| **Transparent One-Time Password (OTP) Support** | To simplify the GlobalProtect user authentication process and make it more transparent for the end user when authenticating to the portal and the gateway, the portal now includes settings for modifying the default authentication behavior on a per-client configuration basis. The following **Authentication Modifier** settings are now available on the **General** tab when configuring a client configuration on the portal (**Network > GlobalProtect > Portals**):<br>• **Cookie authentication for config refresh—**Enables the agent to use an encrypted cookie to authenticate to the portal when refreshing a configuration that has already been cached (the user will always be required to authenticate to the portal for the initial configuration download and upon cookie expiration). This simplifies the authentication process for end users because they will no longer be required to log in to both the portal and the gateway in succession or enter multiple OTPs for authenticating to each. If this option is enabled, the portal will instead use the cookie to authenticate to the user.<br> The cookie will never be used for authentication to the gateway.<br>• **Different password for external gateway—**Disables the forwarding of credentials to some or all gateways, enabling the gateway to immediately prompt for its own set of credentials. This option speeds up the authentication process when the portal and the gateway require different credentials (either different OTPs or different login credentials entirely). Or, you can choose to use a different password on manual gateways only. With this option, the portal will forward credentials to automatic gateways but not to manual gateways, allowing you to have the same security on your portals and automatic gateways, while requiring a second factor OTP or a different password for access to those gateways that provide access to your most sensitive resources. |
| **HIP Profile Support for Client DLP Products** | The GlobalProtect agent by default now collects vendor-specific data about whether data loss prevention (DLP) software is installed and/or enabled on Windows hosts. DLP software is used to prevent sensitive corporate information from leaving the corporate network or from being stored on a potentially insecure device. Because this information is now collected from Windows host systems, you can include DLP as matching criteria for the host information profiles (HIPs) you create, thereby enabling you to use DLP compliance as criteria for your security policies. |
| **Agent Update Control** | The client configurations delivered by the GlobalProtect portal now have two additional options for controlling when users can upgrade the GlobalProtect agent: **disable** and **manual**. This means there are now four options for the **Agent Upgrade** field on the **Agent** tab in the Configs dialog of the portal configuration:<br>• By default, the portal will **prompt** the agent to upgrade whenever a new version is available.<br>• To enable automatic upgrades that do not require user interaction, select **transparent**.<br>• (New option) To prevent agent upgrades, select **disable**.<br>• (New option) To allow end users to initiate agent upgrades, select **manual**. In this case, the user would select the **Check Version** option in the agent to determine if there is a new agent version and then upgrade if desired. |

| New GlobalProtect Feature | Description |
|---|---|
| **Certificate Authentication Enforcement** | Enhancements have been made to how client certificate authentication is enforced in various scenarios as follows:<br>• If a certificate profile is configured on the GlobalProtect portal, the client must present a certificate in order to connect. This means that certificates must be deployed to the end clients before their initial portal connection.<br>• If the certificate profile specifies a **Username Field**, the certificate presented by the client must contain a username in order to connect. Furthermore, if both an authentication profile and a certificate profile with the **Username Field** are configured, the end user will be forced to use the username from the certificate to log in for authentication against the configured authentication profile.<br>• For agents configured with the pre-logon connect method, if the new **Cookie authentication for config refresh** setting is enabled, you no longer need to configure a certificate profile for pre-logon authentication; in this case the portal will use the cookie to authenticate the client prior to user logon. Note, however, that you must still configure a certificate profile on the gateway to enable establishment of the VPN tunnel. |

© Palo Alto Networks, Inc.

## Management Features

The following Management features are introduced in PAN-OS 6.0. For more details about these features and for instructions on configuring them, refer to Management Features in the New Features Guide.

| New Management Feature | Description |
|---|---|
| **New Documentation Portal** | The all new web-based Palo Alto Networks Technical Documentation portal is now available at https://www.paloaltonetworks.com/documentation.html. The new content you will find here features concepts and workflows that focus on enabling start-to-finish network security solutions. The documentation suite now covers the full Palo Alto Networks product and feature set, including the following new guides introduced in this release:<br>• PAN-OS 6.0 New Features Guide<br>• The new and improved PAN-OS Administrator's Guide<br>• GlobalProtect Administrator's Guide<br>• VM-Series Deployment Guide<br>As of PAN-OS 6.0.4, this site has been enhanced so that all of the new workflow-based content is available in HTML with PDF downloads available on demand. This new format simplifies access to the documentation by allowing you to search for answers to specific questions, browse by product, or narrow the results by search facet. For details on how to get the most out of the new portal, watch the video. |
| **Commit Improvement** | The commit operation in Panorama and in PAN-OS has been enhanced to allow configuration edits during a commit. For example, if two administrators are logged in to the same firewall and the first administrator performs a commit, the second administrator can make updates to the configuration during the commit. This enhancement does not, however, allow multiple administrators to commit simultaneously. |
| **Content Delivery Network (CDN)/Update Server Verification** | Palo Alto Networks will begin transitioning to use of a CDN for delivery of software and content updates to devices running Panorama/PAN-OS 6.0 or later release version. This new process will provide a secure and distributed infrastructure to improve the software update process and license installation/verification for customers around the world.<br>In addition, a new option has been added to strengthen all secure communication between firewalls/Panorama and the Palo Alto Networks update servers. To enable this option, select **Device** (or **Panorama**) **> Setup > Services** and select the **Verify Update Server Identity** check box in the **Services** dialog. When enabled, Panorama or PAN-OS will not perform a software/content download unless the update server has an SSL certificate signed by a trusted authority. This will help ensure that software updates and license verification will only be performed from Palo Alto Networks and will eliminate the possibility of man-in-the-middle attacks. |

