was a vendor information field, which could contain a number of tagged fields containing various types of information, such as the subnet mask, the BOOTP file size, and many other values. RFC 1497 describes the BOOTP Vendor Information Extensions. DHCP replaces BOOTP; BOOTP is not supported on the firewall.

These extensions eventually expanded with the use of DHCP and DHCP host configuration parameters, also known as options. Similar to vendor extensions, DHCP options are tagged data items that provide information to a DHCP client. The options are sent in a variable-length field at the end of a DHCP message. For example, the DHCP Message Type is option 53, and a value of 1 indicates the DHCPDISCOVER message. DHCP options are defined in RFC 2132, DHCP Options and BOOTP Vendor Extensions.

A DHCP client can negotiate with the server, limiting the server to send only those options that the client requests.

- Predefined DHCP Options
- Multiple Values for a DHCP Option
- DHCP Options 43, 55, and 60 and Other Customized Options

## Predefined DHCP Options

Palo Alto Networks firewalls support user-defined and predefined DHCP options in the DHCP server implementation. Such options are configured on the DHCP server and sent to the clients that sent a DHCPREQUEST to the server. The clients are said to *inherit* and implement the options that they are programmed to accept.

The firewall supports the following predefined options on its DHCP servers, shown in the order in which they appear on the **DHCP Server** configuration screen:

| DHCP Option | DHCP Option Name |
|---|---|
| 51 | Lease duration |
| 3 | Gateway |
| 1 | IP Pool Subnet (mask) |
| 6 | Domain Name System (DNS) server address (primary and secondary) |
| 44 | Windows Internet Name Service (WINS) server address (primary and secondary) |
| 41 | Network Information Service (NIS) server address (primary and secondary) |
| 42 | Network Time Protocol (NTP) server address (primary and secondary) |
| 70 | Post Office Protocol Version 3 (POP3) server address |

| DHCP Option | DHCP Option Name |
|---|---|
| 69 | Simple Mail Transfer Protocol (SMTP) server address |
| 15 | DNS suffix |

As mentioned, you can also configure vendor-specific and customized options, which support a wide variety of office equipment, such as IP phones and wireless infrastructure devices. Each option code supports multiple values, which can be IP address, ASCII, or hexadecimal format. With the firewall enhanced DCHP option support, branch offices do not need to purchase and manage their own DHCP servers in order to provide vendor-specific and customized options to DHCP clients.

## Multiple Values for a DHCP Option

You can enter multiple option values for an **Option Code** with the same **Option Name**, but all values for a particular code and name combination must be the same type (IP address, ASCII, or hexadecimal). If one type is inherited or entered, and later a different type is entered for the same code and name combination, the second type will overwrite the first type.

You can enter an **Option Code** more than once by using a different **Option Name**. In this case, the **Option Type** for the Option Code can differ among the multiple option names. For example, if option Coastal Server (option code 6) is configured with IP address type, option Server XYZ (option code 6) with ASCII type is also allowed.

The firewall sends multiple values for an option (strung together) to a client in order from top to bottom. Therefore, when entering multiple values for an option, enter the values in the order of preference, or else move the options to achieve your preferred order in the list. The order of options in the firewall configuration determines the order that the options appear in DHCPOFFER and DHCPACK messages.

You can enter an option code that already exists as a predefined option code, and the customized option code will override the predefined DHCP option; the firewall issues a warning.

## DHCP Options 43, 55, and 60 and Other Customized Options

The following table describes the option behavior for several options described in RFC 2132.

| Option Code | Option Name | Option Description/Behavior |
|---|---|---|
| 43 | Vendor Specific Information | Sent from server to client. Vendor-specific information that the DHCP server has been configured to offer to the client. The information is sent to the client only if the server has a Vendor Class Identifier (VCI) in its table that matches the VCI in the client's DHCPREQUEST.<br>An Option 43 packet can contain multiple vendor-specific pieces of information. It can also include encapsulated, vendor-specific extensions of data. |
| 55 | Parameter Request List | Sent from client to server. List of configuration parameters (option codes) that a DHCP client is requesting, possibly in order of the client's preference. The server tries to respond with options in the same order. |

 © Palo Alto Networks, Inc.

| Option Code | Option Name | Option Description/Behavior |
|---|---|---|
| 60 | Vendor Class Identifier (VCI) | Sent from client to server. Vendor type and configuration of a DHCP client. The DHCP client sends option code 60 in a DHCPREQUEST to the DHCP server. When the server receives option 60, it sees the VCI, finds the matching VCI in its own table, and then it returns option 43 with the value (that corresponds to the VCI), thereby relaying vendor-specific information to the correct client. Both the client and server have knowledge of the VCI. |

You can send custom, vendor-specific option codes that are not defined in RFC 2132. The option codes can be in the range 1-254 and of fixed or variable length.

Custom DHCP options are not validated by the DHCP Server; you must ensure that you enter correct values for the options you create.

For ASCII and hexadecimal DHCP option types, the option value can be a maximum of 255 octets.

## Firewall as a DHCP Server and Client

The firewall can function as a DHCP server and as a DHCP client. The firewall DHCP server operates in the following manner:

- When the DHCP server receives a DHCPDISCOVER message from a client, the server replies with a DHCPOFFER message containing all of the predefined and user-defined options in the order they appear in the configuration. The client selects the options it needs and responds with a DHCPREQUEST message.
- When the server receives a DHCPREQUEST message from a client, the server replies with its DHCPACK message containing only the options specified in the request.
- Dynamic Host Configuration Protocol, RFC 2131, is designed to support IPv4 and IPv6 addresses. The Palo Alto Networks implementation of DHCP server supports IPv4 addresses only.

The firewall DHCP Client operates in the following manner:

- When the DHCP client receives a DHCPOFFER from the server, the client automatically caches all of the options offered for future use, regardless of which options it had sent in its DHCPREQUEST.
- By default and to save memory consumption, the client caches only the first value of each option code if it receives multiple values for a code.
- There is no maximum length for DHCP messages unless the DHCP client specifies a maximum in option 57 in its DHCPDISCOVER or DHCPREQUEST messages.

 © Palo Alto Networks, Inc.

## Configure an Interface as a DHCP Server

The prerequisites for this task are:

- Configure a Layer 3 Ethernet or Layer 3 VLAN interface.
- Assign the interface to a virtual router and a zone.
- Determine a valid pool of IP addresses from your network plan that you can designate to be assigned by your DHCP server to clients.
- Collect the DHCP options, values, and Vendor Class Identifiers you plan to configure.

Perform the following task to configure an interface on the firewall to act as a DHCP server. You can configure multiple DHCP servers.

| **Configure an Interface as a DHCP Server** | |
|---|---|
| Step 1 Select an interface to be a DHCP Server. | 1. Select **Network > DHCP > DHCP Server** and click **Add**.<br>2. Enter an **Interface** name or select one from the drop-down.<br>3. For **Mode**, select **enabled** or **auto** mode. Auto mode enables the server and disables it if another DHCP server is detected on the network. The **disabled** setting disables the server.<br>4. (Optional) Click the **Ping IP when allocating new IP** check box if you want the server to ping the IP address before it assigns that address to its client.<br>If the ping receives a response, that means a different device already has that address, so it is not available. The server assigns the next address from the pool instead. This behavior is similar to Optimistic Duplicate Address Detection (DAD) for IPv6, RFC 4429.<br>After you set options and return to the DHCP server tab, the **Probe IP** column for the interface indicates if this check box was checked. |

| Configure an Interface as a DHCP Server (Continued) | |
|---|---|
| Step 2 Configure the predefined DHCP Options that the server sends to its clients. | • In the Options section, select a **Lease** type:<br>  • **Unlimited** causes the server to dynamically choose IP addresses from the **IP Pools** and assign them permanently to clients.<br>  • **Timeout** determines how long the lease will last. Enter the number of **Days** and **Hours**, and optionally the number of **Minutes**.<br>• **Inheritance Source**—Leave **None** or select a source DHCP client interface or PPPoE client interface to propagate various server settings into the DHCP server. If you specify an **Inheritance Source**, select one or more options below that you want **inherited** from this source.<br>Specifying an inheritance source allows the firewall to quickly add DHCP options from the upstream server received by the DHCP client. It also keeps the client options updated if the source changes an option. For example, if the source replaces its NTP server (which had been identified as the **Primary NTP** server), the client will automatically inherit the new address as its **Primary NTP** server.<br> When inheriting DHCP option(s) that contain multiple IP addresses, the firewall uses only the first IP address contained in the option to conserve cache memory. If you require multiple IP addresses for a single option, configure the DHCP options directly on that firewall rather than configure inheritance.<br>• **Check inheritance source status**—If you selected an **Inheritance Source**, clicking this link opens the **Dynamic IP Interface Status** window, which displays the options that were inherited from the DHCP client.<br>• **Gateway**—IP address of the network gateway (an interface on the firewall) that is used to reach any device not on the same LAN as this DHCP server.<br>• **Subnet Mask**—Network mask used with the addresses in the **IP Pools**. |

© Palo Alto Networks, Inc.

| Configure an Interface as a DHCP Server (Continued) | |
|---|---|
| | For the following fields, click the down arrow and select **None**, or **inherited**, or enter a remote server's IP address that your DHCP server will send to clients for accessing that service. If you select **inherited,** the DHCP server inherits the values from the source DHCP client specified as the **Inheritance Source**.<br>• **Primary DNS, Secondary DNS**—IP address of the preferred and alternate Domain Name System (DNS) servers.<br>• **Primary WINS, Secondary WINS**—IP address of the preferred and alternate Windows Internet Naming Service (WINS) servers.<br>• **Primary NIS, Secondary NIS**—IP address of the preferred and alternate Network Information Service (NIS) servers.<br>• **Primary NTP, Secondary NTP**—IP address of the available Network Time Protocol servers.<br>• **POP3 Server**—IP address of a Post Office Protocol (POP3) server.<br>• **SMTP Server**—IP address of a Simple Mail Transfer Protocol (SMTP) server.<br>• **DNS Suffix**—Suffix for the client to use locally when an unqualified hostname is entered that it cannot resolve. |

| Configure an Interface as a DHCP Server (Continued) | |
|---|---|
| Step 3 (Optional) Configure a vendor-specific or custom DHCP option that the DHCP server sends to its clients. | 1. In the Custom DHCP Options section, click **Add** and enter a descriptive **Name** to identify the DHCP option.<br>2. Enter the **Option Code** you want to configure the server to offer (range is 1-254). (See RFC 2132 for option codes.)<br>3. If the **Option Code** is **43**, the **Vendor Class Identifier** field appears. Enter a VCI, which is a string or hexadecimal value (with 0x prefix) used as a match against a value that comes from the client Request containing option 60. The server looks up the incoming VCI in its table, finds it, and returns Option 43 and the corresponding option value.<br>4. **Inherit from DHCP server inheritance source**—Select this check box only if you specified an **Inheritance Source** for the DHCP Server predefined options and you want the vendor-specific and custom options also to be **inherited** from this source.<br>5. **Check inheritance source status**—If you selected an **Inheritance Source**, clicking this link opens **Dynamic IP Interface Status**, which displays the options that were inherited from the DHCP client.<br>6. If you did not select the **Inherit from DHCP server inheritance source** check box, select an **Option Type**: **IP Address**, **ASCII**, or **Hexadecimal**. Hexadecimal values must start with the 0x prefix.<br>7. Enter the **Option Value** you want the DHCP server to offer for that **Option Code**. You can enter multiple values on separate lines.<br>8. Click **OK.** |
| Step 4 (Optional) Add another vendor-specific or custom DHCP option. | 1. Repeat Step 3 to enter another custom DHCP Option.<br>• You can enter multiple option values for an **Option Code** with the same **Option Name**, but all values for an **Option Code** must be the same type (**IP Address**, **ASCII**, or **Hexadecimal**). If one type is inherited or entered and a different type is entered for the same **Option Code** and the same **Option Name**, the second type will overwrite the first type.<br>When entering multiple values for an option, enter the values in the order of preference, or else move the Custom DHCP Options to achieve the preferred order in the list. Select an option and click **Move Up** or **Move Down**.<br>• You can enter an **Option Code** more than once by using a different **Option Name**. In this case, the **Option Type** for the Option Code can differ among the multiple option names.<br>2. Click **OK.** |

 © Palo Alto Networks, Inc.

| Configure an Interface as a DHCP Server (Continued) | | |
|---|---|---|
| Step 5 | Identify the stateful pool of IP addresses from which the DHCP server chooses an address and assigns it to a DHCP client.<br> If you are not the network administrator for your network, ask the network administrator for a valid pool of IP addresses from the network plan that can be designated to be assigned by your DHCP server. | 1. In the **IP Pools** field, click **Add** and enter the range of IP addresses from which this server assigns an address to a client. Enter an IP subnet and subnet mask (for example, 192.168.1.0/24) or a range of IP addresses (for example, 192.168.1.10-192.168.1.20). At least one IP pool is required.<br>2. Optionally repeat to specify another IP address pool. |
| Step 6 | (Optional) Specify an IP address from the IP pools that will not be assigned dynamically. If you also specify a **MAC Address**, the **Reserved Address** is assigned to that device when the device requests an IP address through DHCP.<br> See the DHCP Addressing section for an explanation of allocation of a **Reserved Address**. | 1. In the **Reserved Address** field, click **Add.**<br>2. Enter an IP address from the **IP Pools** (format *x.x.x.x*) that you do not want to be assigned dynamically by the DHCP server.<br>3. (Optional) Specify the **MAC Address** (format *xx:xx:xx:xx:xx:xx*) of the device to which you want to permanently assign the IP address specified in Step 2.<br>4. (Optional) Repeat Steps 2-3 to reserve another address. |
| Step 7 | Save the configuration. | Click **OK** and **Commit** the change. |

## Configure an Interface as a DHCP Client

Before configuring a firewall interface as a DHCP Client, make sure you have configured a Layer 3 Ethernet or Layer 3 VLAN interface, and the interface is assigned to a virtual router and a zone. Perform this task if you need to use DHCP to request an IPv4 address for an interface on your firewall.

| **Configure an Interface as a DHCP Client** | |
|---|---|
| Step 1 Configure an interface as a DHCP client. | 1. Select **Network** > **Interfaces**.<br>2. On the **Ethernet** tab or the **VLAN** tab, click **Add** and enter an interface, or click a configured interface, that you want to be a DHCP client.<br>The following shows the **Ethernet Interface** screen:<br> <br>3. Click the **IPv4** tab; for **Type**, select **DHCP Client**.<br>4. Select the **Enable** check box.<br>5. Optionally select the **Automatically create default route pointing to default gateway provided by server** check box. This causes the firewall to create a static route to a default gateway that will be useful when clients are trying to access many destinations that do not need to have routes maintained in a routing table on the firewall.<br>6. Optionally enter a **Default Route Metric** (priority level) for the route between the firewall and the DHCP server (range is 1-65535; there is no default metric). A route with a lower number has higher priority during route selection. For example, a route with a metric of 10 is used before a route with a metric of 100.<br>7. Optionally click **Show DHCP Client Runtime Info** to see all of the settings the client has inherited from its DHCP server. |
| Step 2 Save the configuration. | Click **OK** and **Commit** the change.<br>Now the Ethernet interface indicates **Dynamic-DHCP Client** in its **IP Address** field on the **Ethernet** tab. |

 © Palo Alto Networks, Inc.

| Configure an Interface as a DHCP Client | | |
|---|---|---|
| Step 3 | (Optional) See which interfaces on the firewall are configured as DHCP clients. | 1. Select **Network > Interfaces > Ethernet** and look in the **IP Address** field to see which interfaces indicate DHCP Client.<br>2. Select **Network > Interfaces > VLAN** and look in the **IP Address** field to see which interfaces indicate DHCP Client. |

## Configure an Interface as a DHCP Relay Agent

Before configuring a firewall interface as a DHCP relay agent, make sure you have configured a Layer 3 Ethernet or Layer 3 VLAN interface, and the interface is assigned to a virtual router and a zone. You want that interface be able to pass DHCP messages between clients and servers. The interface can forward messages to a maximum of four external DHCP servers. A client DHCPDISCOVER message is sent to all configured servers, and the DHCPOFFER message of the first server that responds is relayed back to the requesting client.

Perform the following task to configure an interface on the firewall to act as a DHCP relay agent:

| **Configure an Interface as a DHCP Relay Agent** | | |
|---|---|---|
| Step 1 | Select DHCP Relay. | Select **Network** > **DHCP > DHCP Relay**. |
| Step 2 | Specify the IP address of each DHCP server with which the DHCP relay agent will communicate. | 1. In the **Interface** field, select from the drop-down the interface you want to be the DHCP relay agent.<br>2. Check either the **IPv4** or **IPv6** check box, indicating the type of DHCP server address you will specify.<br>3. If you checked **IPv4**, in the **DHCP Server IP Address** field, click **Add**. Enter the address of the DHCP server to and from which you will relay DHCP messages.<br>4. If you checked **IPv6**, in the **DHCP Server IPv6 Address** field, click **Add**. Enter the address of the DHCP server to and from which you will relay DHCP messages. If you specify a *multicast* address, also specify an outgoing **Interface**.<br>5. Optionally repeat Steps 2-4 to enter a maximum of four DHCP server addresses. |
| Step 3 | Save the configuration. | Click **OK** and **Commit** the change. |

 © Palo Alto Networks, Inc.

# Monitor and Troubleshoot DHCP

You can view the status of dynamic address leases that your DHCP server has assigned or that your DHCP client has been assigned by issuing commands from the CLI. You can also clear leases before they time out and are released automatically.

- View DHCP Server Information
- Clear Leases Before They Expire Automatically
- View DHCP Client Information
- Gather Debug Output about DHCP

## View DHCP Server Information

To view DHCP pool statistics, IP addresses the server has assigned, the corresponding MAC address, state and duration of the lease, and time the lease began, use the following command. If the address was configured as a **Reserved Address**, the `state` column indicates `reserved` and there is no `duration` or `lease_time`. If the lease was configured as **Unlimited**, the `duration` column displays a value of `0`.

```
admin@PA-200> show dhcp server lease all
interface: "ethernet1/2"
Allocated IPs: 1, Total number of IPs in pool: 5. 20.0000% used
ip              mac                state      duration    lease_time
192.168.3.11    f0:2f:af:42:70:cf  committed  0           Wed Jul  2 08:10:56 2014
admin@PA-200>
```

To view the options that a DHCP server has assigned to clients, use the following command:

```
admin@PA-200> show dhcp server settings all
Interface       GW            DNS1           DNS2         DNS-Suffix    Inherit source
------------------------------------------------------------------------------------------
ethernet1/2     192.168.3.1   10.43.2.10     10.44.2.10                 ethernet1/3
admin@PA-200>
```

## Clear Leases Before They Expire Automatically

The following example shows how to release expired DHCP Leases of an interface (server) before the hold timer releases them automatically. Those addresses will be available in the IP pool again.

```
admin@PA-200> clear dhcp lease interface ethernet1/2 expired-only
```

The following example shows how to release the lease of a particular IP address:

```
admin@PA-200> clear dhcp lease interface ethernet1/2 ip 192.168.3.1
```

The following example shows how to release the lease of a particular MAC address:

```
admin@PA-200> clear dhcp lease interface ethernet1/2 mac f0:2c:ae:29:71:34
```

© Palo Alto Networks, Inc.

## View DHCP Client Information

To view the status of IP address leases sent to the firewall when it is acting as a DHCP client, use the `show dhcp client state` *`interface_name`* command or the following command:

```
admin@PA-200> show dhcp client state all
Interface       State        IP              Gateway         Leased-until
--------------------------------------------------------------------------
ethernet1/1     Bound        10.43.14.80     10.43.14.1      70315
admin@PA-200>
```

## Gather Debug Output about DHCP

To gather debug output about DHCP, use one of the following commands:

```
admin@PA-200> debug dhcpd
admin@PA-200> debug management-server dhcpd
```

 © Palo Alto Networks, Inc.

# NAT

This section describes Network Address Translation (NAT) and how to configure NAT rules and features. NAT was introduced to solve the problem of an organization not having enough public, globally-routable IPv4 addresses assigned to it by the Internet Assigned Numbers Authority (IANA) or a Regional Internet Registry. NAT translates private, non-routable IPv4 addresses to one or more globally-routable IPv4 addresses, thereby conserving an organization's routable IP addresses.

Since its origination, the use of NAT has expanded. For example, NAT is used as a way to not disclose the real IP addresses of hosts that need access to public addresses. It is also used to manage traffic by performing port forwarding. NAT can be used to solve network design challenges, enabling networks with identical IP subnets to communicate with each other.

The NAT64 option translates between IPv6 and IPv4 addresses, providing connectivity between networks using disparate IP addressing schemes, and therefore a migration path to IPv6 addressing. IPv6-to-IPv6 Network Prefix Translation (NPTv6) translates one IPv6 prefix to another IPv6 prefix. PAN-OS supports all of these functions.

If you use private IP addresses within your internal networks, you must use NAT to translate the private addresses to public addresses that can be routed on external networks. In PAN-OS, you create NAT policy rules that instruct the firewall which packet addresses need translation and what the translated addresses are.

- NAT Policy Rules
- Source NAT and Destination NAT
- NAT Rule Capacities
- Dynamic IP and Port NAT Oversubscription
- Dataplane NAT Memory Statistics
- Configure NAT
- NAT Configuration Examples

# NAT Policy Rules

- NAT Policy Rule Functionality
- NAT Address Pools Identified as Address Objects
- Proxy ARP for NAT Address Pools

## NAT Policy Rule Functionality

You configure a NAT rule to match a packet's source zone and destination zone, at a minimum. In addition to zones, you can configure matching criteria based on the packet's destination interface, source and destination address, and service. You can configure multiple NAT rules. The firewall evaluates the rules in order from the top down. Once a packet matches the criteria of a single NAT rule, the packet is not subjected to additional NAT rules. Therefore, your list of NAT rules should be in order from most specific to least specific so that packets are subjected to the most specific rule you created for them.

Static NAT rules do not have precedence over other forms of NAT. Therefore, for static NAT to work, the static NAT rules must be above all other NAT rules in the list on the firewall.

NAT rules provide address translation, and are different from security policy rules, which allow or deny packets. It is important to understand the firewall's flow logic when it applies NAT rules and security policy rules so that you can determine what rules you need, based on the zones you have defined.

Upon ingress, the firewall inspects the packet and does a route lookup to determine the egress interface and zone. Then the firewall determines if the packet matches one of the NAT rules that have been defined, based on source and/or destination zone. It then evaluates and applies any security policies that match the packet based on the original (pre-NAT) source and destination addresses, but the post-NAT zones. Finally, upon egress, for a matching NAT rule, the firewall translates the source and/or destination address and port numbers.

Keep in mind that the translation of the IP address and port do not occur until the packet leaves the firewall. The NAT rules and security policies apply to the original IP address (the pre-NAT address). A NAT rule is configured based on the zone associated with a pre-NAT IP address.

Security policies differ from NAT rules because security policies examine post-NAT zones to determine whether the packet is allowed or not. Because the very nature of NAT is to modify source or destination IP addresses, which can result in modifying the packet's outgoing interface and zone, security policies are enforced on the post-NAT zone.

You can verify the NAT rules processed by using the CLI `test nat-policy-match` command in operational mode. For example:

```
user@device1> test nat-policy-match ?
+ destination       Destination IP address
+ destination-port  Destination port
+ from              From zone
+ ha-device-id      HA Active/Active device ID
+ protocol          IP protocol value
+ source            Source IP address
+ source-port       Source port
+ to                To Zone
+ to-interface      Egress interface to use
  |                 Pipe through a command
```

## NAT Address Pools Identified as Address Objects

When configuring a **Dynamic IP** or **Dynamic IP and Port** NAT address pool in a NAT policy rule, it is typical to configure the pool of translated addresses with address objects. Each address object can be a host IP address, IP address range, or IP subnet.

Because both NAT rules and security policy rules use address objects, it is a best practice to distinguish between them by naming an address object used for NAT with a prefix, such as "NAT-*name*."

## Proxy ARP for NAT Address Pools

NAT address pools are not bound to any interfaces. The following figure illustrates the behavior of the firewall when it is performing proxy ARP for an address in a NAT address pool.

The firewall performs source NAT for a client, translating the source address 1.1.1.1 to the address in the NAT pool, 2.2.2.2. The translated packet is sent on to a router.

For the return traffic, the router does not know how to reach 2.2.2.2 (because the IP address 2.2.2.2 is just an address in the NAT address pool), so it sends an ARP request packet to the firewall.

- If the address pool (2.2.2.2) is in the same subnet as the egress/ingress interface IP address (2.2.2.3/24), the firewall can send a proxy ARP reply to the router, indicating the Layer 2 MAC address of the IP address, as shown in the figure above.
- If the address pool (2.2.2.2) is not a subnet of an interface on the firewall, the firewall will not send a proxy ARP reply to the router. This means that the router must be configured with the necessary route to know where to send packets destined for 2.2.2.2, in order to ensure the return traffic is routed back to the firewall, as shown in the figure below.

 © Palo Alto Networks, Inc.

# Source NAT and Destination NAT

The firewall supports both source address and/or port translation and destination address and/or port translation.

## Source NAT

Source NAT is typically used by internal users to access the Internet; the source address is translated and thereby kept private. There are three types of source NAT:

- **Dynamic IP and Port (DIPP)**—Allows multiple hosts to have their source IP addresses translated to the same public IP address with different port numbers. The dynamic translation is to the next available address in the NAT address pool, which you configure as a **Translated Address** pool be to an IP address, range of addresses, a subnet, or a combination of these.

  As an alternative to using the next address in the NAT address pool, DIPP allows you to specify the address of the **Interface** itself. The advantage of specifying the interface in the NAT rule is that the NAT rule will be automatically updated to use any address subsequently acquired by the interface. DIPP is sometimes referred to as interface-based NAT or network address port translation (NAPT).

  DIPP has a default NAT oversubscription rate, which is the number of times that the same translated IP address and port pair can be used concurrently. For more information, see Dynamic IP and Port NAT Oversubscription and Modify the Oversubscription Rate for DIPP NAT.

- **Dynamic IP**—Allows the one-to-one, dynamic translation of a source IP address only (no port number) to the next available address in the NAT address pool. The size of the NAT pool should be equal to the number of internal hosts that require address translations. By default, if the source address pool is larger than the NAT address pool and eventually all of the NAT addresses are allocated, new connections that need address translation are dropped. To override this default behavior, use **Advanced (Dynamic IP/Port Fallback)** to enable use of DIPP addresses when necessary. In either event, as sessions terminate and the addresses in the pool become available, they can be allocated to translate new connections.

  Dynamic IP NAT supports the option for you to Reserve Dynamic IP NAT Addresses.

- **Static IP**—Allows the 1-to-1, static translation of a source IP address, but leaves the source port unchanged. A common scenario for a static IP translation is an internal server that must be available to the Internet.

## Destination NAT

Destination NAT is performed on incoming packets, when the firewall translates a public destination address to a private address. Destination NAT does not use address pools or ranges. It is a 1-to-1, static translation with the option to perform port forwarding or port translation.

- **Static IP**—Allows the 1-to-1, static translation of a destination IP address and optionally the port number.

One common use of destination NAT is to configure several NAT rules that map a single public destination address to several private destination host addresses assigned to servers or services. In this case, the destination port numbers are used to identify the destination hosts. For example:

© Palo Alto Networks, Inc.

- **Port Forwarding**—Can translate a public destination address and port number to a private destination address, but keeps the same port number.
- **Port Translation**—Can translate a public destination address and port number to a private destination address and a different port number, thus keeping the real port number private. It is configured by entering a **Translated Port** on the **Translated Packet** tab in the NAT policy rule. See the Destination NAT with Port Translation Example.

 © Palo Alto Networks, Inc.

## NAT Rule Capacities

The number of NAT rules allowed is based on the firewall platform. Individual rule limits are set for static, Dynamic IP (DIP), and Dynamic IP and Port (DIPP) NAT. The sum of the number of rules used for these NAT types cannot exceed the total NAT rule capacity. For DIPP, the rule limit is based on the device's oversubscription setting (8, 4, 2, or 1) and the assumption of one translated IP address per rule. To see platform-specific NAT rule limits and translated IP address limits, use the Compare Firewalls tool.

Consider the following when working with NAT rules:

- If you run out of pool resources, you cannot create more NAT rules, even if the platform's maximum rule count has not been reached.
- If you consolidate NAT rules, the logging and reporting will also be consolidated. The statistics are provided per the rule, not per all of the addresses within the rule. If you need granular logging and reporting, do not combine the rules.

# Dynamic IP and Port NAT Oversubscription

Dynamic IP and Port (DIPP) NAT allows you to use each translated IP address and port pair multiple times (8, 4, or 2 times) in concurrent sessions. This reusability of an IP address and port (known as oversubscription) provides scalability for customers who have too few public IP addresses. The design is based on the assumption that hosts are connecting to different destinations, therefore sessions can be uniquely identified and collisions are unlikely. The oversubscription rate in effect multiplies the original size of the address/port pool to 8, 4, or 2 times the size. For example, the default limit of 64K concurrent sessions allowed, when multiplied by an oversubscription rate of 8, results in 512K concurrent sessions allowed.

The oversubscription rates that are allowed vary based on the platform. The oversubscription rate is global; it applies to the device. This oversubscription rate is set by default and consumes memory, even if you have enough public IP addresses available to make oversubscription unnecessary. You can reduce the rate from the default setting to a lower setting or even 1 (which means no oversubscription). By configuring a reduced rate, you decrease the number of source device translations possible, but increase the DIP and DIPP NAT rule capacities. To change the default rate, see Modify the Oversubscription Rate for DIPP NAT.

If you select **Platform Default**, your explicit configuration of oversubscription is turned off and the default oversubscription rate for the platform applies, as shown in the table below. The **Platform Default** setting allows for an upgrade or downgrade of a software release.

The following table lists the default (highest) oversubscription rate for each platform.

| Platform | Default Oversubscription Rate |
|---|---|
| PA-200 | 2 |
| PA-500 | 2 |
| PA-2020 | 2 |
| PA-2050 | 2 |
| PA-3020 | 2 |
| PA-3050 | 2 |
| PA-3060 | 2 |
| PA-4020 | 4 |
| PA-4050 | 8 |
| PA-4060 | 8 |
| PA-5020 | 4 |
| PA-5050 | 8 |
| PA-5060 | 8 |
| PA-7050 | 8 |
| PA-7080 | 8 |
| VM-100 | 1 |

 © Palo Alto Networks, Inc.

| Platform | Default Oversubscription Rate |
|---|---|
| VM-200 | 1 |
| VM-300 | 2 |
| VM-1000-HV | 2 |

The firewall supports a maximum of 256 translated IP addresses per NAT rule, and each platform supports a maximum number of translated IP addresses (for all NAT rules combined). If oversubscription causes the maximum translated addresses per rule (256) to be exceeded, the firewall will automatically reduce the oversubscription ratio in an effort to have the commit succeed. However, if your NAT rules result in translations that exceed the maximum translated addresses for the platform, the commit will fail.

© Palo Alto Networks, Inc.

## Dataplane NAT Memory Statistics

The `show running global-ippool` command displays statistics related to NAT memory consumption for a pool. The Size column displays the number of bytes of memory that the resource pool is using. The Ratio column displays the oversubscription ratio (for DIPP pools only). The lines of pool and memory statistics are explained in the following sample output:

For NAT pool statistics for a virtual system, the `show running ippool` command has columns indicating the memory size used per NAT rule and the oversubscription ratio used (for DIPP rules). The following is sample output for the command.

A field in the output of the `show running nat-rule-ippool rule` command shows the memory (bytes) used per NAT rule. The following is sample output for the command, with the memory usage for the rule encircled.

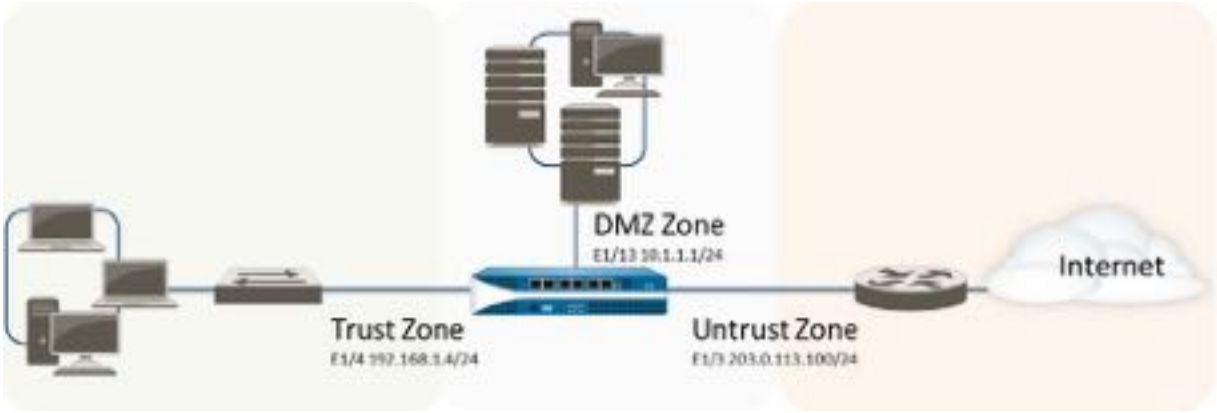
 © Palo Alto Networks, Inc.

## Configure NAT

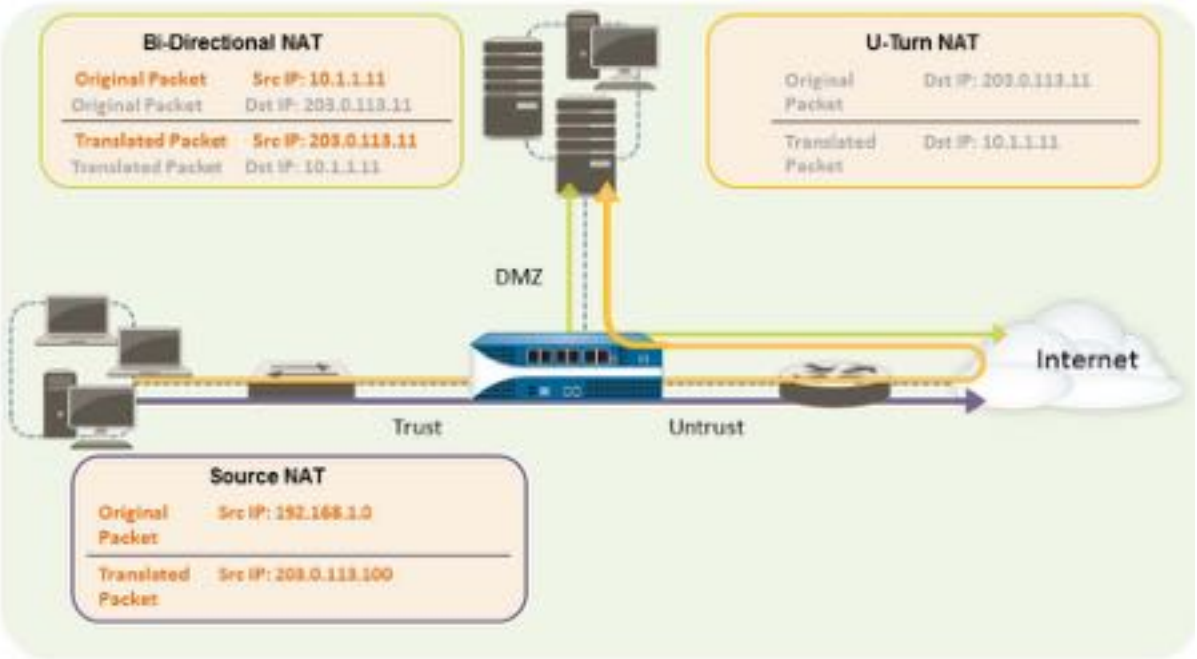
Perform the following tasks to configure various aspects of NAT. In addition to the examples below, there are examples in the section NAT Configuration Examples.

- Translate Internal Client IP Addresses to Your Public IP Address (Source DIPP NAT)
- Enable Clients on the Internal Network to Access your Public Servers (Destination U-Turn NAT)
- Enable Bi-Directional Address Translation for Your Public-Facing Servers (Static Source NAT)
- Modify the Oversubscription Rate for DIPP NAT
- Disable NAT for a Specific Host or Interface
- Reserve Dynamic IP NAT Addresses

The NAT example in this section is based on the following topology, which was also used in Getting Started for setting up interfaces and zones:



Based on the topology initially used in Getting Started to create the interfaces and zones, there are three NAT policies we need to create as follows:



- To enable the clients on the internal network to access resources on the Internet, the internal 192.168.1.0 addresses will need to be translated to publicly routable addresses. In this case, we will configure source NAT (the purple enclosure and arrow above), using the egress interface address, 203.0.113.100, as the source address in all packets that leave the firewall from the internal zone. See Translate Internal Client IP Addresses to Your Public IP Address (Source DIPP NAT) for instructions.
- To enable clients on the internal network to access the public web server in the DMZ zone, we must configure a NAT rule that redirects the packet from the external network, where the original routing table lookup will determine it should go based on the destination address of 203.0.113.11 within the packet, to the actual address of the web server on the DMZ network of 10.1.1.11. To do this you must create a NAT rule from the trust zone (where the source address in the packet is) to the untrust zone (where the original destination address is) to translate the destination address to an address in the DMZ zone. This type of destination NAT is called *U-Turn NAT* (the yellow enclosure and arrow above). See Enable Clients on the Internal Network to Access your Public Servers (Destination U-Turn NAT) for instructions.
- To enable the web server—which has both a private IP address on the DMZ network and a public-facing address for access by external users—to both send and receive requests, the firewall must translate the incoming packets from the public IP address to the private IP address and the outgoing packets from the private IP address to the public IP address. On the firewall, you can accomplish this with a single bi-directional static source NAT policy (the green enclosure and arrow above). See Enable Bi-Directional Address Translation for Your Public-Facing Servers (Static Source NAT).

 © Palo Alto Networks, Inc.

## Translate Internal Client IP Addresses to Your Public IP Address (Source DIPP NAT)

When a client on your internal network sends a request, the source address in the packet contains the IP address for the client on your internal network. If you use private IP address ranges internally, the packets from the client will not be able to be routed on the Internet unless you translate the source IP address in the packets leaving the network into a publicly routable address.

On the firewall you can do this by configuring a source NAT policy that translates the source address (and optionally the port) into a public address. One way to do this is to translate the source address for all packets to the egress interface on your firewall, as shown in the following procedure.

| **Configure Source NAT** | |
|---|---|
| Step 1 Create an address object for the external IP address you plan to use. | 1. Select **Objects > Addresses** and then click **Add**.<br>2. Enter a **Name** and optionally a **Description** for the object.<br>3. Select **IP Netmask** from the **Type** drop-down and then enter the IP address of the external interface on the firewall, 203.0.113.100 in this example.<br> <br>4. To save the address object, click **OK**.<br>Although you do not have to use address objects in your policies, it is a best practice because it simplifies administration by allowing you to make updates in one place rather than having to update every policy where the address is referenced. |

| Configure Source NAT (Continued) | |
|---|---|
| Step 2 Create the NAT policy. | 1. Select **Policies > NAT** and click **Add**.<br>2. On the **General** tab, enter a descriptive **Name** for the policy.<br>3. (Optional) Enter a tag, which is a keyword or phrase that allows you to sort or filter policies.<br>4. For **NAT Type**, select **ipv4** (default).<br>5. On the **Original Packet** tab, select the zone you created for your internal network in the **Source Zone** section (click **Add** and then select the zone) and the zone you created for the external network from the **Destination Zone** drop-down.<br> <br>6. On the **Translated Packet** tab, select **Dynamic IP And Port** from the **Translation Type** drop-down in the Source Address Translation section of the screen.<br>7. For **Address Type**, there are two choices. You could select **Translated Address** and then click **Add**. Select the address object you just created.<br>  <br>An alternative **Address Type** is **Interface Address**, in which case the translated address will be the IP address of the interface. For this choice, you would select an **Interface** and optionally an **IP Address** if the interface has more than one IP address.<br>8. Click **OK** to save the NAT policy. |
| Step 3 Save the configuration. | Click **Commit**. |

© Palo Alto Networks, Inc.

| Configure Source NAT (Continued) | |
|---|---|
| Step 4 (Optional) Access the CLI to verify the translation. | 1. Use the `show session all` command to view the session table, where you can verify the source IP address and port and the corresponding translated IP address and port.<br>2. Use the `show session id <id_number>` to view more details about a session.<br>3. If you configured Dynamic IP NAT, use the `show counter global filter aspect session severity drop \| match nat` command to see if any sessions failed due to NAT IP allocation. If all of the addresses in the Dynamic IP NAT pool are allocated when a new connection is supposed to be translated, the packet will be dropped. |

## Enable Clients on the Internal Network to Access your Public Servers (Destination U-Turn NAT)

When a user on the internal network sends a request for access to the corporate web server in the DMZ, the DNS server will resolve it to the public IP address. When processing the request, the firewall will use the original destination in the packet (the public IP address) and route the packet to the egress interface for the untrust zone. In order for the firewall to know that it must translate the public IP address of the web server to an address on the DMZ network when it receives requests from users on the trust zone, you must create a destination NAT rule that will enable the firewall to send the request to the egress interface for the DMZ zone as follows.

| Configure U-Turn NAT | |
|---|---|
| Step 1 Create an address object for the web server. | 1. Select **Objects > Addresses** and click **Add**.<br>2. Enter a **Name** and optionally a **Description** for the object.<br>3. Select **IP Netmask** from the **Type** drop-down and enter the public IP address of the web server, 203.0.113.11 in this example.<br> <br>4. Click **OK**. |

| Configure U-Turn NAT (Continued) | |
|---|---|
| Step 1 Create the NAT policy. | 1. Select **Policies > NAT** and click **Add**.<br>2. On the **General** tab, enter a descriptive **Name** for the NAT rule.<br>3. On the **Original Packet** tab, select the zone you created for your internal network in the **Source Zone** section (click **Add** and then select the zone) and the zone you created for the external network from the **Destination Zone** drop-down.<br>4. In the **Destination Address** section, click **Add** and select the address object you created for your public web server.<br>  <br>5. On the **Translated Packet** tab, select the **Destination Address Translation** check box and then enter the IP address that is assigned to the web server interface on the DMZ network, 10.1.1.11 in this example.<br> <br>6. Click **OK** to save the NAT policy. |
| Step 2 Save the configuration. | Click **Commit**. |

## Enable Bi-Directional Address Translation for Your Public-Facing Servers (Static Source NAT)

When your public-facing servers have private IP addresses assigned on the network segment where they are physically located, you need a source NAT rule to translate the source address of the server to the external address upon egress. You create a static NAT rule to translate the internal source address, 10.1.1.11, to the external web server address, 203.0.113.11 in our example.

However, a public-facing server must be able to both send and receive packets. You need a reciprocal policy that translates the public address (the destination IP address in incoming packets from Internet users) into the private address so that the firewall can route the packet to your DMZ network. You create a bi-directional static NAT rule, as described in the following procedure. Bi-directional translation is an option for static NAT only.

 © Palo Alto Networks, Inc.

| Configure Bi-Directional NAT | |
|---|---|
| Step 1 Create an address object for the web server's internal IP address. | 1. Select **Objects > Addresses** and click **Add**.<br>2. Enter a **Name** and optionally a **Description** for the object.<br>3. Select **IP Netmask** from the **Type** drop-down and enter the IP address of the web server on the DMZ network, 10.1.1.11 in this example.<br> <br>4. Click **OK**.<br>If you did not already create an address object for the *public* address of your web server, you should create that object now. |

| Configure Bi-Directional NAT (Continued) | |
|---|---|
| Step 2 Create the NAT policy. | 1. Select **Policies > NAT** and click **Add**.<br>2. On the **General** tab, enter a descriptive **Name** for the NAT rule.<br>3. On the **Original Packet** tab, select the zone you created for your DMZ in the **Source Zone** section (click **Add** and then select the zone) and the zone you created for the external network from the **Destination Zone** drop-down.<br>4. In the **Source Address** section, click **Add** and select the address object you created for your internal web server address.<br>  <br>5. On the **Translated Packet** tab, select **Static IP** from the **Translation Type** drop-down in the **Source Address Translation** section and then select the address object you created for your external web server address from the **Translated Address** drop-down.<br>6. In the **Bi-directional** field, select **Yes**.<br> <br>7. Click **OK** to save the NAT policy. |
| Step 3 Save the configuration. | Click **Commit**. |

© Palo Alto Networks, Inc.

## Modify the Oversubscription Rate for DIPP NAT

If you have enough public IP addresses that you do not need to use DIPP NAT oversubscription, you can reduce the oversubscription rate and thereby gain more DIP and DIPP NAT rules allowed.

| **Set NAT Oversubscription** | | |
|---|---|---|
| Step 1 | View the DIPP NAT oversubscription rate. | 1. Select **Device > Setup > Session > Session Settings.** View the **NAT Oversubscription Rate** setting. |
| Step 2 | Set the DIPP NAT oversubscription rate. | 1. Click the Edit icon in the Session Settings section.<br>2. In the **NAT Oversubscription Rate** drop-down, select **1x**, **2x**, **4x**, or **8x**, depending on which ratio you want.<br>The **Platform Default** setting applies the default oversubscription setting for the platform. If you want no oversubscription, select **1x**.<br>3. Click **OK** and **Commit** the change. |

## Disable NAT for a Specific Host or Interface

Both source NAT and destination NAT rules can be configured to disable address translation. You may have exceptions where you do not want NAT to occur for a certain host in a subnet or for traffic exiting a specific interface. The following procedure shows how to disable source NAT for a host.

| **Create a Source NAT Exemption** | | |
|---|---|---|
| Step 1 | Create the NAT policy. | 1. Select **Policies > NAT** and click **Add**.<br>2. Enter a descriptive **Name** for the policy.<br>3. On the **Original Packet** tab, select the zone you created for your internal network in the **Source Zone** section (click **Add** and then select the zone) and the zone you created for the external network from the **Destination Zone** drop-down.<br>4. For **Source Address**, click **Add** and enter the host address. Click **OK**.<br>5. On the **Translated Packet** tab, select **None** from the **Translation Type** drop-down in the Source Address Translation section of the screen.<br>6. Click **OK** to save the NAT policy. |
| Step 2 | Save the configuration. | Click **Commit**. |

NAT rules are processed in order from the top to the bottom, so place the NAT exemption policy before other NAT policies to ensure it is processed before an address translation occurs for the sources you want to exempt.

## Reserve Dynamic IP NAT Addresses

You can reserve Dynamic IP NAT addresses (for a configurable period of time) to prevent them from being allocated as translated addresses to a different source IP address that needs translation. When configured, the reservation applies to all of the translated Dynamic IP addresses in progress and any new translations.

For both translations in progress and new translations, when a source IP address is translated to an available translated IP address, that pairing is retained even after all sessions related to that specific source IP are expired. The reservation timer for each source IP address begins after all sessions that use that source IP address translation expire. Dynamic IP NAT is a one-to-one translation; one source IP address translates to one translated IP address that is chosen dynamically from those addresses available in the configured pool. Therefore, a translated IP address that is reserved is not available for any other source IP address until the reservation expires because a new session has not started. The timer is reset each time a new session for a source IP/translated IP mapping begins, after a period when no sessions were active.

By default, no addresses are reserved. You can reserve Dynamic IP NAT addresses for the firewall or for a virtual system.

| **Reserve Dynamic IP NAT Addresses for a Firewall** | |
|---|---|
| Step 1 | `user@device1# set setting nat reserve-ip yes` |
| Step 2 | `user@device1# set setting nat reserve-time <1-604800 secs>` |

| **Reserve Dynamic IP NAT Addresses for a Virtual System** | |
|---|---|
| Step 1 | `user@device1# set vsys <vsysid> setting nat reserve-ip yes` |
| Step 2 | `user@device1# set vsys <vsysid> setting nat reserve-time <1-604800 secs>` |

For example, suppose there is a Dynamic IP NAT pool of 30 addresses and there are 20 translations in progress when the `nat reserve-time` is set to 28800 seconds (8 hours). Those 20 translations are now reserved, so that when the last session (of any application) that uses each source IP/translated IP mapping expires, the translated IP address is reserved for only that source IP address for 8 hours, in case that source IP address needs translation again. Additionally, as the 10 remaining translated addresses are allocated, they each are reserved for their source IP address, each with a timer that begins when the last session for that source IP address expires.

In this manner, each source IP address can be repeatedly translated to its same NAT address from the pool; another host will not be assigned a reserved translated IP address from the pool, even if there are no active sessions for that translated address.

Suppose a source IP/translated IP mapping has all of its sessions expire, and the reservation timer of 8 hours begins. After a new session for that translation begins, the timer stops, and the sessions continue until they all end, at which point the reservation timer starts again, reserving the translated address.

The reservation timer remain in effect on the Dynamic IP NAT pool until you disable it by entering the `set setting nat reserve-ip no` command or you change the `nat reserve-time` to a different value.

The CLI commands for reservations do not affect Dynamic IP and Port (DIPP) or Static IP NAT pools.

# NAT Configuration Examples

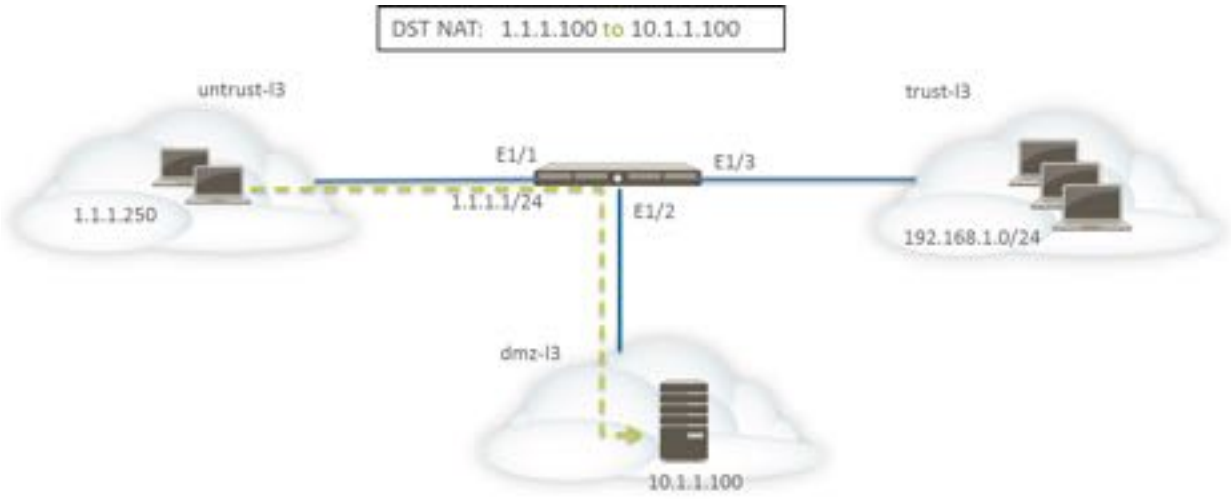
- Destination NAT Example—One-to-One Mapping
- Destination NAT with Port Translation Example
- Destination NAT Example—One-to-Many Mapping
- Source and Destination NAT Example
- Virtual Wire Source NAT Example
- Virtual Wire Static NAT Example
- Virtual Wire Destination NAT Example

## Destination NAT Example—One-to-One Mapping

The most common mistakes when configuring NAT and security rules are the references to the zones and address objects. The addresses used in destination NAT rules always refer to the original IP address in the packet (that is, the pre-translated address). The destination zone in the NAT rule is determined after the route lookup of the destination IP address in the original packet (that is, the pre-NAT destination IP address).

The addresses in the security policy also refer to the IP address in the original packet (that is, the pre-NAT address). However, the destination zone is the zone where the end host is physically connected. In other words, the destination zone in the security rule is determined after the route lookup of the post-NAT destination IP address.

In the following example of a one-to-one destination NAT mapping, users from the zone named untrust-l3 access the server 10.1.1.100 in the zone named dmz-l3 using the IP address 1.1.1.100.



Before configuring the NAT rules, consider the sequence of events for this scenario.

- Host 1.1.1.250 sends an ARP request for the address 1.1.1.100 (the public address of the destination server).

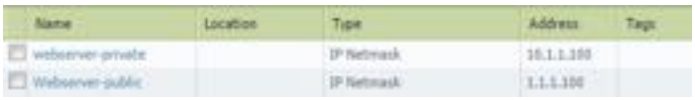
- The firewall receives the ARP request packet for destination 1.1.1.100 on the Ethernet1/1 interface and processes the request. The firewall responds to the ARP request with its own MAC address because of the destination NAT rule configured.
- The NAT rules are evaluated for a match. For the destination IP address to be translated, a destination NAT rule from zone untrust-l3 to zone untrust-l3 must be created to translate the destination IP of 1.1.1.100 to 10.1.1.100.
- After determining the translated address, the firewall performs a route lookup for destination 10.1.1.100 to determine the egress interface. In this example, the egress interface is Ethernet1/2 in zone dmz-l3.
- The firewall performs a security policy lookup to see if the traffic is permitted from zone untrust-l3 to dmz-l3.

The direction of the policy matches the ingress zone and the zone where the server is physically located.

The security policy refers to the IP address in the original packet, which has a destination address of 1.1.1.100.

- The firewall forwards the packet to the server out egress interface Ethernet1/2. The destination address is changed to 10.1.1.100 as the packet leaves the firewall.

For this example, the following address objects are configured:



The configured NAT rule would look like this:

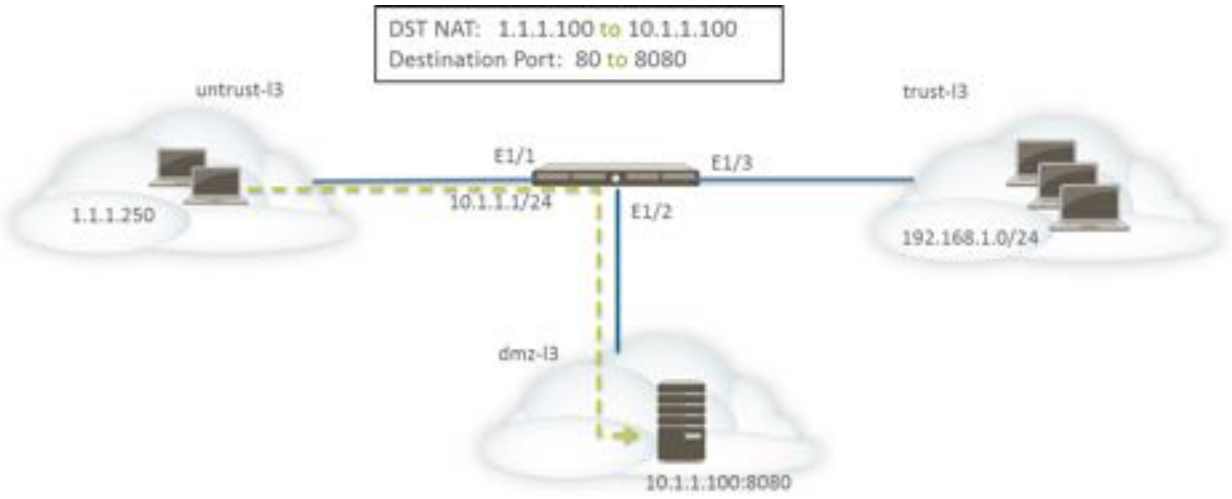
The direction of the NAT rules is based on the result of route lookup.

The configured security policy to provide access to the server from the untrust-l3 zone would look like this:

## Destination NAT with Port Translation Example

In this example, the web server is configured to listen for HTTP traffic on port 8080. The clients access the web server using the IP address 1.1.1.100 and TCP Port 80. The destination NAT rule is configured to translate both IP address and port to 10.1.1.100 and TCP port 8080.

 © Palo Alto Networks, Inc.



The following NAT and security rules must be configured on the firewall:

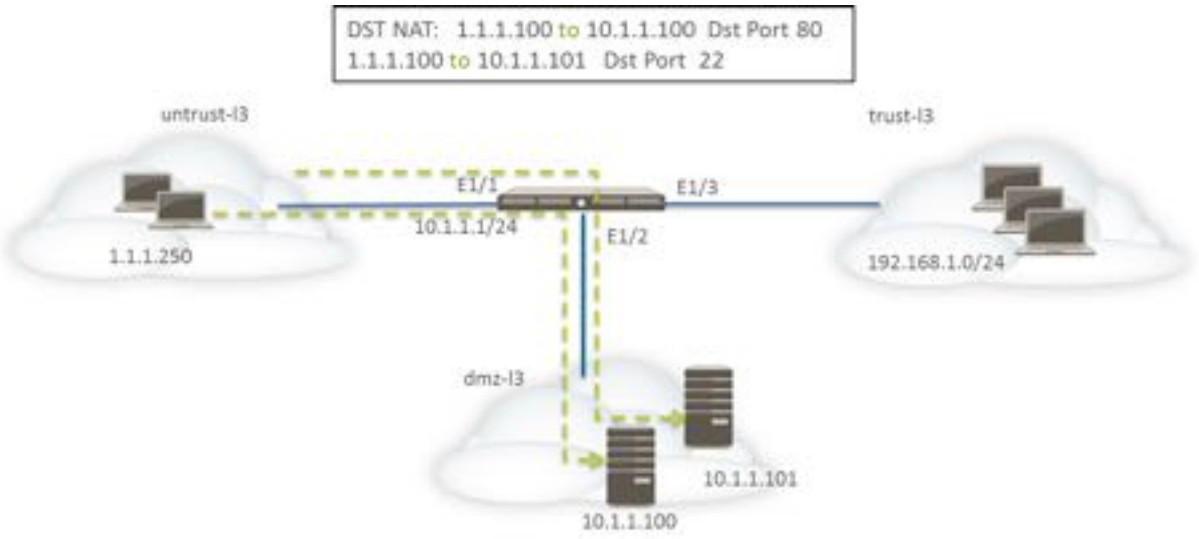
| | Original Packet | | | | | | Translated Packet | |
|---|---|---|---|---|---|---|---|---|
| Name | Source Zone | Destination Zone | Destination Interface | Source Address | Destination Address | Service | Source Translation | Destination Translation |
| Dst NAT-webserv | untrust-l3 | untrust-l3 | none | any | Servers-public | service-http | none | address: webserver-private<br>port: 8080 |

| | Source | | Destination | | | |
|---|---|---|---|---|---|---|
| Name | Zone | Address | Zone | Address | Application | Service |
| Webserver access | untrust-l3 | any | dmz-l3 | Servers-public | web-browsing | any |

Use the `show session all` CLI command to verify the translation.

## Destination NAT Example—One-to-Many Mapping

In this example, one IP address maps to two different internal hosts. The firewall uses the application to identify the internal host to which the firewall forwards the traffic.



All HTTP traffic is sent to host 10.1.1.100 and SSH traffic is sent to server 10.1.1.101. The following address objects are required:

- Address object for the one pre-translated IP address of the server
- Address object for the real IP address of the SSH server
- Address object for the real IP address of the web server

The configured address objects would look like this:

| Name | Type | Address |
|---|---|---|
| Servers-public | IP Netmask | 1.1.1.100 |
| SSH-server | IP Netmask | 10.1.1.101 |
| webserver-private | IP Netmask | 10.1.1.100 |

The NAT rules would look like this:

| | Original Packet | | | | | | Translated Packet | |
|---|---|---|---|---|---|---|---|---|
| Name | Source Zone | Destination Zone | Destination Interface | Source Address | Destination Address | Service | Source Translation | Destination Translation |
| Dst NAT-webserv | untrust-l3 | untrust-l3 | none | any | Servers-public | service-http | none | address: webserver-private |
| Dst NAT-SSH | untrust-l3 | untrust-l3 | none | any | Servers-public | custom-ssh | none | address: SSH-server |

The security rules would look like this:

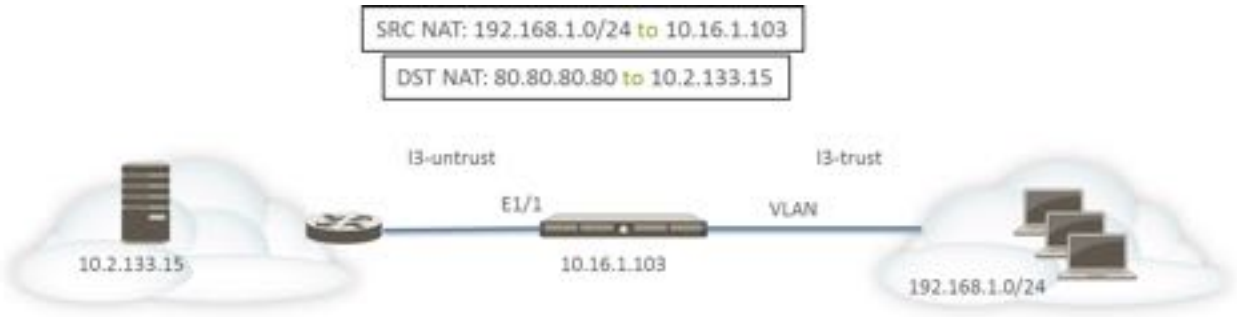
| | Source | | Destination | | | | |
|---|---|---|---|---|---|---|---|
| Name | Zone | Address | Zone | Address | Application | Service | Action |
| Webserver access | untrust-l3 | any | dmz-l3 | Servers-public | web-browsing | application-default | ✓ |
| SSH access | untrust-l3 | any | dmz-l3 | Servers-public | ssh | application-default | ✓ |

 © Palo Alto Networks, Inc.

## Source and Destination NAT Example

In this example, NAT rules translate both the source and destination IP address of packets between the clients and the server.

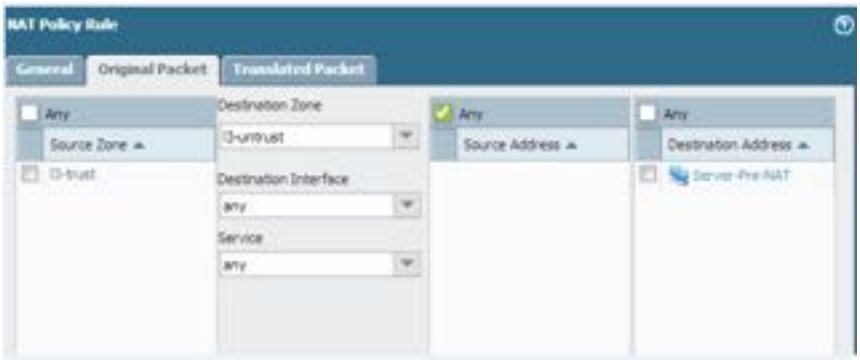
- Source NAT—The source addresses in the packets from the clients in the l3-trust zone to the server in the l3-untrust zone are translated from the private addresses in the network 192.168.1.0/24 to the IP address of the egress interface on the firewall (10.16.1.103). Dynamic IP and Port translation causes the port numbers to be translated also.
- Destination NAT—The destination addresses in the packets from the clients to the server are translated from the server's public address (80.80.80.80) to the server's private address (10.2.133.15).

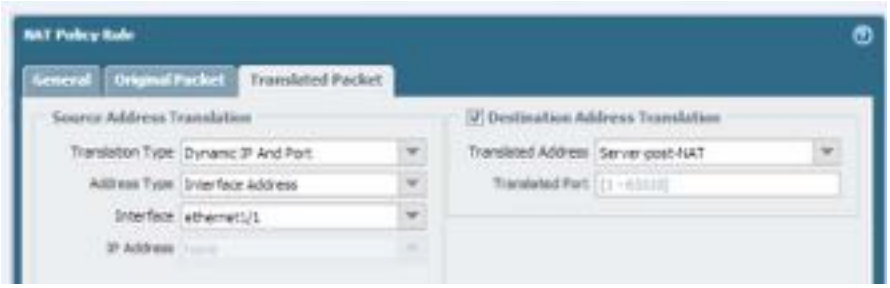


The following address objects are created for destination NAT.

- Server-Pre-NAT: 80.80.80.80
- Server-post-NAT: 10.2.133.15

The following screen shots illustrate how to configure the source and destination NAT policies for the example.





To verify the translations, use the CLI command `show session all filter destination 80.80.80.80`. Note that a client address 192.168.1.11 and its port number are translated to 10.16.1.103 and a port number. The destination address 80.80.80.80 is translated to 10.2.133.15.

## Virtual Wire Source NAT Example

Virtual wire deployment of a Palo Alto Networks firewall includes the benefit of providing security transparently to the end devices. It is possible to configure NAT for interfaces configured in a virtual wire. All of the NAT types are allowed: source NAT (Dynamic IP, Dynamic IP and Port, static) and destination NAT.

Because interfaces in a virtual wire do not have an IP address assigned, it is not possible to translate an IP address to an interface IP address. You must configure an IP address pool.

The firewall will not proxy ARP for NAT addresses. Ensure that routes are configured on the upstream and downstream devices. See Proxy ARP for NAT Address Pools for more explanation about proxy ARP.

Proper routing must be configured on the upstream and downstream routers in order for the packets to be translated in virtual wire mode.

In the source NAT and static NAT examples below, security policies (not shown) are configured from the virtual wire zone named vw-trust to the zone named vw-untrust.

In the following topology, two routers are configured to provide connectivity between subnets 1.1.1.0/24 and 3.1.1.0/24. The link between the routers is configured in subnet 2.1.1.0/30. Static routing is configured on both routers to establish connectivity between the networks. Before the firewall is deployed in the environment, the topology and the routing table for each router look like this:

Route on R1:

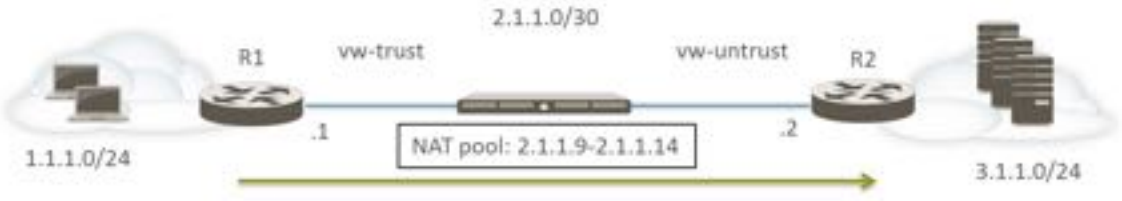
| Destination | Next Hop |
|---|---|
| 3.1.1.0/24 | 2.1.1.2 |

 © Palo Alto Networks, Inc.

Route on R2:

| Destination | Next Hop |
|---|---|
| 1.1.1.0/24 | 2.1.1.1 |

Now the firewall is deployed in virtual wire mode between the two Layer 3 devices. All communications from clients in network 1.1.1.0/24 accessing servers in network 3.1.1.0/24 are translated to an IP address in the range 2.1.1.9-2.1.1.14. A NAT IP address pool with range 2.1.1.9-2.1.1.14 is configured on the firewall.



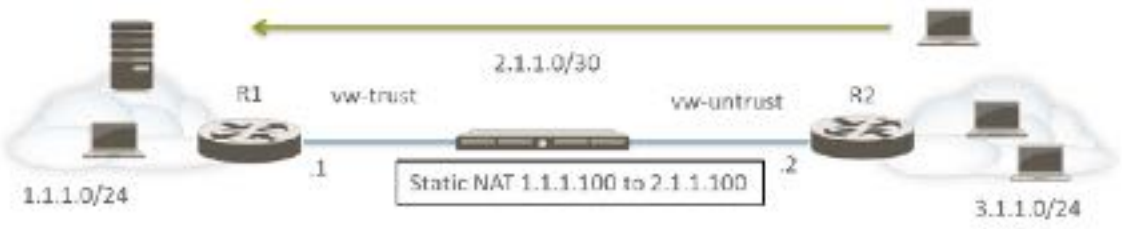
All connections from the clients in subnet 1.1.1.0/24 will arrive at router R2 with a translated source address in the range 2.1.1.9-2.1.1.14. The response from servers will be directed to these addresses. In order for source NAT to work, you must configure proper routing on router R2, so that packets destined for other addresses are not dropped. The routing table below shows the modified routing table on router R2. The route ensures the traffic to the destinations 2.1.1.9-2.1.1.14 (that is, hosts on subnet 2.1.1.8/29) will be sent back through the firewall to router R1.

Route on R2:

| Destination | Next Hop |
|---|---|
| 2.1.1.8/29 | 2.1.1.1 |

## Virtual Wire Static NAT Example

In this example, security policies are configured from the virtual wire zone named vw-trust to vw-untrust. Host 1.1.1.100 is statically translated to address 2.1.1.100. With the **Bi-directional** option enabled, the firewall generates a NAT policy from the vw-untrust zone to the vw-trust zone. Clients on the vw-untrust zone access the server using the IP address 2.1.1.100, which the firewall translates to 1.1.1.100. Any connections initiated by the server at 1.1.1.100 are translated to source IP address 2.1.1.100.

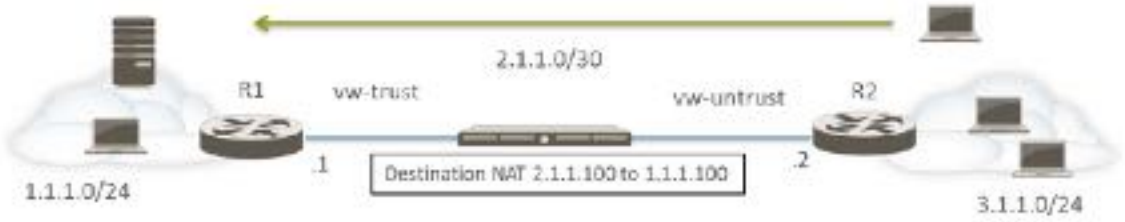


Route on R2:

| Destination | Next Hop |
|---|---|
| 2.1.1.100/32 | 2.1.1.1 |

## Virtual Wire Destination NAT Example

Clients in the vw-untrust zone access the server using the IP address 2.1.1.100, which the firewall translates to 1.1.1.100. Both the NAT and security policies must be configured from the vw-untrust zone to the vw-trust zone.



Route on R2:

| Destination | Next Hop |
|---|---|
| 2.1.1.100/32 | 2.1.1.1 |

# NPTv6

IPv6-to-IPv6 Network Prefix Translation (NPTv6) performs a stateless, static translation of one IPv6 prefix to another IPv6 prefix (port numbers are not changed). There are four primary benefits of NPTv6:

- You can prevent the asymmetrical routing problems that result from Provider Independent addresses being advertised from multiple datacenters.
- NPTv6 allows more specific routes to be advertised so that return traffic arrives at the same firewall that transmitted the traffic.
- Private and public addresses are independent; you can change one without affecting the other.
- You have the ability to translate Unique Local Addresses to globally routable addresses.

This topic builds on a basic understanding of NAT. You should be sure you are familiar with NAT concepts before configuring NPTv6.

▲ NPTv6 Overview
▲ How NPTv6 Works
▲ NDP Proxy
▲ NPTv6 and NDP Proxy Example
▲ Create an NPTv6 Policy

# NPTv6 Overview

This section describes IPv6-to-IPv6 Network Prefix Translation (NPTv6) and how to configure it. NPTv6 is defined in RFC 6296. Palo Alto Networks does not implement all functionality defined in the RFC, but is compliant with the RFC in the functionality it has implemented.

NPTv6 performs stateless translation of one IPv6 prefix to another IPv6 prefix. It is stateless, meaning that it does not keep track of ports or sessions on the addresses translated. NPTv6 differs from NAT66, which is stateful. Palo Alto Networks supports NPTv6 RFC 6296 prefix translation; it does not support NAT66.

With the limited addresses in the IPv4 space, NAT was required to translate private, non-routable IPv4 addresses to one or more globally-routable IPv4 addresses.

For organizations using IPv6 addressing, there is no need to translate IPv6 addresses to IPv6 addresses due to the abundance of IPv6 addresses. However, there are Reasons to Use NPTv6 to translate IPv6 prefixes at the firewall.

NPTv6 translates the prefix portion of an IPv6 address but not the host portion or the application port numbers. The host portion is simply copied, and therefore remains the same on either side of the firewall. The host portion also remains visible within the packet header.

- NPTv6 Does Not Provide Security
- Platform Support for NPTv6
- Unique Local Addresses
- Reasons to Use NPTv6

## NPTv6 Does Not Provide Security

It is important to understand that NPTv6 does not provide security. In general, stateless network address translation does not provide any security; it provides an address translation function. NPTv6 does not hide or translate port numbers. You must set up firewall security policies correctly in each direction to ensure that traffic is controlled as you intended.

## Platform Support for NPTv6

NPTv6 is supported on the following platforms (NPTv6 with hardware lookup but packets go through the CPU): PA-7000 Series, PA-5000 Series, PA-4000 Series, PA-3050 firewall, and PA-2000 Series. Platforms supported with no ability to have hardware perform a session look-up: PA-3020 firewall, PA 500 firewall, PA-200 firewall, and VM-Series.

## Unique Local Addresses

RFC 4193, Unique Local IPv6 Unicast Addresses, defines unique local addresses (ULAs), which are IPv6 unicast addresses. They can be considered IPv6 equivalents of the private IPv4 addresses identified in RFC 1918, Address Allocation for Private Internets, which cannot be routed globally.

 © Palo Alto Networks, Inc.

A ULA is globally unique, but not expected to be globally routable. It is intended for local communications and to be routable in a limited area such as a site or among a small number of sites. Palo Alto Networks does not recommend that you assign ULAs, but a firewall configured with NPTv6 will translate prefixes sent to it, including ULAs.

## Reasons to Use NPTv6

Although there is no shortage of public, globally routable IPv6 addresses, there are reasons you might want to translate IPv6 addresses. NPTv6:

- **Prevents asymmetrical routing**—Asymmetric routing can occur if a Provider Independent address space (/48, for example) is advertised by multiple data centers to the global Internet. By using NPTv6, you can advertise more specific routes from regional firewalls, and the return traffic will arrive at the same firewall where the source IP address was translated by the translator.
- **Provides address independence**—You need not change the IPv6 prefixes used inside your local network if the global prefixes are changed (for example, by an ISP or as a result of merging organizations). Conversely, you can change the inside addresses at will without disrupting the addresses that are used to access services in the private network from the Internet. In either case, you update a NAT rule rather than reassign network addresses.
- **Translates ULAs for routing**—You can have Unique Local Addresses assigned within your private network, and have the firewall translate them to globally routable addresses. Thus, you have the convenience of private addressing and the functionality of translated, routable addresses.
- **Reduces exposure to IPv6 prefixes**—IPv6 prefixes are less exposed than if you didn't translate network prefixes, however, NPTv6 is not a security measure. The interface identifier portion of each IPv6 address is not translated; it remains the same on each side of the firewall and visible to anyone who can see the packet header. Additionally, the prefixes are not secure; they can be determined by others.

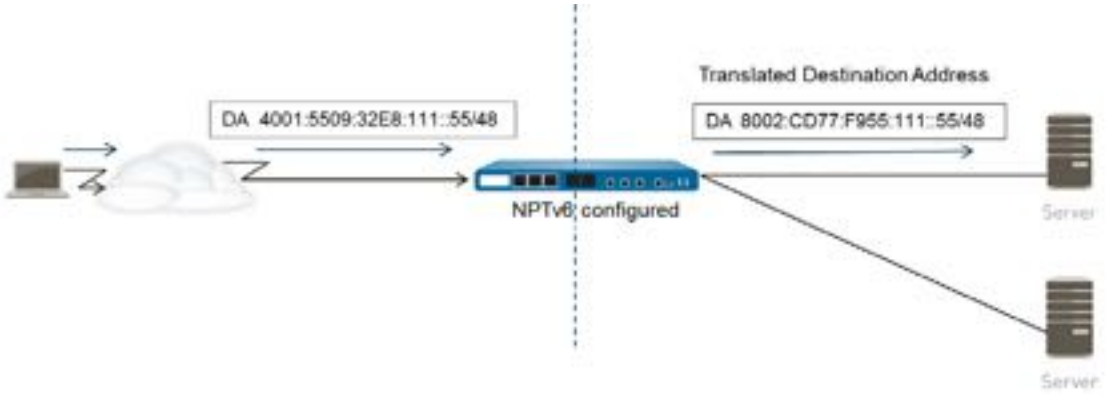
© Palo Alto Networks, Inc.

## How NPTv6 Works

When you configure a policy for NPTv6, the Palo Alto Networks firewall performs a static, one-to-one IPv6 translation in both directions. The translation is based on the algorithm described in RFC 6296.

In one use case, the firewall performing NPTv6 is located between an internal network and an external network (such as the Internet) that uses globally routable prefixes. When datagrams are going in the outbound direction, the internal source prefix is replaced with the external prefix; this is known as source translation.

In another use case, when datagrams are going in the inbound direction, the destination prefix is replaced with the internal prefix (known as destination translation). The figure below illustrates destination translation and a characteristic of NPTv6: only the prefix portion of an IPv6 address is translated. The host portion of the address is not translated and remains the same on either side of the firewall. In the figure below, the host identifier is 111::55 on both sides of the firewall.



It is important to understand that NPTv6 does not provide security. While you are planning your NPTv6 NAT policies, remember also to configure security policies in each direction.

A NAT or NPTv6 policy rule cannot have both the Source Address and the Translated Address set to Any.

In an environment where you want IPv6 prefix translation, three firewall features work together: NPTv6 NAT policies, security policies, and NDP Proxy.

The firewall does not translate the following:

- Addresses that the firewall has in its Neighbor Discovery (ND) cache.
- The subnet 0xFFFF (in accordance with RFC 6296, Appendix B).
- IP multicast addresses.
- IPv6 addresses with a prefix length of /31 or shorter.
- Link-local addresses. If the firewall is operating in virtual wire mode, there are no IP addresses to translate, and the firewall does not translate link-local addresses.
- Addresses for TCP sessions that authenticate peers using the TCP Authentication Option (RFC 5925).

When using NPTv6, performance for fast path traffic is impacted because NPTv6 is performed in the slow path.

 © Palo Alto Networks, Inc.

NPTv6 will work with IPSec IPv6 only if the firewall is originating and terminating the tunnel. Transit IPSec traffic would fail because the source and/or destination IPv6 address would be modified. A NAT traversal technique that encapsulates the packet would allow IPSec IPv6 to work with NPTv6.

- Checksum-Neutral Mapping
- Bi-Directional Translation
- NPTv6 Applied to a Specific Service

## Checksum-Neutral Mapping

The NPTv6 mapping translations that the firewall performs are checksum-neutral, meaning that "... they result in IP headers that will generate the same IPv6 pseudo-header checksum when the checksum is calculated using the standard Internet checksum algorithm [RFC 1071]." See RFC 6296, Section 2.6, for more information about checksum-neutral mapping.

If you are using NPTv6 to perform destination NAT, you can provide the internal IPv6 address and the external prefix/prefix length of the firewall interface in the syntax of the `test nptv6` CLI command. The CLI responds with the checksum-neutral, public IPv6 address to use in your NPTv6 configuration to reach that destination.

## Bi-Directional Translation

When you Create an NPTv6 Policy, the **Bi-directional** check box in the **Translated Packet** tab provides a convenient way for you to have the firewall create a corresponding NAT or NPTv6 translation in the opposite direction of the translation you configured. By default, **Bi-directional** translation is disabled.

If you enable **Bi-directional** translation, it is very important to make sure you have security policies in place to control the traffic in both directions. Without such policies, the **Bi-directional** feature will allow packets to be automatically translated in both directions, which you might not want.

## NPTv6 Applied to a Specific Service

The Palo Alto Networks implementation of NPTv6 offers the ability to filter packets to limit which packets are subject to translation. Keep in mind that NPTv6 does not perform port translation. There is no concept of Dynamic IP and Port (DIPP) translation because NPTv6 translates IPv6 prefixes only. However, you can specify that only packets for a certain service port undergo NPTv6 translation. To do so, Create an NPTv6 Policy that specifies a **Service** in the Original Packet.

## NDP Proxy

Neighbor Discovery Protocol (NDP) for IPv6 performs functions similar to those provided by Address Resolution Protocol (ARP) for IPv4. RFC 4861 defines Neighbor Discovery for IP version 6 (IPv6). Hosts, routers, and firewalls use NDP to determine the link-layer addresses of neighbors on connected links, to keep track of which neighbors are reachable, and to update neighbors' link-layer addresses that have changed. Peers advertise their own MAC address and IPv6 address, and they also solicit addresses from peers.

NDP also supports the concept of *proxy*, when a node has a neighboring device that is able to forward packets on behalf of the node. The device (firewall) performs the role of NDP Proxy.

Palo Alto Networks firewalls support NDP and NDP Proxy on their interfaces. When you configure the firewall to act as an NDP Proxy for addresses, it allows the firewall to send Neighbor Discovery (ND) advertisements and respond to ND solicitations from peers that are asking for MAC addresses of IPv6 prefixes assigned to devices behind the firewall. You can also configure addresses for which the firewall will not respond to proxy requests (negated addresses).

In fact, NDP is enabled by default, and you need to configure NDP Proxy when you configure NPTv6, for the following reasons:

- The stateless nature of NPTv6 requires a way to instruct the firewall to respond to ND packets sent to specified NDP Proxy addresses, and to not respond to negated NDP Proxy addresses.

It is recommended that you negate your neighbors' addresses in the NDP Proxy configuration, because NDP Proxy indicates the firewall will reach those addresses behind the firewall, but the neighbors are not behind the firewall.

- NDP causes the firewall to save the MAC addresses and IPv6 addresses of neighbors in its ND cache. (Refer to the figure in NPTv6 and NDP Proxy Example.) The firewall does not perform NPTv6 translation for addresses that it finds in its ND cache because doing so could introduce a conflict. If the host portion of an address in the cache happens to overlap with the host portion of a neighbor's address, and the prefix in the cache is translated to the same prefix as that of the neighbor (because the egress interface on the firewall belongs to the same subnet as the neighbor), then you would have a translated address that is exactly the same as the legitimate IPv6 address of the neighbor, and a conflict occurs. (If an attempt to perform NPTv6 translation occurs on an address in the ND cache, an informational syslog message logs the event: `NPTv6 Translation Failed.`)

When an interface with NDP Proxy enabled receives an ND solicitation requesting a MAC address for an IPv6 address, the following sequence occurs:

1. The firewall searches the ND cache to ensure the IPv6 address from the solicitation is not there. If the address is there, the firewall ignores the ND solicitation.
2. If the source IPv6 address is 0, that means the packet is a Duplicate Address Detection packet, and the firewall ignores the ND solicitation.
3. The firewall does a Longest Prefix Match search of the NDP Proxy addresses and finds the best match to the address in the solicitation. If the Negate field for the match is checked (in the NDP Proxy list), the firewall drops the ND solicitation.
4. Only if the Longest Prefix Match search matches, and that matched address is not negated, will the NDP Proxy respond to the ND solicitation. The firewall responds with an ND packet, providing its own MAC address as the MAC address of the next hop toward the queried destination.

 © Palo Alto Networks, Inc.

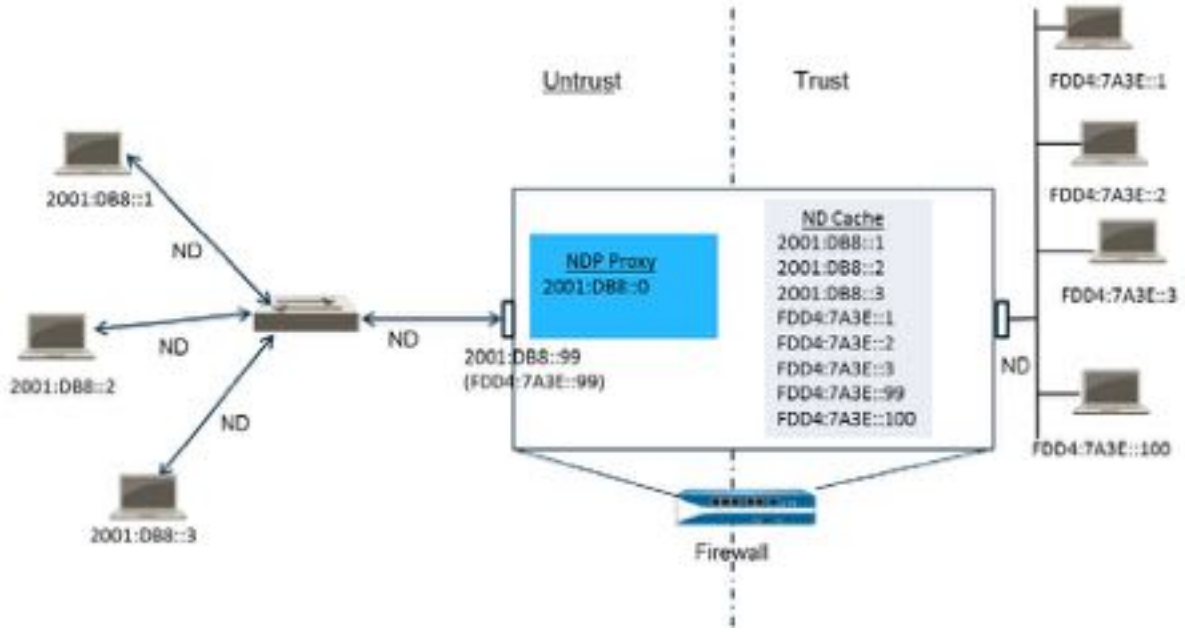
In order to successfully support NDP, the firewall does not perform NDP Proxy for the following:

- Duplicate Address Detection (DAD).
- Addresses in the ND cache (because such addresses do not belong to the firewall; they belong to discovered neighbors).