© Palo Alto Networks, Inc.

| New Management Feature | Description |
|---|---|
| **Enumeration of Rules within a Rulebase** | The **Policies** tab on the web interface includes a new column for displaying rule numbers. Each rule is automatically numbered and the ordering adjusts as rules are moved or reordered. When filtering rules to find rules that match the specified filter(s), each rule is listed with its number in the context of the complete set of rules in the rulebase and its place in the evaluation order.<br><br>In Panorama, pre-rules and post-rules are independently numbered. When rules are pushed from Panorama to a managed firewall, the rule numbering incorporates hierarchy in pre-rules, device rules, and post-rules within a rulebase and reflects the rule sequence and its evaluation order. |
| **Enhancements in Reports** | The reporting enhancements in this release include support for creating group activity reports and the ability to disable predefined reports.<br><br>To generate reports for user groups on the firewall, select **Monitor > PDF Reports > User Activity Report**, select Type: **Group** and pick the group for which to generate the report. Because Panorama does not have the user to group mapping information, you cannot generate group activity reports on Panorama.<br><br>To disable one or more predefined reports, select **Device** (or **Panorama**) **> Setup > Management**. Edit the Logging and Reporting Settings section and select the **Log Export and Reporting** tab and clear the check boxes for each report you want to disable. |
| **CLI Find Command** | The new `find command` CLI command helps you find a command when you don't know where to start looking in the hierarchy. This new command—which is available in all CLI modes—has two forms:<br>• You can use `find command` alone to display the entire command hierarchy in the current command mode.<br>Or<br>• You can use `find command` with the `keyword` argument to locate all commands that have the specified keyword. For example, to find all configure mode commands with the `username` keyword, you would enter the following:<br>`admin@mgmt-ui-4060# find command keyword username`<br>`set deviceconfig system log-export-schedule <name> protocol ftp username <value>`<br>`set deviceconfig system log-export-schedule <name> protocol scp username <value>`<br>`set deviceconfig setting wildfire session-info-select exclude-username <yes\|no>`<br>`set mgt-config password-complexity block-username-inclusion <yes\|no>`<br>`set network interface ethernet <name> layer3 pppoe username <value>`<br>`set shared certificate-profile <name> username-field` |

© Palo Alto Networks, Inc.

| New Management Feature | Description |
|---|---|
| **Support for Syslog over TCP and SSL** | The firewall and Panorama now support using TCP or SSL (default is UDP) for reliable and secure transport of logs to an external syslog server. SSLv3 and TLSv1 are supported and the default SSL port is 6514. To separate individual syslog messages in a TCP stream, the delimiter formats available are LF- Line Feed (BSD format, the default), and Message Length (IETF format). If the syslog server requires client authentication, you can configure the firewall/Panorama to use a certificate for secure communication. The option to mark a **Certificate for Secure Syslog** as available in **Device** (or **Panorama**) **> Certificate Management > Certificates > Device Certificates**.<br><br>To monitor and alert you to a connection failure, a system log of high severity is generated when the firewall or Panorama is disconnected from the syslog server; an SNMP trap is also generated. |
| **Support for Color-Coded Tags** | Tags allow you to group objects using keywords/phrases and color (optional) to visually distinguish objects. You can apply tags to address objects, address groups (static and dynamic), zones, services, service groups, and policy rules. Use the **Objects > Tags** tab to create a tag, assign tag color, or to delete, rename and clone tags. When tagged, the keyword can be used to sort or filter objects. |
| **SNMP Resource Monitoring Extensions** | All Palo Alto Networks firewalls support SNMP objects that provide resource utilization and failure reporting, including alerts for hardware failure, the insertion and removal of the power supply, disks, or system fans, and monitoring of resource utilization for high session use or load on the gateway.<br><br>The HOST-RESOURCES-MIB includes objects for monitoring the following:<br>• Memory and disk usage on the management plane. Swap utilization tracks how the swap space is used to store all the running programs that aren't being actively used to free up memory.<br>• Packet buffers on the dataplane.<br><br>The Enterprise MIBs include objects for monitoring the following:<br>• GlobalProtect gateway utilization in the PAN-Common MIB to monitor the total number of current active tunnels on the firewall device and the percentage on current tunnel utilization that is based on the number of active tunnels and the maximum number of tunnels allowed.<br>• Session utilization in the PAN-Common MIB for each virtual system to track the active sessions, and the percentage of current session utilization based on session limit configured for the virtual system. |
| **Enhancement in the Syslog Header** | You can now choose the format of the hostname field in the syslog header. The syslog header can display one of the following: FQDN (hostname and domain name), hostname, the IPv4 address, or the IPv6 address of the sending device. Configure this option in the **Send Hostname in Syslog** drop-down on the **Device** (or **Panorama**) **> Setup > Management > Logging and Reporting Settings** section. The drop-down provides the following choices: **FQDN**, **Hostname**, **IPv4 address**, **IPv6 address**, or **None**; select **None** to leave the hostname field in the syslog header empty. |

## Networking Features

The following Networking features are introduced in PAN-OS 6.0. For more details about these features and for instructions on configuring them, refer to Networking Features in the New Features Guide.

| New Networking Feature | Description |
|---|---|
| **OSPFv3 Support** | OSPFv3 provides support for the OSPF routing protocol within an IPv6 network. OSPFv3 offers similar structure and functionality to OSPFv2 (for IPv4). OSPPv3 and OSPFv2 can be run concurrently on the same firewall in a dual stack configuration. To configure a firewall to operate with OSPFv3, navigate to **Network > Virtual Routers** and then add or edit a virtual router configuration. |
| **OSPF Graceful Restart** | Reduces high availability (HA) active/passive failover times by allowing OSPF neighbors to continue using routes through a device during a short transition while out of service. This increases network stability by reducing the network outage experienced when OSPF adjacencies are reestablished. To configure a firewall to operate with OSPF Graceful Restart, navigate to **Network > Virtual Routers** and edit any OSPF or OSPFv3 virtual router configuration. |
| **IKE PKI Certificate Authentication for IPSec Site-to-Site VPNs** | With this release authentication security has been enhanced over previous releases that only supported pre-shared-key authentication. To configure a firewall for IKE PKI certificate authentication, navigate to **Network > IKE Gateways** and then edit any IKE gateway configuration to select **Certificate** as the **Authentication** type and then specify which certificates to use for **Local Identification** and **Peer Identification**. |
| **Decryption Port Mirror** | Provides the ability to create a copy of decrypted traffic from a firewall and send it to a traffic collection tool that is capable of receiving raw packet captures—such as an RSA NetWitness or Solera Security Analytics Platform appliance—for archiving and analysis. This feature is necessary for organizations that require comprehensive data capture for forensic and historical purposes or data leak prevention (DLP) functionality. To enable use of this feature, you must download and install a free license. You can then configure a decryption profile (**Objects > Decryption Profile**) to enable forwarding to the decrypt mirror interface. Decryption port mirroring is available on the PA-7050, PA-5000 Series and PA-3000 Series platforms only. |
| **TLS 1.2 Decryption** | Previous releases of PAN-OS only supported TLS version 1.0. This release provides the Palo Alto Networks firewall with the ability to decrypt inbound sessions and forward proxy sessions that negotiate with TLS 1.2. |
| **Increase Jumbo Frame Size** | The maximum transmission unit (MTU) size has been increased to provide compatibility with equipment from other vendors. Jumbo frames must specifically be enabled at the global level. Once enabled, the default MTU size for all Layer 3 interfaces (the **Global MTU**) is set to a value of 9192 bytes, but can be configured for any value in the range of 512 - 9216 bytes. Because this value is applied globally, any other value required must be explicitly configured on a per-interface basis. To configure jumbo frame support, navigate to **Device > Setup > Session** and then select the **Enable Jumbo Frame** check box in the Session Settings dialog. After enabling jumbo frame support, you can customize the default MTU to be used globally and the minimum NAT64 MTU. |
| **Remove TCP Timestamp** | A new option has been added to the Zone Protection profile to enable you to strip the TCP timestamp from the TCP header. |

© Palo Alto Networks, Inc.

| New Networking Feature | Description |
|---|---|
| **IPv6 Neighbor Discovery Table Capacity Increase** | In previous versions of the PAN-OS software, the Neighbor Discovery (ND) table was smaller than the ARP table for IPv4. With this release the IPv6 ND table size has been increased to account for larger IPv6 networks and implementation of v4/v6, dual-stack configurations. |
| **Enhanced Use for Address Objects** | A Layer 3 interface on the firewall can now use an address object in lieu of an IP address. Using an address object allows you to separate the object from its value/IP address. The address object (**Objects > Addresses**) only has to be defined once and then it can be referenced multiple places in policy configuration. When the IP address(es) that was defined for the address object changes, you can edit the address object and the change in value is automatically inherited by all instances where the address object is used.<br><br>For improved scalability, Panorama templates also allow you to add or select an address object when configuring a Layer 3 interface on the managed firewalls. Previously, when configuring a Layer 3 interface in a template you could not define a unique IP address for each managed firewall. With this new feature a template can reference an address object; the value for the address object can either be defined locally on the firewall or it can be defined as a shared object or as a device group object on Panorama. Defining the address object on the firewall allows you to configure a unique IP address for each managed device. To prevent a commit failure, you must create the address object on each firewall before pushing the template to the managed firewalls.<br><br>Panorama templates support address objects in the following locations:<br>• IP addresses for Layer 3 interfaces<br>• Virtual address of the virtual IP address in a high availability (HA) active/active configuration<br>• Service routes<br>• NAT policy for source translation<br>• GlobalProtect portal and gateway IP addresses<br>• GlobalProtect satellite and site-to-site IP addresses<br>• IKE Gateway local address<br>• Multicast static and candidate IP addresses<br>• BGP peer group local addresses<br>• Hardware Security Module client IP addresses |
| **Consolidation of Timers Used in a High Availability (HA) Setup** | High availability (HA) timers are used to detect a firewall failure and trigger a failover. To reduce the complexity in configuring HA timers, three profiles have been added: **Recommended**, **Aggressive** and **Advanced**. These profiles auto-populate the optimum HA timer values for the specific firewall platform to enable a speedier HA deployment.<br><br>Use the **Recommended** profile for typical failover timer settings and the **Aggressive** profile for faster failover timer settings. The **Advanced** profile allows you to customize the timer values to accommodate your network requirements.<br><br>On upgrade, the current/existing HA settings are saved to the **Advanced** profile. If you prefer to load the preset values for the **Recommended** or **Aggressive** profiles, use the **HA Timer Settings** option in the **Election Settings** section of the **Device > High Availability** tab. |