© Palo Alto Networks, Inc.

## NPTv6 and NDP Proxy Example

The following figure and text illustrate how NPTv6 and NDP Proxy function together.



### The ND Cache in NPTv6 Example

In the above example, multiple peers connect to the firewall though a switch, with ND occurring between the peers and the switch, between the switch and the firewall, and between the firewall and the devices on the trust side.

As the firewall learns of peers, it saves their addresses to its ND cache. Trusted peers FDDA:7A3E::1, FDDA:7A3E::2, and FDDA:7A3E::3 are connected to the firewall on the trust side. FDDA:7A3E::99 is the untranslated address of the firewall itself; its public-facing address is 2001:DB8::99. The addresses of the peers on the untrust side have been discovered and appear in the ND cache: 2001:DB8::1, 2001:DB8::2, and 2001:DB8::3.

### The NDP Proxy in NPTv6 Example

In our scenario, we want the firewall to act as NDP Proxy for the prefixes on devices behind the firewall. When the firewall is NDP Proxy for a specified set of addresses/ranges/prefixes, and it sees an address from this range in an ND solicitation or advertisement, the firewall will respond as long as a device with that specific address doesn't respond first, the address is not negated in the NDP proxy configuration, and the address is not in the ND cache. The firewall does the prefix translation (described below) and sends the packet to the trust side, where that address might or might not be assigned to a device.

 © Palo Alto Networks, Inc.

In this example, the ND Proxy table contains the network address 2001:DB8::0. When the interface sees an ND for 2001:DB8::100, no other devices on the L2 switch claim the packet, so the proxy range causes the firewall to claim it, and after translation to FDD4:7A3E::100, the firewall sends it out to the trust side.

## The NPTv6 Translation in NPTv6 Example

In this example, the **Original Packet** is configured with a **Source Address** of FDD4:7A3E::0 and a **Destination** of **Any**. The **Translated Packet** is configured with the **Translated Address** of 2001:DB8::0.

Therefore, outgoing packets with a source of FDD4:7A3E::0 are translated to 2001:DB8::0. Incoming packets with a destination prefix in the network 2001:DB8::0 are translated to FDD4:7A3E::0.

## Neighbors in the ND Cache are Not Translated

In our example, there are hosts behind the firewall with host identifiers :1, :2, and :3. If the prefixes of those hosts are translated to a prefix that exists beyond the firewall, and if those devices also have host identifiers :1, :2, and :3, because the host identifier portion of the address remains unchanged, the resulting translated address would belong to the existing device, and an addressing conflict would result. In order to avoid a conflict with overlapping host identifiers, NPTv6 does not translate addresses that it finds it its ND cache.

## Create an NPTv6 Policy

Perform this task when you want to configure a NAT NPTv6 policy to translate one IPv6 prefix to another IPv6 prefix. The prerequisites for this task are:

- Enable IPv6. Select **Device > Setup > Session**. Click **Edit** and select **IPv6 Firewalling**.
- Configure a Layer 3 Ethernet interface with a valid IPv6 address and with IPv6 enabled. Select **Network > Interfaces > Ethernet**, select an interface, and on the **IPv6** tab, select **Enable IPv6 on the interface**.
- Create network security policies, because NPTv6 does not provide security.
- Decide whether you want source translation, destination translation, or both.
- Identify the zones to which you want to apply the NPTv6 policy.
- Identify your original and translated IPv6 prefixes.

| **Configure an NPTv6 Policy** | | |
|---|---|---|
| Step 1 | Create a new NPTv6 policy. | 1. Select **Policies** > **NAT** and click **Add**.<br>2. On the **General** tab, enter a descriptive **Name** for the NPTv6 policy rule.<br>3. (Optional) Enter a **Description** and **Tag**.<br>4. For **NAT Type**, select **NPTv6**. |
| Step 2 | Specify the match criteria for incoming packets; packets that match all of the criteria are subject to the NPTv6 translation.<br><br>Zones are required for both types of translation. | 1. On the **Original Packet** tab, for **Source Zone**, leave **Any** or click **Add** to enter the source zone to which the policy applies.<br>2. Enter the **Destination Zone** to which the policy applies.<br>3. (Optional) Select a **Destination Interface**.<br>4. (Optional) Select a **Service** to restrict what type of packets are translated.<br>5. If you are doing source translation, enter a **Source Address** or select **Any**. The address could be an address object. The following constraints apply to **Source Address** and **Destination Address**:<br>• Prefixes of **Source Address** and **Destination Address** for the **Original Packet** and **Translated Packet** must be in the format xxxx:xxxx::/yy, although leading zeros in the prefix can be dropped.<br>• The IPv6 address cannot have an interface identifier (host) portion defined.<br>• The range of supported prefix lengths is /32 to /64.<br>• The **Source Address** and **Destination Address** cannot both be set to **Any**.<br>6. If you are doing source translation, you can optionally enter a **Destination Address**. If you are doing destination translation, the **Destination Address** is required. See the constraints listed in the prior step. |

© Palo Alto Networks, Inc.

| Configure an NPTv6 Policy (Continued) | | |
|---|---|---|
| Step 3 | Specify the translated packet. | 1. On the **Translated Packet** tab, if you want to do source translation, in the Source Address Translation section, for **Translation Type**, select **Static IP**. If you do not want to do source translation, select **None**.<br>2. If you chose **Static IP**, the **Translated Address** field appears. Enter the translated IPv6 prefix or address object. See the constraints listed in Step 5.<br>It is a best practice to configure your **Translated Address** to be the prefix of the untrust interface address of your firewall. For example, if your untrust interface has the address 2001:1a:1b:1::99/64, make your **Translated Address** 2001:1a:1b:1::0/64.<br>3. (Optional) Select **Bi-directional** if you want the firewall to create a corresponding NPTv6 translation in the opposite direction of the translation you configure.<br>If you enable **Bi-directional** translation, it is very important to make sure you have security policies in place to control the traffic in both directions. Without such policies, the **Bi-directional** feature will allow packets to be automatically translated in both directions, which you might not want.<br>4. If you want to do destination translation, select **Destination Address Translation**. In the **Translated Address** field, choose an address object from the drop-down or enter your internal destination address.<br>5. Click **OK**. |
| Step 4 | Configure NDP Proxy.<br>When you configure the firewall to act as an NDP Proxy for addresses, it allows the firewall to send Neighbor Discovery (ND) advertisements and respond to ND solicitations from peers that are asking for MAC addresses of IPv6 prefixes assigned to devices behind the firewall. | 1. Select **Network > Interfaces > Ethernet** and select an interface.<br>2. On the **Advanced** > **NDP Proxy** tab, select **Enable NDP Proxy** and click **Add**.<br>3. Enter the **IP Address(es)** for which NDP Proxy is enabled. It can be an address, a range of addresses, or a prefix and prefix length. The order of IP addresses does not matter. These addresses are ideally the same as the Translated Addresses that you configured in an NPTv6 policy.<br>If the address is a subnet, the NDP Proxy will respond to all addresses in the subnet, so you should list the neighbors in that subnet with **Negate** selected, as described in the next step.<br>4. (Optional) Enter one or more addresses for which you do not want NDP Proxy enabled, and select **Negate**. For example, from an IP address range or prefix range configured in the prior step, you could negate a smaller subset of addresses. It is recommended that you negate the addresses of the neighbors of the firewall. |
| Step 5 | Save the configuration. | Click **OK** and **Commit**. |

# LACP

The firewall can now use Link Aggregation Control Protocol (LACP) to detect the physical interfaces between itself and a connected device (peer) and manage those interfaces as a single virtual interface (aggregate group). An aggregate group increases the bandwidth between peers. Enabling LACP provides redundancy within the group: the protocol automatically detects interface failures and performs failover to standby interfaces. Without LACP, you must manually identify interface failures occurring at layers above the physical or occurring between peers that are not directly connected.

The following Palo Alto Networks firewalls support LACP: PA-500, PA-3000 Series, PA-4000 Series, PA-5000 Series, and PA-7000 Series. The firewalls support LACP for HA3 (only on the PA-500, PA-3000 Series, PA-4000 Series, and PA-5000 Series), Layer 2, and Layer 3 interfaces.

The following topics describe LACP and how to configure it for aggregate groups:

- LACP Settings
- Configure LACP

## LACP Settings

To implement LACP, you must configure an aggregate group on each LACP peer that will use the protocol. Before you Configure LACP, determine the optimal settings for each peer, as described in the following topics:

- Mode
- Transmission Rate
- Fast Failover
- Port Priority and System Priority

### Mode

In LACP active mode, a device actively searches the network for peers and queries their status (available or unresponsive). In passive mode, a device only responds to queries from an active peer. Between any two peers, it is recommended that one be active and the other passive. LACP cannot function if both peers are passive.

### Transmission Rate

You can configure a device to detect the state (available or unresponsive) of peers and individual interfaces at fast (every second) or slow (every 30 seconds) intervals. When the device does not receive an LACP update from the peer within a period that is three times the transmission rate (3 seconds or 90 seconds), it flags the peer as unresponsive. Therefore, set the transmission rate according to how much LACP processing your network can support and how quickly a device should detect and resolve interface failures.

 © Palo Alto Networks, Inc.

For example, in a network where peers have many redundant links, a single interface failure would not disrupt traffic. In this case, a slow rate would suffice for detecting failures and would avoid the extra processing associated with the fast rate. If the network can support the extra processing and requires high availability (for example, datacenters supporting critical business operations), a fast transmission rate would enable the firewall to substitute failed interfaces quicker.

If devices have different transmission rates, each uses the rate of its peer.

## Fast Failover

When an interface goes down, it fails over to a standby interface. The IEEE 802.1ax standard that defines LACP specifies a failover process that takes at least three seconds. For networks that require quicker failover, the firewall provides an option that performs fast failover within one second. This option is recommended for deployments in which critical data might be lost during the standard failover interval. For example, if the amount of traffic between peers is close to the maximum that the active interfaces can support and one interface fails, the risk of data being lost while a standby interface becomes active is significantly less for fast failover than for standard failover.

Because both peers perform failover when an interface goes down, it is recommended that you configure fast failover on both so that they complete the process within the same time frame.

## Port Priority and System Priority

When you configure an aggregate group, the **Max Ports** parameter determines how many interfaces can be active at any given time. If the number of interfaces you assign to the group exceeds the **Max Ports**, the remaining interfaces are in standby mode. If an active interface fails, a standby interface becomes active. LACP uses the **LACP Port Priority** assigned to each interface to determine which interfaces are initially active and to determine the order in which standby interfaces become active upon failover. (You set port priorities when configuring individual interfaces, not when configuring the aggregate group.)

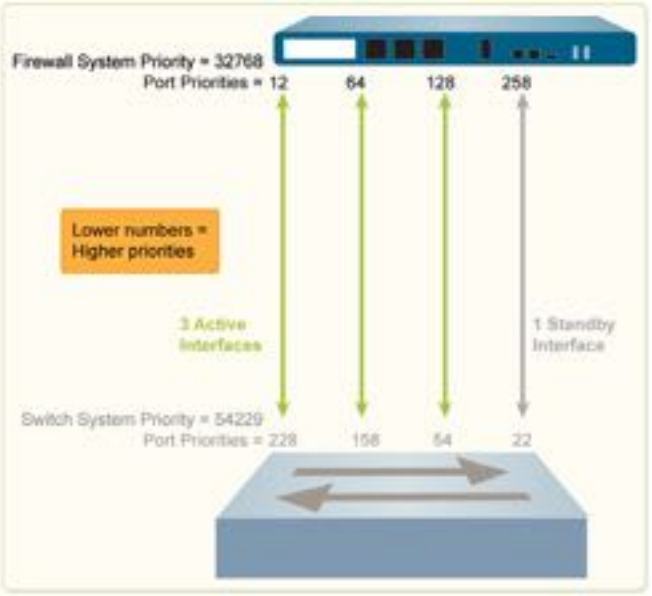
It is recommended that you assign a unique priority number to each interface in an aggregate group. However, if multiple interfaces have the same priority number, the interface with the lowest port number has the highest priority.

To enable LACP between two peers, each requires an aggregate group configuration. If the port priority values for the member interfaces differ in each peer, the values of the peer with the higher **System Priority** will override the other peer in determining active and standby interfaces.

For port and system priorities, the priority level is the inverse of its numerical value: a priority of 1 designates the highest priority level; a value of 65535 designates the lowest priority level. The default is 32768.

The following figure shows an aggregate group instance configured on a firewall and on a switch. The group has four interfaces and the **Max Ports** parameter is set to three. That means three interfaces are active and one is standby. The firewall administrator assigned port priorities 12, 64, 128, and 258 to the interfaces. The switch administrator assigned port priorities 22, 54, 158, and 228 to the interfaces. LACP uses the port priorities of the firewall instance because the **System Priority** of the firewall is higher than that of the switch.

**Figure: LACP System Priority**



It is a best practice to assign a unique system priority to each peer. However, in some cases, peers might have the same value. This could happen if a different administrator configured the aggregate group on each peer. In such cases, the peer for which the *system ID* is a lower numerical value will override the other peer with respect to port priorities. LACP automatically derives the system ID from the system priority and system MAC address. A numerically lower MAC address produces a numerically lower system ID.

The following figure shows the same peers as in Figure: LACP System Priority but with identical system priorities. In this case, LACP uses the system IDs to determine port prioritization: the switch overrides the firewall.

**Figure: LACP System ID**

 © Palo Alto Networks, Inc.

Firewalls in a high availability (HA) pair have the same system priority value. However, in an active/passive deployment, the system ID for each can be the same or different, depending on whether you assign the same MAC address. (Firewalls in an active/active deployment require unique MAC addresses so PAN-OS automatically assigns them.) When the LACP peers (also in HA mode) are virtualized (appearing to the network as a single device), selecting the **Same System MAC Address for Active-Passive HA** option for the firewalls is a best practice to minimize latency during failover. When the LACP peers are not virtualized, using the unique MAC address of each firewall is the best practice to minimize failover latency. In the latter case, if the HA firewall pair and the LACP peer devices all have the same system priority but each firewall in the HA pair has a unique system ID, one firewall might have a lower system ID than the LACP peers while the other firewall has a higher system ID than the LACP peers. In this case, when failover occurs on the firewalls, port prioritization switches between the LACP peers and the firewall that becomes active.

## Configure LACP

Before starting this procedure:

- Determine which physical interfaces connect the LACP peers. This procedure assumes the cabling is complete.
- Determine the optimal LACP Settings for the peers.

This procedure only covers the configuration steps for an LACP peer that is a Palo Alto Networks firewall. Other devices have proprietary methods for configuring LACP.

Perform the following steps to configure LACP on a firewall. In a high availability deployment, configure the primary (for active/active) or active (for active/passive) firewall; the secondary or passive firewall automatically synchronizes with it.

| Configure LACP | |
|---|---|
| Step 1 Add an aggregate group with LACP enabled. | 1. Select **Network > Interfaces > Ethernet** and click **Add Aggregate Group**.<br>2. In the field adjacent to the read-only **Interface Name**, enter a number (1-8) to identify the group.<br>3. For the **Interface Type**, select **HA**, **Layer 2**, or **Layer 3**.<br>Only select **HA** if the interface is an HA3 link between two firewalls in an active/active deployment.<br>4. On the **LACP** tab, select **Enable LACP**.<br>5. For the LACP **Mode**, select whether the firewall is **Passive** (default) or **Active**.<br>6. For the **Transmission Rate**, select **Fast** or **Slow**.<br>7. If desired, select **Fast Failover** (under one second) for when interfaces go down. Otherwise, the standard failover (at least three seconds) applies.<br>8. Enter a **System Priority** number (1-65535, default 32768) that determines whether the firewall or peer overrides the other with respect to port priorities. Note that the lower the number, the higher the priority.<br>9. For the **Max Ports**, enter the number of interfaces (1-8) that are active. The value cannot exceed the number of interfaces you assign to the group. If the number of assigned interfaces exceeds the number of active interfaces, the remaining interfaces will be in standby mode.<br>10. By default, each firewall in an HA pair has a unique MAC address. A **Same System MAC Address for Active-Passive HA** configuration is recommended only when the LACP peers are virtualized (appearing to the network as a single device). In such cases, select the check box and select the system-generated **MAC Address**, or enter your own. You must verify the address is globally unique.<br>If the firewalls are not in active/passive HA mode, PAN-OS ignores your selections for these fields. Firewalls in an active/active deployment require unique MAC addresses so PAN-OS automatically assigns them. If the **Interface Type** is **HA**, these fields do not appear.<br>11. Click **OK**. |

 © Palo Alto Networks, Inc.

| Configure LACP (Continued) | | |
|---|---|---|
| Step 2 | Assign interfaces to the aggregate group. | Perform the following steps for each physical interface (1-8) that will belong to the aggregate group.<br>During normal operations, assign more than one interface. You would only assign a single interface if a troubleshooting procedure requires it.<br>1. Select **Network > Interfaces** and select the interface name. It must be the same type (HA, Layer 2, or Layer 3) as the aggregate group.<br>2. Change the **Interface Type** to **Aggregate Ethernet**.<br>3. Select the **Aggregate Group** you just defined.<br>4. Select the **Link Speed**, **Link Duplex**, and **Link State**. It is a best practice to set the same link speed and duplex values for every interface in the group. For non-matching values, the commit operation displays a warning and PAN-OS defaults to the higher speed and full duplex.<br>5. Enter an **LACP Port Priority** (1-65535, default 32768). If the number of interfaces you assign exceeds the **Max Ports** value you configured for the group, the port priorities determine which interfaces are active or standby. The lower the numeric value, the higher the priority.<br>6. Click **OK** and **Commit**. |
| Step 3 | Verify the status of the aggregate group. | 1. Select **Network > Interfaces > Ethernet**.<br>2. Verify that the Features column displays an LACP enabled icon for the aggregate group.<br>3. Verify that the Link State column displays a green icon for the aggregate group, indicating that all member interfaces are up. If the icon is yellow, at least one member is down but not all. If the icon is red, all members are down.<br>4. If the Link State icon for the aggregate group is yellow or red, select **Monitor > Logs > System** and review the logs for the LACP subtype to investigate the causes of the interface failures. |
| Step 4 | (Optional) If you selected **HA** as the **Interface Type** for the aggregate group, enable forwarding of packets over the HA3 link. | 1. Select **Device > High Availability > Active/Active Config** and edit the Packet Forwarding section.<br>2. For the **HA3 Interface**, select the aggregate group you configured.<br>3. Click **OK** and **Commit**. |

# ECMP

Equal Cost Multiple Path (ECMP) processing is a networking feature that enables the firewall to use up to four equal-cost routes to the same destination. Without this feature, if there are multiple equal-cost routes to the same destination, the virtual router chooses one of those routes from the routing table and adds it to its forwarding table; it will not use any of the other routes unless there is an outage in the chosen route.

Enabling ECMP functionality on a virtual router allows the firewall to have up to four equal-cost paths to a destination in its forwarding table, allowing the firewall to:

- Load balance flows (sessions) to the same destination over multiple equal-cost links.
- Efficiently use all available bandwidth on links to the same destination rather than leave some links unused.
- Dynamically shift traffic to another ECMP member to the same destination if a link fails, rather than having to wait for the routing protocol or RIB table to elect an alternative path/route. This can help reduce downtime when links fail.

The following sections describe ECMP and how to configure it.

- ECMP Load-Balancing Algorithms
- ECMP Platform, Interface, and IP Routing Support
- HA Active/Active Failover Behavior with ECMP
- Configure ECMP on a Virtual Router
- Enable ECMP for Multiple BGP Autonomous Systems
- Verify ECMP

 © Palo Alto Networks, Inc.

## ECMP Load-Balancing Algorithms

Let's suppose the Routing Information Base (RIB) of the firewall has multiple equal-cost paths to a single destination. The maximum number of equal-cost paths defaults to 2. ECMP chooses the best two equal-cost paths from the RIB to copy to the Forwarding Information Base (FIB). ECMP then determines, based on the load-balancing method, which of the two paths in the FIB that the firewall will use for the destination during this session.

ECMP load balancing is done at the session level, not at the packet level—the start of a new session is when the firewall (ECMP) chooses an equal-cost path. The equal-cost paths to a single destination are considered ECMP path members or ECMP group members. ECMP determines which one of the multiple paths to a destination in the FIB to use for an ECMP flow, based on which load-balancing algorithm you set. A virtual router can use only one load-balancing algorithm.

Enabling, disabling, or changing ECMP on an existing virtual router causes the system to restart the virtual router, which might cause existing sessions to be terminated.

The four algorithm choices emphasize different priorities, as follows:

- **Hash-based algorithms prioritize session stickiness**—The **IP Modulo** and **IP Hash** algorithms use hashes based on information in the packet header, such as source and destination address. Because the header of each flow in a given session contains the same source and destination information, these options prioritize session *stickiness*. If you choose the **IP Hash** algorithm, you can optionally set a **Hash Seed** value to further randomize load balancing if you have a large number of sessions to the same destination and they're not being distributed evenly over the ECMP links.

- **Balanced algorithm prioritizes load balancing**—The **Balanced Round Robin** algorithm distributes incoming sessions equally across the links, favoring load balancing over session stickiness. (Round robin indicates a sequence in which the least recently chosen item is chosen.) In addition, if new routes are added or removed from an ECMP group (for example if a path in the group goes down), the virtual router will re-balance the sessions across links in the group. Additionally, if the flows in a session have to switch routes due to an outage, when the original route associated with the session becomes available again, the flows in the session will revert to the original route when the virtual router once again re-balances the load.

- **Weighted algorithm prioritizes link capacity and/or speed**—As an extension to the ECMP protocol standard, the Palo Alto Networks implementation provides for a **Weighted Round Robin** load-balancing option that takes into account differing link capacities and speeds on the egress interfaces of the firewall. With this option, you can assign **ECMP Weights** (range is 1-255; default is 100) to the interfaces based on link performance using factors such as link capacity, speed, and latency to ensure that loads are balanced to fully leverage the available links.

  For example, suppose the firewall has redundant links to an ISP: ethernet1/1 (100 Mbps) and ethernet1/8 (200 Mbps). Although these are equal-cost paths, the link via ethernet1/8 provides greater bandwidth and therefore can handle a greater load than the ethernet1/1 link. Therefore, to ensure that the load-balancing functionality takes into account link capacity and speed, you might assign ethernet1/8 a weight of 200 and ethernet1/1 a weight of 100. The 2:1 weight ratio causes the virtual router to send twice as many sessions to ethernet1/8 as it sends to ethernet1/1. However, because the ECMP protocol is inherently session-based, when using the **Weighted Round Robin** algorithm, the firewall will be able to load balance across the ECMP links only on a best-effort basis.

© Palo Alto Networks, Inc.

Assign lower-speed or lower-capacity links with a lower weight. Assign higher-speed or higher-capacity links with a higher weight. In this manner, the firewall can distribute sessions based on these ratios, rather than overdrive a low-capacity link that is one of the equal-cost paths.

Keep in mind that ECMP weights are assigned to interfaces to determine load balancing (to influence which *equal-cost* path is chosen), not for route selection (a route choice from routes that could have different costs).

 © Palo Alto Networks, Inc.

## ECMP Platform, Interface, and IP Routing Support

ECMP is supported on all Palo Alto Networks firewall platforms, with hardware forwarding support on the PA-7000 Series, PA-5000 Series, PA-3060 firewalls, and PA-3050 firewalls. PA-3020 firewalls, PA-500 firewalls, PA-200 firewalls, and VM-Series firewalls support ECMP through software only. Performance is affected for sessions that cannot be hardware offloaded.

ECMP is supported on Layer 3, Layer 3 subinterface, VLAN, tunnel, and Aggregated Ethernet interfaces.

ECMP can be configured for static routes and any of the dynamic routing protocols the firewall supports.

ECMP affects the route table capacity because the capacity is based on the number of paths, so an ECMP route with four paths will consume four entries of route table capacity. ECMP implementation might slightly decrease the route table capacity because more memory is being used by session-based tags to map traffic flows to particular interfaces.

ECMP has the following restrictions:

- PA-2000 Series firewalls and PA-4000 Series firewalls with ECMP enabled might not be able to offload sessions to hardware for forwarding. Packets matching ECMP routes will be sent to software, while packets matching non-ECMP routes can still be forwarded by hardware.
- For the PA-4000 Series firewalls, packets to be forwarded by ECMP routes will be sent to software for route lookup and forwarding, even though the session is in offloaded state.
- Virtual router-to-virtual router routing using static routes does not support ECMP.

© Palo Alto Networks, Inc.

## HA Active/Active Failover Behavior with ECMP

In the event of a failover in a high availability (HA) active/active configuration, the sessions on the failed peer are transferred to the HA peer. When this happens, the new active primary device tries to use the same egress interface that the former failed active/active device was using. If such interface is found among the ECMP paths, the transferred sessions will take the same egress interface and path. This behavior takes place regardless of the ECMP algorithm in use; using the same interface is desirable.

Only if no ECMP path matches the original egress interface will the active-primary select a new ECMP path.

In an HA active/active configuration, if you did not configure the same interfaces on both peers, when a failover occurs, the active-primary will select the next best path from the FIB table. In this scenario, the existing sessions might not be distributed according to the ECMP algorithm.

## Configure ECMP on a Virtual Router

Use the following procedure to enable ECMP on a virtual router. The prerequisites are to:

- ❒ Specify the interfaces that belong to a virtual router (**Network > Virtual Routers > Router Settings > General**).
- ❒ Specify the IP routing protocol.

Enabling, disabling, or changing ECMP for an existing virtual router causes the system to restart the virtual router, which might cause sessions to be terminated.

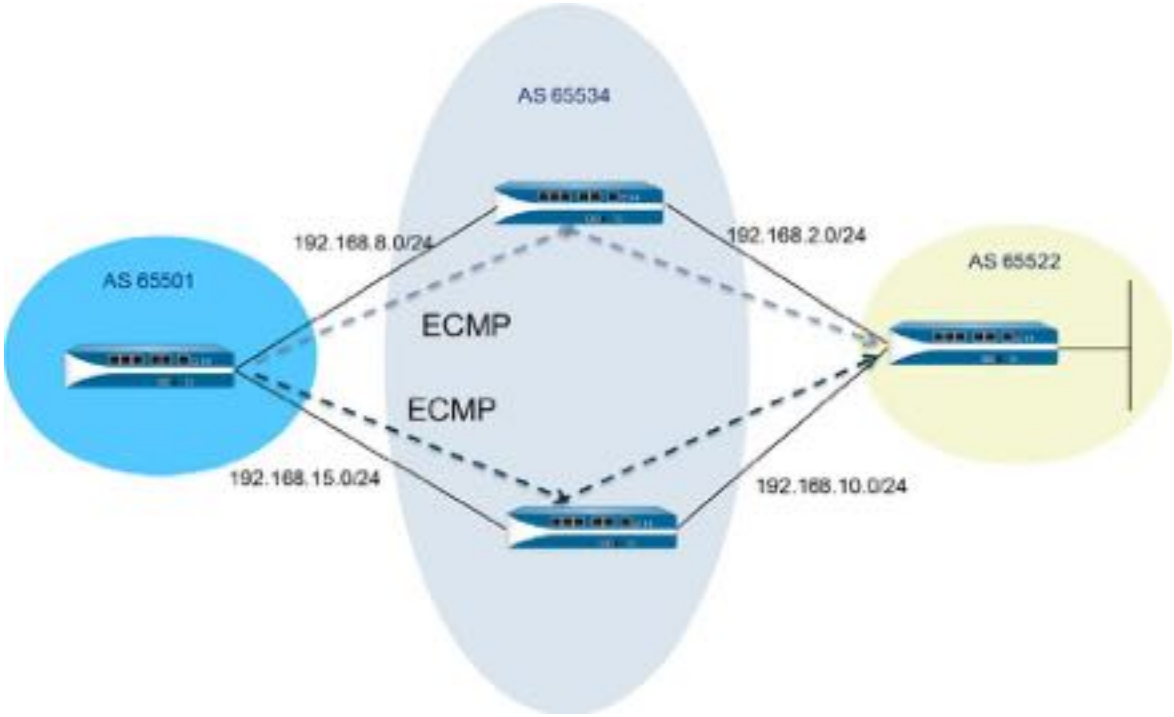
| **Configure ECMP on a Virtual Router** | | |
|---|---|---|
| Step 1 | Enable ECMP for a virtual router. | 1. Select **Network > Virtual Routers** and select the virtual router on which to enable ECMP.<br>2. Select **Router Settings > ECMP** and select the **Enable** check box. |
| Step 2 | (Optional) Enable symmetric return of packets from server to client. | (Optional) Select the **Symmetric Return** check box to cause return packets to egress out the same interface on which the associated ingress packets arrived. That is, the firewall will use the ingress interface on which to send return packets, rather than use the ECMP interface. The **Symmetric Return** setting overrides load balancing. This behavior occurs only for traffic flows from the server to the client. |
| Step 3 | Specify the maximum number of equal-cost paths (to a destination network) that can be copied from the Routing Information Base (RIB) to the Forwarding Information Base (FIB). | For **Max Path** allowed, enter **2**, **3**, or **4**. Default: 2. |
| Step 4 | Select the load-balancing algorithm for the virtual router. For more information on load-balancing methods and how they differ, see ECMP Load-Balancing Algorithms. | For **Load Balance**, select one of the following options from the **Method** drop-down:<br>• **IP Modulo** (default)—Uses a hash of the source and destination IP addresses in the packet header to determine which ECMP route to use.<br>• **IP Hash**—Uses a hash of the source and destination IP addresses and optionally the source and destination port numbers in the packet header to determine which ECMP route to use. Specify options in Step 5 below.<br>• **Balanced Round Robin**—Uses round robin among the ECMP paths and re-balances paths when the number of paths changes.<br>• **Weighted Round Robin**—Uses round robin and a relative weight to select from among ECMP paths. Specify the weights in Step 6 below. |

| Configure ECMP on a Virtual Router (Continued) | |
|---|---|
| Step 5 (Optional) (**IP Hash** only) Configure IP Hash options. | If you selected **IP Hash** as the **Method**:<br>1. Check the **Use Source/Destination Ports** check box if you want to use source or destination port numbers in the **IP Hash** calculation.<br>2. Enter a **Hash Seed** value (an integer with a maximum of 9 digits). Specify a **Hash Seed** value to further randomize load balancing. Specifying a hash seed value is useful if you have a large number of sessions with the same tuple information. |
| Step 6 (**Weighted Round Robin** only) Define a weight for each interface in the ECMP group. | If you selected **Weighted Round Robin** as the **Method**, define a weight for each of the interfaces that are the egress points for traffic to be routed to the same destinations (that is, interfaces that are part of an ECMP group, such as the interfaces that provide redundant links to your ISP or interfaces to the core business applications on your corporate network).<br>The higher the weight, the more often that equal-cost path will be selected for a new session.<br>A higher speed link should be given a higher weight than a slower link so that more of the ECMP traffic goes over the faster link.<br>1. Create an ECMP group by clicking **Add** and selecting an **Interface** from the drop-down.<br>2. **Add** the other interfaces in the ECMP group.<br>3. Click on **Weight** and specify the relative weight for each interface (range is 1-255; default is 100). |
| Step 7 Save the configuration. | 1. Click **OK**.<br>2. Click **Yes** to restart the virtual router. Restarting the virtual router might cause existing sessions to be terminated.<br> <br>This message displays only if you are modifying an existing virtual router with ECMP. |
| Step 8 Save the configuration. | **Commit** the configuration. |

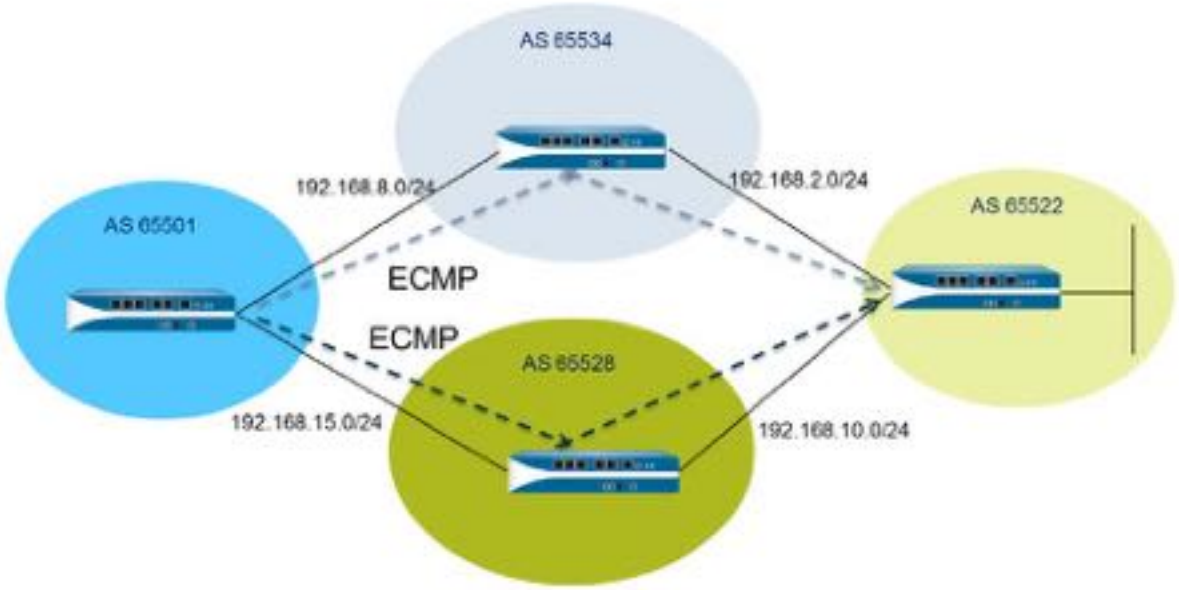
 © Palo Alto Networks, Inc.

## Enable ECMP for Multiple BGP Autonomous Systems

Perform the following task if you have BGP configured, and you want to enable ECMP over multiple autonomous systems. This task presumes that BGP is already configured. In the following figure, two ECMP paths to a destination go through two firewalls belonging to a single ISP in a single BGP autonomous system.



In the following figure, two ECMP paths to a destination go through two firewalls belonging to two different ISPs in different BGP autonomous systems.



| Enable ECMP for BGP Autonomous Systems | | |
|---|---|---|
| Step 1 | Configure ECMP. | See Configure ECMP on a Virtual Router. |
| Step 2 | For BGP routing, enable ECMP over multiple autonomous systems. | 1. Select **Network > Virtual Routers** and select the virtual router on which to enable ECMP for multiple BGP autonomous systems.<br>2. Select **BGP > Advanced** and select the **ECMP Multiple AS Support** check box. |
| Step 3 | Save the configuration. | Click **OK** and **Commit** the configuration. |

 © Palo Alto Networks, Inc.

## Verify ECMP

A virtual router configured for ECMP indicates in the Forwarding Information Base (FIB) table which routes are ECMP routes. An ECMP flag (E) for a route indicates that it is participating in ECMP for the egress interface to the next hop for that route.

| **Confirm That Routes Are Equal-Cost Multiple Paths** | |
|---|---|
| Look at the FIB and confirm that some routes are equal-cost multiple paths. | 1. Select **Network > Virtual Routers**.<br>2. In the row of the virtual router for which you enabled ECMP, click **More Runtime Stats**.<br>3. Select **Routing** > **Forwarding Table** to see the FIB. In the table, note that multiple routes to the same Destination (out a different Interface) have the "E" flag.<br>An asterisk "*" denotes the preferred path for the ECMP group. |

# LLDP

Palo Alto Networks firewalls support Link Layer Discovery Protocol (LLDP), which functions at the link layer to discover neighboring devices and their capabilities. LLDP allows the firewall and other network devices to send and receive LLDP data units (LLDPDUs) to and from neighbors. The receiving device stores the information in a MIB, which the Simple Network Management Protocol (SNMP) can access. LLDP makes troubleshooting easier, especially for virtual wire deployments where the firewall would typically go undetected by a ping or traceroute.

- LLDP Overview
- Supported TLVs in LLDP
- LLDP Syslog Messages and SNMP Traps
- Configure LLDP
- View LLDP Settings and Status
- Clear LLDP Statistics

 © Palo Alto Networks, Inc.

## LLDP Overview

LLDP operates at Layer 2 of the OSI model, using MAC addresses. An LLDPDU is a sequence of type-length-value (TLV) elements encapsulated in an Ethernet frame. The IEEE 802.1AB standard defines three MAC addresses for LLDPDUs: 01-80-C2-00-00-0E, 01-80-C2-00-00-03, and 01-80-C2-00-00-00.

The Palo Alto Networks firewall supports only one MAC address for transmitting and receiving LLDP data units: 01-80-C2-00-00-0E. When transmitting, the firewall uses 01-80-C2-00-00-0E as the destination MAC address. When receiving, the firewall processes datagrams with 01-80-C2-00-00-0E as the destination MAC address. If the firewall receives either of the other two MAC addresses for LLDPDUs on its interfaces, the firewall takes the same forwarding action it took prior to this feature, as follows:

- If the interface type is vwire, the firewall forwards the datagram to the other port.
- If the interface type is L2, the firewall floods the datagram to the rest of the VLAN.
- If the interface type is L3, the firewall drops the datagrams.

The PA-2000 Series platform is not supported due to the hardware limitation of how Aggregated Ethernet interfaces function. Panorama, the GlobalProtect Mobile Security Manager, and the WildFire appliance are also not supported.

Interface types that do not support LLDP are TAP, high availability (HA), Decrypt Mirror, virtual wire/vlan/L3 subinterfaces, and PA-7000 Series Log Processing Card (LPC) interfaces.

An LLDP Ethernet frame has the following format:

| Preamble | Destination MAC | Source MAC | Ethertype | Chassis ID TLV | Port ID TLV | Time To Live TLV | Optional TLVs | End of LLDPDU TLV | Frame Check Sequence |
|---|---|---|---|---|---|---|---|---|---|
| | 01:80:C2:00:00:0E or 01:80:C2:00:00:03 or 01:80:C2:00:00:00 | Station's Address | 0x88CC | Type=1 | Type=2 | Type=3 | Zero or more complete TLVs | Type=0, Length=0 | |

Within the LLDP Ethernet frame, the TLV structure has the following format:

| TLV Type | TLV Information String Length | TLV Information String |
|---|---|---|
| 7 bits | 9 bits | 0-511 octets |

## Supported TLVs in LLDP

LLDPDUs include mandatory and optional TLVs. The following table lists the mandatory TLVs that the firewall supports:

**Mandatory TLVs in an LLDPDU Message**

| Mandatory TLVs | TLV Type | Description |
|---|---|---|
| Chassis ID TLV | 1 | Identifies the firewall chassis. Each firewall must have exactly one unique Chassis ID. The Chassis ID subtype is 4 (MAC address) on Palo Alto Networks platforms will use the MAC address of Eth0 to ensure uniqueness. |
| Port ID TLV | 2 | Identifies the port from which the LLDPDU is sent. Each firewall uses one Port ID for each LLDPDU message transmitted. The Port ID subtype is 5 (interface name) and uniquely identifies the transmitting port. The firewall uses the interface's ifname as the Port ID. |
| Time-to-live (TTL) TLV | 3 | Specifies how long (in seconds) LLDPDU information received from the peer is retained as valid in the local firewall (range is 0-65535). The value is a multiple of the LLDP Hold Time Multiplier. When the TTL value is 0, the information associated with the device is no longer valid and the firewall removes that entry from the MIB. |
| End of LLDPDU TLV | 0 | Indicates the end of the TLVs in the LLDP Ethernet frame. |

The following table lists the optional TLVs that the Palo Alto Networks firewall supports:

**Optional TLVs in an LLDPDU Message**

| Optional TLVs | TLV Type | Purpose and Notes Regarding Firewall Implementation |
|---|---|---|
| Port Description TLV | 4 | Describes the port of the firewall in alpha-numeric format. The ifAlias object is used. |
| System Name TLV | 5 | Configured name of the firewall in alpha-numeric format. The sysName object is used. |
| System Description TLV | 6 | Describes the firewall in alpha-numeric format. The sysDescr object is used. |
| System Capabilities | 7 | Describes the deployment mode of the interface, as follows:<br>• An L3 interface is advertised with router (bit 6) capability and the "other" bit (bit 1).<br>• An L2 interface is advertised with MAC Bridge (bit 3) capability and the "other" bit (bit 1).<br>• A virtual wire interface is advertised with Repeater (bit 2) capability and the "other" bit (bit 1). |

© Palo Alto Networks, Inc.

**Optional TLVs in an LLDPDU Message (Continued)**

| Optional TLVs | TLV Type | Purpose and Notes Regarding Firewall Implementation |
|---|---|---|
| Management Address | 8 | One or more IP addresses used for the management of the device, as follows:<br>• IP address of the management (MGT) interface<br>• IPv4 and/or IPv6 address of the interface<br>• Loopback address<br>• User-defined address entered in the management address field<br>If no management IP address is provided, the default is the MAC address of the transmitting interface.<br>Included is the interface number of the management address specified. Also included is the OID of the hardware interface with the management address specified (if applicable).<br>If more than one management address is specified, they will be sent in the order they are specified, starting at the top of the list. A maximum of four Management Addresses are supported.<br>This is an optional parameter and can be left disabled. |

## LLDP Syslog Messages and SNMP Traps

The firewall stores LLDP information in MIBs, which an SNMP Manager can monitor. If you want the firewall to send SNMP trap notifications and syslog messages about LLDP events, you must enable **SNMP Syslog Notification** in an LLDP profile.

Per RFC 5424, The Syslog Protocol, and RFC 1157, A Simple Network Management Protocol, LLDP sends syslog and SNMP trap messages when MIB changes occur. These messages are rate-limited by the **Notification Interval**, an LLDP global setting that defaults to 5 seconds and is configurable.

Because the LLDP syslog and SNMP trap messages are rate-limited, some LLDP information provided to those processes might not match the current LLDP statistics seen when you View the LLDP status information. This is normal, expected behavior.

A maximum of 5 MIBs can be received per interface (Ethernet or AE). Each different source has one MIB. If this limit is exceeded, the error message `tooManyNeighbors` is triggered.

 © Palo Alto Networks, Inc.