## Panorama Features

The following Panorama™ features are introduced in PAN-OS 6.0. For more details about these features and for instructions on configuring them, refer to Panorama Features in the New Features Guide:

| New Virtualization Feature | Description |
|---|---|
| **Log Forwarding from Panorama** | Panorama now allows for forwarding of aggregated logs, email notifications, and SNMP traps to external servers. Forwarding logs from Panorama reduces the load on the firewalls and provides a reliable and streamlined approach to combine and forward logs/SNMP traps/email notifications to external destinations. To facilitate this change the Panorama interface has been changed.<br>See the Panorama Log Forwarding to an External Destination Per Platform table in the New Features Guide to configure log forwarding from Panorama: |
| **Scheduling Dynamic Updates from Panorama** | Dynamic updates for Application and Threats, WildFire, Antivirus, and URL Database can be scheduled using the **Schedules** link on the **Panorama > Device Deployment > Dynamic Updates** tab.<br>The frequency of the updates, and the option to only download or to download and install updates to all managed devices and managed collectors using Panorama is configurable. |
| **Support for PAN-DB and BrightCloud Databases** | In deployments where both PAN-DB and BrightCloud databases are used concurrently for URL filtering, Panorama provides the capability to create shared policies and push the policies to devices running different databases. When a mismatch occurs between the URL database vendor configured on Panorama and what is configured on the device, the device now maps and auto-migrates URL categories and URL profiles so that the policies are relevant for the database enabled on the device. |
| **Enhanced Use for Address Objects** | See Enhanced Use for Address Objects feature in the Networking Features section. |

© Palo Alto Networks, Inc.

## User-ID Features

The following User-ID™ features are introduced in PAN-OS 6.0. For more details about these features and for instructions on configuring them, refer to User-ID Features in the New Features Guide:

| New User Identification Feature | Description |
|---|---|
| **Windows Server 2012/2012 R2 Support**<br><br>(Supported in PAN-OS 6.0.3 and later release versions) | You can now install the Windows-based User-ID agent on a system running the Windows Server 2012/2012 R2 operating system and you can now install the Terminal Server agent on a system running the Microsoft Windows Server 2012 R2 operating system. The User-ID agent that runs on the firewall can also integrate with Windows Server 2012/2012 R2 for user mapping and group mapping. The procedures to install the User-ID agent and Terminal Server agent and to configure user mapping are the same as for servers supported in earlier releases (Windows Server 2003 and 2008). |
| **User-ID Integration with Syslog** | In environments with existing network services that authenticate users, such as wireless controllers, 802.1x devices, Apple Open Directory servers, or other network access control (NAC) mechanisms, the firewall can now listen for syslog messages from those services so that the User-ID agent (either the Windows agent or the agentless user mapping feature on the firewall) can extract the authentication events from the log. Syslog filters that you define allow User-ID to parse the messages and extract the IP addresses and usernames of users who successfully authenticated to the external service and add the information to the IP address to username mappings it maintains. Previously you had to use the XML API in order to integrate with these external devices and extract this information. |
| **Increased User-ID Active Users Limit** | To support organizations with a large number of active users requiring IP address to username mapping for policy enforcement, the active user limit has been increased on the high-end firewall platforms based on the memory capacity of the individual platforms.<br>The following list summarizes User-ID active limits on all Palo Alto Networks next-generation firewall platforms:<br>PA-7050 and PA-5060: 256,000<br>PA-5050 and PA-5020: 28,000<br>PA-4000 Series, PA-3000 Series, PA-2000 Series, PA-500, and PA-200: 64,000 |
| **API Enhancement to Support Custom Terminal Service Solutions** | The Terminal Services agent enables IP address to username mapping for users on Windows-based terminal servers by assigning a unique port range to individual users. The User-ID XML API has been extended to enable you to create scripts that allow for the same type of IP address to username mappings on non-Windows based terminal services. Specifically, the existing XML API calls that notify the firewall of IP address to username mappings have been extended to facilitate multi-user host log in and log off by including port mappings in addition to IP addresses. |

© Palo Alto Networks, Inc.

## Virtualization Features

The following virtualization features are introduced in PAN-OS 6.0. For more details about these features and for instructions on configuring them, refer to Virtualization Features in the New Features Guide:

| New Virtualization Feature | Description |
|---|---|
| **Virtual Machine (VM) Monitoring Agent** | In previous releases, you had to use external scripts and the XML API on the firewall to furnish information about virtual machine IP addresses to the firewall. This feature allows you to dynamically retrieve changes in your virtualized environment without making configuration changes on the firewall.<br>The Windows User-ID agent and the firewall can now be configured to proactively monitor the supported VM Sources: VMware ESXi server (4.1 and 5.0) and the VMware vCenter Server. The firewall supports up to 10 sources and the Windows User-ID agent supports up to 100 sources. In order to enable VM monitoring, the VM guest on the supported VM Sources must have VMware Tools installed and running. When you configure VM Information Sources on the **Device > VM Information Sources** tab, the firewall can access and retrieve the IP addresses of virtual machines (newly provisioned or modified) on the monitored sources. For each VM, you can also tag a predefined list of attributes. Each of these attributes can be used as match criterion in the new dynamic address groups feature and then referenced in policies. See Dynamic Address Groups for more details. |