# Configure LLDP

To configure LLDP, and create an LLDP profile, you must be a superuser or device administrator (deviceadmin). A firewall interface supports a maximum of five LLDP peers.

| Configure LLDP | | |
|---|---|---|
| Step 1 | Enable LLDP on the firewall. | Select **Network > LLDP** and edit the LLDP General section; select the **Enable** check box. |
| Step 2 | (Optional) Change LLDP global settings. | 1. For **Transmit Interval (sec)**, specify the interval (in seconds) at which LLDPDUs are transmitted. Default: 30 seconds. Range: 1-3600 seconds.<br>2. For **Transmit Delay (sec)**, specify the delay time (in seconds) between LLDP transmissions sent after a change is made in a TLV element. The delay helps to prevent flooding the segment with LLDPDUs if many network changes spike the number of LLDP changes, or if the interface flaps. The **Transmit Delay** must be less than the **Transmit Interval**. Default: 2 seconds. Range: 1-600 seconds.<br>3. For **Hold Time Multiple**, specify a value that is multiplied by the **Transmit Interval** to determine the total TTL Hold Time. Default: 4. Range: 1-100. The maximum TTL Hold Time is 65535 seconds, regardless of the multiplier value.<br>4. For **Notification Interval**, specify the interval (in seconds) at which LLDP Syslog Messages and SNMP Traps are transmitted when MIB changes occur. Default: 5 seconds. Range: 1-3600 seconds.<br>5. Click **OK**. |

| Configure LLDP | |
|---|---|
| Step 3 Create an LLDP profile.<br>For descriptions of the optional TLVs, see Supported TLVs in LLDP. | 1. Select **Network > Network Profiles > LLDP Profile** and click **Add**.<br>2. Enter a **Name** for the LLDP profile.<br>3. For **Mode**, select **transmit-receive** (default), **transmit-only**, or **receive-only**.<br>4. Click the **SNMP Syslog Notification** check box to enable SNMP notifications and syslog messages. If enabled, the global **Notification Interval** is used. The firewall will send both an SNMP trap and a syslog event as configured in the **Device > Log Settings > System > SNMP Trap Profile** and **Syslog Profile**.<br>5. For Optional TLVs, select the TLVs you want transmitted:<br>• **Port Description**<br>• **System Name**<br>• **System Description**<br>• **System Capabilities**<br>6. Specifying a **Management Address** is optional. To add one or more, select the check box and **Add** a **Name**.<br>7. Select the **Interface** from which to obtain the management address. At least one management address is required if **Management Address** TLV is enabled. If no management IP address is configured, the system uses the MAC address of the transmitting interface as the management address TLV.<br>8. Select **IPv4** or **IPv6**, and in the adjacent field, select an IP address from the drop-down (which lists the addresses configured on the selected interface), or enter an address.<br>9. Click **OK**.<br>10. Up to four management addresses are allowed. If you specify more than one **Management Address**, they will be sent in the order they are specified, starting at the top of the list. To change the order of the addresses, select an address and use the **Move Up** or **Move Down** buttons.<br>11. Click **OK**. |
| Step 4 Assign an LLDP profile to an interface. | 1. Select **Network > Interfaces** and select the interface where you will assign an LLDP profile.<br>2. Select **Advanced > LLDP**.<br>3. Select the **Enable LLDP** check box to assign an LLDP profile to the interface.<br>4. For **Profile**, select the profile you created. Selecting **None** enables LLDP with basic functionality: sends the three mandatory TLVs and enables **transmit-receive** mode.<br>If you want to create a new profile, click **LLDP Profile** and follow the instructions in Step 4.<br>5. Click **OK**. |
| Step 5 Save the configuration. | Click **Commit**. |

© Palo Alto Networks, Inc.

## View LLDP Settings and Status

Perform the following procedure to view LLDP settings and status.

| View LLDP Settings and Status | |
|---|---|
| Step 1 View LLDP global settings. | 1. Select **Network > LLDP**.<br>• On the LLDP General screen, the **Enable** check box indicates whether LLDP is enabled or not.<br>– If LLDP is enabled, the configured global settings (Transmit Interval, Transmit Delay, Hold Time Multiple, and Notification Interval) are displayed.<br>– If LLDP is not enabled, the default values of the global settings are displayed.<br>For descriptions of these values, see (Optional) Change LLDP global settings. |

| View LLDP Settings and Status (Continued) | |
|---|---|
| Step 2 View the LLDP status information. | 1. Select the **Status** tab.<br>2. (Optional) Enter a filter to restrict the information that is displayed.<br>Interface Information:<br>• **Interface**—Name of the interfaces that have LLDP profiles assigned to them.<br>• **LLDP**—LLDP status: enabled or disabled.<br>• **Mode**— LLDP mode of the interface: Tx/Rx, Tx Only, or Rx Only.<br>• **Profile**—Name of the profile assigned to the interface.<br>Transmission Information:<br>• **Total Transmitted**—Count of LLDPDUs transmitted out the interface.<br>• **Dropped Transmit**—Count of LLDPDUs that were not transmitted out the interface because of an error. For example, a length error when the system is constructing an LLDPDU for transmission.<br>Received Information:<br>• **Total Received**—Count of LLDP frames received on the interface.<br>• **Dropped TLV**—Count of LLDP frames discarded upon receipt.<br>• **Errors**—Count of TLVs that were received on the interface and contained errors. Types of TLV errors include: one or more mandatory TLVs missing, out of order, containing out-of-range information, or length error.<br>• **Unrecognized**—Count of TLVs received on the interface that are not recognized by the LLDP local agent. For example, the TLV type is in the reserved TLV range.<br>• **Aged Out**—Count of items deleted from the Receive MIB due to proper TTL expiration. |

© Palo Alto Networks, Inc.

| View LLDP Settings and Status (Continued) | |
|---|---|
| Step 3 View summary LLDP information for each neighbor seen on an interface. | 1. Select the **Peers** tab.<br>2. Optionally enter a filter to restrict the information being displayed.<br>• Local Interface—Interface on the firewall that detected the neighboring device.<br>• Remote Chassis ID—Chassis ID of the peer. The MAC address will be used.<br>• Port ID—Port ID of the peer.<br>• Name—Name of peer.<br>• More info—Provides the following remote peer details, which are based on the Mandatory and Optional TLVs:<br>– Chassis Type: MAC address.<br>– MAC Address: MAC address of the peer.<br>– System Name: Name of the peer.<br>– System Description: Description of the peer.<br>– Port Description: Port description of the peer.<br>– Port Type: Interface name.<br>– Port ID: The firewall uses the interface's ifname.<br>– System Capabilities: Capabilities of the system. O=Other, P=Repeater, B=Bridge, W=Wireless-LAN, R=Router, T=Telephone<br>– Enabled Capabilities: Capabilities enabled on the peer.<br>– Management Address: Management address of the peer. |

## Clear LLDP Statistics

You can clear LLDP statistics for specific interfaces.

| Clear LLDP Statistics | | |
|---|---|---|
| Step 1 | Clear LLDP statistics for specific interfaces. | 1. Select **Network > LLDP > Status** and in the left hand column, select one or more interfaces for which you want to clear LLDP statistics.<br>2. Click **Clear LLDP Statistics** at the bottom of the screen. |

# Policy

Policies allow you to enforce rules and take action. The different types of policy rules that you can create on the firewall are: Security, NAT, Quality of Service (QoS), Policy Based Forwarding (PBF), Decryption, Application Override, Captive Portal, Denial of Service (DoS), and Zone protection policies. All these different policies work together to allow, deny, prioritize, forward, encrypt, decrypt, make exceptions, authenticate access, and reset connections as needed to help secure your network. The following topics describe how to work with policy:

- Policy Types
- Security Policy
- Policy Objects
- Security Profiles
- Enumeration of Rules Within a Rulebase
- Move or Clone a Policy Rule or Object to a Different Virtual System
- Use Tags to Group and Visually Distinguish Objects
- Use a Dynamic Block List in Policy
- Register IP Addresses and Tags Dynamically
- Monitor Changes in the Virtual Environment
- CLI Commands for Dynamic IP Addresses and Tags
- Identify Users Connected through a Proxy Server
- Policy-Based Forwarding
- DoS Protection Against Flooding of New Sessions

© Palo Alto Networks, Inc.

# Policy Types

The Palo Alto Networks next-generation firewall supports a variety of policy types that work together to safely enable applications on your network.

| Policy Type | Description |
|---|---|
| Security | Determine whether to block or allow a session based on traffic attributes such as the source and destination security zone, the source and destination IP address, the application, user, and the service. For more details, see Security Policy. |
| NAT | Instruct the firewall which packets need translation and how to do the translation. The firewall supports both source address and/or port translation and destination address and/or port translation. For more details, see NAT. |
| QoS | Identify traffic requiring QoS treatment (either preferential treatment or bandwidth-limiting) using a defined parameter or multiple parameters and assign it a class. For more details, see Quality of Service. |
| Policy Based Forwarding | Identify traffic that should use a different egress interface than the one that would normally be used based on the routing table. For details, see Policy-Based Forwarding. |
| Decryption | Identify encrypted traffic that you want to inspect for visibility, control, and granular security. For more details, see Decryption. |
| Application Override | Identify sessions that you do not want processed by the App-ID engine, which is a Layer-7 inspection. Traffic matching an application override policy forces the firewall to handle the session as a regular stateful inspection firewall at Layer-4. For more details, see Manage Custom or Unknown Applications. |
| Captive Portal | Identify traffic that requires the user to be known. The captive portal policy is only triggered if other User-ID mechanisms did not identify a user to associate with the source IP address. For more details, see Captive Portal. |
| DoS Protection | Identify potential denial-of-service (DoS) attacks and take protective action in response to rule matches. DoS Protection Profiles. |

© Palo Alto Networks, Inc.

# Security Policy

Security policies protect network assets from threats and disruptions and aid in optimally allocating network resources for enhancing productivity and efficiency in business processes. On the Palo Alto Networks firewall, security policies determine whether to block or allow a session based on traffic attributes such as the source and destination security zone, the source and destination IP address, the application, user, and the service.

All traffic passing through the firewall is matched against a session and each session is matched against a security policy. When a session match occurs, the security policy is applied to bi-directional traffic (client to server and server to client) in that session. For traffic that doesn't match any defined rules, the default rules apply. The default rules—displayed at the bottom of the security rulebase—are predefined to allow all intrazone (within the zone) traffic and deny all interzone (between zones) traffic. Although these rules are part of the pre-defined configuration and are read-only by default, you can override them and change a limited number of settings, including the tags, action (allow or block), log settings, and security profiles.

Security policies are evaluated left to right and from top to bottom. A packet is matched against the first rule that meets the defined criteria; after a match is triggered the subsequent rules are not evaluated. Therefore, the more specific rules must precede more generic ones in order to enforce the best match criteria. Traffic that matches a rule generates a log entry at the end of the session in the traffic log, if logging is enabled for that rule. The logging options are configurable for each rule, and can for example be configured to log at the start of a session instead of, or in addition to, logging at the end of a session.

- Components of a Security Policy Rule
- Security Policy Best Practices

# Components of a Security Policy Rule

The security policy rule construct permits a combination of the required and optional fields as detailed in the following tables:

- Required Fields
- Optional Fields

## Required Fields

| Required Field | Description |
|---|---|
| **Name** | A label that supports up to 31 characters, used to identify the rule. |
| **Rule Type** | Specifies whether the rule applies to traffic within a zone, between zones, or both:<br>• **universal** (default)—Applies the rule to all matching interzone and intrazone traffic in the specified source and destination zones. For example, if you create a universal role with source zones A and B and destination zones A and B, the rule would apply to all traffic within zone A, all traffic within zone B, and all traffic from zone A to zone B and all traffic from zone B to zone A.<br>• **intrazone**—Applies the rule to all matching traffic within the specified source zones (you cannot specify a destination zone for intrazone rules). For example, if you set the source zone to A and B, the rule would apply to all traffic within zone A and all traffic within zone B, but not to traffic between zones A and B.<br>• **interzone**—Applies the rule to all matching traffic between the specified source and destination zones. For example, if you set the source zone to A, B, and C and the destination zone to A and B, the rule would apply to traffic from zone A to zone B, from zone B to zone A, from zone C to zone A, and from zone C to zone B, but not traffic within zones A, B, or C. |
| **Source Zone** | The zone from which the traffic originates. |
| **Destination Zone** | The zone at which the traffic terminates. If you use NAT, make sure to always reference the post-NAT zone. |
| **Application** | The application which you wish to control. The firewall uses App-ID, the traffic classification technology, to identify traffic on your network. App-ID provides application control and visibility in creating security policies that block unknown applications, while enabling, inspecting, and shaping those that are allowed. |

 © Palo Alto Networks, Inc.

| Required Field | Description (Continued) |
|---|---|
| **Action** | Specifies an *Allow* or *Block* action for the traffic based on the criteria you define in the rule. When you configure the firewall to block traffic, it either resets the connection or silently drops packets. To provide a better user experience, you can configure granular options to block traffic instead of silently dropping packets, which can cause some applications to break and appear unresponsive to the user.<br>• **Allow**—(default action) Allows the traffic.<br>• **Deny**—Blocks traffic, and enforces the default *Deny Action* defined for the application that is being denied. To view the deny action defined by default for an application, view the application details in **Objects > Applications** or check the application details in Applipedia.<br>• **Drop**—Silently drops the traffic; for an application, it overrides the default deny action. A TCP reset is not sent to the host/application.<br>For Layer 3 interfaces, to optionally send an ICMP unreachable response to the client, set Action: **Drop** and enable the **Send ICMP Unreachable** checkbox. When enabled, the firewall sends the ICMP code for *communication with the destination is administratively prohibited*— ICMPv4: Type 3, Code 13; ICMPv6: Type 1, Code 1.<br>• Reset—Resets a connection in one of the following ways.<br>  • **Reset client**—Sends a TCP reset to the client-side device.<br>  • **Reset server**—Sends a TCP reset to the server-side device.<br>  • **Reset both**—Sends a TCP reset to both the client-side and server-side devices.<br>A reset is sent only after a session is formed. If the session is blocked before a 3-way handshake is completed, the firewall does not send a reset. For a TCP session with a reset action, the firewall does not send an ICMP Unreachable response. For a UDP session with a drop or reset action, if the **ICMP Unreachable** checkbox is selected, the firewall sends an ICMP message to the client. |

## Optional Fields

| Optional Field | Description |
|---|---|
| **Tag** | A keyword or phrase that allows you to filter security rules. This is handy when you have defined many rules and wish to then review those that are tagged with a keyword such as *IT-sanctioned applications* or *High-risk applications*. |
| **Description** | A text field, up to 255 characters, used to describe the rule. |
| **Source IP Address** | Define host IP or FQDN, subnet, named groups, or country-based enforcement. If you use NAT, make sure to always refer to the original IP addresses in the packet (i.e. the pre-NAT IP address). |
| **Destination IP Address** | The location or destination for the traffic. If you use NAT, make sure to always refer to the original IP addresses in the packet (i.e. the pre-NAT IP address). |
| **User** | The user or group of users for whom the policy applies. You must have User-ID enabled on the zone. To enable User-ID, see User-ID Overview. |

| Optional Field | Description (Continued) |
|---|---|
| **URL Category** | Using the URL Category as match criteria allows you to customize security profiles (antivirus, anti-spyware, vulnerability, file-blocking, Data Filtering, and DoS) on a per-URL-category basis. For example, you can prevent.exe file download/upload for URL categories that represent higher risk while allowing them for other categories. This functionality also allows you to attach schedules to specific URL categories (allow social-media websites during lunch & after-hours), mark certain URL categories with QoS (financial, medical, and business), and select different log forwarding profiles on a per-URL-category-basis.<br>Although you can manually configure URL categories on your device, to take advantage of the dynamic URL categorization updates available on the Palo Alto Networks firewalls, you must purchase a URL filtering license.<br> To block or allow traffic based on URL category, you must apply a URL Filtering profile to the security policy rules. Define the URL Category as *Any* and attach a URL Filtering profile to the security policy. See Define Basic Security Rules for information on using the default profiles in your security policy and see Control Access to Web Content for more details. |
| **Service** | Allows you to select a Layer 4 (TCP or UDP) port for the application. You can choose *any*, specify a port, or use *application-default* to permit use of the standards-based port for the application. For example, for applications with well- known port numbers such as DNS, the *application-default* option will match against DNS traffic only on TCP port 53. You can also add a custom application and define the ports that the application can use.<br> For inbound allow rules (for example, from untrust to trust), using *application-default* prevents applications from running on unusual ports and protocols. Application-default is the default option; while the device still checks for all applications on all ports, with this configuration, applications are only allowed on their standard ports/protocols. |
| **Security Profiles** | Provide additional protection from threats, vulnerabilities, and data leaks. Security profiles are only evaluated for rules that have an *allow* action. |
| **HIP Profile** (for GlobalProtect) | Allows you to identify clients with Host Information Profile (HIP) and then enforce access privileges. |
| **Options** | Allow you to define logging for the session, log forwarding settings, change Quality of Service (QoS) markings for packets that match the rule, and schedule when (day and time) the security rule should be in effect. |

 © Palo Alto Networks, Inc.

## Security Policy Best Practices

The task of safely enabling Internet access and preventing misuse of web access privileges, and exposure to vulnerabilities and attacks is a continuous process. The key principle when defining policy on the Palo Alto Networks firewall is to use a positive enforcement approach. Positive enforcement implies that you selectively allow what is required for day-to-day business operations as opposed to a negative enforcement approach where you would selectively block everything that is not allowed. Consider the following suggestions when creating policy:

- If you have two or more zones with identical security requirements, combine them into one security rule.
- The ordering of rules is crucial to ensure the best match criteria. Because policy is evaluated top down, the more specific policy must precede the ones that are more general, so that the more specific rule is not *shadowed*. The term shadow refers to a rule that is not evaluated or is skipped because it is placed lower in the policy list. When the rule is placed lower, it is not evaluated because the match criteria was met by another rule that preceded it, thereby shadowing the rule from policy evaluation.
- To restrict and control access to inbound applications, in the security policy, explicitly define the port that the service/application will be listening on.
- Logging for broad allow rules—for example access to well known servers like DNS—can generate a lot of traffic. Hence it is not recommended unless absolutely necessary.
- By default, the firewall creates a log entry at the end of a session. However, you can modify this default behavior and configure the firewall to log at the start of the session. Because this significantly increases the log volume, logging at session start is recommended only when you are troubleshooting an issue. Another alternative for troubleshooting without enabling logging at session start is to use the session browser (**Monitor > Session Browser**) to view the sessions in real time.

© Palo Alto Networks, Inc.

# Policy Objects

A *policy object* is a single object or a collective unit that groups discrete identities such as IP addresses, URLs, applications, or users. With policy objects that are a collective unit, you can reference the object in security policy instead of manually selecting multiple objects one at a time. Typically, when creating a policy object, you group objects that require similar permissions in policy. For example, if your organization uses a set of server IP addresses for authenticating users, you can group the set of server IP addresses as an *address group* policy object and reference the address group in the security policy. By grouping objects, you can significantly reduce the administrative overhead in creating policies.

You can create the following policy objects on the firewall:

| Policy Object | Description |
|---|---|
| Address/Address Group, Region | Allow you to group specific source or destination addresses that require the same policy enforcement. The address object can include an IPv4 or IPv6 address (single IP, range, subnet) or the FQDN. Alternatively, a region can be defined by the latitude and longitude coordinates or you can select a country and define an IP address or IP range. You can then group a collection of address objects to create an *address group* object.<br>You can also use dynamic address groups to dynamically update IP addresses in environments where host IP addresses change frequently. |
| User/User Group | Allow you to create a list of users from the local database or an external database and group them. |
| Application Group and Application Filter | An *Application Filter* allows you to filter applications dynamically. It allows you to filter, and save a group of applications using the attributes defined in the application database on the firewall. For example, you can Create an Application Filter by one or more attributes—category, sub-category, technology, risk, characteristics. With an application filter, when a content update occurs, any new applications that match your filter criteria are automatically added to your saved application filter.<br>An *Application Group* allows you to create a static group of specific applications that you want to group together for a group of users or for a particular service, or to achieve a particular policy goal. See Create an Application Group. |
| Service/Service Groups | Allows you to specify the source and destination ports and protocol that a service can use. The firewall includes two pre-defined services—service-http and service-https—that use TCP ports 80 and 8080 for HTTP, and TCP port 443 for HTTPS. You can however, create any custom service on any TCP/UDP port of your choice to restrict application usage to specific ports on your network (in other words, you can define the default port for the application).<br> To view the standard ports used by an application, in **Objects > Applications** search for the application and click the link. A succinct description displays. |

 © Palo Alto Networks, Inc.

# Security Profiles

While security policies enable you to allow or block traffic on your network, security profiles help you define an *allow but scan* rule, which scan allowed applications for threats, such as viruses, malware, spyware, and DDOS attacks. When traffic matches the allow rule defined in the security policy, the security profile(s) that are attached to the rule are applied for further content inspection rules such as antivirus checks and data filtering.

Security profiles are not used in the match criteria of a traffic flow. The security profile is applied to scan traffic after the application or category is allowed by the security policy.

The firewall provides default security profiles that you can use out of the box to begin protecting your network from threats. See Set Up Basic Security Policies for information on using the default profiles in your security policy. As you get a better understanding about the security needs on your network, you can create custom profiles. See Scan Traffic for Threats for more information.

You can add security profiles that are commonly applied together to a security profile group; this set of profiles can be treated as a unit and added to security policies in one step (or included in security policies by default, if you choose to set up a default security profile group).

The following topics provide more detailed information about each type of security profile and how to set up a security profile group:

- Antivirus Profiles
- Anti-Spyware Profiles
- Vulnerability Protection Profiles
- URL Filtering Profiles
- Data Filtering Profiles
- File Blocking Profiles
- WildFire Analysis Profiles
- DoS Protection Profiles
- Zone Protection Profiles
- Security Profile Group

© Palo Alto Networks, Inc.

## Antivirus Profiles

Antivirus profiles protect against viruses, worms, and trojans as well as spyware downloads. Using a stream-based malware prevention engine, which inspects traffic the moment the first packet is received, the Palo Alto Networks antivirus solution can provide protection for clients without significantly impacting the performance of the firewall. This profile scans for a wide variety of malware in executables, PDF files, HTML and JavaScript viruses, including support for scanning inside compressed files and data encoding schemes. If you have enabled Decryption on the firewall, the profile also enables scanning of decrypted content.

The default profile inspects all of the listed protocol decoders for viruses, and generates alerts for SMTP, IMAP, and POP3 protocols while blocking for FTP, HTTP, and SMB protocols. You can configure the action for a decoder or antivirus signature and specify how the firewall responds to a threat event:

- **Default**—For each threat signature and Antivirus signature that is defined by Palo Alto Networks, a default action is specified internally. Typically, the default action is an alert or a reset-both. The default action is displayed in parenthesis, for example default (alert) in the threat or Antivirus signature.
- **Allow**—Permits the application traffic
- **Alert**—Generates an alert for each application traffic flow. The alert is saved in the threat log.
- **Drop**—Drops the application traffic.
- **Reset Client**—For TCP, resets the client-side connection. For UDP, drops the connection.
- **Reset Server**—For TCP, resets the server-side connection. For UDP, drops the connection.
- **Reset Both**—For TCP, resets the connection on both client and server ends. For UDP, drops the connection.

Customized profiles can be used to minimize antivirus inspection for traffic between trusted security zones, and to maximize the inspection of traffic received from untrusted zones, such as the Internet, as well as the traffic sent to highly sensitive destinations, such as server farms.

The Palo Alto Networks WildFire system also provides signatures for persistent threats that are more evasive and have not yet been discovered by other antivirus solutions. As threats are discovered by WildFire, signatures are quickly created and then integrated into the standard antivirus signatures that can be downloaded by Threat Prevention subscribers on a daily basis (sub-hourly for WildFire subscribers).

 © Palo Alto Networks, Inc.

## Anti-Spyware Profiles

Anti-Spyware profiles blocks spyware on compromised hosts from trying to phone-home or beacon out to external command-and-control (C2) servers, allowing you to detect malicious traffic leaving the network from infected clients. You can apply various levels of protection between zones. For example, you may want to have custom Anti-Spyware profiles that minimize inspection between trusted zones, while maximizing inspection on traffic received from an untrusted zone, such as Internet facing zones.

You can define your own custom Anti-Spyware profiles, or choose one of the following predefined profiles when applying anti-spyware to a security policy:

- **Default**—Uses the default action for every signature, as specified by Palo Alto Networks when the signature is created.
- **Strict**—Overrides the default action of critical, high, and medium severity threats to the block action, regardless of the action defined in the signature file. This profile still uses the default action for medium and informational severity signatures.

When the firewall detects a threat event, you can configure the following actions in an Anti-Spyware profile:

- **Default**—For each threat signature and anti-spyware signature that is defined by Palo Alto Networks, a default action is specified internally. Typically the default action is an alert or a reset-both. The default action is displayed in parenthesis, for example default (alert) in the threat or Antivirus signature.
- **Allow**—Permits the application traffic
- **Alert**—Generates an alert for each application traffic flow. The alert is saved in the threat log.
- **Drop**—Drops the application traffic.
- **Reset Client**—For TCP, resets the client-side connection. For UDP, drops the connection.
- **Reset Server**—For TCP, resets the server-side connection. For UDP, drops the connection.
- **Reset Both**—For TCP, resets the connection on both client and server ends. For UDP, drops the connection.
- **Block IP**— This action blocks traffic from either a source or a source-destination pair. It is configurable for a specified period of time.

In addition, you can enable the DNS Sinkholing action in Anti-Spyware profiles to enable the firewall to forge a response to a DNS query for a known malicious domain, causing the malicious domain name to resolve to an IP address that you define. This feature helps to identify infected hosts on the protected network using DNS traffic Infected hosts can then be easily identified in the traffic and threat logs because any host that attempts to connect to the sinkhole IP address are most likely infected with malware.

Anti-Spyware and Vulnerability Protection profiles are configured similarly.

© Palo Alto Networks, Inc.

## Vulnerability Protection Profiles

Vulnerability Protection profiles stop attempts to exploit system flaws or gain unauthorized access to systems. While Anti-Spyware profiles help identify infected hosts as traffic leaves the network, Vulnerability Protection profiles protect against threats entering the network. For example, Vulnerability Protection profiles help protect against buffer overflows, illegal code execution, and other attempts to exploit system vulnerabilities. The default Vulnerability Protection profile protects clients and servers from all known critical, high, and medium-severity threats. You can also create exceptions, which allow you to change the response to a specific signature.

To configure how the firewall responds to a threat, see Anti-Spyware Profiles for a list of supported actions.

 © Palo Alto Networks, Inc.

## URL Filtering Profiles

URL Filtering profiles enable you to monitor and control how users access the web over HTTP and HTTPS. The firewall comes with a default profile that is configured to block websites such as known malware sites, phishing sites, and adult content sites. You can use the default profile in a security policy, clone it to be used as a starting point for new URL filtering profiles, or add a new URL profile that will have all categories set to allow for visibility into the traffic on your network. You can then customize the newly added URL profiles and add lists of specific websites that should always be blocked or allowed, which provides more granular control over URL categories.

# Data Filtering Profiles

Data filtering profiles prevent sensitive information such as credit card or social security numbers from leaving a protected network. The data filtering profile also allows you to filter on key words, such as a sensitive project name or the word confidential. It is important to focus your profile on the desired file types to reduce false positives. For example, you may only want to search Word documents or Excel spreadsheets. You may also only want to scan web-browsing traffic, or FTP.

You can use default profiles, or create custom data patterns. There are two default profiles:

- CC# (Credit Card)—Identifies credit card numbers using a hash algorithm. The content must match the hash algorithm in order for data to be detected as a credit card number. This method will reduce false positives.
- SSN# (Social Security Number)—Uses an algorithm to detect nine digit numbers, regardless of format. There are two fields: SSN# and SSN# (no dash).

## Weight and Threshold Values

It is important to understand how the weight of an object (SSN, CC#, pattern) is calculated in order to set the appropriate threshold for a condition you are trying to filter. Each occurrence multiplied by the weight value will be added together in order to reach an action threshold (alert or block).

### Example: Filter for Social Security Numbers Only

For simplicity, if you only want to filter files with Social Security Numbers (SSN) and you define a weight of 3 for SSN#, you would use the following formula: each instance of a SSN x weight = threshold increment. In this case, if a Word document has 10 social security numbers you multiply that by the weight of 3, so 10 x 3 = 30. In order to take action for a file that contains 10 social security numbers you would set the threshold to 30. You may want to set an alert at 30 and then block at 60. You may also want to set a weight in the field SSN# (no dash) for Social Security Numbers that do not contain dashes. If multiple settings are used, they will accumulate to reach a given threshold.

### Example: Filter for Social Security Numbers and a Custom Pattern

In this example, we will filter on files that contain Social Security Numbers and the custom pattern confidential. In other words, if a file has Social Security Numbers in addition to the word confidential and the combined instances of those items hit the threshold, the file will trigger an alert or block, depending on the action setting.

SSN# weight = 3

Custom Pattern confidential weight = 20

The custom pattern is case sensitive.

 © Palo Alto Networks, Inc.

If the file contains 20 Social Security Numbers and a weight of 3 is configured, that is 20 x 3 = 60. If the file also contains one instance of the term confidential and a weight of 20 is configured, that is 1 x 20 = 20 for a total of 80. If your threshold for block is set to 80, this scenario would block the file. The alert or block action will be triggered as soon as the threshold is hit.

## File Blocking Profiles

The firewall uses file blocking profiles to block specified file types over specified applications and in the specified session flow direction (inbound/outbound/both). You can set the profile to alert or block on upload and/or download and you can specify which applications will be subject to the file blocking profile. You can also configure custom block pages that will appear when a user attempts to download the specified file type. This allows the user to take a moment to consider whether or not they want to download a file.

Configure a file blocking profile with the following actions:

- **Alert**—When the specified file type is detected, a log is generated in the data filtering log.
- **Block**—When the specified file type is detected, the file is blocked and a customizable block page is presented to the user. A log is also generated in the data filtering log.
- **Continue**—When the specified file type is detected, a customizable response page is presented to the user. The user can click through the page to download the file. A log is also generated in the data filtering log. Because this type of forwarding action requires user interaction, it is only applicable for web traffic.

 © Palo Alto Networks, Inc.

## WildFire Analysis Profiles

Use a WildFire analysis profile to enable the firewall to forward unknown files or email links for WildFire analysis. Specify files to be forwarded for analysis based on application, file type, and transmission direction (upload or download). Files or email links matched to the profile rule are forwarded either the WildFire public cloud or the WildFire private cloud (hosted with a WF-500 appliance), depending on the analysis location defined for the rule.

You can also use the WildFire analysis profiles to set up a Wildfire hybrid cloud deployment. If you are using a WildFire appliance to analyze sensitive files locally (such as PDFs), you can specify for less sensitive files types (such as PE files) or file types that are not supported for WildFire appliance analysis (such as APKs) to be analyzed by the WildFire public cloud. Using both the WildFire appliance and the WildFire cloud for analysis allows you to benefit from a prompt verdict for files that have already been processed by the cloud, and for files that are not supported for appliance analysis, and frees up the appliance capacity to process sensitive content.

© Palo Alto Networks, Inc.

## DoS Protection Profiles

DoS protection profiles provide detailed control for Denial of Service (DoS) protection policies. DoS policies allow you to control the number of sessions between interfaces, zones, addresses, and countries based on aggregate sessions or source and/or destination IP addresses. There are two DoS protection mechanisms that the Palo Alto Networks firewalls support.

- **Flood Protection**—Detects and prevents attacks where the network is flooded with packets resulting in too many half-open sessions and/or services being unable to respond to each request. In this case the source address of the attack is usually spoofed. See DoS Protection Against Flooding of New Sessions.
- **Resource Protection**— Detects and prevent session exhaustion attacks. In this type of attack, a large number of hosts (bots) are used to establish as many fully established sessions as possible to consume all of a system's resources.

You can enable both types of protection mechanisms in a single DoS protection profile.

The DoS profile is used to specify the type of action to take and details on matching criteria for the DoS policy. The DoS profile defines settings for SYN, UDP, and ICMP floods, can enable resource protect and defines the maximum number of concurrent connections. After you configure the DoS protection profile, you then attach it to a DoS policy.

When configuring DoS protection, it is important to analyze your environment in order to set the correct thresholds and due to some of the complexities of defining DoS protection policies, this guide will not go into detailed examples. For more information, refer to the Threat Prevention Tech Note.

 © Palo Alto Networks, Inc.

## Zone Protection Profiles

Zone protection profiles provide additional protection between specific network zones in order to protect the zones against attack. The profile must be applied to the entire zone, so it is important to carefully test the profiles in order to prevent issues that may arise with the normal traffic traversing the zones. When defining packets per second (pps) thresholds limits for zone protection profiles, the threshold is based on the packets per second that do not match a previously established session. For more information, refer to the Threat Prevention Tech Note.

© Palo Alto Networks, Inc.

# Security Profile Group

A security profile group is a set of security profiles that can be treated as a unit and then easily added to security policies. Profiles that are often assigned together can be added to profile groups to simplify the creation of security policies. You can also setup a default security profile group—new security policies will use the settings defined in the default profile group to check and control traffic that matches the security policy. Name a security profile group *default* to allow the profiles in that group to be added to new security policies by default. This allows you to consistently include your organization's preferred profile settings in new policies automatically, without having to manually add security profiles each time you create new rules.

The following sections show how to create a security profile group and how to enable a profile group to be used by default in new security policies:

- Create a Security Profile Group
- Set Up or Override a Default Security Profile Group

## Create a Security Profile Group

Use the following steps to create a security profile group and add it to a security policy.

| **Create a Security Profile Group** | |
|---|---|
| Step 1 Create a security profile group. | 1. Select **Objects > Security Profile Groups** and **Add** a new security profile group.<br>2. Give the profile group a descriptive **Name**, for example, Threats.<br>3. If the firewall is in Multiple Virtual System Mode, enable the profile to be **Shared** by all virtual systems.<br>4. Add existing profiles to the group.<br>  <br>5. Click **OK** to save the profile group. |

 © Palo Alto Networks, Inc.

| Create a Security Profile Group | | |
|---|---|---|
| Step 2 | Add a security profile group to a security policy. | 1. Select **Policies > Security** and **Add** or modify a security policy rule.<br>2. Select the **Actions** tab.<br>3. In the Profile Setting section, select **Group** for the **Profile Type**.<br>4. In the **Group Profile** drop-down, select the group you created (for example, select the Threats group):<br>  <br>5. Click **OK** to save the policy and **Commit** your changes. |
| Step 3 | Save your changes. | Click **Commit**. |

## Set Up or Override a Default Security Profile Group

Use the following options to set up a default security profile group to be used in new security policies, or to override an existing default group. When an administrator creates a new security policy, the default profile group will be automatically selected as the policy's profile settings, and traffic matching the policy will be checked according to the settings defined in the profile group (the administrator can choose to manually select different profile settings if desired). Use the following options to set up a default security profile group or to override your default settings.

If no default security profile exists, the profile settings for a new security policy are set to **None** by default.

| Set Up or Override a Default Security Profile Group | |
|---|---|
| • Create a security profile group. | 1. Select **Objects > Security Profile Groups** and Add a new security profile group.<br>2. Give the profile group a descriptive **Name**, for example, Threats.<br>3. If the firewall is in Multiple Virtual System Mode, enable the profile to be **Shared** by all virtual systems.<br>4. Add existing profiles to the group. For details on creating profiles, see Security Profiles.<br>  <br>5. Click **OK** to save the profile group.<br>6. **Add the security profile group to a security policy.**<br>7. **Add** or modify a security policy rule and select the **Actions** tab.<br>8. Select **Group** for the **Profile Type**.<br>9. In the **Group Profile** drop-down, select the group you created (for example, select the Threats group):<br> <br>10. Click **OK** to save the policy and **Commit** your changes. |

 © Palo Alto Networks, Inc.

| Set Up or Override a Default Security Profile Group | |
|---|---|
| • Set up a default security profile group. | 1. Select **Objects > Security Profile Groups** and add a new security profile group or modify an existing security profile group.<br>2. **Name** the security profile group *default*:<br>  <br>3. Click **OK** and **Commit**.<br>4. Confirm that the *default* security profile group is included in new security policies by default:<br>a. Select **Policies > Security** and **Add** a new security policy.<br>b. Select the **Actions** tab and view the **Profile Setting** fields:<br> <br>By default, the new security policy correctly shows the **Profile Type** set to Group and the *default* **Group Profile** is selected. |
| • Override a default security profile group. | If you have an existing default security profile group, and you do not want that set of profiles to be attached to a new security policy, you can continue to modify the Profile Setting fields according to your preference. Begin by selecting a different Profile Type for your policy (**Policies > Security > Security Policy Rule > Actions**). |

# Enumeration of Rules Within a Rulebase

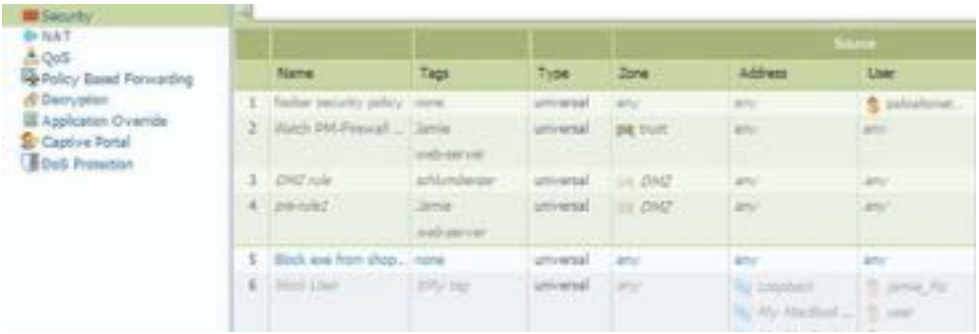
Each rule within a rulebase is automatically numbered and the ordering adjusts as rules are moved or reordered. When filtering rules to find rules that match the specified filter(s), each rule is listed with its number in the context of the complete set of rules in the rulebase and its place in the evaluation order.

On Panorama, pre-rules, post-rules, and default rules are independently numbered. When Panorama pushes rules to a firewall, the rule numbering reflects the hierarchy and evaluation order of shared rules, device-group pre-rules, firewall rules, device-group post-rules, and default rules. The **Preview Rules** option in Panorama displays an ordered list view of the total number of rules on a firewall.

### View the Ordered List of Rules Within a Rulebase

- View the numbered list of rules on the firewall.

  Select **Policies** and any rulebase under it. For example, **Policies > QoS**. The left-most column in the table displays the rule number.



- View the numbered list of rules on Panorama.

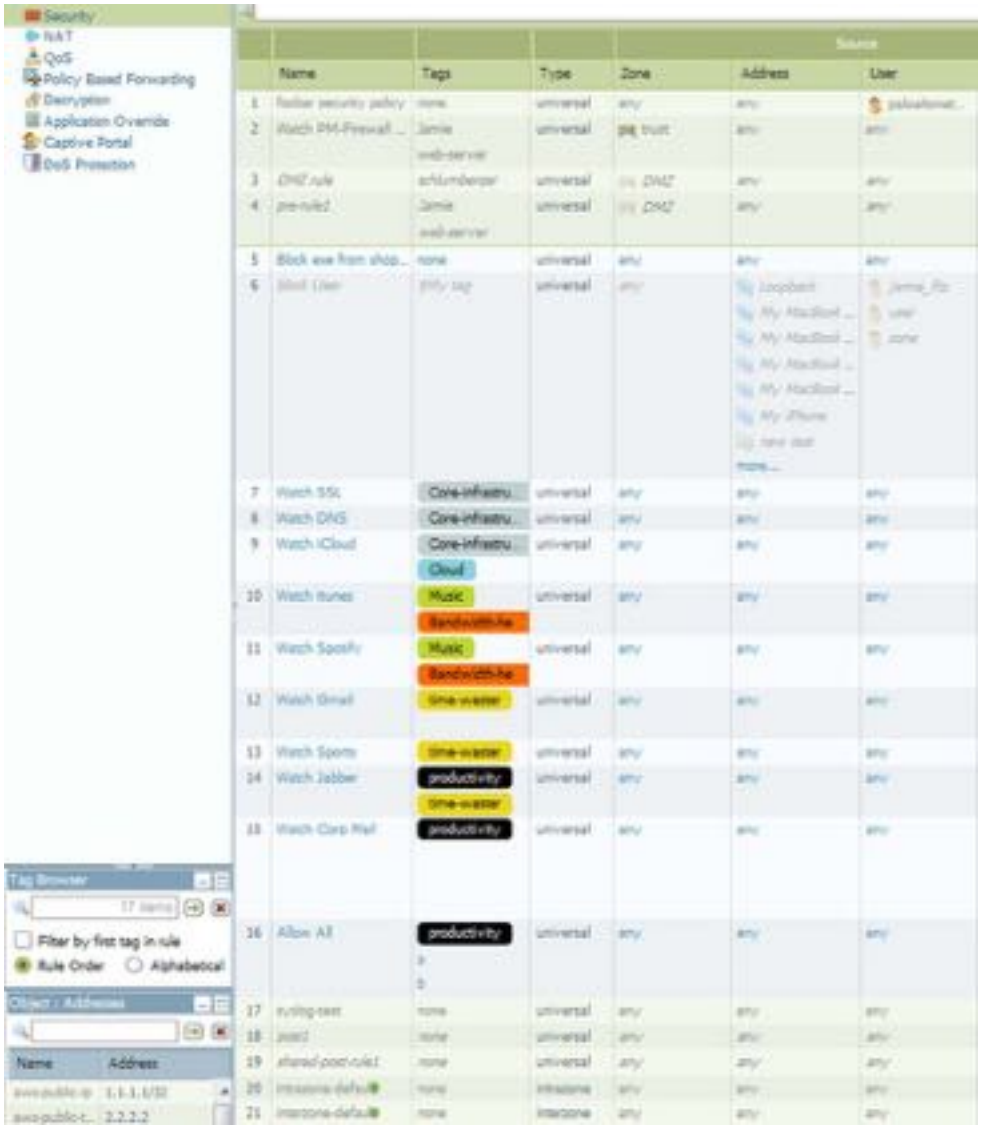
  Select **Policies** and any rulebase under it. For example, **Policies > Security> Pre-rules**.

 © Palo Alto Networks, Inc.

**View the Ordered List of Rules Within a Rulebase (Continued)**

- After you push the rules from Panorama, view the complete list of rules with numbers on the firewall.

  From the web interface of the firewall, select **Policies** and pick any rulebase under it. For example, select **Policies > Security** and view the complete set of numbered rules that the firewall will evaluate.