© Palo Alto Networks, Inc.

| New Virtualization Feature | Description |
|---|---|
| **Dynamic Address Groups** | The Dynamic Address Groups feature allows you to dynamically update the network address of an object referenced in policy. Unlike a static address group where you specify the network address of a host, the members of a dynamic address group are populated using the match criteria that you define. The match criteria uses logical `and` or `or` operators; each host that you want to add to the dynamic address group must contain the tag that is defined in the match criteria.<br><br>Tags can be defined directly on the firewall or on Panorama or they can be dynamically defined using the XML API and registered with the firewall. When an IP address and the corresponding tag (one or more) are registered, each dynamic group evaluates the tags and updates the list of members in its group. This capability allows you to add/ remove/update the members of a group without making any changes on the firewall; a commit is not required for policy to take effect when you provision new hosts or decommission existing hosts on your network. The dynamic address group will use the tags to populate its members. All matching tags-both static and dynamic-are evaluated to populate the group. The difference between static and dynamic tags is that statically added tags are part of the configuration on the firewall, and dynamically added tags are part of the runtime configuration.<br><br>Because the members of the group are included based on the tags you match against, if an object has tags that match the specified criteria for the dynamic address group, the object will become a group member and the corresponding policy will be applied. For example, when provisioning a new server in a datacenter, you could tag the server's IP address as HTTP and DMZ. Using Dynamic Address Groups and the security rules on the firewall, the newly provisioned server would automatically be included in the existing policies to:<br>• Allow incoming HTTP connections to all machines tagged as HTTP.<br>• Allow all authenticated users to access all DMZ tagged machines through SSH and the web management console for the server.<br><br>If you have a virtual environment with VMware, instead of using scripts to call the XML API, you can use the **Virtual Machine (VM) Monitoring Agent** to retrieve information (network address and corresponding tags) on new servers/guests deployed on the monitored hosts/servers. To learn about this feature, see Virtual Machine (VM) Monitoring Agent. |
| **VM-Series on Citrix SDX** | The VM-Series firewall is now supported on the Citrix SDX hardware platform running Citrix XenServer version 6.0.2 or later. Deploying the VM-Series firewall (one or more instances) on the SDX server provides the ability to consolidate the NetScaler VPX appliance and the Palo Alto Networks VM-Series firewall on the same physical platform and protect north-south and/or east-west traffic on your network. For a list of supported SDX platforms, deployment examples, and installation instructions, refer to Set Up a VM-Series Firewall on the Citrix SDX Server in the VM-Series Deployment Guide. |

| New Virtualization Feature | Description |
|---|---|
| **Support for the VM-Series NSX Edition Firewall** | Traditionally, the lack of context between the security and virtual environments made implementing security policies a challenge at the data center. To meet the security challenges in the software defined datacenter, Palo Alto Networks and VMware introduce a joint solution to safely enable all datacenter traffic, including intra-server virtual machine communications.<br><br>NSX, the VMware Networking and Security platform that is designed for the software-defined datacenter, automates the process of deploying and provisioning the VM-Series firewall as a service (also called Security Virtual Machine) on ESXi servers.<br><br>Refer to the table of components in the Support for the VM-Series NSX Edition Firewall section of the New Features Guide for information about the components of this joint Palo Alto Networks and VMware solution.<br><br>To automate the process of deploying the VM-Series firewall, Panorama registers the VM-Series firewall as a service on the NSX Manager. The NSX Manager then deploys one VM-Series firewall on every ESXi host in a cluster. When a new ESXi host is added to the cluster, the NSX Manager automatically deploys a new firewall. Because each instance of the NSX edition of the VM-Series firewall is directly hooked in to the hypervisor, the firewall is seamlessly placed in the data path and can see all traffic that flows through the ESXi host.<br><br>The NSX Manager and the VM-Series firewall work in concert to enforce security; each provides a set of traffic management rules that are applied to the traffic on each ESXi host. The first set of rules determines which traffic to direct to the VM-Series firewall on each host, and the second set of rules determines how the firewall must process-allow, deny, inspect, and constrain- the application for enabling it safely on your network. The tight integration of the NSX Manager, Panorama and the firewalls in this solution augments the ability to enforce consistent security policies using dynamic address groups. The NSX Manager updates Panorama of all changes in the virtual environment, and Panorama pushes the updates to the firewalls. All policy rules that reference these dynamic address groups are updated to reflect the changes in the virtualized environment and security policies are consistently applied to secure all network resources. To learn more about this solution refer to information about how to Set Up a VM-Series NSX Edition Firewall in the VM-Series Deployment Guide. |

© Palo Alto Networks, Inc.

# Changes to Default Behavior

The following is a list of changes to default behavior in PAN-OS 6.0:

- Added a new SSL root certificate in WF-500 6.0.12 for secure communication with PAN-OS and Panorama.

  December 1, 2015 is the expiration date for the previous certificate. You should update WF-500 appliances running release 6.0.11 or earlier releases to WF-500 6.0.12 or a later release to ensure successful communication with PAN-OS and Panorama after that date.