# Move or Clone a Policy Rule or Object to a Different Virtual System

On a firewall that has more than one virtual system (vsys), you can move or clone policy rules and objects to a different vsys or to the Shared location. Moving and cloning save you the effort of deleting, recreating, or renaming rules and objects. If the policy rule or object that you will move or clone from a vsys has references to objects in that vsys, move or clone the referenced objects also. If the references are to shared objects, you do not have to include those when moving or cloning. You can perform a Global Find to check for references.

| Move or Clone a Policy Rule or Object to a Virtual System | |
|---|---|
| Step 1 | Select the policy type (for example, **Policy > Security**) or object type (for example, **Objects > Addresses**). |
| Step 2 | Select the **Virtual System** and select one or more policy rules or objects. |
| Step 3 | Perform one of the following steps:<br>• Select **Move > Move to other vsys** (for policy rules).<br>• Click **Move** (for objects).<br>• Click **Clone** (for policy rules or objects). |
| Step 4 | In the **Destination** drop-down, select the new virtual system or **Shared**. The default is the **Virtual System** selected in Step 2. |
| Step 5 | (Policy rules only) Select the **Rule order**:<br>• **Move top** (default)—The rule will come before all other rules.<br>• **Move bottom**—The rule will come after all other rules.<br>• **Before rule**—In the adjacent drop-down, select the rule that comes after the Selected Rules.<br>• **After rule**—In the adjacent drop-down, select the rule that comes before the Selected Rules. |
| Step 6 | The **Error out on first detected error in validation** check box is selected by default. The firewall stops performing the checks for the move or clone action when it finds the first error, and displays just this error. For example, if an error occurs when the **Destination** vsys doesn't have an object that the policy rule you are moving references, the firewall will display the error and stop any further validation. When you move or clone multiple items at once, selecting this check box will allow you to find one error at a time and troubleshoot it. If you clear the check box, the firewall collects and displays a list of errors. If there are any errors in validation, the object is not moved or cloned until you fix all the errors. |
| Step 7 | Click **OK** to start the error validation. If the firewall displays errors, fix them and retry the move or clone operation. If the firewall doesn't find errors, the object is moved or cloned successfully. After the operation finishes, click **Commit**. |

© Palo Alto Networks, Inc.

# Use Tags to Group and Visually Distinguish Objects

You can tag objects to group related items and add color to the tag in order to visually distinguish tagged objects. Tags can be added to the following objects: address objects, address groups, zones, service groups, and policy rules.

The firewall and Panorama support both static tags and dynamic tags, dynamic tags are registered from a variety of sources and are not displayed with the static tags, because dynamic tags are not part of the device configuration. See Register IP Addresses and Tags Dynamically for information on registering tags dynamically. The tags discussed in this section are statically added and are part of the device configuration.

One or more tags can be applied to objects and to policy rules; a maximum of 64 tags can be applied to an object. Panorama supports a maximum of 10,000 tags that can be apportioned across Panorama (shared and device groups) and the managed devices (including devices with multiple virtual systems).

To use tags effectively, see the following topics:

- Create and Apply Tags
- Modify Tags
- Use the Tag Browser

# Create and Apply Tags

| Create and Apply tags | |
|---|---|
| Step 1 Create tags.<br><br>To tag a zone, you must create a tag with the same name as the zone. When the zone is attached in policy rules, the tag color automatically displays as the background color against the zone name. | 1. Select **Objects > Tags**.<br>2. On Panorama or a multiple virtual system firewall, select the **Device Group** or the **Virtual System** to which this object must belong.<br>3. Click **Add** and enter a **Name** to identify the tag. The maximum length is 127 characters.<br>4. (Optional) Select **Shared** to create the object in a shared location for access as a shared object in Panorama or for use across all virtual systems in a multiple virtual system firewall.<br>5. (Optional) Assign one of the 16 predefined colors to the tag. By default, no color is selected.<br>  <br>6. Click **OK** and **Commit** to save the changes. |
| Step 2 Apply tags to policy. | 1. Select **Policies** and any rulebase under it.<br>2. Click **Add** to create a policy rule and use the tagged objects you created in Step 1.<br>3. Verify that the tags are in use.<br> |
| Step 3 Apply tags to an address object, address group, service, or service group. | 1. Create the object.<br>For example to create a service group, select **Objects > Service Groups > Add**.<br>2. Select the tag(s) from the **Tag** drop-down or enter a phrase to create a new tag.<br>To edit a tag or add color to the tag, see Modify Tags. |

 © Palo Alto Networks, Inc.

## Modify Tags

| Modify Tags |
| --- |
| • Select **Objects > Tags** to perform any of the following operations with tags:<br>  • Click the link in the **Name** column to edit the properties of a tag.<br>  • Select a tag in the table, and click **Delete** to remove the tag from the firewall.<br>  • Click **Clone** to create a duplicate tag with the same properties. A numerical suffix is added to the tag name. For example, FTP-1. |

For details on creating tags, see Create and Apply Tags. For information on working with tags, see Use the Tag Browser.

## Use the Tag Browser

The tag browser provides a way to view all the tags used within a rulebase. In rulebases with a large number of rules, the tag browser simplifies the display by presenting the tags, the color code, and the rule numbers in which the tags are used.

It also allows you to group rules using the first tag applied to the rule. As a best practice, use the first tag to identify the primary purpose for a rule. For example, the first tag can identify a rule by a high-level function such as best practice, or Internet access or IT sanctioned applications or high-risk applications. In the tag browser, when you **Filter by first tag in rule**, you can easily identify gaps in coverage and move rules or add new rules within the rulebase. All the changes are saved to the candidate configuration until you commit the changes on the firewall and make them a part of the running configuration.

For devices that are managed by Panorama, the tags applied to pre-rules and post-rules that have been pushed from Panorama, display in a green background and are demarcated with green lines so that you can identify these tags from the local tags on the device.

 © Palo Alto Networks, Inc.

| Use the Tag Browser | |
|---|---|
| • Explore the tag browser. | 1. Access the **Tag Browser** on the left pane of the **Policies >** tab. The tag browser displays the tags that have been used in the rules for the selected rulebase, for example **Policies > Security**.<br>2. **Tag (#)**—Displays the label and the rule number or range of numbers in which the tag is used contiguously. Hover over the label to see the location where the rule was defined, it can be inherited from a shared location, a device group, or a virtual system.<br>3. **Rule**—Lists the rule number or range of numbers associated with the tags.<br>4. Sort the tags.<br>• **Filter by first tag in rule**—Sorts rules using the first tag applied to each rule in the rulebase. This view is particularly useful if you want to narrow the list and view related rules that might be spread around the rulebase. For example if the first tag in each rule denotes its function—best practices, administration, web-access, data center access, proxy—you can narrow the result and scan the rules based on function.<br>• **Rule Order**—Sorts the tags in the order of appearance within the selected rulebase. When displayed in order of appearance, tags used in contiguous rules are grouped. The rule number with which the tag is associated is displayed along with the tag name.<br>• **Alphabetical**—Sorts the tags in alphabetical order within the selected rulebase. The display lists the tag name and color (if a color is assigned) and the number of times it is used within the rulebase.<br>The label **None** represents rules without any tags; it does not display rule numbers for untagged rules. When you select **None**, the right pane is filtered to display rules that have no tags assigned to them.<br>5. **Clear**—Clears the filter on the currently selected tags in the search bar.<br>6. **Search bar**—To search for a tag, enter the term and click the green arrow icon to apply the filter. It also displays the total number of tags in the rulebase and the number of selected tags.<br>7. Expand or collapse the tag browser. |

| Use the Tag Browser (Continued) | |
|---|---|
| • Tag a rule. | 1. Select a rule on the right pane.<br>2. Do one of the following:<br>• Select a tag in the tag browser and select **Apply the Tag to the Selection(s)** from the drop-down.  <br>• Drag and drop tag(s) from the tag browser on to the Tags column of the rule. When you drop a tag, a confirmation dialog displays.<br>3. **Commit** the changes. |
| • View rules that match the selected tags.<br>You can filter rules based on tags with an AND or an OR operator. | • OR filter: To view rules that have specific tags, select one or more tags in the tag browser; the right pane only displays the rules that include any of the currently selected tags.<br>• AND filter: To view rules that have all the selected tags, hover over the number associated with the tag in the **Rule** column of the tag browser and select **Filter**. Repeat to add more tags. <br>Click the apply filter icon in the search bar on the right pane. The results are displayed using an AND operator. |
| • View the currently selected tags. | To view the currently selected tags, hover over the **Clear** label in the tag browser. |
| • Untag a rule. | Hover over the rule number associated with a tag in the **Rule** column of the tag browser and select **Untag Rule(s)**. Confirm that you want to remove the selected tag from the rule. **Commit** the changes. |
| • Reorder rules using tags. | Select one or more tags and hover over the rule number in the Rule column of the tag browser and select **Move Rule(s)**.<br>Select a tag from the drop-down in the move rule window and select whether you want to **Move Before** or **Move After** the tag selected in the drop-down. **Commit** the changes. |

 © Palo Alto Networks, Inc.

| Use the Tag Browser (Continued) | |
|---|---|
| • Add a new rule that applies the selected tags. | Select one or more tags and hover over the rule number in the **Rule** column of the tag browser, and select **Add New Rule**. Define the rule and **Commit** the changes.<br>The numerical order of the new rule varies by whether you selected a rule on the right pane. If you did not select a rule on the right pane, the new rule will be added after the rule to which the selected tag(s) belongs. Otherwise, the new rule is added after the selected rule. |
| • Search for a tag. | In the tag browser, enter the first few letters of the tag name you want to search for and click the Apply Filter icon. The tags that match your input will display. |

# Use a Dynamic Block List in Policy

The firewall or Panorama typically enforce policy for a source or destination IP address that is defined as a static object on the firewall. If you need agility in enforcing policy for a list of source/destination IP addresses that emerge ad hoc, you can use dynamic block lists.

A dynamic block list is a text file that contains a list of IP addresses, IP ranges, or IP subnets, and is hosted on a web server. The dynamic block list can be used to deny or allow access to the IP addresses (IPv4 and IPv6) included in the list. For example, you can use it as a whitelist for allowing a set of IP addresses or as a blacklist to disallow access to the specified IP addresses. At a configured interval, the firewall dynamically imports the list and enforces policy for the IP addresses included in the list. When you modify the list, the firewall retrieves the updates; a configuration change or commit is not required on the firewall. If the web server is unreachable, the firewall or Panorama will use the last successfully retrieved list for enforcing policy until the connection is restored with the web server that hosts the list.

- View the IP Address Limit For Your Firewall Model
- Formatting Guidelines for Dynamic Block Lists
- Enforce Policy with a Dynamic Block List
- View the List of IP addresses in the Dynamic Block List
- Retrieve a Dynamic Block List from Web Server

## View the IP Address Limit For Your Firewall Model

Irrespective of the firewall model, each firewall supports a maximum of 10 Dynamic Block Lists.

To find the maximum number of addresses, address groups, and IP addresses per group, for your model of the firewall, use the following CLI command:

**show system state | match cfg.general.max-address**

For example:

```
admin@PA-7050> show system state | match cfg.general.max-address
cfg.general.max-address: 80000
cfg.general.max-address-group: 8000
cfg.general.max-address-per-group: 500
```

Each list can contain the maximum number of addresses supported by your firewall model minus 300. Up to 300 IP addresses are reserved for internal use on the firewall and are deducted from the available limit. Therefore, in the example above, the firewall can have a maximum of 79,700 IP addresses.

 © Palo Alto Networks, Inc.

## Formatting Guidelines for Dynamic Block Lists

The dynamic block list can include individual IP addresses, subnet addresses (address/mask), or range of IP addresses. In addition, the block list can include comments and special characters such as * , : , ; , #, or /. The syntax for each line in the list is `[IP address, IP/Mask, or IP start range-IP end range] [space] [comment].`

Because the firewall ignores incorrectly formatted lines, use these guidelines when defining the list:

- Enter each IP address/range/subnet in a new line; URLs are not supported in this list.
- If you add comments, the comment must be on the same line as the IP address/range/subnet. The space at the end of the IP address is the delimiter that separates a comment from the IP address.

An example:

```
192.168.20.10/32
2001:db8:123:1::1 #test IPv6 address
192.168.20.0/24 ; test internal subnet
2001:db8:123:1::/64 test internal IPv6 range
192.168.20.40-192.168.20.50
```

For an IP address that is blocked, you can display a notification page only if the protocol is HTTP.

## Enforce Policy with a Dynamic Block List

| Enforce Policy with a Dynamic Block List | | |
|---|---|---|
| Step 1 | Create the dynamic block list and host it on a web server, so that the firewall can retrieve the list for policy evaluation. | 1. Create a text file and enter the IP addresses for which you want to enforce policy. For syntax, see Formatting Guidelines for Dynamic Block Lists. |
| Step 2 | Create a dynamic block list object on the firewall. | 1. Select **Objects > Dynamic Block Lists**.<br>2. Click **Add** and enter a descriptive **Name** for the list.<br>3. (Optional) Select **Shared**, to share the list with all virtual systems on a device that is enabled for multiple virtual systems. By default, the object is created on the virtual system that is currently selected in the **Virtual Systems** drop-down.<br>4. Enter the **Source** URL (hostname or IP address and the path) for the list you just created on the web server. For example, https://1.2.3.4/DBL_2014<br>5. Click **Test Source URL** to verify that the firewall or Panorama can connect to the web server.<br>6. (Optional) Specify the **Repeat** frequency at which the firewall or Panorama must retrieve the list. By default the list is retrieved ever hour.<br>7. Click **OK** to save the changes. |

| Enforce Policy with a Dynamic Block List | | |
|---|---|---|
| Step 3 | Use the dynamic block list as a source or destination address object in policy.<br> Create separate dynamic block lists if you want to specify allow and deny actions for specific IP addresses.<br>The list can be referenced in any policy type. In this example, we attach it as a destination object in security policy. | 1. Select **Policies > Security**.<br>2. Click **Add** and give the rule a descriptive name in the **General** tab.<br>3. In the **Source** tab, select the **Source Zone**.<br>4. In the **Destination** tab, select the **Destination Zone** and select the dynamic block list as the Destination Address.<br>5. In the **Service/ URL Category** tab, make sure the **Service** is set to **application-default**.<br>6. In the **Actions** tab, set the **Action Setting** to Allow or Deny.<br>7. Leave all the other options at the default values.<br>8. Click **OK** to save the changes.<br>9. **Commit** the changes. |
| Step 4 | Test that the policy action is enforced. | 1. Access a IP address that is included in the dynamic block list and verify that action you defined is enforced.<br>2. Select **Monitor > Logs > Traffic** and see the log entry for the session.<br>3. To verify the policy rule that matches a flow, use the following CLI command:<br>**test security-policy-match source** *<IP_address>* **destination** *<IP_address>* **destination port** *<port_number>* **protocol** *<protocol_number>* |

## View the List of IP addresses in the Dynamic Block List

**View the IP Addresses Included in the Dynamic Block List**

To view the list of IP addresses that the firewall has retrieved from the web server enter the following CLI command:

**request system external-list show name *<name>***

For example, for a list named case DBL_2014, the output is:

```
vsys1/DBL_2014:
  Next update at: Wed Aug 27 16:00:00 2014
  IPs:
  1.1.1.1
  1.2.2.2/20 #test China
  192.168.255.0; test internal
  192.168.254.0/24 test internal range
```

 © Palo Alto Networks, Inc.

## Retrieve a Dynamic Block List from Web Server

The firewall or Panorama can be configured to retrieve the list from the web server on an hourly, daily, weekly, or monthly basis. If you have added or deleted IP addresses on the list and need to trigger an immediate refresh, you must use the Command Line Interface.

**Retrieve a Dynamic Block List**

1. Enter the command: **request system external-list refresh name *<name>***

   For example, `request system external-list refresh name DBL_2014`
2. Get the job ID for the refresh job using the CLI command: **show jobs all**

   Look for the last EBL Refresh job in the list.
3. View the details for the job ID. Use the command **show jobs id *<number>***

   A message indicating the success or failure displays. For example:

```
admin@PA-200> show jobs id 55
Enqueued                    ID             Type    Status Result Completed
------------------------------------------------------------------------------
2014/08/26 15:34:14         55       EBLRefresh       FIN     OK 15:34:40
Warnings:
Details:
```

# Register IP Addresses and Tags Dynamically

To mitigate the challenges of scale, lack of flexibility and performance, the architecture in networks today allows for clients, servers, and applications to be provisioned, changed, and deleted on demand. This agility poses a challenge for security administrators because they have limited visibility into the IP addresses of the dynamically provisioned clients and servers, and the plethora of applications that can be enabled on these virtual resources.

The firewall (hardware-based platforms and the VM-Series) supports the ability to register IP addresses and tags dynamically. The IP addresses and tags can be registered on the firewall directly or registered on the firewall through Panorama.This dynamic registration process can be enabled using any of the following options:

- **User-ID agent for Windows**—In an environment where you've deployed the User-ID agent, you can enable the User-ID agent to monitor up to 100 VMware ESXi and/or vCenter Servers. As you provision or modify virtual machines on these VMware servers, the agent can retrieve the IP address changes and share them with the firewall.
- **VM Information Sources**—Allows you to monitor VMware ESXi and vCenter Server, and the AWS-VPC to retrieve IP address changes when you provision or modify virtual machines on these sources. VM Information Sources polls for a predefined set of attributes and does not require external scripts to register the IP addresses through the XML API. See Monitor Changes in the Virtual Environment.
- **VMware Service Manager** (only available for the integrated NSX solution)—The integrated NSX solution is designed for automated provisioning and distribution of Palo Alto Networks next-generation security services and the delivery of dynamic context-based security policies using Panorama. The NSX Manager updates Panorama with the latest information on the IP addresses and tags associated with the virtual machines deployed in this integrated solution. For information on this solution, see Set Up a VM-Series NSX Edition Firewall.
- **XML API**—The firewall and Panorama support an XML API that uses standard HTTP requests to send and receive data. You can use this API to register IP addresses and tags with the firewall or Panorama. API calls can be made directly from command line utilities such as cURL or using any scripting or application framework that supports REST-based services. Refer to the PAN-OS XML API Usage Guide for details.

For information on creating and using Dynamic Address Groups, see Use Dynamic Address Groups in Policy.

For the CLI commands for registering tags dynamically, see CLI Commands for Dynamic IP Addresses and Tags.

 © Palo Alto Networks, Inc.

# Monitor Changes in the Virtual Environment

To secure applications and prevent threats in an environment where new users and servers are constantly emerging, your security policy must be nimble. To be nimble, the firewall must be able to learn about new or modified IP addresses and consistently apply policy without requiring configuration changes on the firewall.

This capability is provided by the coordination between the **VM Information Sources** and **Dynamic Address Groups** features on the firewall. The firewall and Panorama provide an automated way to gather information on the virtual machine (or guest) inventory on each monitored source and create policy objects that stay in sync with the dynamic changes on the network.

- Enable VM Monitoring to Track Changes on the Virtual Network
- Attributes Monitored in the AWS and VMware Environments
- Use Dynamic Address Groups in Policy

# Enable VM Monitoring to Track Changes on the Virtual Network

VM information sources provides an automated way to gather information on the Virtual Machine (VM) inventory on each monitored source (host); the firewall can monitor the VMware ESXi and vCenter Server, and the AWS-VPC. As virtual machines (guests) are deployed or moved, the firewall collects a predefined set of attributes (or metadata elements) as tags; these tags can then be used to define Dynamic Address Groups (see Use Dynamic Address Groups in Policy) and matched against in policy.

Up to 10 VM information sources can be configured on the firewall or pushed using Panorama templates. By default, the traffic between the firewall and the monitored sources uses the management (MGT) port on the firewall.

**VM Information Sources** offers easy configuration and enables you to monitor a predefined set of 16 metadata elements or attributes. See Attributes Monitored in the AWS and VMware Environmentsfor the list.

 © Palo Alto Networks, Inc.

**Set up the VM Monitoring Agent**

Step 1 Enable the VM Monitoring Agent.

Up to 10 sources can be configured for each firewall, or for each virtual system on a multiple virtual systems capable firewall.

If your firewalls are configured in a high availability configuration:

- An active/passive setup, only the active firewall monitors the VM sources.
- An active/active setup, only the firewall with the priority value of primary monitors the VM sources.

1. Select **Device > VM Information Sources**.
2. Click **Add** and enter the following information:
   - A **Name** to identify the VMware ESX(i) or vCenter Server that you want to monitor.
   - Enter the **Host information for the server—**hostname or IP address and the **Port** on which it is listening.
   - Select the **Type** to indicate whether the source is a **VMware ESX(i)** server or a **VMware vCenter** Server.
   - Add the credentials (**Username** and **Password**) to authenticate to the server specified above.
   - Use the credentials of an administrative user to enable access.
   - (Optional) Modify the **Update interval** to a value between 5-600 seconds. By default, the firewall polls every 5 seconds. The API calls are queued and retrieved within every 60 seconds, so updates may take up to 60 seconds plus the configured polling interval.

   - (Optional) Enter the interval in hours when the connection to the monitored source is closed, if the host does not respond. (default: 2 hours, range 2-10 hours)
     To change the default value, select the check box to **Enable timeout when the source is disconnected** and specify the value. When the specified limit is reached or if the host cannot be accessed or does not respond, the firewall will close the connection to the source.
   - Click **OK**, and **Commit** the changes.
   - Verify that the connection **Status** displays as connected .

| Set up the VM Monitoring Agent (Continued) | |
|---|---|
| Step 2 Verify the connection status. | Verify that the connection **Status** displays as connected.<br> <br>If the connection status is pending or disconnected, verify that the source is operational and that the firewall is able to access the source. If you use a port other than the MGT port for communicating with the monitored source, you must change the service route (**Device > Setup > Services**, click the **Service Route Configuration** link and modify the **Source Interface** for the **VM Monitor** service). |

## Attributes Monitored in the AWS and VMware Environments

Each VM on a monitored ESXi or vCenter server must have VMware Tools installed and running. VMware Tools provide the capability to glean the IP address(es) and other values assigned to each VM.

In order to collect the values assigned to the monitored VMs, the firewall monitors the following predefined set of attributes:

| Attributes Monitored on a VMware Source | Attributes Monitored on the AWS-VPC |
|---|---|
| • UUID | • Architecture |
| • Name | • Guest OS |
| • Guest OS | • Image ID |
| • VM State — the power state can be poweredOff, poweredOn, standBy, and unknown. | • Instance ID |
| • Annotation | • Instance State |
| • Version | • Instance Type |
| • Network — Virtual Switch Name, Port Group Name, and VLAN ID | • Key Name |
| • Container Name —vCenter Name, Data Center Object Name, Resource Pool Name, Cluster Name, Host, Host IP address. | • Placement—Tenancy, Group Name, Availability Zone |
| | • Private DNS Name |
| | • Public DNS Name |
| | • Subnet ID |
| | • Tag (key, value) (up to5 tags supported per instance |
| | • VPC ID |

## Use Dynamic Address Groups in Policy

Dynamic address groups are used in policy. They allow you to create policy that automatically adapts to changes—adds, moves, or deletions of servers. It also enables the flexibility to apply different rules to the same server based on *tags* that define its role on the network, the operating system, or the different kinds of traffic it processes.

A dynamic address group uses tags as a filtering criteria to determine its members. The filter uses logical *and* and *or* operators. All IP addresses or address groups that match the filtering criteria become members of the dynamic address group. Tags can be defined statically on the firewall and/or registered (dynamically) to the firewall. The difference between static and dynamic tags is that static tags are part of the configuration on the firewall, and dynamic tags are part of the runtime configuration. This implies that a commit is not required to update dynamic tags; the tags must however be used by Dynamic Address Groups that are referenced in policy, and the policy must be committed on the device.

To dynamically register tags, you can use the XML API or the VM Monitoring agent on the firewall or on the User-ID agent. Each tag is a metadata element or attribute-value pair that is registered on the firewall or Panorama. For example, IP1 {tag1, tag2,.....tag32}, where the IP address and the associated tags are maintained as a list; each registered IP address can have up to 32 tags such as the operating system, the datacenter or the virtual switch to which it belongs. Within 60 seconds of the API call, the firewall registers the IP address and associated tags, and automatically updates the membership information for the dynamic address group(s).

The maximum number of IP addresses that can be registered for each platform is different. Use the following table for specifics on your platform:

| Platform | Maximum number of dynamically registered IP addresses |
|---|---|
| PA-7000 Series, PA-5060, VM-1000-HV | 100,000 |
| PA-5050 | 50,000 |
| PA-5020 | 25,000 |
| PA-4000 Series, PA-3000 Series | 5,000 |
| PA-2000 Series, PA-500, PA-200, VM-300, VM-200, VM-100 | 1,000 |

The following example shows how dynamic address groups can simplify network security enforcement. The example workflow shows how to:

- Enable the VM Monitoring agent on the firewall, to monitor the VMware ESX(i) host or vCenter Server and register VM IP addresses and the associated tags.
- Create dynamic address groups and define the tags to filter. In this example, two address groups are created. One that only filters for dynamic tags and another that filters for both static and dynamic tags to populate the members of the group.
- Validate that the members of the dynamic address group are populated on the firewall.
- Use dynamic address groups in policy. This example uses two different security policies:
  - A security policy for all Linux servers that are deployed as FTP servers; this rule matches on dynamically registered tags.

 © Palo Alto Networks, Inc.

– A security policy for all Linux servers that are deployed as web servers; this rule matches on a dynamic address group that uses static and dynamic tags.

- Validate that the members of the dynamic address groups are updated as new FTP or web servers are deployed. This ensure that the security rules are enforced on these new virtual machines too.

| **Use Dynamic Address Groups in Policy** | |
|---|---|
| Step 1 Enable VM Source Monitoring. | See Enable VM Monitoring to Track Changes on the Virtual Network. |
| Step 2 Create dynamic address groups on the firewall.<br><br>View the tutorial to see a big picture view of the feature. | 1. Log in to the web interface of the firewall.<br>2. Select **Object > Address Groups**.<br>3. Click **Add** and enter a **Name** and a **Description** for the address group.<br>4. Select **Type** as **Dynamic**.<br>5. Define the match criteria. You can select dynamic and static tags as the match criteria to populate the members of the group. Click **Add Match Criteria**, and select the **And** or **Or** operator and select the attributes that you would like to filter for or match against. and then click **OK**.<br> <br>6. Click **Commit**. |

The match criteria for each dynamic address group in this example is as follows:

ftp_server: matches on the guest operating system “Linux 64-bit” and annotated as “ftp” ('guestos.Ubuntu Linux 64-bit' and 'annotation.ftp').

web-servers: matches on two criteria—the tag black or if the guest operating system is Linux 64-bit and the name of the server us Web_server_Corp. ('guestos.Ubuntu Linux 64-bit' and 'vmname.WebServer_Corp' or 'black')

**Use Dynamic Address Groups in Policy (Continued)**

Step 3 Use dynamic address groups in policy.

View the tutorial.

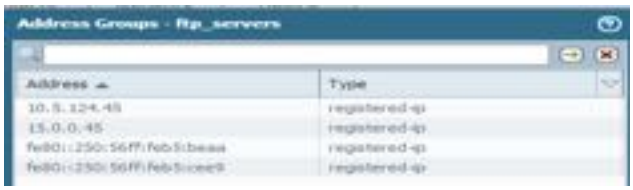
1. Select **Policies > Security**.
2. Click **Add** and enter a **Name** and a **Description** for the policy.
3. Add the **Source Zone** to specify the zone from which the traffic originates.
4. Add the **Destination Zone** at which the traffic is terminating.
5. For the **Destination Address**, select the Dynamic address group you created in Step 2 above.
6. Specify the action— **Allow** or **Deny**—for the traffic, and optionally attach the default security profiles to the rule.
7. Repeats Steps 1 through 6 above to create another policy rule.
8. Click **Commit**.

This example shows how to create two policies: one for all access to FTP servers and the other for access to web servers.

Step 4 Validate that the members of the dynamic address group are populated on the firewall.

1. Select **Policies > Security**, and select the rule.
2. Select the drop-down arrow next to the address group link, and select **Inspect**. You can also verify that the match criteria is accurate.

3. Click the **more** link and verify that the list of registered IP addresses is displayed.



Policy will be enforced for all IP addresses that belong to this address group, and are displayed here.

# CLI Commands for Dynamic IP Addresses and Tags

The Command Line Interface on the firewall and Panorama give you a detailed view into the different sources from which tags and IP addresses are dynamically registered. It also allows you to audit registered and unregistered tags. The following examples illustrate the capabilities in the CLI.

| Example | CLI Command |
|---|---|
| View all registered IP addresses that match the tag, `state.poweredOn` or that are not tagged as `vSwitch0` | `show log iptag tag_name equal state.poweredOn`<br>`show log iptag tag_name not-equal switch.vSwitch0` |
| View all dynamically registered IP addresses that were sourced by VM Information Source with name `vmware1` and tagged as `poweredOn` | `show vm-monitor source source-name vmware1 tag state.poweredOn registered-ip all`<br><br>`registered IP Tags`<br>`---------- ----------`<br>`fe80::20c:29ff:fe69:2f76 "state.poweredOn"`<br>`10.1.22.100 "state.poweredOn"`<br>`2001:1890:12f2:11:20c:29ff:fe69:2f76 "state.poweredOn"`<br>`fe80::20c:29ff:fe69:2f80 "state.poweredOn"`<br>`192.168.1.102 "state.poweredOn"`<br>`10.1.22.105 "state.poweredOn"`<br>`2001:1890:12f2:11:2cf8:77a9:5435:c0d "state.poweredOn"`<br>`fe80::2cf8:77a9:5435:c0d "state.poweredOn"` |
| Clear all IP addresses and tags learned from a specific VM Monitoring source without disconnecting the source. | `debug vm-monitor clear source-name <name>` |
| Display IP addresses registered from all sources. | `show object registered-ip all` |
| Display the count for IP addresses registered from all sources. | `show object registered-ip all option count` |
| Clear IP addresses registered from all sources | `debug object registered-ip clear all` |
| Add or delete tags for a given IP address that was registered using the XML API. | `debug object test registered-ip [<register/unregister>] <ip/netmask> <tag>` |

| Example | CLI Command |
|---|---|
| View all tags registered from a specific information source. | `show vm-monitor source source-name vmware1 tag all`<br>`vlanId.4095`<br>`vswitch.vSwitch1`<br>`host-ip.10.1.5.22`<br>`portgroup.TOBEUSED`<br>`hostname.panserver22`<br>`portgroup.VM Network 2`<br>`datacenter.ha-datacenter`<br>`vlanId.0`<br>`state.poweredOn`<br>`vswitch.vSwitch0`<br>`vmname.Ubuntu22-100`<br>`vmname.win2k8-22-105`<br>`resource-pool.Resources`<br>`vswitch.vSwitch2`<br>`guestos.Ubuntu Linux 32-bit`<br>`guestos.Microsoft Windows Server 2008 32-bit`<br>`annotation.`<br>`version.vmx-08`<br>`portgroup.VM Network`<br>`vm-info-source.vmware1`<br>`uuid.564d362c-11cd-b27f-271f-c361604dfad7`<br>`uuid.564dd337-677a-eb8d-47db-293bd6692f76`<br>`Total: 22` |
| View all tags registered from a specific data source, for example from the VM Monitoring Agent on the firewall, the XML API, Windows User-ID Agent or the CLI. | • To view tags registered from the CLI:<br>`show log iptag datasource_type equal unknown`<br>• To view tags registered from the XML API:<br>`show log iptag datasource_type equal xml-api`<br>• To view tags registered from VM Information sources:<br>`show log iptag datasource_type equal vm-monitor`<br>• To view tags registered from the Windows User-ID agent:<br>`show log iptag datasource_type equal xml-api datasource_subtype equal user-id-agent` |
| View all tags that are registered for a specific IP address (across all sources). | `debug object registered-ip show tag-source ip` *`ip_address`* `tag all` |

# Identify Users Connected through a Proxy Server

If you have a proxy server deployed between the users on your network and the firewall, in HTTP/HTTPS requests the firewall might see the proxy server IP address as the source IP address in the traffic that the proxy forwards rather than the IP address of the client that requested the content. In many cases, the proxy server adds an X-Forwarded-For (XFF) header to traffic packets that includes the actual IPv4 or IPv6 address of the client that requested the content or from whom the request originated. In such cases, you can configure the firewall to read the XFF header values and determine the IP addresses of the client who requested the content. The firewall matches the XFF IP addresses with usernames that your policy rules reference so that those rules can control access for the associated users and groups. The firewall also uses the XFF-derived usernames to populate the source user fields of logs so you can monitor user access to web services.

You can also configure the firewall to add XFF values to URL Filtering logs. In these logs, an XFF value can be the client IP address, client username (if available), the IP address of the last proxy server traversed in a proxy chain, or any string of up to 128 characters that the XFF header stores.

XFF user identification applies only to HTTP or HTTPS traffic, and only if the proxy server supports the XFF header. If the header has an invalid IP address, the firewall uses that IP address as a username for group mapping references in policies. If the XFF header has multiple IP addresses, the firewall uses the first entry from the left.

- Use XFF Values for Policies and Logging Source Users
- Add XFF Values to URL Filtering Logs

## Use XFF Values for Policies and Logging Source Users

You can configure the firewall to use XFF values in user-based policies and in the source user fields of logs. To use XFF values in policies, you must also Map IP Addresses to Users, Map Users to Groups (if you have group-based policies), and configure policies based on users or groups.

Logging XFF values doesn't populate the source IP address values of logs. When you view the logs, the source field displays the IP address of the proxy server if one is deployed between the user clients and the firewall. However, you can configure the firewall to Add XFF Values to URL Filtering Logs so that you can see user IP addresses in those logs.

To ensure that attackers can't read and exploit the XFF values in web request packets that exit the firewall to retrieve content from an external server, you can also configure the firewall to strip the XFF values from outgoing packets.

These options are not mutually exclusive: if you configure both, the firewall zeroes out XFF values only after using them in policies and logs.

| **Use XFF Values for Policies and Logging Source Users** | | |
|---|---|---|
| Step 1 | Enable the firewall to use XFF values in policies and in the source user fields of logs. | 1. Select **Device > Setup > Content-ID** and edit the X-Forwarded-For Headers settings.<br>2. Select the **Use X-Forwarded-For Header in User-ID** check box. |
| Step 2 | Remove XFF values from outgoing web requests. | 1. Select the **Strip X-Forwarded-For Header** check box.<br>2. Click **OK** and **Commit**. |

| Use XFF Values for Policies and Logging Source Users (Continued) | | |
|---|---|---|
| Step 3 | Verify the firewall is populating the source user fields of logs. | 1. Select a log type that has a source user field (for example, **Monitor > Logs > Traffic**).<br>2. Verify that the Source User column displays the usernames of users who access the web. |

## Add XFF Values to URL Filtering Logs

You can configure the firewall to add the XFF values from web requests to URL Filtering logs. The XFF values that the logs display can be client IP addresses, usernames if available, or any values of up to 128 characters that the XFF fields store.

This method of logging XFF values doesn't add usernames to the source user fields in URL Filtering logs. To populate the source user fields, see Use XFF Values for Policies and Logging Source Users.

| Add XFF Values to URL Filtering Logs | | |
|---|---|---|
| Step 1 | Configure a URL Filtering profile. | 1. Select **Objects > Security Profiles > URL Filtering**.<br>2. Select an existing profile or **Add** a new profile and enter a descriptive **Name**.<br>You can't enable XFF logging in the default URL Filtering profile.<br>3. In the **Categories** tab, Define how to control access to web content.<br>4. Select the **Settings** tab and select the **X-Forwarded-For** check box.<br>5. Click **OK** to save the profile. |
| Step 2 | Attach the URL Filtering profile to a policy rule. | 1. Select **Policies > Security** and click the rule.<br>2. Select the **Actions** tab, set the **Profile Type** to **Profiles**, and select the **URL Filtering** profile you just created.<br>3. Click **OK** and **Commit**. |
| Step 3 | Verify the firewall is logging XFF values. | 1. Select **Monitor > Logs > URL Filtering**.<br>2. Display the XFF values in one of the following ways:<br>• To display the XFF value for a single log—Click the icon for the log to displays its details. The HTTP Headers section displays the X-Forwarded-For value.<br>• To display the XFF values for all logs—Open the drop-down in any column header, select **Columns**, and select the **X-Forwarded-For** check box. The page then displays an X-Forwarded-For column. |

# Policy-Based Forwarding

Normally, the firewall uses the destination IP address in a packet to determine the outgoing interface. The firewall uses the routing table associated with the virtual router to which the interface is connected to perform the route lookup. Policy-Based Forwarding (PBF) allows you to override the routing table, and specify the outgoing or *egress* interface based on specific parameters such as source or destination IP address, or type of traffic.

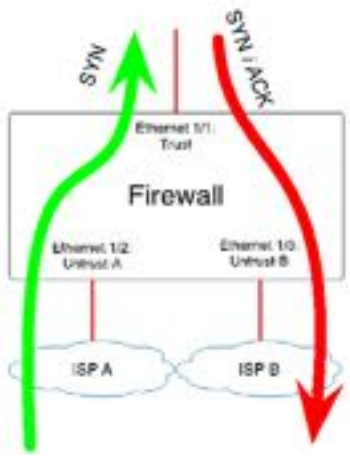
- PBF
- Create a Policy-Based Forwarding Rule
- Use Case: PBF for Outbound Access with Dual ISPs
- Use Case: PBF for Routing Traffic Through Virtual Systems

# PBF

PBF rules allow traffic to take an alternative path from the next hop specified in the route table, and are typically used to specify an egress interface for security or performance reasons. Let's say your company has two links between the corporate office and the branch office: a cheaper Internet link and a more expensive leased line. The leased line is a high-bandwidth, low-latency link. For enhanced security, you can use PBF to send applications that aren't encrypted traffic, such as FTP traffic, over the private leased line and all other traffic over the Internet link. Or, for performance, you can choose to route business-critical applications over the leased line while sending all other traffic, such as web browsing, over the cheaper link.

## Egress Path and Symmetric Return

Using PBF, you can direct traffic to a specific interface on the firewall, drop the traffic, or direct traffic to another virtual system (on systems enabled for multiple virtual systems).



In networks with asymmetric routes, such as in a dual ISP environment, connectivity issues occur when traffic arrives at one interface on the firewall and leaves from another interface. If the route is asymmetrical, where the forward (SYN packet) and return (SYN/ACK) paths are different, the firewall is unable to track the state of the entire session and this causes a connection failure. To ensure that the traffic uses a symmetrical path, which means that the traffic arrives at and leaves from the same interface on which the session was created, you can enable the *Symmetric Return* option.

With symmetric return, the virtual router overrides a routing lookup for return traffic and instead directs the flow back to the MAC address from which it received the SYN packet (or first packet). However, if the destination IP address is on the same subnet as the ingress/egress interface's IP address, a route lookup is performed and symmetric return is not enforced. This behavior prevents traffic from being blackholed.

To determine the next hop for symmetric returns, the firewall uses an Address Resolution Protocol (ARP) table. The maximum number of entries that this ARP table supports is limited by the firewall model and the value is not user configurable. To determine the limit for your model, use the CLI command: **`show pbf return-mac all`**.

## Path Monitoring

Path monitoring allows you to verify connectivity to an IP address so that the firewall can direct traffic through an alternate route, when needed. The firewall uses ICMP pings as *heartbeats* to verify that the specified IP address is reachable.

A monitoring profile allows you to specify the threshold number of heartbeats to determine whether the IP address is reachable. When the monitored IP address is unreachable, you can either disable the PBF rule or specify a *fail-over* or *wait-recover* action. Disabling the PBF rule allows the virtual router to take over the routing

 © Palo Alto Networks, Inc.

decisions. When the fail-over or wait-recover action is taken, the monitoring profile continues to monitor whether the target IP address is reachable, and when it comes back up, the firewall reverts back to using the original route.

The following table lists the difference in behavior for a path monitoring failure on a new session versus an established session.

| Behavior of a session on a monitoring failure | If the rule stays enabled when the monitored IP address is unreachable<br>☐ Disable this rule if nexthop/monitor ip is unreachable | If rule is disabled when the monitored IP address is unreachable<br>☑ Disable this rule if nexthop/monitor ip is unreachable |
|---|---|---|
| For an established session | **wait-recover**—Continue to use egress interface specified in the PBF rule | **wait-recover**—Continue to use egress interface specified in the PBF rule |
| | **fail-over**—Use path determined by routing table (no PBF) | **fail-over**—Use path determined by routing table (no PBF) |
| For a new session | **wait-recover**—Use path determined by routing table (no PBF) | **wait-recover**—Check the remaining PBF rules. If no match, use the routing table |
| | **fail-over**—Use path determined by routing table (no PBF) | **fail-over**—Check the remaining PBF rules. If no match, use the routing table |

## Service Versus Applications in PBF

PBF rules are applied either on the first packet (SYN) or the first response to the first packet (SYN/ACK). This means that a PBF rule may be applied before the firewall has enough information to determine the application. Therefore, application-specific rules are not recommended for use with PBF. Whenever possible, use a service object, which is the Layer 4 port (TCP or UDP) used by the protocol or application.

However, if you specify an application in a PBF rule, the firewall performs *App-ID caching*. When an application passes through the firewall for the first time, the firewall does not have enough information to identify the application and therefore cannot enforce the PBF rule. As more packets arrive, the firewall determines the application and creates an entry in the App-ID cache and retains this App-ID for the session.When a new session is created with the same destination IP address, destination port, and protocol ID, the firewall could identify the application as the same from the initial session (based on the App-ID cache) and apply the PBF rule. Therefore, a session that is not an exact match and is not the same application, can be forwarded based on the PBF rule.

Further, applications have dependencies and the identity of the application can change as the firewall receives more packets. Because PBF makes a routing decision at the start of a session, the firewall cannot enforce a change in application identity. YouTube, for example, starts as web-browsing but changes to Flash, RTSP, or YouTube based on the different links and videos included on the page. However with PBF, because the firewall identifies the application as web-browsing at the start of the session, the change in application is not recognized thereafter.

PBF rules cannot be based on domain names; only IP addresses are valid; also, you cannot use custom-applications, application-filters or application groups in PBF rules.

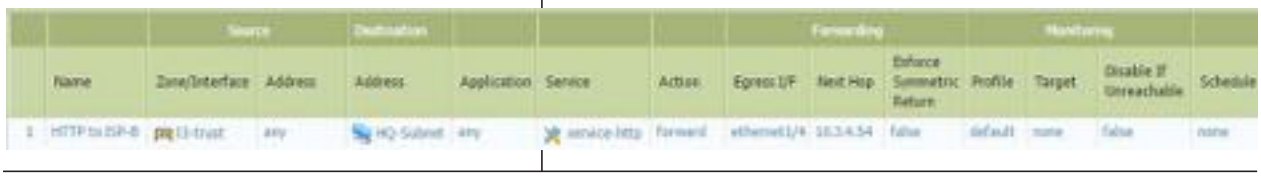
# Create a Policy-Based Forwarding Rule

Use a PBF rule to direct traffic to a specific egress interface on the firewall, and override the default path for the traffic.

| Create a PBF Rule | |
|---|---|
| Step 1 Create a PBF rule.<br><br>When creating a PBF rule you must specify a name for the rule, a source zone or interface, and an egress interface. All other components are either optional or have a default value provided. | 1. Select **Policies > Policy Based Forwarding** and click **Add.**<br>2. Give the rule a descriptive name in the **General** tab.<br>3. In the **Source** tab, select the following:<br>a. Select the **Type**—**Zone** or **Interface**— to which the forwarding policy will be applied, and the relevant zone or interface.<br><br>PBF is only supported on Layer 3 interfaces.<br><br>b. (Optional) Specify the **Source Address** to which PBF will apply. For example, a specific IP address or subnet IP address from which you want to forward traffic to the interface or zone specified in this rule.<br><br>Use the **Negate** option to exclude a one or more source IP addresses from the PBF rule. For example, if your PBF rule directs all traffic from the specified zone to the Internet, **Negate** allows you to exclude internal IP addresses from the PBF rule.<br><br>The evaluation order is top down. A packet is matched against the first rule that meets the defined criteria; after a match is triggered the subsequent rules are not evaluated.<br><br>c. (Optional) **Add** and select the **Source User** or groups of users to whom the policy applies.<br>4. In the **Destination/Application/Service** tab, select the following:<br>a. **Destination Address**. By default the rule applies to **Any** IP address. Use the **Negate** option to exclude one or more destination IP addresses from the PBF rule.<br><br>b. Select the Application(s) or Service(s) that you want to control using PBF.<br><br>Application-specific rules are not recommended for use with PBF. Whenever possible, use a service object, which is the Layer 4 port (TCP or UDP) used by the protocol or application. For more details, see Service Versus Applications in PBF. |

© Palo Alto Networks, Inc.

| Create a PBF Rule | |
|---|---|
| | 5. In the **Forwarding** tab, select the following:<br>a. Set the **Action.** The options are as follows:<br>– **Forward**—Directs the packet to a specific **Egress Interface**. Enter the **Next Hop** IP address for the packet.<br>– **Forward To VSYS**—(On a device enabled for multiple virtual systems) Select the virtual system to which to forward the packet.<br>– **Discard**—Drop the packet.<br>– **No PBF**—Exclude the packets that match the criteria for source/destination/application/service defined in the rule. Matching packets use the route table instead of PBF; the firewall uses the route table to exclude the matched traffic from the redirected port.<br>To trigger the specified action at a daily, weekly or non-recurring frequency, create and attach a **Schedule**.<br>b. (Optional) Enable Monitoring to verify connectivity to a target IP address or to the next hop IP address. Select **Monitor** and attach a monitoring **Profile** (default or custom) that specifies the action when the IP address is unreachable.<br>c. (Optional, required for asymmetric routing environments) Select **Enforce Symmetric Return** and enter one or more IP addresses in the **Next Hop Address List**.<br>Enabling symmetric return ensures that return traffic (say, from the Trust zone on the LAN to the Internet) is forwarded out through the same interface through which traffic ingresses from the Internet. |
| Step 2 Save the policies to the running configuration on the device. | Click **Commit**.<br>The PBF rule is in effect. |



## Use Case: PBF for Outbound Access with Dual ISPs

In this use case, the branch office has a dual ISP configuration and implements PBF for redundant Internet access. The backup ISP is the default route for traffic from the client to the web servers. In order to enable redundant Internet access without using an internetwork protocol such as BGP, we use PBF with destination interface-based source NAT and static routes, and configure the firewall as follows:

- Enable a PBF rule that routes traffic through the primary ISP, and attach a monitoring profile to the rule. The monitoring profile triggers the firewall to use the default route through the backup ISP when the primary ISP is unavailable.
- Define Source NAT rules for both the primary and backup ISP that instruct the firewall to use the source IP address associated with the egress interface for the corresponding ISP. This ensures that the outbound traffic has the correct source IP address.
- Add a static route to the backup ISP, so that when the primary ISP is unavailable, the default route comes into effect and the traffic is directed through the backup ISP.

 © Palo Alto Networks, Inc.

| PBF for Outbound Access with Dual ISPs | | |
|---|---|---|
| Step 1 | Configure the ingress and the egress interfaces on the firewall.<br><br>Egress interfaces can be in the same zone. In this example we assign the egress interfaces to different zones. | 1. Select **Network > Interfaces** and then select the interface you want to configure, for example, Ethernet1/1 and Ethernet1/3.<br>The interface configuration on the firewall used in this example is as follows:<br>• Ethernet 1/1 connected to the primary ISP:<br>– Zone: ISP-East<br>– IP Address:1.1.1.2/30<br>– Virtual Router: Default<br>• Ethernet 1/3 connected to the backup ISP:<br>– Zone: ISP-West<br>– IP Address:2.2.2.2/30<br>– Virtual Router: Default<br>• Ethernet 1/2 is the ingress interface, used by the network clients to connect to the Internet:<br>– Zone: Trust<br>– IP Address:192.168. 54.1/24<br>– Virtual Router: Default<br>2. To save the interface configuration, click **OK**. |
| Step 2 | On the virtual router, add a static route to the backup ISP. | 1. Select **Network > Virtual Router** and then select the **default** link to open the Virtual Router dialog.<br>2. Select the **Static Routes** tab and click **Add**. Enter a **Name** for the route and specify the **Destination** IP address for which you are defining the static route. In this example, we use 0.0.0.0/0 for all traffic.<br>3. Select the **IP Address** radio button and set the **Next Hop** IP address for your router that connects to the backup Internet gateway. In this example, 2.2.2.1.<br>4. Specify a cost metric for the route. In this example, we use 10.<br> <br>5. Click **OK** twice to save the virtual router configuration. |

**PBF for Outbound Access with Dual ISPs**

Step 3 Create a PBF rule that directs traffic to the interface that is connected to the primary ISP.

Make sure to exclude traffic destined to internal servers/IP addresses from PBF. Define a negate rule so that traffic destined to internal IP addresses is not routed through the egress interface defined in the PBF rule.

1. Select **Policies > Policy Based Forwarding** and click **Add.**
2. Give the rule a descriptive **Name** in the **General** tab.
3. In the **Source** tab, set the **Source Zone** to Trust.
4. In the **Destination/Application/Service** tab, set the following:
   a. In the Destination Address section, **Add** the IP addresses or address range for servers on the internal network or create an address object for your internal servers. Select **Negate** to exclude the IP addresses or address object listed above from using this rule.
   b. In the Service section, **Add** the **service-http** and **service-https** services to allow HTTP and HTTPS traffic to use the default ports. For all other traffic that is allowed by security policy, the default route will be used.

   To forward all traffic using PBF, set the Service to **Any**.

5. In the **Forwarding** tab, specify the interface to which you want to forward traffic and enable path monitoring.
   a. To forward traffic, set the **Action** to **Forward**, and select the **Egress Interface** and specify the **Next Hop**. In this example, the egress interface is ethernet1/1, and the next hop IP address is 1.1.1.1.

© Palo Alto Networks, Inc.

**PBF for Outbound Access with Dual ISPs**

b. Enable **Monitor** and attach the default monitoring profile, to trigger a failover to the backup ISP. In this example, we do not specify a target IP address to monitor. The firewall will monitor the next hop IP address; if this IP address is unreachable the firewall will direct traffic to the default route specified on the virtual router.

c. (Required if you have asymmetric routes). Select **Enforce Symmetric Return** to ensure that return traffic from the Trust zone to the Internet is forwarded out on the same interface through which traffic ingressed from the Internet.

NAT ensures that the traffic from the Internet is returned to the correct interface/IP address on the firewall.

d. Click **OK** to save the changes.

**PBF for Outbound Access with Dual ISPs**

Step 4 Create NAT rules based on the egress interface and ISP. These rules ensure that the correct source IP address is used for outbound connections.

1. Select **Policies > NAT** and click **Add**.
2. In this example, the NAT rule we create for each ISP is as follows:

**NAT for Primary ISP**

In the **Original Packet** tab,

- **Source Zone**: Trust
- **Destination Zone**: ISP-West

In the **Translated Packet** tab, under Source Address Translation

- **Translation Type**: Dynamic IP and Port
- **Address Type**: Interface Address
- **Interface**: ethernet1/1
- **IP Address**: 1.1.1.2/30

**NAT for Backup ISP**

In the **Original Packet** tab,

- **Source Zone**: Trust
- **Destination Zone**: ISP-East

In the **Translated Packet** tab, under Source Address Translation

- **Translation Type**: Dynamic IP and Port
- **Address Type**: Interface Address
- **Interface**: ethernet1/3
- **IP Address**: 2.2.2.2/30

 © Palo Alto Networks, Inc.

| PBF for Outbound Access with Dual ISPs | | |
|---|---|---|
| Step 5 | Create security policy to allow outbound access to the Internet. | To safely enable applications, create a simple rule that allows access to the Internet and attach the security profiles available on the firewall.<br>1. Select **Policies > Security** and click **Add**.<br>2. Give the rule a descriptive **Name** in the **General** tab.<br>3. In the **Source** tab, set the **Source Zone** to Trust.<br>4. In the **Destination** tab, Set the **Destination Zone** to ISP-East and ISP-West.<br>5. In the **Service/ URL Category** tab, leave the default **application-default**.<br>6. In the **Actions** tab, complete these tasks:<br>a. Set the **Action Setting** to **Allow**.<br>b. Attach the default profiles for antivirus, anti-spyware, vulnerability protection and URL filtering, under **Profile Setting.**<br>7. Under **Options**, verify that logging is enabled at the end of a session. Only traffic that matches a security rule is logged.<br>  |
| Step 6 | Save the policies to the running configuration on the device. | Click **Commit**. |

**PBF for Outbound Access with Dual ISPs**

**Step 7** Verify that the PBF rule is active and that the primary ISP is used for Internet access.

1. Launch a web browser and access a web server. On the firewall check the traffic log for web-browsing activity.

2. From a client on the network, use the ping utility to verify connectivity to a web server on the Internet. and check the traffic log on the firewall.

```
C:\Users\pm-user1>ping 4.2.2.1
Pinging 4.2.2.1 with 32 bytes of data:
Reply from 4.2.2.1: bytes=32 time=34ms TTL=117
Reply from 4.2.2.1: bytes=32 time=13ms TTL=117
Reply from 4.2.2.1: bytes=32 time=25ms TTL=117
Reply from 4.2.2.1: bytes=32 time=3ms TTL=117
Ping statistics for 4.2.2.1:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
    Minimum = 3ms, Maximum = 34ms, Average = 18ms
```

3. To confirm that the PBF rule is active, use the CLI command **show pbf rule all**

```
admin@PA-NGFW> show pbf rule all
Rule       ID    Rule State Action   Egress IF/VSYS  NextHop
========== === ========== ====== ============== =======
Use ISP-Pr 1     Active     Forward ethernet1/1     1.1.1.1
```

**Step 8** Verify that the failover to the backup ISP occurs and that the Source NAT is correctly applied.

1. Unplug the connection to the primary ISP.
2. Confirm that the PBF rule is inactive with the CLI command **show pbf rule all**

```
admin@PA-NGFW> show pbf rule all
Rule       ID    Rule State Action   Egress IF/VSYS  NextHop
========== === ========== ====== ============== =======
Use ISP-Pr 1   Disabled   Forward   ethernet1/1     1.1.1.1
```

3. Access a web server, and check the traffic log to verify that traffic is being forwarded through the backup ISP.

 © Palo Alto Networks, Inc.

**PBF for Outbound Access with Dual ISPs**

4. View the session details to confirm that the NAT rule is working properly.

```
admin@PA-NGFW> show session all
--------------------------------------------------------------
ID Application    State   Type Flag Src[Sport]/Zone/Proto
  (translated IP[Port]) Vsys Dst[Dport]/Zone (translated
  IP[Port])
--------------------------------------------------------------
87212 ssl ACTIVE  FLOW  NS   192.168.54.56[53236]/Trust/6
  (2.2.2.2[12896]) vsys1 204.79.197.200[443]/ISP-East
  (204.79.197.200[443])
```

5. Obtain the session identification number from the output and view the session details. Note that the PBF rule is not used and hence is not listed in the output.

```
admin@PA-NGFW> show session id 87212

Session           87212

        c2s flow:
                source:      192.168.54.56 [Trust]
                dst:         204.79.197.200
                proto:       6
                sport:       53236          dport:      443

# DoS Protection Against Flooding of New Sessions

DoS protection against flooding of new sessions is beneficial against high-volume single-session and multiple-session attacks. In a single-session attack, an attacker uses a single session to target a device behind the firewall. If a Security rule allows the traffic, the session is established and the attacker initiates an attack by sending packets at a very high rate with the same source IP address and port number, destination IP address and port number, and protocol, trying to overwhelm the target. In a multiple-session attack, an attacker uses multiple sessions (or connections per second [cps]) from a single host to launch a DoS attack.

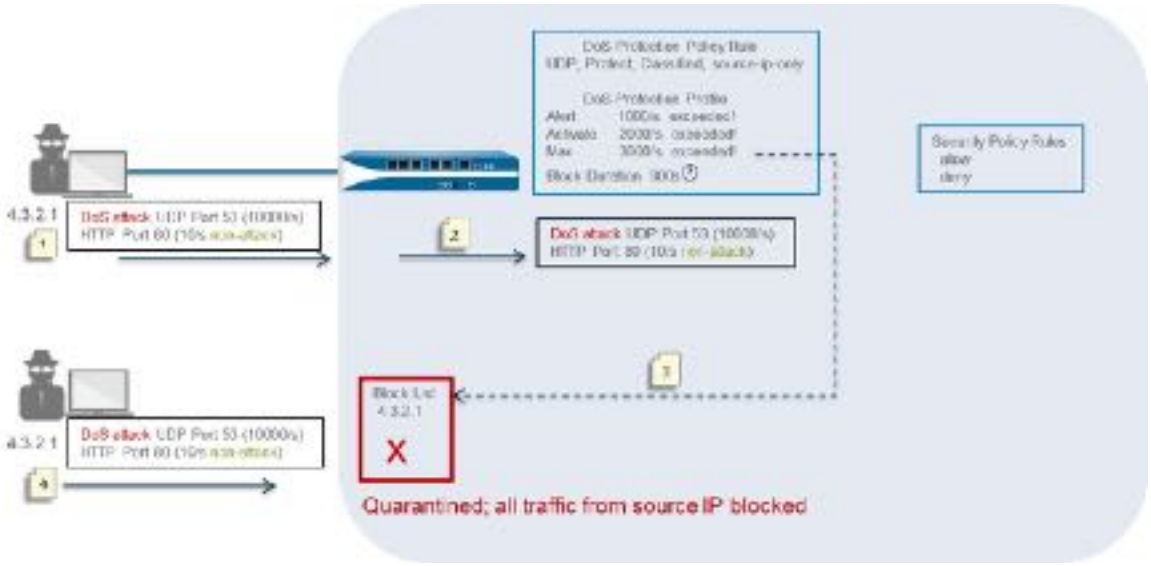
This feature defends only against DoS attacks of new sessions, that is, traffic that has not been offloaded to hardware. An offloaded attack is not protected by this feature. However, this topic describes how you can create a Security policy rule to reset the client; the attacker reinitiates the attack with numerous connections per second and is blocked by the defenses illustrated in this topic.

- Multiple-Session DoS Attack
- Single-Session DoS Attack

## Multiple-Session DoS Attack

Configure DoS Protection Against Flooding of New Sessions by configuring a DoS Protection policy rule, which determines the criteria that, when matched by incoming packets, trigger the protect action. The DoS Protection profile counts each new connection toward the Alarm Rate, Activate Rate, and Max Rate thresholds. When the incoming new connections per second exceed the Max Rate allowed, the firewall takes the action specified in the DoS Protection policy rule.

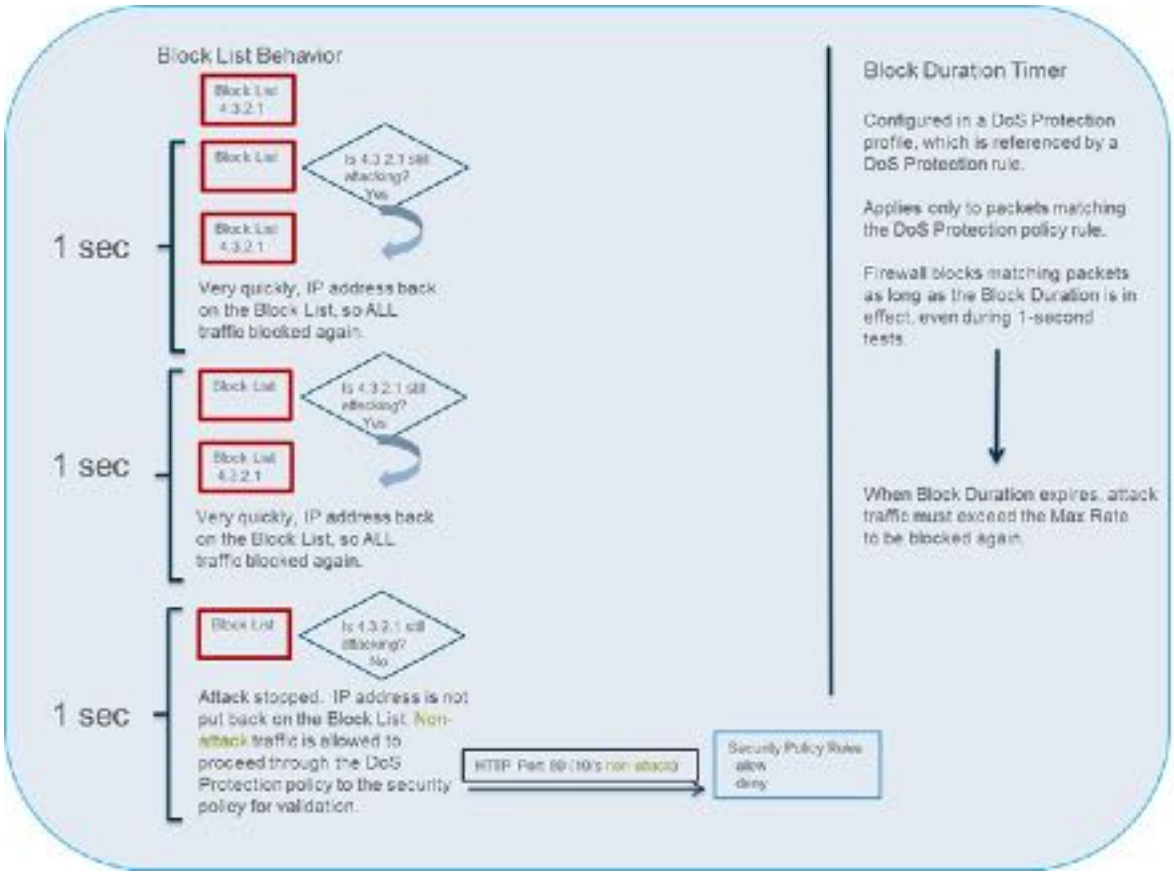
The following figure and table describe how the Security policy rules, DoS Protection policy rules and profile work together in an example.



| Sequence of Events as Firewall Quarantines an IP Address | |
|---|---|
| 1 | In this example, an attacker launches a DoS attack at a rate of 10,000 new connections per second to UDP port 53. The attacker also sends 10 new connections per second to HTTP port 80. |
| 2 | The new connections match criteria in the DoS Protection policy rule, such as a source zone or interface, source IP address, destination zone or interface, destination IP address, or a service, among other settings. In this example, the policy rule specifies UDP.<br>The DoS rule also specifies the Protect action and Classified, two settings that dynamically put the DoS Protection Profile settings into effect. The DoS Protection Profile specifies that a Max Rate of 3000 packets per second is allowed. When incoming packets match the DoS rule, new connections per second are counted toward the Alert, Activate, and Max Rate thresholds.<br>You can also use a Security policy rule to block all traffic from the source IP address if you deem that address to be malicious all the time. |
| 3 | The 10,000 new connections per second exceed the Max Rate threshold. When all of the following occur:<br>• the threshold is exceeded,<br>• a Block Duration is specified, and<br>• Classified is set to includes source IP address,<br>the firewall puts the offending source IP address on the block list. |
| 4 | An IP address on the block list is in quarantine, meaning all traffic from that IP address is blocked. The firewall blocks the offending source IP address before additional attack packets reach the Security policy. |

The following figure describes in more detail what happens after an IP address that matches the DoS Protection policy rule is put on the block list. It also describes the Block Duration timer.

 © Palo Alto Networks, Inc.



Every one second, the firewall allows the IP address to come off the Block List so that the firewall can test the traffic patterns and determine if the attack is ongoing. The firewall takes the following action:

- During this one-second test period, the firewall allows packets that do not match the DoS Protection policy criteria (HTTP traffic in this example) through the DoS Protection policy rules to the Security policy for validation. Very few packets, if any, have time to get through because the first attack packet that the firewall receives after the IP address is let off the Block List will match the DoS Protection policy criteria, quickly causing the IP address to be placed back on the block list for another second. The firewall repeats this test each second until the attack stops.
- The firewall blocks all attack traffic from going past the DoS Protection policy rules until the Block Duration expires.

When the attack stops, the firewall does not put the IP address back on the block list. The firewall allows non-attack traffic to proceed through the DoS Protection policy rules to the Security policy rules for validation. You must configure a Security policy rule because without one, an implicit deny rule denies all traffic.

The block list is based on a source zone and source address combination. This behavior allows duplicate IP addresses to exist as long as they are in different zones belonging to separate virtual routers.

The Block Duration setting in a DoS Protection profile specifies how long the firewall blocks the [offending] packets that exactly match a DoS Protection policy rule. The attack traffic remains blocked until the Block Duration expires, after which the attack traffic must again exceed the Max Rate threshold to be blocked again.

© Palo Alto Networks, Inc.

If the attacker uses multiple sessions or bots that initiate multiple attack sessions, the sessions count toward the thresholds in the DoS Protection profile without a Security policy deny rule in place. Hence, a single-session attack requires a Security policy deny rule in order for each packet to count toward the thresholds; a multiple-session attack does not.

Therefore, the DoS protection against flooding of new sessions allows the firewall to efficiently defend against a source IP address while attack traffic is ongoing and to permit non-attack traffic to pass as soon as the attack stops. Putting the offending IP address on the block list allows the DoS protection functionality to take advantage of the block list, which is designed to quarantine all activity. Quarantining the IP address from all activity protects against a modern attacker who attempts a rotating application attack, in which the attacker simply changes applications to start a new attack or uses a combination of different attacks in a hybrid DoS attack.

Beginning with PAN-OS 7.0.2, it is a change in behavior that the firewall places the attacking source IP address on the block list. When the attack stops, non-attack traffic is allowed to proceed to the Security policy rules. The attack traffic that matched the DoS Protection profile and DoS Protection policy rules remains blocked until the Block Duration expires.

## Single-Session DoS Attack

A single-session DoS attack typically will not trigger Zone or DoS Protection profiles because they are attacks that are formed after the session is created. These attacks are allowed by the Security policy because a session is allowed to be created, and after the session is created, the attack drives up the packet volume and takes down the target device.

Configure DoS Protection Against Flooding of New Sessions to protect against flooding of new sessions (single-session and multiple-session flooding). In the event of a single-session attack that is underway, additionally Use the CLI to End a Single Attacking Session.

 © Palo Alto Networks, Inc.

# Configure DoS Protection Against Flooding of New Sessions

| Configure DoS Protection Against Flooding of New Sessions | | |
|---|---|---|
| Step 1 | (Required for single-session attack mitigation or attacks that have not triggered the DoS Protection policy threshold; optional for multiple-session attack mitigation)<br><br>Configure Security policy rules to deny traffic from the attacker's IP address and allow other traffic based on your network needs. You can specify any of the match criteria in a Security policy rule, such as source IP address.<br><br> This step is one of the steps typically performed to stop an existing attack. See Use the CLI to End a Single Attacking Session. | • Set Up Basic Security Policies<br>• Components of a Security Policy Rule |

**Configure DoS Protection Against Flooding of New Sessions (Continued)**

Step 2 Configure a DoS Protection profile for flood protection.

Because flood attacks can occur over multiple protocols, as a best practice, activate protection for all of the flood types in the DoS Protection profile.

1. Select **Objects > Security Profiles > DoS Protection** and **Add** a profile **Name**.
2. Select **Classified** as the **Type**.
3. For **Flood Protection**, select the check boxes for all of the following types of flood protection:
   - **SYN Flood**
   - **UDP Flood**
   - **ICMP Flood**
   - **ICMPv6 Flood**
   - **Other IP Flood**
4. (Optional) On each of the flood tabs, change the following thresholds to suit your environment:
   - **Alarm Rate (packets/s)**—Specify the threshold rate (packets per second [pps]) above which a DoS alarm is generated. (Range is 0-2000000; default is 10000.)
   - **Activate Rate (packets/s)**—Specify the threshold rate (pps) above which a DoS response is activated. The DoS response is configured in the **Action** field of the DoS policy where this profile is referenced. When the **Activate Rate** threshold is reached, **Random Early Drop** occurs. (Range is 0-2000000; default is 10000.)
   - **Max Rate (packets/s)**—Specify the threshold rate of incoming packets per second that the firewall allows. When the threshold is exceeded, new packets that arrive are dropped and the **Action** specified in the DoS Policy rule is triggered. (Range is 2-2000000; default is 40000.)

   The default threshold values in this step are only starting points and might not be appropriate for your network. You must analyze the behavior of your network to properly set initial threshold values.
5. On each of the flood tabs, specify the **Block Duration** (in seconds), which is the length of time the firewall blocks packets that match the DoS Protection policy rule that references this profile. Specify a value greater than zero. (Range is 1-21600; default is 300.)

   Set a low Block Duration value if you are concerned that packets you incorrectly identified as attack traffic will be blocked unnecessarily.

   Set a high Block Duration value if you are more concerned about blocking volumetric attacks than you are about incorrectly blocking packets that are not part of an attack.
6. Click **OK**.

© Palo Alto Networks, Inc.

| Configure DoS Protection Against Flooding of New Sessions (Continued) | | |
|---|---|---|
| Step 3 | Configure a DoS Protection policy rule that specifies the criteria for matching the incoming traffic. | 1. Select **Policies > DoS Protection** and **Add** a **Name** on the **General** tab. The name is case-sensitive and can be a maximum of 31 characters, including letters, numbers, spaces, hyphens, and underscores.<br>2. On the **Source** tab, choose the **Type** to be a **Zone** or **Interface**, and then **Add** the zone(s) or interface(s).<br>3. (Optional) For **Source Address**, select **Any** for any incoming IP address to match the rule or **Add** an address object such as a geographical region.<br>4. (Optional) For **Source User**, select **any** or specify a user.<br>5. (Optional) Select **Negate** to match any sources except those you specify.<br>6. (Optional) On the **Destination** tab, choose the **Type** to be a **Zone** or **Interface**, and then **Add** the destination zone(s) or interface(s). For example, enter the security zone you want to protect.<br>7. (Optional) For **Destination Address**, select **Any** or enter the IP address of the device you want to protect.<br>8. (Optional) On the **Option/Protection** tab, **Add** a **Service**. Select a service or click **Service** and enter a **Name**. Select **TCP** or **UDP**. Enter a **Destination Port**. Not specifying a particular service allows the rule to match a flood of any protocol type without regard to an application-specific port.<br>9. On the **Option/Protection** tab, for **Action**, select **Protect**.<br>10. Select the **Classified** check box.<br>11. For **Profile**, select the name of the **DoS Protection** profile you created in Step 2.<br>12. For **Address**, select **source-ip-only** or **src-dest-ip-both**, which determines the type of IP address to which the rule applies. Choose the setting based on how you want the firewall to identify offending traffic.<br>• Specify **source-ip-only** if you want the firewall to classify only on the source IP address. Because attackers often test the entire network for hosts to attack, **source-ip-only** is the typical setting for a wider examination.<br>• Specify **src-dest-ip-both** if you want to protect only against DoS attacks on the server that has a specific destination address and also ensure that every source IP address will not surpass a specific connections-per-second threshold to that server.<br>13. Click **OK**. |
| Step 4 | Save the configuration. | Click **Commit**. |

## Use the CLI to End a Single Attacking Session

To mitigate a single-session DoS attack, you would still Configure DoS Protection Against Flooding of New Sessions in advance. At some point after you configure the feature, a session might be established before you realize a DoS attack (from the IP address of that session) is underway. When you see a single-session DoS attack, perform the following task to end the session, so that subsequent connection attempts from that IP address trigger the DoS protection against flooding of new sessions.

| Use the CLI to End a Single Attacking Session | |
|---|---|
| Step 1 | Identify the source IP address that is causing the attack.<br>For example, use the firewall Packet Capture feature with a destination filter to collect a sample of the traffic going to the destination IP address. Alternatively, in PAN-OS 7.0 and later, you can use ACC to filter on destination address to view the activity to the target host being attacked. |
| Step 2 | Create a DoS Protection policy rule that will block the attacker's IP address after the attack thresholds are exceeded. |
| Step 3 | Create a Security policy rule to deny the source IP address and its attack traffic. |
| Step 4 | End any existing attacks from the attacking source IP address by executing the `clear session all filter source <ip-address>` operational command.<br>Alternatively, if you know the session ID, you can execute the `clear session id <value>` command to end that session only.<br>If you use the `clear session all filter source <ip-address>` command, all sessions matching the source IP address are discarded, which can include both good and bad sessions. |

After you end the existing attack session, any subsequent attempts to form an attack session are blocked by the Security policy. The DoS Protection policy counts all connection attempts toward the thresholds. When the Max Rate threshold is exceeded, the source IP address is blocked for the Block Duration, as described in Sequence of Events as Firewall Quarantines an IP Address.

 © Palo Alto Networks, Inc.

## Identify Sessions That Use an Excessive Percentage of the Packet Buffer

When a firewall exhibits signs of resource depletion, it might be experiencing an attack that is sending an overwhelming number of packets. In such events, the firewall starts buffering inbound packets. With PAN-OS 7.0.6 and later PAN-OS 7.0 releases, you can quickly identify the sessions that are using an excessive percentage of the packet buffer and mitigate their impact by discarding them.

Perform the following task on any hardware-based firewall platform (not a VM-Series firewall) to identify, for each slot and dataplane, the packet buffer percentage used, the top five sessions using more than two percent of the packet buffer, and the source IP addresses associated with those sessions. Having that information allows you to take appropriate action.

**View Firewall Resource Usage, Top Sessions, and Session Details**

Step 1 View firewall resource usage, top sessions, and session details. Execute the following operational command in the CLI (sample output from the command follows):

```
admin@PA-7050> show running resource-monitor ingress-backlogs

-- SLOT:s1, DP:dp1 --
USAGE - ATOMIC: 92%  TOTAL: 93%

TOP SESSIONS:
SESS-ID      PCT   GRP-ID   COUNT
6            92%   1        156
                   7        1732

SESSION DETAILS
SESS-ID PROTO SZONE SRC           SPORT  DST       DPORT  IGR-IF    EGR-IF       APP
6       6     trust 192.168.2.35 55653  10.1.8.89 80  ethernet1/21 ethernet1/22
undecided
```

The command displays a maximum of the top five sessions that each use 2% or more of the packet buffer.

The sample output above indicates that Session 6 is using 92% of the packet buffers with TCP packets (protocol 6) coming from source IP address 192.168.2.35.

- **GRP-ID**—indicates an internal stage of processing packets.
- **COUNT**—indicates how many packets are in that GRP-ID for that session.
- **SESS-ID**—indicates the global session ID that is used in all other `show session` commands. The global session ID is unique within the firewall.
- **APP**—indicates the App-ID extracted from the Session information, which can help you determine whether the traffic is legitimate. For example, if packets use a common TCP or UDP port but the CLI output indicates an APP of `undecided`, the packets are possibly attack traffic. The APP is `undecided` when Application IP Decoders cannot get enough information to determine the application. An APP of `unknown` indicates that Application IP Decoders cannot determine the application; a session of `unknown` APP that uses a high percentage of the packet buffer is also suspicious.

To restrict the display output:

On a PA-7000 Series platform, you can limit output to a slot, a dataplane, or both. For example:

```
admin@PA-7050> show running resource-monitor ingress-backlogs slot s1
admin@PA-7050> show running resource-monitor ingress-backlogs slot s1 dp dp1
```

On a PA-5000 Series platform, you can limit output to a dataplane. For example:

```
admin@PA-5060> show running resource-monitor ingress-backlogs dp dp1
```

**View Firewall Resource Usage, Top Sessions, and Session Details (Continued)**

Step 2 Use the command output to determine whether the source at the source IP address using a high percentage of the packet buffer is sending legitimate or attack traffic.

In the sample output above, a single-session attack is likely occurring. A single session (Session ID 6) is using 92% of the packet buffer for Slot 1, DP 1, and the application at that point is `undecided`.

- If you determine a single user is sending an attack and the traffic is in the slow path, you can Use the CLI to End a Single Attacking Session. At a minimum, you can Configure DoS Protection Against Flooding of New Sessions.
- If the traffic is offloaded to hardware (the traffic is in the fast path), clearing the session does not help because the software then has to handle the barrage of packets. You should Discard a Session Without a Commit instead.

To see whether a session is offloaded or not, use the `show session id <session-id>` operational command in the CLI as shown in the following example. The `layer7 processing value` indicates `completed` for sessions offloaded or `enabled` for sessions not offloaded.

```
admin@PA-5060> show session id 68088184

Session       68088184

        c2s flow:
                source:      1.1.42.15 [trust]
                dst:         1.2.27.99
                proto:       6
                sport:       55993           dport:      6881
                state:       ACTIVE          type:       FLOW
                src user:    unknown
                dst user:    unknown
                offload:     Yes

        s2c flow:
                source:      1.2.27.99 [untrust]
                dst:         1.1.42.15
                proto:       6
                sport:       6881            dport:      55993
                state:       ACTIVE          type:       FLOW
                src user:    unknown

## Discard a Session Without a Commit

With PAN-OS 7.0.6 and later PAN-OS 7.0 releases, you can perform this task to permanently discard a session, such as a session that is overloading the packet buffer. No commit is required; the session is discarded immediately after executing the command. The commands you use for this task apply to both offloaded and non-offloaded sessions.

| **Discard a Session Without a Commit** | |
|---|---|
| Step 1 | In the CLI, execute the following operational command on any hardware platform:<br>`admin@PA-7050>` **request session-discard [timeout <seconds>] [reason <reason-string>] id <session-id>**<br>The default timeout is 3600 seconds. |
| Step 2 | Verify that sessions have been discarded:<br>`admin@PA-7050>` **show session all filter state discard** |

# Virtual Systems Overview

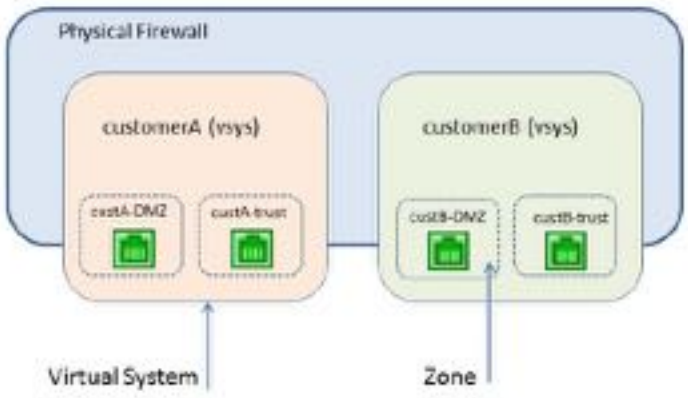
Virtual systems are separate, logical firewall instances within a single physical Palo Alto Networks firewall. Rather than using multiple firewalls, managed service providers and enterprises can use a single pair of firewalls (for high availability) and enable virtual systems on them. Each virtual system (vsys) is an independent, separately-managed firewall with its traffic kept separate from the traffic of other virtual systems.

This topic includes the following:

- Virtual System Components and Segmentation
- Benefits of Virtual Systems
- Use Cases for Virtual Systems
- Platform Support and Licensing for Virtual Systems
- Administrative Roles for Virtual Systems
- Shared Objects for Virtual Systems

## Virtual System Components and Segmentation

A virtual system is an object that creates an administrative boundary, as shown in the following figure.



A virtual system consists of a set of physical and logical interfaces and subinterfaces (including VLANs and virtual wires), virtual routers, and security zones. You choose the deployment mode(s) (any combination of virtual wire, Layer 2, or Layer 3) of each virtual system. By using virtual systems, you can segment any of the following:

- Administrative access
- The management of all policies (security, NAT, QoS, policy-based forwarding, decryption, application override, captive portal, and DoS protection)
- All objects (such as address objects, application groups and filters, dynamic block lists, security profiles, decryption profiles, custom objects, etc.)
- User-ID

 © Palo Alto Networks, Inc.

- Certificate management
- Server profiles
- Logging, reporting, and visibility functions

Virtual systems affect the security functions of the firewall, but virtual systems alone do not affect networking functions such as static and dynamic routing. You can segment routing for each virtual system by creating one or more virtual routers for each virtual system, as in the following use cases:

- If you have virtual systems for departments of one organization, and the network traffic for all of the departments is within a common network, you can create a single virtual router for multiple virtual systems.
- If you want routing segmentation and each virtual system's traffic must be isolated from other virtual systems, you can create one or more virtual routers for each virtual system.

## Benefits of Virtual Systems

Virtual systems provide the same basic functions as a physical firewall, along with additional benefits:

- **Segmented administration**—Different organizations (or customers or business units) can control (and monitor) a separate firewall instance, so that they have control over their own traffic without interfering with the traffic or policies of another firewall instance on the same physical device.
- **Scalability**—After the physical firewall is configured, adding or removing customers or business units can be done efficiently. An ISP, managed security service provider, or enterprise can provide different security services to each customer.
- **Reduced capital and operational expenses**—Virtual systems eliminate the need to have multiple physical firewalls at one location because virtual systems co-exist on one firewall. By not having to purchase multiple firewalls, an organization can save on the hardware expense, electric bills, and rack space, and can reduce maintenance and management expenses.

## Use Cases for Virtual Systems

There are many ways to use virtual systems in a network. One common use case is for an ISP or a managed security service provider (MSSP) to deliver services to multiple customers with a single firewall. Customers can choose from a wide array of services that can be enabled or disabled easily. The firewall's role-based administration allows the ISP or MSSP to control each customer's access to functionality (such as logging and reporting) while hiding or offering read-only capabilities for other functions.

Another common use case is within a large enterprise that requires different firewall instances because of different technical or confidentiality requirements among multiple departments. Like the above case, different groups can have different levels of access while IT manages the firewall itself. Services can be tracked and/or billed back to departments to thereby make separate financial accountability possible within an organization.

© Palo Alto Networks, Inc.

## Platform Support and Licensing for Virtual Systems

Virtual systems are supported on the PA-2000, PA-3000, PA-4000, PA-5000, and PA-7000 Series firewalls. Each firewall series supports a base number of virtual systems; the number varies by platform. A Virtual Systems license is required in the following cases:

- To support multiple virtual systems on PA-2000 or PA-3000 Series firewalls.
- To create more than the base number of virtual systems supported on a platform.

For license information, see Activate Licenses and Subscriptions. For the base and maximum number of virtual systems supported, see Compare Firewalls tool.

Multiple virtual systems are not supported on the PA-200, PA-500 or VM-Series firewalls.

## Administrative Roles for Virtual Systems

A **superuser** administrator can create virtual systems and add a **Device Administrator**, **vsysadmin**, or **vsysreader**. A **Device Administrator** can access all virtual systems, but cannot add administrators. The two types of virtual system administrative roles are:

- **vsysadmin**—Grants full access to a virtual system.
- **vsysreader**—Grants read-only access to a virtual system.

A virtual system administrator can view logs of only the virtual systems assigned to that administrator. Someone with **superuser** or **Device Admin** permission can view all of the logs or select a virtual system to view.

Persons with **vsysadmin** permission can commit configurations for only the virtual systems assigned to them.

## Shared Objects for Virtual Systems

If your administrator account extends to multiple virtual systems, you can choose to configure objects (such as an address object) and policies for a specific virtual system or as shared objects, which apply to all of the virtual systems on the firewall. If you try to create a shared object with the same name and type as an existing object in a virtual system, the virtual system object is used.

# Communication Between Virtual Systems

There are two typical scenarios where communication between virtual systems (inter-vsys traffic) is desirable. In a multi-tenancy environment, communication between virtual systems can occur by having traffic leave the firewall, go through the Internet, and re-enter the firewall. In a single organization environment, communication between virtual systems can remain within the firewall. This section discusses both scenarios.

- Inter-VSYS Traffic That Must Leave the Firewall
- Inter-VSYS Traffic That Remains Within the Firewall
- Inter-VSYS Communication Uses Two Sessions

## Inter-VSYS Traffic That Must Leave the Firewall

An ISP that has multiple customers on a firewall (known as multi-tenancy) can use a virtual system for each customer, and thereby give each customer control over its virtual system configuration. The ISP grants **vsysadmin** permission to customers. Each customer's traffic and management are isolated from the others. Each virtual system must be configured with its own IP address and one or more virtual routers in order to manage traffic and its own connection to the Internet.

If the virtual systems need to communicate with each other, that traffic goes out the firewall to another Layer 3 routing device and back to the firewall, even though the virtual systems exist on the same physical firewall, as shown in the following figure.

 © Palo Alto Networks, Inc.

# Inter-VSYS Traffic That Remains Within the Firewall

Unlike the preceding multi-tenancy scenario, virtual systems on a firewall can be under the control of a single organization. The organization wants to both isolate traffic between virtual systems and allow communications between virtual systems. This common use case arises when the organization wants to provide departmental separation and still have the departments be able to communicate with each other or connect to the same network(s). In this scenario, the inter-vsys traffic remains within the firewall, as described in the following topics:

- External Zone
- External Zones and Security Policies For Traffic Within a Firewall

## External Zone

The communication desired in the use case above is achieved by configuring security policies that point to or from an *external* zone. An external zone is a security object that is associated with a specific virtual system that it can reach; the zone is external to the virtual system. A virtual system can have only one external zone, regardless of how many security zones the virtual system has within it. External zones are required to allow traffic between zones in different virtual systems, without the traffic leaving the firewall.