- After upgrading from a PAN-OS 5.0 release to a PAN-OS 6.0 release, interface errors are reported by SNMP monitoring tools. Although interface errors existed in PAN-OS 5.0 and earlier releases, firewalls running PAN-OS 5.0 releases did not display those interface errors using SNMP. Instead, SNMP monitoring tools displayed a value of `zero` for interface errors. A fix was added in PAN-OS 6.0 so that an SNMP monitoring tool displays interface errors with the correct values. Refer to the following KB article for more detail on this change: https://live.paloaltonetworks.com/docs/DOC-6864.

- If the Safe Search Enforcement option is enabled and the firewall has content update **422** or later installed, Safe Search enforcement will also apply to YouTube searches. With the Safe Search for YouTube, users will be able to search YouTube for videos, but if YouTube Safety Mode is not enabled, the user will not be able to watch any videos. The Safety Mode icon is located at the bottom of the YouTube.com page and will either show **Safety On** or **Safety Off**.

- The output for the `show session` command is modified to include tracker session information. A new line shows `tracker stage firewall` with the following possible values: `TCP RST-client`, `TCP RST-server`, `TCP FIN`, and `Aged out`.

- PAN-DB is now the default URL filtering database.

- The default value in the WildFire Server field (**Device > Setup > WildFire > General Settings**) is changed from `default-cloud` to `wildfire-public-cloud` in order to enable support for the WF-500 WildFire appliance.

- When creating a security policy, the policy will now by default match services running on the **application-default** port for the service rather than on an any port. The **application-default** setting prevents applications from running on unusual ports and protocols, which if not intentional, can be a sign of undesired application behavior and usage. Note that when you use this option, the firewall still checks for all applications on all ports, but with this configuration, applications are only allowed on their default ports/protocols.

- The GlobalProtect gateway client **Login Lifetime** is extended to enable configuration of the validity period an IKE security association (SA) for third-party IPSec clients connecting to GlobalProtect using the extended authentication (X-Auth) capabilities. Previously, the **Login Lifetime** field only controlled the length of time a GlobalProtect agent gateway login was valid. The SA for IPSec tunnels between a third-party VPN client and the gateway was valid for eight hours before requiring an IKE phase 1 re-key, and this SA lifetime was not configurable. Now, the GlobalProtect **Login Lifetime** set on the **Network > GlobalProtect > Gateways Client Configuration** tab controls both the amount of time a gateway login is valid (for GlobalProtect agents) as well as the amount of time the IPSec client SA with the gateway is valid. In addition, to enable support for IPSec

© Palo Alto Networks, Inc.

clients that require a shorter key lifetime and to provide more configuration granularity for GlobalProtect agent configurations, the minimum value allowed for the **Login Lifetime** has been changed from 24 hours to two hours.

- If you enable the **Send Hostname in Syslog** (Logging and Reporting section of **Device > Setup > Management**) option, the default value used in the syslog header now is the fully qualified domain name (FQDN) which comprises the hostname and the domain of the device (firewall or Panorama) that sends the syslogs.

  In PAN-OS 5.0, if the **Send Hostname in Syslog** was enabled, the syslog header contained the device's FQDN when both the hostname and domain were configured or just the hostname when the domain was not configured. If neither hostname nor domain was configured, the syslog header contained the IP address of the sending device.

  In PAN-OS 4.1 and earlier versions, if the **Send Hostname in Syslog** option was enabled, the syslog header contained the IP address of the sending device.

 © Palo Alto Networks, Inc.

# Associated Software Versions

The following minimum software versions are supported with PAN-OS 6.0:

| Palo Alto Networks Software | Minimum Supported Version with PAN-OS 6.0.0 |
|---|---|
| Panorama | 6.0.0 |
| User-ID Agent | 6.0.0 |
| Terminal Services Agent | 5.0.0 |

# Known Issues

▲ Known Issues in PAN-OS 6.0
▲ Known Issues Specific to VM-Series Firewalls

For recent updates to known issues for a given PAN-OS release, refer to https://live.paloaltonetworks.com/t5/Articles/Critical-Issues-Addressed-in-PAN-OS-Releases/ta-p/52882.

## Known Issues in PAN-OS 6.0

| Issue Identifier | Issue Description |
|---|---|
| | While using Firefox version 30.0 with the Firebug add-on enabled, some aspects of the web interface and Panorama can be unresponsive.<br>Workaround: Disable the Firebug plug-in or downgrade your Firefox version. You can also upgrade your Firefox browser—this incompatibility is a known issue in Firefox version 30.0 and is addressed in Firefox version 31.0. |
| **68588**<br>*This issue is now resolved. See* PAN-OS 6.0.7 Addressed Issues. | If you configure a firewall as a Panorama-managed device but you do not restart the firewall after doing so, the firewall will forward predefined reports to Panorama that do not display any data.<br>Workaround: To ensure that predefined reports forwarded to Panorama are populated correctly after configuring the firewall as a managed device, restart the management server in one of two ways: either reboot the firewall or execute the `debug software restart management-server` CLI command. |
| **66059** | Regardless of the **Time Frame** you specify for a scheduled custom report on a Panorama M-100 appliance, the earliest possible start date for the report data is effectively the date when you configured the report. For example, if you configure the report on the 15th of the month and set the **Time Frame** to **Last 30 Days**, the report that Panorama generates on the 16th will include only data from the 15th onward. This issue applies only to scheduled reports; on-demand reports include all data within the specified **Time Frame**.<br>Workaround: To generate an on-demand report, click **Run Now** when you configure the custom report. |
| **63854**<br>*This issue is now resolved. See* PAN-OS 6.0.5 Addressed Issues. | For PAN-OS 6.0 release versions, virtual system administrators can perform XML API configuration commands only for the virtual systems they are an administrator for and no longer have access to XML API operational mode commands. |
| **63186** | If you perform a factory reset on a Panorama virtual appliance and configure the serial number, logging does not work until you reboot Panorama or execute the `debug software restart management-server` CLI command. |