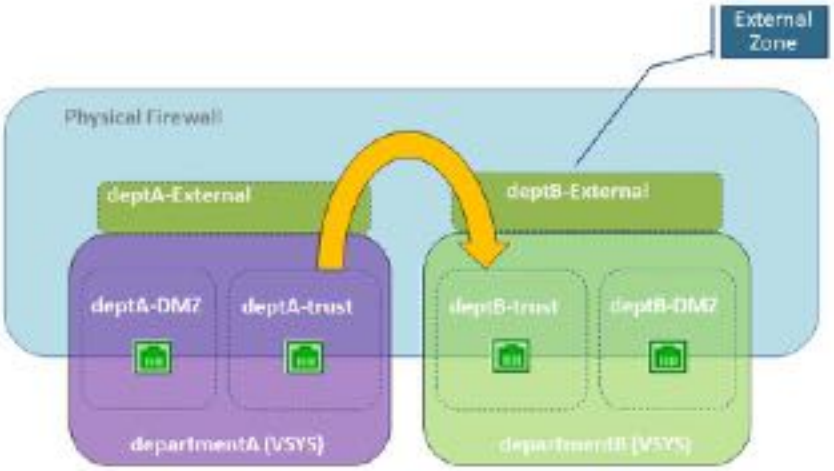
The virtual system administrator configures the security policies needed to allow traffic between two virtual systems. Unlike security zones, an external zone is not associated with an interface; it is associated with a virtual system. The security policy allows or denies traffic between the security (internal) zone and the external zone.

Because external zones do not have interfaces or IP addresses associated with them, some zone protection profiles are not supported on external zones.

Remember that each virtual system is a separate instance of a firewall, which means that each packet moving between virtual systems is inspected for security policy and App-ID evaluation.

## External Zones and Security Policies For Traffic Within a Firewall

In the following example, an enterprise has two separate administrative groups: the departmentA and departmentB virtual systems. The following figure shows the external zone associated with each virtual system, and traffic flowing from one trust zone, out an external zone, into an external zone of another virtual system, and into its trust zone.



In order to create external zones, the device administrator must configure the virtual systems so that they are *visible* to each other. External zones do not have security policies between them because their virtual systems are visible to each other.

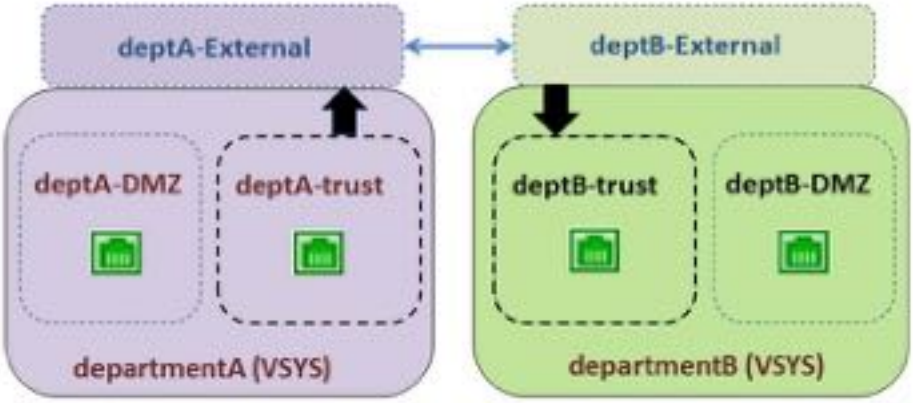
To communicate between virtual systems, the ingress and egress interfaces on the firewall are either assigned to a single virtual router or else they are connected using inter-virtual router static routes. The simpler of these two approaches is to assign all virtual systems that must communicate with each other to a single virtual router.

There might be a reason that the virtual systems need to have their own virtual router, for example, if the virtual systems use overlapping IP address ranges. Traffic can be routed between the virtual systems, but each virtual router must have static routes that point to the other virtual router(s) as the next hop.

Referring to the scenario in the figure above, we have an enterprise with two administrative groups: departmentA and departmentB. The departmentA group manages the local network and the DMZ resources. The departmentB group manages traffic in and out of the sales segment of the network. All traffic is on a local network, so a single virtual router is used. There are two external zones configured for communication between the two virtual systems. The departmentA virtual system has three zones used in security policies: deptA-DMZ, deptA-trust, and deptA-External. The departmentB virtual system also has three zones: deptB-DMZ, deptB-trust, and deptB-External. Both groups can control the traffic passing through their virtual systems.

In order to allow traffic from deptA-trust to deptB-trust, two security policies are required. In the following figure, the two vertical arrows indicate where the security policies (described below the figure) are controlling traffic.

 © Palo Alto Networks, Inc.



- Security Policy 1: In the preceding figure, traffic is destined for the deptB-trust zone. Traffic leaves the deptA-trust zone and goes to the deptA-External zone. A security policy must allow traffic from the source zone (deptA-trust) to the destination zone (deptA-External). A virtual system allows any policy type to be used for this traffic, including NAT.

  No policy is needed between external zones because traffic sent to an external zone appears in and has automatic access to the other external zones that are visible to the original external zone.

- Security Policy 2: In the preceding figure, the traffic from deptB-External is still destined to the deptB-trust zone, and a security policy must be configured to allow it. The policy must allow traffic from the source zone (deptB-External) to the destination zone (deptB-trust).

The departmentB virtual system could be configured to block traffic from the departmentA virtual system, and vice versa. Like traffic from any other zone, traffic from external zones must be explicitly allowed by policy to reach other zones in a virtual system.

In addition to external zones being required for inter-virtual system traffic that does not leave the firewall, external zones are also required if you configure a Shared Gateway, in which case the traffic is intended to leave the firewall.

## Inter-VSYS Communication Uses Two Sessions

It is helpful to understand that communication between two virtual systems uses two sessions, unlike the one session used for a single virtual system. Let's compare the scenarios.

Scenario 1—Vsys1 has two zones: trust1 and untrust1. A host in the trust1 zone initiates traffic when it needs to communicate with a device in the untrust1 zone. The host sends traffic to the firewall, and the firewall creates a new session for source zone trust1 to destination zone untrust1. Only one session is needed for this traffic.

Scenario 2—A host from vsys1 needs to access a server on vsys2. A host in the trust1 zone initiates traffic to the firewall, and the firewall creates the first session: source zone trust1 to destination zone untrust1. Traffic is routed to vsys2, either internally or externally. Then the firewall creates a second session: source zone untrust2 to destination zone trust2. Two sessions are needed for this inter-vsys traffic.

# Shared Gateway

This topic includes the following information about shared gateways:

- External Zones and Shared Gateway
- Networking Considerations for a Shared Gateway

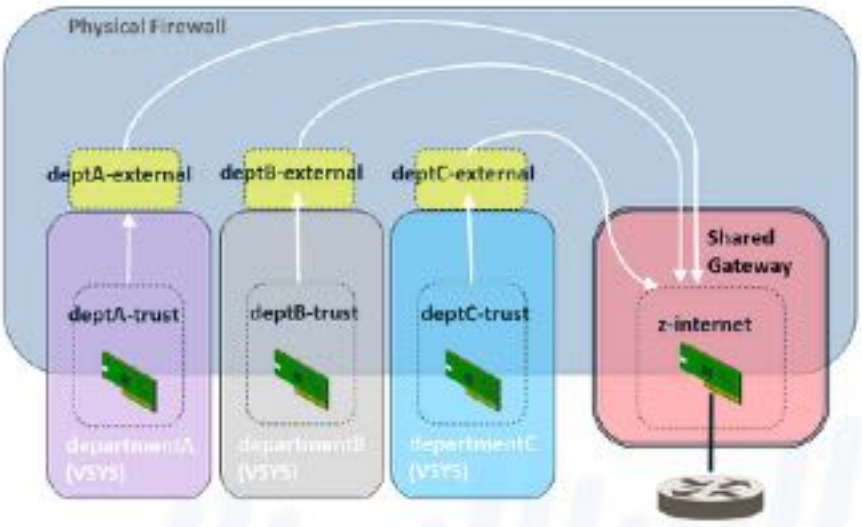
## External Zones and Shared Gateway

A shared gateway is an interface that multiple virtual systems share in order to communicate over the Internet. Each virtual system requires an External Zone, which acts as an intermediary, for configuring security policies that allow or deny traffic from the virtual system's internal zone to the shared gateway.

The shared gateway uses a single virtual router to route traffic for all virtual systems. A shared gateway is used in cases when an interface does not need a full administrative boundary around it, or when multiple virtual systems must share a single Internet connection. This second case arises if an ISP provides an organization with only one IP address (interface), but multiple virtual systems need external communication.

Unlike the behavior between virtual systems, security policy and App-ID evaluations are not performed between a virtual system and a shared gateway. That is why using a shared gateway to access the Internet involves less overhead than creating another virtual system to do so.

In the following figure, three customers share a firewall, but there is only one interface accessible to the Internet. Creating another virtual system would add the overhead of App-ID and security policy evaluation for traffic being sent to the interface through the added virtual system. To avoid adding another virtual system, the solution is to configure a shared gateway, as shown in the following diagram.



The shared gateway has one globally-routable IP address used to communicate with the outside world. Interfaces in the virtual systems have IP addresses too, but they can be private, non-routable IP addresses.

You will recall that an administrator must specify whether a virtual system is visible to other virtual systems. Unlike a virtual system, a shared gateway is always visible to all of the virtual systems on the firewall.

A shared gateway ID number appears as **sg<ID>** on the web interface. It is recommended that you name your shared gateway with a name that includes its ID number.

When you add objects such as zones or interfaces to a shared gateway, the shared gateway appears as an available virtual system in the vsys drop-down menu.

A shared gateway is a limited version of a virtual system; it supports NAT and policy-based forwarding (PBF), but does not support security, DoS policies, QoS, decryption, application override, or captive portal policies.

## Networking Considerations for a Shared Gateway

Keep the following in mind while you are configuring a shared gateway.

- The virtual systems in a shared gateway scenario access the Internet through the shared gateway's physical interface, using a single IP address. If the IP addresses of the virtual systems are not globally routable, configure source NAT to translate those addresses to globally-routable IP addresses.
- A virtual router routes the traffic for all of the virtual systems through the shared gateway.
- The default route for the virtual systems should point to the shared gateway.
- Security policies must be configured for each virtual system to allow the traffic between the internal zone and external zone, which is visible to the shared gateway.
- A device administrator should control the virtual router, so that no member of a virtual system can affect the traffic of other virtual systems.
- Within a Palo Alto Networks firewall, a packet may hop from one virtual system to another virtual system or a shared gateway. A packet may not traverse more than two virtual systems or shared gateways. For example, a packet cannot go from one virtual system to a shared gateway to a second virtual system within the firewall.

To save configuration time and effort, consider the following advantages of a shared gateway:

- Rather than configure NAT for multiple virtual systems associated with a shared gateway, you can configure NAT for the shared gateway.
- Rather than configure policy-based routing (PBR) for multiple virtual systems associated with a shared gateway, you can configure PBR for the shared gateway.

 © Palo Alto Networks, Inc.

# Service Routes for Virtual Systems

The firewall uses the MGT interface (by default) to access external services, such as DNS servers, software updates, and software licenses. An alternative to using the MGT interface is to configure a data port (a regular interface) to access these services. The path from the interface to the service on a server is known as a *service route*. Service routes can be configured for the firewall or for individual virtual systems. Each service allows redirection of management services to the respective virtual system owner through one of the interfaces associated with that virtual system.

The ability to configure service routes per virtual system provides the flexibility to customize service routes for numerous tenants or departments on a single firewall. The service packets exit the firewall on a port that is assigned to a specific virtual system, and the server sends its response to the configured source interface and source IP address. Any virtual system that does not have a service route configured for a particular service inherits the interface and IP address that are set globally for that service.

- Use Cases for Service Routes for a Virtual System
- PA-7000 Series Firewall LPC Support for Per-Virtual System Paths to Logging Servers
- DNS Proxy Object
- DNS Server Profile
- Multi-Tenant DNS Deployments

To configure service routes for a virtual system, see Customize Service Routes for a Virtual System.

## Use Cases for Service Routes for a Virtual System

One use case for configuring service routes at the virtual system level is when a large customer (such as an ISP) needs to support multiple individual tenants on a single Palo Alto Networks firewall. The ISP has configured virtual systems on the firewall, and wants to have separate service routes for each virtual system, rather than services routes configured at the global level. Each tenant requires service route capabilities so that it can customize service route parameters for DNS, email, Kerberos, LDAP, NetFlow, RADIUS, SNMP trap, syslog, TACACS+, User-ID Agent, and VM Monitor.

Another use case is an IT organization that wants to provide full autonomy to groups that set servers for services. Each group can have a virtual system and define its own service routes.

If **Multi Virtual System Capability** is enabled, any virtual system that does not have specific service routes configured inherits the global service and service route settings for the device.

An organization can have multiple virtual systems, but use a global service route for a service rather than different service routes for each virtual system. For example, the firewall can use a shared email server to originate email alerts to its virtual systems.

A firewall with multiple virtual systems must have interfaces and subinterfaces with non-overlapping IP addresses.

A per-virtual system service route for SNMP traps or for Kerberos is for IPv4 only.

You can select a virtual router for a service route in a virtual system; you cannot select the egress interface. After you select the virtual router and the firewall sends the packet from the virtual router, the firewall selects the egress interface based on the destination IP address. Therefore:

- If a virtual system has multiple virtual routers, packets to all of the servers for a service must egress out of only one virtual router.
- A packet with an interface source address may egress a different interface, but the return traffic would be on the interface that has the source IP address, creating asymmetric traffic.

 © Palo Alto Networks, Inc.

## PA-7000 Series Firewall LPC Support for Per-Virtual System Paths to Logging Servers

For Traffic, HIP Match, Threat, and Wildfire log types, the PA-7000 Series firewall does not use service routes for SNMP Trap, syslog and email services. Instead, the PA-7000 Series firewall Log Processing Card (LPC) supports virtual system-specific paths from LPC subinterfaces to an on-premise switch to the respective service on a server. For System and Config logs, the PA-7000 Series firewall uses global service routes, and not the LPC.

In other Palo Alto Networks platforms, the dataplane sends logging service route traffic to the management plane, which sends the traffic to logging servers. In the PA-7000 Series firewall, each LPC has only one interface, and data planes for multiple virtual systems send logging server traffic (types mentioned above) to the PA-7000 Series firewall LPC. The LPC is configured with multiple subinterfaces, over which the platform sends the logging service traffic out to a customer's switch, which can be connected to multiple logging servers.

Each LPC subinterface can be configured with a subinterface name and a dotted subinterface number. The subinterface is assigned to a virtual system, which is configured for logging services. The other service routes on a PA-7000 Series firewall function similarly to service routes on other Palo Alto Networks platforms.

To configure the LPC for per-virtual system logging services, see Configure a PA-7000 Series Firewall for Logging Per Virtual System. For information about the LPC itself, see the PA-7000 Series Hardware Reference Guide.

## DNS Proxy Object

Domain Name System (DNS) servers perform the service of resolving a domain name to an IP address, and vice versa. DNS proxy is a role in which the firewall is an intermediary between DNS clients and servers; it acts as a DNS server itself by resolving queries from its DNS proxy cache. If the domain name is not found in the DNS proxy cache, the firewall searches for a match to the domain name among the entries in the specific DNS proxy object (on the interface on which the DNS query arrived), and forwards the query to a DNS server based on the match results. If no match is found, the default DNS servers are used.

A DNS proxy object is where you configure the settings that determine how the firewall functions as a DNS proxy. You can assign a DNS proxy object to a single virtual system or it can be shared among all virtual systems.

- If the DNS proxy object is for a virtual system, you can specify a DNS Server Profile, which specifies the primary and secondary DNS server addresses, along with other information. The DNS server profile simplifies configuration.
- If the DNS proxy object is shared, you must specify at least the primary address of a DNS server.

When configuring tenants with DNS services, each tenant should have its own DNS proxy defined, which keeps the tenant's DNS service separate from other tenants' services.

In the proxy object, you specify the interfaces for which the firewall is acting as DNS proxy. The DNS proxy for the interface does not use the service route; responses to the DNS requests are always sent to the interface assigned to the virtual router where the DNS request arrived.

You can supply the DNS proxy with static FQDN-to-address mappings. You can create DNS proxy rules that control to which DNS server the specified domain name queries are directed. A DNS proxy has other options; to configure a DNS proxy, see Configure a DNS Proxy Object. A maximum of 256 DNS proxy objects can be configured on a firewall.

 © Palo Alto Networks, Inc.

## DNS Server Profile

To simplify configuration for a virtual system, a DNS server profile allows you to specify the virtual system that is being configured, an inheritance source or the primary and secondary IP addresses for DNS servers, and a source interface and source address (service route) that will be used in packets sent to the DNS server. The source interface determines the virtual router, which has a route table. The destination IP address is looked up in the routing table of the virtual router where the source interface is assigned. It is possible that the result of the destination IP egress interface differs from the source interface. The packet would egress out of the destination IP egress interface determined by the route table lookup, but the source IP address would be the address configured. The source address is used as the destination address in the reply from the DNS server.

The virtual system report and virtual system server profile send their queries to the DNS server specified for the virtual system, if there is one. (The DNS server used is defined in **Device > Virtual Systems > General > DNS Proxy**.) If there is no DNS server specified for the virtual system, the DNS server specified for the device is queried.

A DNS server profile is for a virtual system only; it is not for a global **Shared** location. To configure a DNS server profile, see Configure a DNS Server Profile.

For more information on DNS server profiles, see DNS Resolution—Three Use Cases.

## Multi-Tenant DNS Deployments

There are three use cases for multi-tenant DNS deployments:

- **Global Management DNS Resolution**—The firewall needs DNS resolution for its own purposes, for example, when the request is coming from the management plane to resolve an FQDN in a security policy. The firewall uses the service route to get to a DNS server because there is no incoming virtual router. The DNS server is configured in **Device > Setup > Services > Global**, and **Servers** are configured by entering a primary and secondary DNS server.
- **Policy and Report FQDN Resolution for a Virtual System**—For DNS queries that need to be resolved from a security policy or a report, you can specify a set of DNS servers specific to the virtual system (tenant) or you can default to the global DNS servers. If your use case requires a different set of DNS servers per virtual system, the DNS server is configured in **Device > Virtual Systems > General > DNS Proxy**. The DNS proxy object is configured in **Network > DNS Proxy**. The resolution is specific to the virtual system to which the DNS proxy is assigned. If you don't have specific DNS servers applicable to this virtual system and want to use the global DNS setting, the global DNS servers take precedence.
- **Dataplane DNS Resolution for a Virtual System**—This method is also known as a Network Request for DNS Resolution. The tenant's virtual system can be configured so that specified domain names are resolved on the tenant's DNS server in its network. This method supports *split DNS*, meaning that the tenant can also use its own ISP DNS servers for the remaining DNS queries not resolved on its own server. DNS Proxy rules control the split DNS; the tenant's domain redirects DNS requests to its DNS servers, which are configured in a DNS server profile. The DNS server profile has primary and secondary DNS servers designated, and also DNS service routes for IPv4 and IPv6, which override the default DNS settings.

For more information on DNS deployments, see DNS Resolution—Three Use Cases.

# Configure Virtual Systems

Creating a virtual system requires that you have the following:

- A **superuser** administrative role.
- An interface configured.
- A Virtual Systems license if you are configuring a PA-2000 or PA-3000 Series firewall, or if you are creating more than the base number of virtual systems supported on the platform. See Platform Support and Licensing for Virtual Systems.

| **Configure a Virtual System** | |
|---|---|
| Step 1 Enable virtual systems. | 1. Select **Device > Setup > Management** and edit the **General Settings**.<br>2. Select the **Multi Virtual System Capability** check box and click **OK**. This action triggers a commit if you approve it.<br>Only after enabling virtual systems will the **Device** tab display the **Virtual Systems** and **Shared Gateways** options. |
| Step 2 Create a virtual system. | 1. Select **Device > Virtual Systems**, click **Add** and enter a virtual system **ID**, which is appended to "vsys" (range is 1-255).<br> The default ID is 1, which makes the default virtual system **vsys1**. This default appears even on platforms that do not support multiple virtual systems.<br>2. Check the **Allow forwarding of decrypted content** check box if you want to allow the firewall to forward decrypted content to an outside service. For example, you must enable this option for the firewall to be able to send decrypted content to WildFire for analysis.<br>3. Enter a descriptive **Name** for the virtual system. A maximum of 31 alphanumeric, space, and underscore characters is allowed. |

| Configure a Virtual System | | |
|---|---|---|
| Step 3 | Assign interfaces to the virtual system.<br>The virtual routers, vwires, or VLANs can either be configured already or you can configure them later, at which point you specify the virtual system associated with each. The procedure to configure a virtual router, for example, is in Step 6 below. | 1. On the **General** tab, select a **DNS Proxy** object if you want to apply DNS proxy rules to the interface.<br>2. In the **Interfaces** field, click **Add** to enter the interfaces or subinterfaces to assign to the virtual system. An interface can belong to only one virtual system.<br>3. Do any of the following, based on the deployment type(s) you need in the virtual system:<br>• In the **VLANs** field, click **Add** to enter the VLAN(s) to assign to the vsys.<br>• In the **Virtual Wires** field, click **Add** to enter the virtual wire(s) to assign to the vsys.<br>• In the **Virtual Routers** field, click **Add** to enter the virtual router(s) to assign to the vsys.<br>4. In the **Visible Virtual System** field, check all virtual systems that should be made visible to the virtual system being configured. This is required for virtual systems that need to communicate with each other.<br>In a multi-tenancy scenario where strict administrative boundaries are required, no virtual systems would be checked.<br>5. Click **OK**. |
| Step 4 | (Optional) Limit the resource allocations for sessions, rules, and VPN tunnels allowed for the virtual system. The flexibility of being able to allocate limits per virtual system allows you to effectively control device resources. | 1. On the **Resource** tab, optionally set limits for a virtual system. There are no default values.<br>• **Sessions Limit**—Range is 1-262144.<br>• **Security Rules**—Range is 0-2500.<br>• **NAT Rules**—Range is 0-3000.<br>• **Decryption Rules**—Range is 0-250.<br>• **QoS Rules**—Range is 0-1000.<br>• **Application Override Rules**—Range is 0-250.<br>• **Policy Based Forwarding Rules**—Range is 0-500.<br>• **Captive Portal Rules**—Range is 0-1000.<br>• **DoS Protection Rules**—Range is 0-1000.<br>• **Site to Site VPN Tunnels**—Range is 0-1024.<br>• **Concurrent SSL VPN Tunnels**—Range is 0-1024.<br>2. Click **OK**. |
| Step 5 | Save the configuration. | Click **Commit** and **OK**. The virtual system is now an object accessible from the **Objects** tab. |

© Palo Alto Networks, Inc.

| Configure a Virtual System | | |
|---|---|---|
| Step 6 | Create at least one virtual router for the virtual system in order to make the virtual system capable of networking functions, such as static and dynamic routing.<br>Alternatively, your virtual system might use a VLAN or a virtual wire, depending on your deployment. | 1. Select **Network > Virtual Routers** and **Add** a virtual router by **Name**.<br>2. For **Interfaces,** click **Add** and from the drop-down, select the interfaces that belong to the virtual router.<br>3. Click **OK**. |
| Step 7 | Configure a security zone for each interface in the virtual system. | For at least one interface, create a Layer 3 security zone. See Configure Interfaces and Zones. |
| Step 8 | Configure the security policies allowing or denying traffic to and from the zones in the virtual system. | See Set Up Basic Security Policies. |
| Step 9 | Save the configuration. | Click **Commit** and **OK**.<br>After a virtual system is created, a device administrator can use the CLI to commit a configuration for only a specific virtual system:<br>`PA-5060> commit partial vsys vsys<id>` |
| Step 10 | (Optional) View the security policies configured for a virtual system. | Open an SSH session to use the CLI. To view the security policies for a virtual system, in operational mode, use the following commands:<br>`PA-5060> set system setting target-vsys <vsys-id>`<br>`PA-5060> show running security-policy` |

# Configure Inter-Virtual System Communication within the Firewall

Perform this task if you have a use case, perhaps within a single enterprise, where you want the virtual systems to be able to communicate with each other within the firewall. Such a scenario is described in Inter-VSYS Traffic That Remains Within the Firewall. This task presumes:

- ❒ You completed the task, Configure Virtual Systems.
- ❒ When configuring the virtual systems, in the **Visible Virtual System** field, you checked the boxes of all virtual systems that must communicate with each other to be visible to each other.

| **Configure Inter-Virtual System Communication within the Firewall** | | |
|---|---|---|
| Step 1 | Configure an external zone for each virtual system. | 1. Select **Network > Zones** and **Add** a new zone by **Name**.<br>2. For **Location**, select the virtual system for which you are creating an external zone.<br>3. For **Type**, select **External**.<br>4. For **Virtual Systems**, click **Add** and enter the virtual system that the external zone can reach.<br>5. **Zone Protection Profile**—Optionally select a zone protection profile (or configure one later) that provides flood, reconnaissance, or packet-based attack protection.<br>6. **Log Setting—**Optionally select a log forwarding profile for forwarding zone protection logs to an external system.<br>7. Optionally select the **Enable User Identification** check box to enable User-ID for the external zone.<br>8. Click **OK**. |
| Step 2 | Configure the security policies allowing or denying traffic from the internal zones to the external zone of the virtual system, and vice versa. | • See Set Up Basic Security Policies.<br>• See Inter-VSYS Traffic That Remains Within the Firewall. |
| Step 3 | Save the configuration. | Click **Commit**. |

 © Palo Alto Networks, Inc.

# Configure a Shared Gateway

Perform this task if you need multiple virtual systems to share an interface (a Shared Gateway) to the Internet. This task presumes:

- You configured an interface with a globally-routable IP address, which will be the shared gateway.
- You completed the prior task, Configure Virtual Systems. For the interface, you chose the external-facing interface with the globally-routable IP address.
- When configuring the virtual systems, in the **Visible Virtual System** field, you checked the boxes of all virtual systems that must communicate to be visible to each other.

| **Configure a Shared Gateway** | | |
|---|---|---|
| Step 1 | Configure a Shared Gateway. | 1. Select **Device > Shared Gateway**, click **Add** and enter an **ID**.<br>2. Enter a helpful **Name**, preferably including the **ID** of the gateway.<br>3. In the **DNS Proxy** field, select a DNS proxy object if you want to apply DNS proxy rules to the interface.<br>4. **Add** an **Interface** that connects to the outside world.<br>5. Click **OK**. |
| Step 2 | Configure the zone for the shared gateway.<br> When adding objects such as zones or interfaces to a shared gateway, the shared gateway itself will be listed as an available vsys in the **VSYS** drop-down menu. | 1. Select **Network > Zones** and **Add** a new zone by **Name**.<br>2. For **Location**, select the shared gateway for which you are creating a zone.<br>3. For **Type**, select **Layer3**.<br>4. **Zone Protection Profile**—Optionally select a zone protection profile (or configure one later) that provides flood, reconnaissance, or packet-based attack protection.<br>5. **Log Setting—**Optionally select a log forwarding profile for forwarding zone protection logs to an external system.<br>6. Optionally select the **Enable User Identification** check box to enable User-ID for the shared gateway.<br>7. Click **OK**. |
| Step 3 | Save the configuration. | Click **Commit**. |

# Customize Service Routes for a Virtual System

- Customize Service Routes to Services for Virtual Systems
- Configure a PA-7000 Series Firewall for Logging Per Virtual System
- Configure a DNS Proxy Object
- Configure a DNS Server Profile
- Configure Administrative Access Per Virtual System or Device

## Customize Service Routes to Services for Virtual Systems

❒ Prior to performing this task, in order to see the **Global** and **Virtual Systems** tabs, you must enable **Multi Virtual System Capability**.

If **Multi Virtual System Capability** is enabled, any virtual system that does not have specific service routes configured inherits the global service and service route settings for the device.

The firewall supports syslog forwarding on a virtual system basis. When multiple virtual systems on a firewall are connecting to a syslog server using SSL transport, the firewall can generate only one certificate for secure communication. The firewall does not support each virtual system having its own certificate.

In the following use case, you are configuring individual services routes for a firewall with multiple virtual systems.

 © Palo Alto Networks, Inc.

| Customize Service Routes to Services Per Virtual System | |
|---|---|
| Step 1 Customize service routes for a virtual system. | 1. Select **Device > Setup > Services > Virtual Systems**, and select the virtual system you want to configure.<br>2. Click the **Service Route Configuration** link.<br>3. Select one of the radio buttons:<br>• **Inherit Global Service Route Configuration**—Causes the virtual system to inherit the global service route settings relevant to a virtual system. If you choose this option, skip down to step 7.<br>• **Customize**—Allows you to specify a source interface and source address for each service.<br>4. If you chose **Customize**, select the **IPv4** or **IPv6** tab, depending on what type of addressing the server offering the service uses. You can specify both IPv4 and IPv6 addresses for a service. Click the check box(es) for the services for which you want to specify the same source information. (Only services that are relevant to a virtual system are available.) Click **Set Selected Service Routes**.<br>• For **Source Interface**, select **Any**, **Inherit Global Setting**, or an interface from the drop-down to specify the source interface that will be used in packets sent to the external service(s). Hence, the server's response will be sent to that source interface. In our example deployment, you would set the source interface to be the subinterface of the tenant.<br>• **Source Address** will indicate **Inherited** if you selected **Inherit Global Setting** for the **Source Interface** or it will indicate the source address of the **Source Interface** you selected. If you selected **Any** for **Source Interface**, select an IP address from the drop-down, or enter an IP address (using the IPv4 or IPv6 format that matches the tab you chose) to specify the source address that will be used in packets sent to the external service.<br>• If you modify an address object and the IP family type (IPv4/IPv6) changes, a **Commit** is required to update the service route family to use.<br>5. Click **OK**.<br>6. Repeat steps 4 and 5 to configure source addresses for other external services.<br>7. Click **OK**. |
| Step 2 Save the configuration. | Click **Commit** and **OK**.<br>If you are configuring per-virtual system service routes for logging services for a PA-7000 Series firewall, continue to the task Configure a PA-7000 Series Firewall for Logging Per Virtual System. |

## Configure a PA-7000 Series Firewall for Logging Per Virtual System

❒ You must have enabled **Multi Virtual System Capability** (**Device > Setup > Management**) in order to access the LPC subinterface configuration.

Perform this task on your PA-7000 Series firewall to configure logging for different virtual systems. For more information, see PA-7000 Series Firewall LPC Support for Per-Virtual System Paths to Logging Servers.

| **Configure a PA-7000 Series Firewall Subinterface for Service Routes per Virtual System** | | |
|---|---|---|
| Step 1 | Create a Log Card subinterface. | 1. Select **Network > Interfaces > Ethernet** and select the interface that will be the Log Card interface.<br>2. Enter the **Interface Name**.<br>3. For **Interface Type**, select **Log Card** from the drop-down.<br>4. Click **OK**. |
| Step 2 | Add a subinterface for each tenant on the LPCs physical interface. | 1. Highlight the Ethernet interface that is a Log Card interface type and click **Add Subinterface**.<br>2. For **Interface Name**, after the period, enter the subinterface assigned to the tenant's virtual system.<br>3. For **Tag**, enter a VLAN tag value.<br> Make the tag the same as the subinterface number for ease of use, but it could be a different number.<br>4. (Optional) Enter a **Comment**.<br>5. On the **Config** tab, in the **Assign Interface to Virtual System** field, select the virtual system to which the LPC subinterface is assigned (from the drop-down). Alternatively, you can click **Virtual Systems** to add a new virtual system.<br>6. Click **OK**. |
| Step 3 | Enter the addresses assigned to the subinterface, and configure the default gateway. | 1. Select the **Log Card Forwarding** tab, and do one or both of the following:<br>• For the IPv4 section, enter the **IP Address** and **Netmask** assigned to the subinterface. Enter the **Default Gateway** (the next hop where packets will be sent that have no known next hop address in the Routing Information Base [RIB]).<br>• For the IPv6 section, enter the **IPv6 Address** assigned to the subinterface. Enter the **IPv6 Default Gateway**.<br>2. Click **OK**. |
| Step 4 | Save the configuration. | Click **OK** and **Commit**. |
| Step 5 | If you haven't already done so, configure the remaining service routes for the virtual system. | Customize Service Routes for a Virtual System. |

 © Palo Alto Networks, Inc.

## Configure a DNS Proxy Object

If your firewall is to act as a DNS proxy for a virtual system, perform this task to configure a DNS Proxy Object. The proxy object can either be shared among all virtual systems or applied to a specific virtual system.

| Configure a DNS Proxy Object | | |
|---|---|---|
| Step 1 | Configure the basic settings for a DNS Proxy object. | 1. Select **Network > DNS Proxy** and **Add** a new object.<br>2. Verify that **Enable** is selected.<br>3. Enter a **Name** for the object.<br>4. For **Location**, select the virtual system to which the object applies. If you select **Shared**, you must specify at least a **Primary** DNS server address., and optionally a **Secondary** address.<br>5. If you selected a virtual system, for **Server Profile**, select a DNS Server profile or else click **DNS Server Profile** to configure a new profile. see Configure a DNS Server Profile.<br>6. For **Interface**, click **Add** and specify the interfaces to which the DNS Proxy object applies.<br>• If you use the DNS Proxy object for performing DNS lookups, an interface is required. The firewall will listen for DNS requests on this interface, and then proxy them.<br>• If you use the DNS Proxy object for a service route, the interface is optional. |
| Step 2 | (Optional) Specify DNS Proxy rules. | 1. On the **DNS Proxy Rules** tab, click **Add** and enter a **Name** for the rule.<br>2. **Turn on caching of domains resolved by this mapping** if you want the firewall to cache the resolved domains.<br>3. For **Domain Name**, click **Add** and enter one or more domains, one entry per row. Each domain name can contain * as a wildcard. The number of tokens in a wildcard string must match the number of tokens in the requested domain. For example, '*.engineering.local' will not match 'engineering.local'. Both entries must be specified if you want both.<br>4. In Step 4 above, for **Location**:<br>• If you chose a virtual system, select a **DNS Server profile** here.<br>• If you chose **Shared**, enter a **Primary** address here.<br>5. Click **OK**. |
| Step 3 | (Optional) Supply the DNS Proxy with static FQDN-to-address entries. Static DNS entries allow the firewall to resolve the FQDN to an IP address without going out to the DNS server. | 1. On the **Static Entries** tab, click **Add** and enter a **Name**.<br>2. Enter the Fully Qualified Domain Name (**FQDN**).<br>3. For **Address**, click **Add** and enter the IP address to which the FQDN should be mapped.<br>4. Repeat steps 1-3 to provide additional static entries.<br>5. Click **OK**. |

© Palo Alto Networks, Inc.

| Configure a DNS Proxy Object (Continued) | | |
|---|---|---|
| Step 4 | (Optional) Enable caching and configure other advanced settings for the DNS Proxy. | 1. On the **Advanced** tab, click **Cache** to enable the firewall to cache FQDN-to-address mappings that the firewall learns.<br>• **Size**—Enter the maximum number of entries the firewall can cache (range is 1024-10240; default is 1024).<br>• **Timeout**—Enter the number of hours after which all cached entries are removed (range is 4-24; default is 4). DNS time-to-live values are used to remove cache entries when they have been stored for less than the configured timeout period. After a timeout, new DNS requests must be resolved and cached again.<br>2. Select **TCP Queries** to enable DNS queries using TCP.<br>• **Max Pending Requests**—Enter the maximum number of concurrent, pending TCP DNS requests that the firewall will support (range is 64-256; default is 64).<br>3. For **UDP Queries Retries**, enter the following:<br>• **Interval**—Enter the length of time (in seconds) after which another request is sent if no response has been received. (range is 1-30; default is 2).<br>• **Attempts**—Enter the maximum number of UDP query attempts (excluding the first attempt) after which the next DNS server is queried (range is 1-30; default is 5.) |
| Step 5 | Save the configuration. | Click **OK** and **Commit**. |

## Configure a DNS Server Profile

Perform this task to configure a DNS Server Profile, which simplifies configuration of a virtual system. The **Primary DNS** or **Secondary DNS** address is used to create the DNS request that the virtual system sends to the DNS server.

 © Palo Alto Networks, Inc.

| Configure a DNS Server Profile | | |
|---|---|---|
| Step 1 | Name the DNS server profile, select the virtual system to which it applies, and specify the primary and secondary DNS server addresses. | 1. Select **Device > Server Profiles > DNS** and click **Add**.<br>2. Enter a **Name** for the DNS server profile.<br>3. For **Location**, select the virtual system to which the profile applies.<br>4. For **Inheritance Source**, from the drop-down, select **None** if the DNS server addresses are not inherited. Otherwise, specify the DNS server from which the profile should inherit settings. If you choose a DNS server, click **Check inheritance source status** to see that information.<br>5. Specify the IP address of the **Primary DNS** server, or leave as **inherited** if you chose an **Inheritance Source**.<br> Keep in mind that if you specify an FQDN instead of an IP address, the DNS for that FQDN is resolved in **Device > Virtual Systems > DNS Proxy**.<br>6. Specify the IP address of the **Secondary DNS** server, or leave as **inherited** if you chose an **Inheritance Source**. |
| Step 2 | Configure the service route that the firewall automatically uses, based on whether the target DNS Server has an IP address family type of IPv4 or IPv6. | 1. Click **Service Route IPv4** to enable the subsequent interface and IPv4 address to be used as the service route, if the target DNS address is an IPv4 address.<br>2. Specify the **Source Interface** to select the DNS server's source IP address that the service route will use. The firewall determines which virtual router is assigned that interface, and then does a route lookup in the virtual router routing table to reach the destination network (based on the **Primary DNS** address).<br>3. Specify the IPv4 **Source Address** from which packets going to the DNS server are sourced.<br>4. Click **Service Route IPv6** to enable the subsequent interface and IPv6 address to be used as the service route, if the target DNS address is an IPv6 address.<br>5. Specify the **Source Interface** to select the DNS server's source IP address that the service route will use. The firewall determines which virtual router is assigned that interface, and then does a route lookup in the virtual router routing table to reach the destination network (based on the **Primary DNS** address).<br>6. Specify the IPv6 **Source Address** from which packets going to the DNS server are sourced.<br>7. Click **OK**. |
| Step 3 | Save the configuration. | Click **OK** and **Commit**. |

## Configure Administrative Access Per Virtual System or Device

If you have a superuser administrative account, you now have the ability to create and configure more granular permissions for a vsysadmin or device admin role.

| Create an Admin Role Profile Per Virtual System or Device | | |
|---|---|---|
| Step 1 | Create an Admin Role Profile that grants or disables permission to an Administrator to configure or read-only various areas of the web interface. | 1. Select **Device > Admin Roles** and **Add** an **Admin Role Profile**.<br>2. Enter a **Name** and optional **Description** of the profile.<br>3. For **Role**, specify which level of control the profile affects:<br>• **Device**—The profile allows the management of the global settings and any virtual systems.<br>• **Virtual System**—The profile allows the management of only the virtual system(s) assigned to the administrator(s) who have this profile. (The administrator will be able to access **Device > Setup > Services > Virtual Systems**, but not the **Global** tab.)<br>4. On the **Web UI** tab for the Admin Role Profile, scroll down to **Device**, and leave the green check mark (Enable).<br>• Under **Device**, enable **Setup**. Under **Setup**, enable the areas to which this profile will grant configuration permission to the administrator, as shown below. (The Read Only lock icon appears in the Enable/Disable rotation if Read Only is allowed for that setting.)<br>– **Management**—Allows an admin with this profile to configure settings on the **Management** tab.<br>– **Operations**—Allows an admin with this profile to configure settings on the **Operations** tab.<br>– **Services**—Allows an admin with this profile to configure settings on the **Services** tab. An admin must have **Services** enabled in order to access the **Device > Setup Services > Virtual Systems** tab. If the **Role** was specified as **Virtual System** in the prior step, **Services** is the only setting that can be enabled under **Device > Setup**.<br>– **Content-ID**—Allows an admin with this profile to configure settings on the **Content-ID** tab.<br>– **WildFire**—Allows an admin with this profile to configure settings on the **WildFire** tab.<br>– **Session**—Allows an admin with this profile to configure settings on the **Session** tab.<br>– **HSM**—Allows an admin with this profile to configure settings on the **HSM** tab.<br>5. Click **OK**.<br>6. (Optional) Repeat the entire step to create another Admin Role profile with different permissions, as necessary. |

 © Palo Alto Networks, Inc.

| Create an Admin Role Profile Per Virtual System or Device (Continued) | | |
|---|---|---|
| Step 2 | Apply the Admin role profile to an administrator. | 1. Select **Device > Administrators**, click **Add** and enter the **Name** to add an Administrator.<br>2. (Optional) Select an **Authentication Profile**.<br>3. (Optional) Select **Use only client certificate authentication (Web)** to have bi-directional authentication; to get the server to authenticate the client.<br>4. Enter a **Password** and **Confirm Password**.<br>5. (Optional) Select **Use Public Key Authentication (SSH)** if you want to use a much stronger, key-based authentication method using an SSH public key rather than just a password.<br>6. For **Administrator Type**, select **Role Based**.<br>7. For **Profile**, select the profile that you just created.<br>8. (Optional) Select a **Password Profile**.<br>9. Click **OK**. |
| Step 3 | Save the configuration. | Click **Commit** and **OK**. |

# DNS Resolution—Three Use Cases

The firewall determines how to handle DNS requests based on where the request originated. This section illustrates three types of DNS resolution, which are listed in the following table. The binding location determines which DNS proxy object is used for the resolution. For illustration purposes, the use cases show how a service provider might configure DNS settings to provide DNS services for resolving DNS queries required on the firewall and for tenant (subscriber) virtual systems.

| Resolution Type | Location: Shared | Location: Specific Vsys |
|---|---|---|
| Firewall DNS resolution—performed by management plane | Binding: Global<br>Illustrated in Use Case 1 | N/A |
| Security profile, reporting, and server profile resolution—performed by management plane | Binding: Global<br>Same behavior as Use Case 1 | Binding: Specific vsys<br>Illustrated in Use Case 2 |
| DNS proxy resolution for DNS client hosts connected to interface on firewall, going through the firewall to a DNS Server—performed by dataplane | Binding: Interface<br>Service Route: Interface and IP address on which the DNS Request was received.<br>Illustrated in Use Case 3 | |

- Use Case 1: Firewall Requires DNS Resolution for Management Purposes
- Use Case 2: ISP Tenant Uses DNS Proxy to Handle DNS Resolution for Security Policies, Reporting, and Services within its Virtual System
- Use Case 3: Firewall Acts as DNS Proxy Between Client and Server

## Use Case 1: Firewall Requires DNS Resolution for Management Purposes

In this use case, the firewall is the client requesting DNS resolutions of FQDNs for management events such as software update services, dynamic software updates, or WildFire. The shared, global DNS services perform the DNS resolution for the management plane functions.

 © Palo Alto Networks, Inc.