© Palo Alto Networks, Inc.

| Issue Identifier | Issue Description |
|---|---|
| **61720** | By default, the GlobalProtect app adds a route on iOS mobile devices that causes traffic to the MDM server to bypass the VPN tunnel.<br>Workaround: To configure the GlobalProtect app on iOS mobile devices to route all traffic—including traffic to the MDM server—to pass through the VPN tunnel, perform the following tasks on the firewall hosting the GlobalProtect gateway (**Network > GlobalProtect > Gateways > Client Configuration > Network Settings > Access Route**):<br>• Add `0.0.0.0/0` as an access route.<br>• Enter the IP address for the MDM server as an additional access route. |
| **59749** | On the Panorama web interface, the **Policies > Security > Post Rules > Combined Rules Preview** window does not display post rules and local rules for managed devices. |
| **58202** | On the **Monitor > Session Browser** tab, refreshing the session causes the Filter menu to be incorrectly displayed on the web interface. |
| **58049** | The Service dialog for adding or editing a service object in the web interface displays the incorrect port range for both source and destination ports: `1-65535`. The correct port range is `0-65535` and specifying port number 0 for either a source or destination port is successful. |
| **57843** | A file blocking profile configured with **continue-and-forward** as the action is not successfully sent to the WildFire cloud. |
| **56434** | When the GlobalProtect app accesses an MDM server through a Squid proxy, you must add the MDM server SSL access ports to the proxy server allow list. For example, if the SSL access port is 8443, add `acl SSL_ports port 8443` to the allow list. |
| **49742** | The following issues apply when configuring a firewall to use a hardware security module (HSM):<br>• Thales nShield Connect—The firewall requires at least four minutes to detect that an HSM has been disconnected, causing SSL functionality to be unavailable during the delay.<br>• SafeNet Luna SA—When losing connectivity to either or both HSMs in a high availability (HA) configuration, the display of information from the `show ha-status` and `show hsm info` commands is blocked for 20 seconds. |

## Known Issues Specific to VM-Series Firewalls

- VM-Series on VMware vSphere Hypervisor (ESXi)
- VM-Series on Citrix SDX
- VM-Series on VMware NSX

**VM-Series on VMware vSphere Hypervisor (ESXi)**

| Issue Identifier | Issue Description |
|---|---|
| **62573**<br>*This issue is now resolved. See* PAN-OS 6.0.3 Addressed Issues. | Upgrading a VM-Series firewall with the VM-1000-HV license can cause the firewall to go into maintenance mode without providing information about the cause.<br>The VM-1000-HV license requires 5GB RAM on the VM-Series firewall due to the higher capacities supported by this license but this memory requirement is not enforced, which makes it possible to apply the VM-1000-HV license to a VM-Series firewall without enough memory allocated (default allocated memory is 4GB). |
| **57321** | After upgrading a VM-Series firewall to PAN-OS 6.0 on an ESXi host, issuing the `request shutdown system` command does not successfully shutdown the virtual firewall; the ESXi host continues to display the virtual firewall as powered on. |

**VM-Series on Citrix SDX**

| Issue Identifier | Issue Description |
|---|---|
| **63282**<br>*This issue is now resolved. See* PAN-OS 6.0.3 Addressed Issues. | A VM-Series firewall on a Citrix SDX server will not reboot into maintenance mode to allow administrators to perform specific tasks, such as reverting images or changing between FIPS and CC mode. |
| **56452** | On the Citrix SDX server, you must disable VLAN stripping on 1-gigabit ports assigned to the VM-Series firewall if you want to configure subinterfaces with VLAN tags (divide a physical interface into multiple logical interfaces that filter traffic based on VLAN tags) on the VM-Series firewall.<br> With VLAN stripping disabled, the NetScaler VPX and the VM-Series firewall cannot share the same port.<br>10-gigabit ports work as expected and do not need to be altered. |
| **52361** | Adding or removing ports on the SDX server after deploying the VM-Series firewall can cause a configuration mismatch on the firewall. To avoid the need to reconfigure the interfaces, consider the total number of data ports that you require on the firewall and assign the relevant number of ports on the SDX server when deploying the VM-Series firewall.<br>For example, if you assign ports 1/3 and 1/4 on the SDX server as data interfaces on the VM-Series firewall, the ports are mapped to eth1 and eth2. If you then add port 1/1 or 1/2 on the SDX server, eth1 will be mapped to 1/1 or 1/2, eth2 will be mapped to 1/3 and eth3 to1/4. If ports 1/3 and 1/4 were set up as a virtual wire, this remapping will require you to reconfigure the network interfaces on the firewall. |

© Palo Alto Networks, Inc.