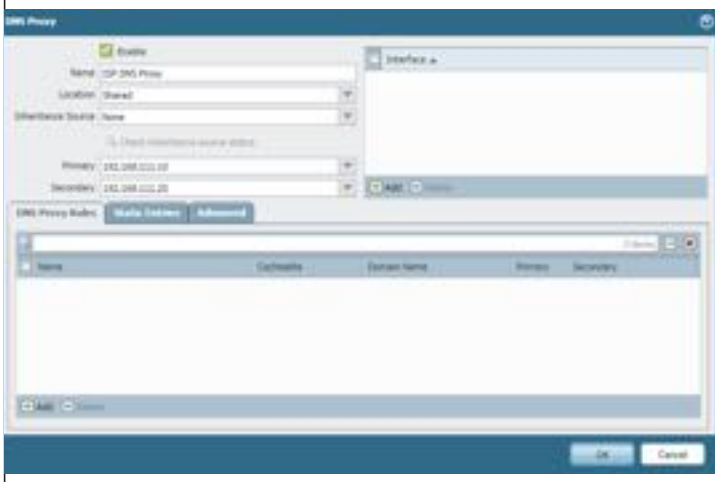
| Configure DNS Services for the Firewall | |
|---|---|
| Step 1 Configure the primary and secondary DNS servers you want the firewall to use for its management DNS resolutions.<br><br>You must manually configure at least one DNS server on the firewall or it will not be able to resolve hostnames; it will not use DNS server settings from another source, such as an ISP. | 1. Select **Device > Setup > Services > Global** and Edit. (For devices that do not support multiple virtual systems, there is no **Global** tab; simply edit the Services.)<br>2. On the **Services** tab, for **DNS**, click **Servers** and enter the **Primary DNS Server** address and **Secondary DNS Server** address.<br> <br>3. Click **OK** and **Commit**. |

**Configure DNS Services for the Firewall (Continued)**

Step 2 Alternatively, you can configure a DNS Proxy Object if you want to configure advanced DNS functions such as split DNS, DNS proxy overrides, DNS proxy rules, static entries, or DNS inheritance.

1. On the **Services** tab, for **DNS**, click **DNS Proxy Object**.

2. From the **DNS Proxy** drop-down, select the DNS proxy that you want to use to configure global DNS services, or click **DNS Proxy** to configure a new DNS proxy object, as shown in the following screenshot and subsequent steps.



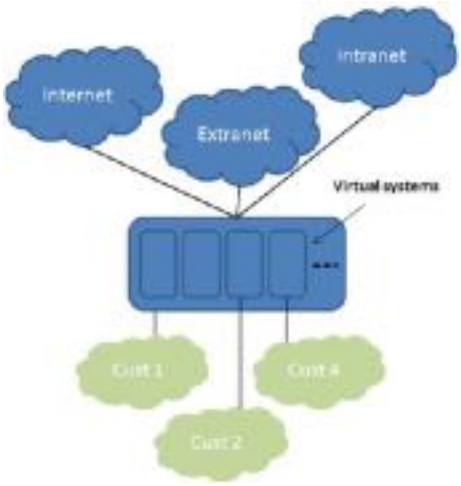
3. To create a new proxy object, click **Enable** and enter a **Name** for the DNS proxy object.
4. For **Location**, select **Shared** for global, device-wide DNS proxy services.

   Shared DNS proxy objects do not use DNS server profiles because they do not require a specific service route belonging to a tenant virtual system.
5. For **Primary**, enter the primary DNS server IP address. Optionally enter a **Secondary** DNS server IP address. In the ISP example in the screenshot above, the DNS proxy defines the primary and secondary DNS servers that are used to resolve the firewall management services.
6. Click **OK** and **Commit**.

© Palo Alto Networks, Inc.

## Use Case 2: ISP Tenant Uses DNS Proxy to Handle DNS Resolution for Security Policies, Reporting, and Services within its Virtual System

In this use case, multiple tenants (ISP subscribers) are defined on the firewall and each tenant is allocated a separate virtual system (vsys) and virtual router in order to segment its services and administrative domains. The following figure illustrates several virtual systems within a firewall.



Each tenant has its own server profiles for its security policies, reporting, and management services (such as email, Kerberos, SNMP, syslog, and more) defined in its own networks.

For the DNS resolutions initiated by these services, each virtual system is configured with its own DNS Proxy object to allow each tenant to customize how DNS resolution is handled within its virtual system. Any service with a **Location** will use the DNS Proxy object configured for the virtual system to determine the primary (or secondary) DNS server to resolve FQDNs, as illustrated in the following figure.

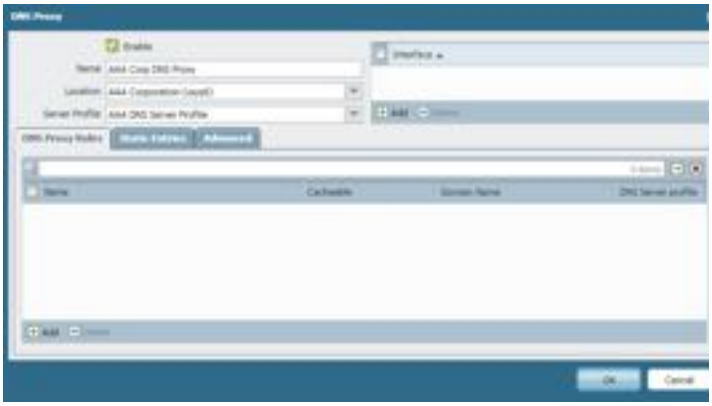
 © Palo Alto Networks, Inc.

| Configure a DNS Proxy for a Virtual System | |
|---|---|
| Step 1 For each virtual system, specify the DNS Proxy to use. | 1. Select **Device > Virtual Systems** and click **Add**.<br>2. Enter the **ID** of the virtual system (range is 1-255), and an optional **Name**, in this example, Corp1 Corporation.<br>3. On the **General** tab, choose a **DNS Proxy** or create a new one. In this example, Corp1 DNS Proxy is selected as the proxy for Corp1 Corporation's virtual system.<br>(If you need to create a new DNS Proxy, Step 2 below shows how to create a DNS Proxy and a Server Profile.)<br>4. For **Interfaces**, click **Add**. In this example, Ethernet1/20 is dedicated to this tenant.<br>5. For **Virtual Routers**, click **Add**. A virtual router named Corp1 VR is assigned to the virtual system in order to separate routing functions.<br>6. Click **OK** to save the configuration.<br>  |

**Configure a DNS Proxy for a Virtual System**

Step 2 Configure a DNS Proxy and a server profile to support DNS resolution for a virtual system.

1. Select **Network > DNS Proxy** and click **Add**.
2. Click **Enable** and enter a **Name** for the DNS Proxy.
3. For **Location**, select the virtual system of the tenant, in this example, Corp1 Corporation (vsys6). (You could choose the **Shared** DNS Proxy resource instead.)



4. For **Server Profile**, choose or create a profile to customize DNS servers to use for DNS resolutions for this tenant's security policy, reporting, and server profile services.

   If the profile is not already configured, in the **Server Profile** field, click **DNS Server Profile** to Configure a DNS Server Profile. In this example, the Corp1 DNS Server Profile was created.

   The DNS server profile identifies the IP addresses of the primary and secondary DNS server to use for management DNS resolutions for this virtual system.
5. Also for this server profile, optionally configure a **Service Route IPv4** and/or a **Service Route IPv6** to instruct the firewall which **Source Interface** to use in its DNS requests. If that interface has more than one IP address, configure the **Source Address** also.
6. Click **OK** to save the DNS Server Profile.
7. Click **OK** and **Commit** to save the DNS Proxy.

 © Palo Alto Networks, Inc.

Optional advanced features such as split DNS can be configured using **DNS Proxy Rules**. A separate DNS server profile can be used to redirect DNS resolutions matching the **Domain Name** in a **DNS Proxy Rule** to another set of DNS servers, if required. Use Case 3 illustrates split DNS.

If you use two separate DNS server profiles in the same DNS Proxy object, one for the DNS Proxy and one for the DNS proxy rule, the following behaviors occur:

- If a service route is defined in the DNS server profile used by the DNS Proxy, it takes precedence and is used.
- If a service route is defined in the DNS server profile used in the DNS proxy rules, it is not used. If the service route differs from the one defined in the DNS server profile used by the DNS Proxy, the following warning message is displayed during the **Commit** process:

  ```
  Warning: The DNS service route defined in the DNS proxy object is different from the DNS proxy rule's service route. Using the DNS proxy object's service route.
  ```

- If no service route is defined in any DNS server profile, the global service route is used if needed.

## Use Case 3: Firewall Acts as DNS Proxy Between Client and Server

In this use case, the firewall is located between a DNS client and a DNS server. A DNS Proxy on the firewall is configured to act as the DNS server for the hosts that reside on the tenant's network connected to the firewall interface. In such a scenario, the firewall performs DNS resolution on its dataplane.

This scenario happens to use *split DNS*, a configuration where **DNS Proxy Rules** are configured to redirect DNS requests to a set of DNS servers based on a domain name match. If there is no match, the **Server Profile** determines the DNS servers to which the request is sent, hence the two, split DNS resolution methods.

For dataplane DNS resolutions, the source IP address from the DNS proxy in PAN-OS to the outside DNS server would be the address of the proxy (the destination IP of the original request). Any service routes defined in the DNS Server Profile are not used. For example, if the request is from host 1.1.1.1 to the DNS proxy at 2.2.2.2, then the request to the DNS server (at 3.3.3.3) would use a source of 2.2.2.2 and a destination of 3.3.3.3.

| Configure a DNS Proxy and DNS Proxy Rules | |
|---|---|
| Step 1 Configure a DNS Proxy and DNS proxy rules. | 1. Select **Network > DNS Proxy** and click **Add**.<br>2. Click **Enable** and enter a **Name** for the DNS Proxy.<br>3. For **Location**, select the virtual system of the tenant, in this example, Corp1 Corporation (vsys6).<br>4. For **Interface**, select the interface that will receive the DNS requests from the tenant's hosts, in this example, Ethernet1/20.<br>5. Choose or create a **Server Profile** to customize DNS servers to resolve DNS requests for this tenant. In this example, the Corp1 DNS Server Profile is selected.<br>  <br>6. On the **DNS Proxy Rules** tab, click **Add** and enter a **Name** for the rule.<br>7. Optionally select **Turn on caching of domains resolved by this mapping**.<br>8. Click **Add** and enter one or more **Domain Name**(s), one entry per row.<br>Each domain name can contain * as a wild card. The number of characters in a wildcard string must equal the number of characters in the requested domain to match. For example, '*.engineering.local' does not match 'engineering.local'. Both domain names must be specified in order for both to be matched.<br>9. For **DNS Server profile**, select a profile from the drop-down. The firewall compares the domain name in the DNS request to the domain name(s) defined in the **DNS Proxy Rules**. If there is a match, the **DNS Server profile** defined in the rule is used to determine the DNS server.<br>In this example, if the domain in the request matches myweb.corp1.com, the DNS server defined in the myweb DNS Server Profile is used. If there is no match, the DNS server defined in the **Server Profile** (Corp1 DNS Server Profile) is used.<br>10. Click **OK** to save the rule.<br>11. Click **OK** to save the DNS Proxy. |

 © Palo Alto Networks, Inc.

# Virtual System Functionality with Other Features

Many of the firewall's features and functionality are capable of being configured, viewed, logged, or reported per virtual system. Therefore, virtual systems are mentioned in other relevant locations in the documentation and that information is not repeated here. Some of the specific chapters are the following:

- If you are configuring Active/Passive HA, the two firewalls must have the same virtual system capability (single or multiple virtual system capability). See High Availability.
- To configure QoS for virtual systems, see Configure QoS for a Virtual System.
- For information about configuring a firewall with virtual systems in a virtual wire deployment that uses subinterfaces (and VLAN tags), see the Virtual Wire Subinterfaces in Interface Deployments.

© Palo Alto Networks, Inc.

 © Palo Alto Networks, Inc.

# Certifications

The following topics describe how to configure the firewall to support the Common Criteria and the Federal Information Processing Standards 140-2 (FIPS 140-2), which are security certifications that ensure a standard set of security assurances and functionalities. These certifications are often required by civilian U.S. government agencies and government contractors.

- Enable FIPS and Common Criteria Support
- CCEAL4 Security Functions

# Enable FIPS and Common Criteria Support

Use the following procedure to enable CCEAL4 mode on a software version that supports Common Criteria and the Federal Information Processing Standards 140-2 (FIPS 140-2). When you enable CCEAL4 mode, all FIPS functionality is also included in this mode.

When you enable CCEAL4 mode, the device will reset to the factory default settings; all configuration will be removed.

| Enable CCEAL4 Mode | |
|---|---|
| Step 1 | Boot the device into maintenance mode as follows:<br>1. Establish a serial connection to the console port on the firewall.<br>2. Enter the following CLI command:<br>`debug system maintenance-mode`<br>3. Press Enter to continue.<br>You can also reboot the firewall and enter `maint` at the maintenance mode prompt. |
| Step 2 | Select **Set CCEAL4 Mode** from the menu.<br>Official certification support is only provided with **CCEAL4** mode; not **FIPS** mode. |
| Step 3 | Select **Enable CCEAL4 Mode** from the menu. |
| Step 4 | When prompted, select **Reboot**.<br>After successfully switching to CCEAL4 mode, the following status displays: `CCEAL4 mode enabled successfully`. In addition, the following changes will take place:<br>• **CC** will display at all times in the status bar at the bottom of the web interface.<br>• The console port functions as a status output port only<br>• The default admin login credentials change to admin/paloalto. |

 © Palo Alto Networks, Inc.

# CCEAL4 Security Functions

When CCEAL4 mode is enabled, the following security functions are enforced:

- To log into the firewall, the browser must be TLS 1.0 (or later) compatible. On a WF-500 appliance, you manage the appliance using the CLI only and you must connect using an SSHv2 compatible client application.
- All passwords on the firewall must be at least six characters.
- You must enforce a **Failed Attempts** and **Lockout Time (min)** value that is greater than 0 in authentication settings. If an administrator reaches the **Failed Attempts** threshold, the administrator is locked out for the duration defined in the **Lockout Time (min)** field.
- You must enforce an **Idle Timeout** value greater than 0 in authentication settings. If a login session is idle for more than the specified value, the account is automatically logged out.
- The firewall automatically determines the appropriate level of self-testing and enforces the appropriate level of strength in encryption algorithms and cipher suites.
- Non-CC/FIPS approved algorithms are not decrypted and are thus ignored during decryption.
- When configuring an IPSec VPN, the administrator must select a cipher suite option presented to them during the IPSec setup.
- Self-generated and imported certificates must contain public keys that are either RSA 2048 bits (or more) or ECDSA 256 bits (or more) and you must use a digest of SHA256 or greater.
- The serial console port is only available as a status output port when CCEAL4 is enabled.
- Telnet, TFTP, and HTTP management connections are unavailable.
- High availability (HA) port encryption is required.

# PAN-OS® New Features Guide

Version 7.0

## Contact Information

Corporate Headquarters:

Palo Alto Networks

4401 Great America Parkway

Santa Clara, CA 95054

www.paloaltonetworks.com/company/contact-us

## About this Guide

This guide describes how to use the new features introduced in PAN-OS 7.0. For additional information, refer to the following resources:

- For information on the additional capabilities and for instructions on configuring the features on the firewall, refer to https://www.paloaltonetworks.com/documentation.
- For access to the knowledge base and community forums, refer to https://live.paloaltonetworks.com.
- For contacting support, for information on support programs, to manage your account or devices, or to open a support case, refer to https://www.paloaltonetworks.com/support/tabs/overview.html.
- For the most current PAN-OS and Panorama 7.0 release notes, go to https://www.paloaltonetworks.com/documentation/70/pan-os/pan-os-release-notes.html.

To provide feedback on the documentation, please write to us at: documentation@paloaltonetworks.com.

# Authentication Features

- Authentication and Authorization Enhancements
- SSL/TLS Service Profiles
- TACACS+ Authentication
- Kerberos V5 Single Sign-On
- Suite B Cryptography Support
- Authentication Server Connectivity Testing

Copyright © 2007-2015 Palo Alto Networks

# Authentication and Authorization Enhancements

This release provides the following authentication and authorization enhancements:

| Enhancement | Description |
|---|---|
| Easier configuration workflow for authentication servers, profiles, and sequences | The workflow to configure server profiles, authentication profiles, and authentication sequences is simpler and more intuitive. Authentication server profiles now have only the parameters for accessing authentication services (for example, IP addresses), while authentication profiles and sequences have only the parameters for the authentication process (for example, user domain). You no longer need to set the allowed login attempts and account lockout duration for authentication sequences, only authentication profiles.<br>To enable authentication, configure a server profile (LDAP, RADIUS, Kerberos, or TACACS+) if you will use an external authentication service, configure an authentication profile (to which you assign the server profile), optionally assign multiple authentication profiles to an authentication sequence, and assign the authentication profile or sequence to administrator accounts, GlobalProtect portals or gateways, or the Captive Portal configuration. For the relevant procedures, refer to:<br>• Manage firewall administrators<br>• Configure the GlobalProtect Portal<br>• Configure GlobalProtect Gateways<br>• Map IP Addresses to User Names Using Captive Portal<br> You can perform Authentication Server Connectivity Testing to check whether the Palo Alto Networks device can successfully communicate with the authentication server specified in an authentication profile. |
| Kerberos V5 single sign-on (SSO) support | Palo Alto Networks devices now support Kerberos V5 single sign-on, and automatic modifications to user-entered domains and usernames. This reduces the number of logins and the amount of typing required to authenticate administrators and end users. You configure these features in authentication profiles. |
| Certificate verification for LDAP connections | To improve security, you can now enable Palo Alto Network devices to verify the certificate that an LDAP server presents for SSL/TLS connections. You enable the verification in an LDAP server profile. |
| Intuitive configuration workflow for group mapping | The workflow to configure username to group mapping for User-ID is more intuitive: you set the user domain override in the group mapping configuration instead of in LDAP server profiles. |
| Delivery of VSAs from GlobalProtect clients to RADIUS servers | You can now configure the firewall send Vendor-Specific Attributes (VSAs) from GlobalProtect clients to RADIUS servers so that RADIUS administrators can perform administrative tasks based on those VSAs. For example, RADIUS administrators might use the client operating system attribute to define a policy that mandates regular password authentication for Microsoft Windows users and one-time password (OTP) authentication for Google Android users. RADIUS administrators can also log in to the firewall CLI as SSH users without first logging in to the web interface. |
| CLI commands for authentication troubleshooting | The device CLI has new commands for displaying authentication statistics, debugging authentication events, and unlocking users. |

Copyright © 2007-2015 Palo Alto Networks

# SSL/TLS Service Profiles

You can now assign SSL/TLS service profiles to device services that use SSL/TLS, including Captive Portal, GlobalProtect portals and gateways, management traffic access using the web interface or XML API, URL Admin Override, and the User-ID Syslog listening service. SSL/TLS service profiles specify a certificate and the allowed protocol version or range of versions (now including TLSv1.2). By defining the protocol versions, the profiles enable you to restrict the cipher suites that are available to secure communication with the clients requesting the services. This improves network security by enabling devices to avoid SSL/TLS versions that have known weaknesses. If a service request involves a protocol version that is outside the specified range, the device downgrades or upgrades the connection to a supported version.

| Configure and Assign an SSL/TLS Service Profile | | |
|---|---|---|
| Step 1 | Configure the SSL/TLS service profile. | 1. For each desired service, Generate a Certificate.<br>Use only signed certificates for SSL/TLS services, not certificate authority (CA) certificates.<br>2. Select **Device > Certificate Management > SSL/TLS Service Profile**.<br>3. For a firewall with more than one virtual system (vsys), select the **Location** (vsys or **Shared**) where the profile is available.<br>4. Click **Add** and enter a **Name** to identify the profile.<br>5. Select the **Certificate** you just generated.<br>6. Define the range of protocols that the service can use:<br>• For the **Min Version**, select the earliest TLS version to support: **TLSv1.0**, **TLSv1.1**, or **TLSv1.2**.<br>• For the **Max Version**, select the latest TLS version to support: **TLSv1.0**, **TLSv1.1**, **TLSv1.2**, or **Max** (the latest available version.<br>7. Click **OK** and **Commit**. |
| Step 2 | Assign the profile to the desired service.<br>SSL/TLS service profiles replace certificates for all these services except the User-ID syslog listener, for which the profile is a new setting. | • Content-ID: URL Admin Override—Select **Device > Setup > Content-ID** and **Add** or edit the URL Admin Override entries.<br>• Captive Portal—Select **Device > User Identification > Captive Portal Settings** and edit the settings.<br>• GlobalProtect portals—Select **Network > GlobalProtect > Portals**, **Add** or edit a portal, select the **Portal Configuration** tab, and edit the Network Settings.<br>• GlobalProtect gateways—Select **Network > GlobalProtect > Gateways**, **Add** or edit a gateway, select the **General** tab, and edit the Network Settings.<br>• Management interface: inbound traffic—Select **Device > Setup > Management** and edit the General settings.<br>• User-ID user mapping, syslog listening service—Select **Device > User Identification > User Mapping**, edit the Palo Alto Networks User-ID Agent Setup settings, select the **Server Monitor** tab, and select a **Syslog Service Profile**. The SSL/TLS service profile secures syslog messages that the firewall parses when it performs user mapping. |

Copyright © 2007-2015 Palo Alto Networks

# TACACS+ Authentication

Palo Alto Networks devices now support Terminal Access Controller Access-Control System Plus (TACACS+) protocol for authenticating administrator and end users. TACACS+ provides greater security than RADIUS because it encrypts usernames and passwords (instead of just passwords), and is also more reliable (it uses TCP instead of UDP).

| Configure TACACS+ Authentication | | |
|---|---|---|
| Step 1 | Configure a TACACS+ server profile. | 1. Select **Device > Server Profiles > TACACS+** and click **Add**.<br>2. Enter a **Profile Name** to identify the server profile.<br>3. If this profile is for a firewall with multiple virtual systems capability, select a virtual system or **Shared** as the **Location** where the profile is available.<br>4. Enter a **Timeout** interval after which an authentication request times out (1-20 seconds, default 3 seconds).<br>5. Select the **Use single connection for all authentication** check box to use the same TCP session for all authentications that use this profile. This option improves performance by avoiding the need to start and end a separate TCP session for each authentication. The check box is cleared by default.<br>6. For each TACACS+ server, click **Add** and enter a **Name** (to identify the server), server IP address or FQDN (**TACACS+ Server** field), **Secret**/**Confirm Secret** (a key to encrypt usernames and passwords), and server **Port** for authentication requests (default 49).<br>7. Click **OK** and **Commit**. |
| Step 2 | Use the profile for authentication. | Assign the TACACS+ server profile to an authentication profile and assign the authentication profile to administrator accounts, GlobalProtect portals or gateways, or the Captive Portal configuration. For the specific steps, refer to:<br>• Create an administrative account<br>• Configure the GlobalProtect Portal<br>• Configure GlobalProtect Gateways<br>• Map IP Addresses to User Names Using Captive Portal |

Copyright © 2007-2015 Palo Alto Networks

# Kerberos V5 Single Sign-On

Palo Alto Networks devices now support Kerberos V5 single sign-on (SSO) for authenticating administrative users to the web interface and end users to Captive Portal. A network that supports Kerberos SSO prompts a user to log in only for initial access to the network (for example, logging in to Microsoft Windows). After this initial login, the user can access any browser-based service in the network (for example, the firewall web interface) without having to log in again, until the SSO session expires. (Your Kerberos administrator sets the duration of SSO sessions.)

You enable SSO for a Palo Alto Networks device by importing a Kerberos *keytab* into an authentication profile and assigning the profile to administrator accounts or the Captive Portal configuration. A keytab is a file that contains Kerberos account information (principal name and hashed password) for the device, which is required for SSO authentication. Each authentication profile can have one keytab. If SSO authentication fails, the device prompts the user to log in manually and performs authentication of the type specified in the profile (for example, RADIUS).

- Configure Kerberos SSO for Administrator Authentication
- Configure Kerberos SSO for Captive Portal Authentication

## Configure Kerberos SSO for Administrator Authentication

Configuring Kerberos SSO for administrator authentication has the following prerequisites:

- Your network has a Kerberos infrastructure set up, including a Key Distribution Center (KDC) with an Authentication Server (AS) and Ticket Granting Service (TGS).
- The Palo Alto Networks device that will authenticate users has a Kerberos account, including a principal name and password. You will use these to create the keytab.

Copyright © 2007-2015 Palo Alto Networks

| Configure Kerberos SSO for Administrator Authentication | | |
|---|---|---|
| Step 1 | Create a Kerberos keytab for the Palo Alto Networks device.<br> <br>If the device is in FIPS or CC mode, the algorithm must be `aes128-cts-hmac-sha1-96` or `aes256-cts-hmac-sha1-96`. Otherwise, you can also use `des3-cbc-sha1` or `arcfour-hmac`. To use an AES algorithm, the functional level of the KDC must be Windows Server 2008 or later and you must enable AES encryption for the device account.<br>The algorithm in the keytab must match the algorithm in the service ticket that the TGS issues to clients. Otherwise, the SSO process will fail. Your Kerberos administrator determines which algorithms the service tickets use. | 1. Log in to the KDC and open a command prompt.<br>2. Enter the following command, where <principal_name>, <password>, and <algorithm> are variables. The Kerberos principal name and password are of the device, not the user.<br>**ktpass /princ** `<principal_name>` **/pass** `<password>` **/crypto** `<algorithm>` **/ptype KRB5_NT_PRINCIPAL /out** `<file_name>`**.keytab**<br>For example:<br>**/princ host/computer.abrealm.com@ABREALM.COM /pass securepwd /crypto des3-cbc-sha1 /ptype KRB5_NT_PRINCIPAL /out device.keytab** |
| Step 2 | (External authentication only) Configure an authentication server profile to authenticate administrators if the SSO process fails. | • Configure a RADIUS Server Profile.<br>• Configure an LDAP Server Profile.<br>• Configure a Kerberos Server Profile.<br>• Configure a TACACS+ server profile. |
| Step 3 | Configure an authentication profile. | 1. Select **Device > Authentication Profile**, click **Add**, and enter a **Name** to identify the authentication profile.<br>2. (External authentication only) If the authentication **Type** is an external server, assign the **Server Profile** you just created.<br>3. (New) Enter the **Kerberos Realm** and import the **Kerberos Keytab** you just created. Usually the realm is the DNS domain name of the administrator, except that the realm name is uppercase.<br>4. In the **Advanced** tab, **Add** the administrator user, user group, or **all** to the **Allow List**, and then click **OK**. |
| Step 4 | Assign the authentication profile to the administrator account. | 1. Configure the administrator account.<br>2. Click **Commit**. |

Copyright © 2007-2015 Palo Alto Networks

# Configure Kerberos SSO for Captive Portal Authentication

Configuring Kerberos SSO for Captive Portal authentication has the following prerequisites:

- Your network has a Kerberos infrastructure set up, including a Key Distribution Center (KDC) with an Authentication Server (AS) and Ticket Granting Service (TGS).
- The Palo Alto Networks device that will authenticate users has a Kerberos account, including a principal name and password. You will use these to create the keytab.
- You have set up the initial Captive Portal and policy configurations. In the following procedure, you modify the configurations by configuring redirect mode.

If you configure both Kerberos SSO and NT LAN Manager (NTLM) authentication, the firewall tries Kerberos SSO authentication first, and if that fails, falls back to NTLM authentication for Microsoft Windows clients. If NTLM authentication also fails, the firewall falls back to web form or client certificate authentication, depending on your Captive Portal configuration.

| Configure Kerberos SSO for Captive Portal Authentication | |
|---|---|
| Step 1 Create a Kerberos keytab for the redirect host you will assign to the Captive Portal configuration. The redirect host is the intranet hostname that resolves to the IP address of the firewall Layer 3 interface to which you are redirecting requests that match a Captive Portal policy.<br> <br>If the device is in FIPS or CC mode, the algorithm must be `aes128-cts-hmac-sha1-96` or `aes256-cts-hmac-sha1-96`. Otherwise, you can also use `des3-cbc-sha1` or `arcfour-hmac`. To use an AES algorithm, the functional level of the KDC must be Windows Server 2008 or later and you must enable AES encryption for the device account.<br>The algorithm in the keytab must match the algorithm in the service ticket that the TGS issues to clients to enable single sign-on (SSO). Otherwise, the SSO process will fail. Your Kerberos administrator determines which algorithms the service tickets use. | 1. Log in to the KDC and open a command prompt.<br>2. Enter the following command, where <principal_name>, <password>, and <algorithm> are variables. The Kerberos principal name and password are of the device, not the user.<br>**ktpass /princ** `<principal_name>` **/pass** `<password>` **/crypto** `<algorithm>` **/ptype KRB5_NT_PRINCIPAL /out** `<file_name>`**.keytab**<br>For example:<br>**/princ host/computer.abrealm.com@ABREALM.COM /pass securepwd /crypto des3-cbc-sha1 /ptype KRB5_NT_PRINCIPAL /out device.keytab** |

Copyright © 2007-2015 Palo Alto Networks

| Configure Kerberos SSO for Captive Portal Authentication (Continued) | | |
|---|---|---|
| Step 2 | Enable Captive Portal redirect requests on a Layer 3 interface. | 1. Create an Interface Management profile so the interface can display Captive Portal response pages:<br>a. Select **Network > Network Profiles > Interface Mgmt** and click **Add**.<br>b. Enter a **Name** for the profile, select **Response Pages**, and click **OK**.<br>2. Assign the Interface Management profile to a Layer 3 interface:<br>a. Select **Network > Interfaces > Ethernet** and click the Name of a Layer 3 interface.<br>b. Select **Advanced > Other**, select the **Management Profile** you just created, and click **OK**.<br>3. Create DNS address (A) and pointer (PTR) records that map the IP address on the Layer 3 interface to the redirect host. |
| Step 3 | To transparently redirect users without displaying certificate errors, install a certificate that matches the IP address of the interface in Step 2. You can generate and import a self-signed certificate (as described in this example) or import a certificate that an external certificate authority (CA) signed. | To use a self-signed certificate, create a root CA certificate and use it to sign the certificate you will use for Captive Portal:<br>1. Select **Device > Certificate Management > Certificates > Device Certificates**.<br>2. Generate a root CA certificate. Be sure to select the **Certificate Authority** check box.<br>3. Generate a certificate to use for Captive Portal. Be sure to configure the following fields:<br>• **Common Name**—Enter the DNS name of the intranet host for the Layer 3 interface.<br>• **Signed By**—Select the CA you created in the previous step.<br>• Certificate Attributes—Click **Add**, for the **Type** select **IP**, and for the **Value** enter the IP address of the Layer 3 interface.<br>4. Configure clients to trust the certificate:<br>a. Select the CA certificate you just created and click **Export**.<br>b. Select a **File Format** and click **OK**.<br>c. Select **Save File** and click **OK** to download the certificate to your default download folder.<br>d. Import the certificate as a trusted root CA into all client browsers, either by manually configuring the browser or by adding the certificate to the trusted roots in an Active Directory Group Policy Object (GPO). |
| Step 4 | (External authentication only) Configure an authentication server profile to authenticate users if the SSO process fails. | • Configure a RADIUS Server Profile.<br>• Configure an LDAP Server Profile.<br>• Configure a Kerberos Server Profile.<br>• Configure a TACACS+ server profile. |

Copyright © 2007-2015 Palo Alto Networks

| Configure Kerberos SSO for Captive Portal Authentication (Continued) | | |
|---|---|---|
| Step 5 | Configure an authentication profile for Captive Portal. | 1. Select **Device > Authentication Profile**, click **Add**, and enter a **Name** to identify the authentication profile.<br>2. (External authentication only) If the authentication **Type** is an external server, assign an authentication **Server Profile**.<br>3. (New) Enter the **Kerberos Realm** and import the **Kerberos Keytab** you just created. Usually the realm is the DNS domain name of the users, except that the realm name is uppercase.<br>4. In the **Advanced** tab, **Add** the users, user groups, or **all** to the **Allow List**, then click **OK**. |
| Step 6 | Assign the authentication profile to the Captive Portal configuration. | 1. Select **Device > User Identification > Captive Portal Settings** and edit the settings.<br>2. Select the **Authentication Profile** you just created.<br>3. Set the **Mode** to **Redirect** and enter the FQDN of the **Redirect Host**.<br>4. Click **OK** to save the configuration. |
| Step 7 | Configure the Captive Portal policy rules for Kerberos SSO. | 1. Perform the following steps for each Captive Portal policy rule that will use Kerberos SSO.<br>a. Select **Policies > Captive Portal** and click the Name of the rule.<br>b. Select the **Actions** tab, select **browser-challenge** in the drop-down, and click **OK**.<br>2. Click **Commit**. |

# Suite B Cryptography Support

You can now use Suite B ciphers to authenticate administrators and to secure site-to-site VPN, remote access VPN, and Large Scale VPN (LSVPN). For the VPN tunnels between GlobalProtect gateways and clients, the ciphers are available in a new GlobalProtect IPSec Crypto profile. Suite B ciphers enable you to meet U.S. federal network security standards. The following topics describe the ciphers and how to implement them:

- Suite B Ciphers
- Generate and Assign ECDSA Certificates
- Configure a GlobalProtect IPSec Crypto Profile

## Suite B Ciphers

| Cipher | Purpose/Benefits | Where Implemented |
|---|---|---|
| Elliptic Curve Digital Signature Algorithm (DSA) algorithm | Use ECDSA to generate certificate keys. See the list of features for which you can Generate and Assign ECDSA Certificates.<br>ECDSA uses smaller key sizes than the RSA algorithm, and therefore provides a performance enhancement for processing SSL/TLS connections. ECDSA also provides equal or greater security than RSA.<br>The **Device > Certificate Management > Certificates** page has a new Algorithm column to indicate the key type for existing certificates. | Certificate generation<br> ECDSA is recommended for client browsers and operating systems that support it. Otherwise, select RSA for compatibility with legacy browsers and operating systems. |
| Elliptic Curve Diffie–Hellman (DH) Group 19 (256-bit) and Group 20 (384-bit) | Use these Internet Key Exchange (IKE) options to secure VPN tunnels based on IPSec. | IKE Crypto profiles<br>IPSec Crypto profiles |
| Advanced Encryption Standard (AES) Galois/Counter Mode (GCM) algorithms: 128-bit (aes-128-gcm) and 256-bit (aes-256-gcm) | Use these algorithms to secure traffic in remote access VPN, site-to-site VPN, and Large Scale VPN deployments.<br>The names of new and existing AES algorithms now indicate their mode:<br>• gcm—Galois/Counter Mode<br>• cbc—Cipher-Block Chaining<br>• ccm—Counter with CBC-MAC | IPSec Crypto profiles<br>GlobalProtect IPSec Crypto profiles |

Copyright © 2007-2015 Palo Alto Networks

# Generate and Assign ECDSA Certificates

Palo Alto Networks devices now support certificates that use **Elliptical Curve DSA (ECDSA)**, a Suite B key generation **Algorithm**. Previously, the only available **Algorithm** was **RSA**.

OCSP responders can verify the revocation status of both ECDSA and RSA certificates.
You can't use ECDSA keys in outbound or inbound SSL/TLS decryption certificates, or for public key authentication for administrators.

| Generate and Assign Certificates | | |
|---|---|---|
| Step 1 | Generate a Certificate. | 1. Select **Device > Certificate Management > Certificates** and click **Generate**.<br>2. Enter a **Certificate Name**.<br>3. For the **Common Name**, enter an IP address or FQDN.<br>4. In the **Signed By** drop-down, select the certificate that will authenticate the certificate you are creating or select **External Authority** to generate a certificate signing request (CSR).<br>5. (New) For the key generation **Algorithm**, select **RSA** (the default option) or **Elliptical Curve DSA** (recommended for client browsers and operating systems that support ECDSA).<br>6. For the **Number of Bits**, select the certificate key length. Higher numbers are more secure but require more processing time. The available options depend on the key generation **Algorithm**:<br>• **RSA**—**512**, **1024**, **2048** (default), or **3072**<br>• **Elliptical Curve DSA**—**256** or **384**<br>7. Select the **Digest** algorithm. From most to least secure, the options are: **sha512**, **sha384**, **sha256** (default), **sha1**, **md5**.<br>8. For the **Expiration**, enter the number of days (default 365) for which the certificate is valid.<br>9. Click **Generate**, **OK**, and **Commit**. |
| Step 2 | Assign the certificate to a certificate profile if you will assign certificate profiles to device services. | If the certificate profile will have multiple certificates, repeat Step 1 for each certificate before creating the profile. |

Copyright © 2007-2015 Palo Alto Networks

| Generate and Assign Certificates (Continued) | |
|---|---|
| Step 3 Assign the certificate or certificate profile to the desired device services. | • Administrator authentication—Configure Certificate-based Authentication for the WebUI.<br>• Captive Portal authentication—Select **Device > User Identification > Captive Portal Settings**, edit the settings, and assign a **Certificate Profile**.<br>• (New) SSL/TLS services—See SSL/TLS Service Profiles.<br>• Site-to-site VPN:<br>  • IKE gateways—Select **Network > Network Profiles > IKE Gateways**, **Add** or edit an IKE gateway, and in the **General** tab select either or both of the following:<br>  – Select **Certificate** as the **Authentication** type, then select a **Local Certificate**.<br>  – **Certificate Profile**<br>  • IPSec tunnels—Select **Network > IPSec Tunnels**, **Add** or edit an IPSec tunnel, set the **Type** to **GlobalProtect Satellite**, select the **Advanced** tab, select the **External Certificate Authority** check box, and select a **Local Certificate** and/or **Certificate Profile**.<br>• Large Scale VPN (LSVPN) or remote access VPN:<br>  • GlobalProtect portals—Select **Network > GlobalProtect > Portals**, **Add** or edit a portal, and select either or both of the following:<br>  – **Portal Configuration** tab—Select a **Client Certificate** or **Certificate Profile** for the portal server.<br>  – **Agent Configuration** tab—Add a **Trusted Root CA**.<br>  – **Satellite Configuration** tab (LSVPN only)—Add a **Trusted Root CA** and/or select an **Issuing Certificate**. Besides using an issuing certificate, you can also manually import certificates into satellite clients.<br>  • GlobalProtect gateway—Select **Network > GlobalProtect > Portals**, **Add** or edit a gateway, select the **General** tab, and select a **Certificate Profile** for the gateway server. |

## Configure a GlobalProtect IPSec Crypto Profile

Use GlobalProtect IPSec Crypto profiles to secure the VPN tunnels between GlobalProtect clients and gateways. To use Suite B ciphers, the clients must run GlobalProtect agent/app v2.2 or later releases. The following procedure assumes you already set up your GlobalProtect infrastructure and will assign a new GlobalProtect IPSec Crypto profile to an existing gateway configuration. The firewall has a default (predefined) profile that uses **aes-128-cbc** encryption and **sha1** authentication.

| Configure an GlobalProtect IPSec Crypto Profile | | |
|---|---|---|
| Step 1 | Create the GlobalProtect IPSec Crypto profile. | 1. Select **Network > Network Profiles > GlobalProtect IPSec Crypto**, click **Add** and enter a **Name** to identify the profile.<br>2. To specify the Encryption and Authentication algorithms that the VPN peers use to negotiate the keys for securing data traversing the tunnel, click **Add** in the corresponding sections and select from the drop-downs, then click **OK** to save the profile.<br>If you are not certain of what the VPN peers support, you can add multiple encryption algorithms in the order of most-to-least secure as follows: **aes-256-gcm**, **aes-128-gcm**, **aes-128-cbc**. The Suite B options are **aes-256-gcm** and **aes-128-gcm**. The peers will use the strongest supported algorithm to establish the tunnel. |
| Step 2 | Assign the profile to the client configuration of a GlobalProtect gateway. | 1. Select **Network > GlobalProtect > Gateways**, and click the Name of a gateway to edit it.<br>2. Select the **Client Configuration** tab and select the **GlobalProtect IPSec Crypto** profile you just created.<br>3. Click **OK** and **Commit**. |

# Authentication Server Connectivity Testing

You can now test an authentication profile to determine if your firewall or Panorama management server can communicate with a backend authentication server and if the authentication request was successful. You can test administrator authentication for Panorama and for PAN-OS. You can additionally test authentication profiles used for GlobalProtect and Captive Portal authentication. You can perform authentication tests on the candidate configuration, so that you know the configuration is correct before committing.

Authentication server connectivity testing is supported for local database, RADIUS, TACACS+, LDAP, and Kerberos authentication.

| Run the Test Authentication Command | |
|---|---|
| Step 1 | On the PAN-OS firewall or Panorama server, configure an authentication profile. You do not need to commit the authentication or server profile configuration prior to testing. |
| Step 2 | Using a terminal emulation application, such as PuTTY, launch an SSH session to the firewall. |
| Step 3 | (Firewalls with virtual systems configured) Define the target virtual system that the test command will access.<br>This is required on firewalls with multiple virtual systems (vsys) configured, so the test authentication command can locate the user (GlobalProtect or Captive Portal, for example) in the correct vsys.<br>To define the target vsys:<br>`admin@PA-3060>` **set system setting target-vsys <vsys-name>**<br>For example, if the user is defined in vsys2, run the following command:<br>`admin@PA-3060>` **set system setting target-vsys vsys2**<br>The `target-vsys` command is per-login session, so the system clears the option when you log off. |
| Step 4 | Test an authentication profile by entering the following command:<br>`admin@PA-3060>` **test authentication authentication-profile <authentication-profile-name> username <username> password**<br>For example, to test an authentication profile named my-profile for a user named bsimpson, run the following command:<br>`admin@PA-3060> test authentication authentication-profile my-profile username bsimpson password`<br>When entering authentication profile names and server profile names in the test command, the names are case sensitive. Also, if the authentication profile has a username modifier defined, you must enter the modifier with the username. For example, if you add the username modifier %USERINPUT%@%USERDOMAIN% for a user named bsimpson and the domain name is mydomain.com, enter bsimpson@mydomain.com as the username. This will ensure that the correct credentials are sent to the authentication server. In this example, mydomain.com is the domain that you define in the **User Domain** field in the Authentication profile. |

**Run the Test Authentication Command**

Step 5 View the output of the test results.

If the authentication profile is configured correctly, the output displays `Authentication succeeded`. If there is a configuration issue, the output displays information to help you troubleshoot the configuration.

The output results vary based on several factors related to the authentication type that you are testing as well as the type of issue. For example, RADIUS and TACACS+ use different underlying libraries, so the same issue that exists for both of these types will produce different errors. Also, if there is a network problem, such as using an incorrect port or IP address in the authentication server profile, the output error is not specific. This is because the test command cannot perform the initial handshake between the firewall and the authentication server to determine details about the issue.