**VM-Series on VMware NSX**

| Issue Identifier | Issue Description |
|---|---|
| **70222** | If the password for the administrator's account on the NSX Manager contains special characters, such as `$`, Panorama cannot communicate with the NSX Manager. The inability to communicate prevents context-based information such as Dynamic Address Objects, from being available to Panorama.<br>Workaround: To fix this issue, remove special characters from the password on the NSX Manager. |
| **59856** | After deploying the VM-Series firewall, when the firewall connects to Panorama, you must issue a Panorama commit to ensure that Panorama recognizes the device as a managed device. If you reboot Panorama without committing the changes, the firewall will not connect back to Panorama; although the Device Group will display the list of devices, the device will not display in **Panorama > Managed Devices**.<br>Further, if Panorama is configured in a high availability (HA) configuration, the VM-Series firewall is not added to the passive Panorama peer until the active Panorama peer synchronizes the configuration. During this time, the passive Panorama peer will log a critical message: `vm-cfg: failed to process registration from svm device. vm-state: active`. This message is logged until you commit the changes on the active Panorama, which then initiates synchronization between the Panorama HA peers and the VM-Series firewall is added to the passive Panorama peer.<br>Workaround: To reestablish the connection to the managed devices, commit your changes to Panorama (click **Commit** and select Commit Type: **Panorama**). In case of an HA set up, the commit will initiate the synchronization of the running configuration between the Panorama peers. |
| **59573** | Live migration of the VM-Series firewall is not supported when you enable SSL decryption using the forward proxy method. Use SSL inbound inspection if you need support for live migration. |
| **58839** | When deleting the VM-Series deployment, all VMs are deleted successfully; however, sometimes a few instances still remain in the datastore.<br>Workaround: Manually delete the VM-Series firewalls from the datastore. |
| **58833** | In some scenarios, traffic from newly added guests or virtual machines is not steered to the VM-Series firewall even when the guests belong to a Security Group and are attached to a Security Policy that redirects traffic to the VM-Series firewall.<br>Workaround: Reapply the Security Policy on the NSX Manager. |
| **58832** | The VM-Series firewall fails to deploy with an error message: `Invalid OVF Format in Agent Configuration`.<br>Workaround: Use the following command to restart the ESX Agent Manager process on the vCenter Server: `/etc/init.d/vmware-vpxd tomcat-restart`. |
| **58260** | If a high availability (HA) failover occurs on Panorama at the same time that the NSX Manager is deploying the NSX edition firewall, the licensing process fails with the error: `vm-cfg: failed to process registration from svm device. vm-state: active.`<br>Workaround: Delete the unlicensed instance of the VM-Series firewall on each ESXi host and then redeploy the Palo Alto Networks next-generation firewall service from the NSX Manager. |

| Issue Identifier | Issue Description |
|---|---|
| **58170** | When the datastore is migrated for a guest, all current sessions are no longer punted to the VM-Series firewall. However, all new sessions are secured properly. |
| **58168** | When deploying the VM-Series firewall, the Task Console displays: `Error while enabling agent. Cannot complete the operation. See the event log for details`. This error displays even on a successful deployment. You can ignore the message if the VM-Series firewall is successfully deployed. |
| **57954** | If you deploy the VM-Series firewall and then assign the firewall to a template, the change is not recorded in the bootstrap file.<br>Workaround: Delete the Palo Alto Networks NGFW Service on the NSX Manager, and verify that the template is specified on **Panorama > VMware Service Manager**, register the service, and re-deploy the VM-Series firewall. |
| **57614** | When an ESXi host is rebooted or shutdown, the functional status of the guests is not updated. Because the IP address is not updated, the dynamic tags do not accurately reflect the functional state of the guests that are unavailable. |
| **57533** | The vCenter Server/vmtools displayed the IP Address for a guest incorrectly after vlan tags were added to an Ethernet port. The display did not accurately show the IP addresses associated with the tagged Ethernet port and the untagged Ethernet port. This issue was seen on some Linux OS versions such as Ubuntu. |
| **57265** | When editing a Security Policy with a network introspect rule, an `invalid (tcp) port number` error—or `invalid (udp) port number` error—displays when you remove the destination (TCP or UDP) port.<br>Workaround: Delete the network introspect rule and create a new one. |
| **57205** | When defining traffic introspection rules (to steer traffic to the VM-Series firewall) on the NSX Manager, either the source or the destination for the rule must reference the name of a Security Group; you cannot create a rule from any to any Security Group.<br>Workaround: To redirect all traffic to the VM-Series firewall, you must create a Security group that includes all the guests in the cluster. Then you can define a security policy that redirects traffic from the cluster and to the cluster. |
| **57203** | Duplicate packets are being punted to the VM-Series firewall. This issue occurs if the distributed vSwitch used for punting is enabled in promiscuous mode.<br>Workaround: Disable promiscuous mode. |
| **55586** | When adding or removing a Security Group (Container) that is bound to a Security Policy, Panorama does not get a dynamic update of the added or removed Security Group.<br>Workaround: On **Panorama > VMware Service Manager**, click the **Synchronize Dynamic Objects** link to initiate a manual synchronization to get the latest update. |
| **55393** | Dynamic Tags (update) do not reflect the actual IP address set on the guest. This issue occurs because the vCenter Server cannot accurately view the IP address of the guest. |

© Palo Alto Networks, Inc.

# PAN-OS 6.0.13 Addressed Issues

The following table lists the issues that are fixed in the PAN-OS 6.0.13 release. For new features introduced in PAN-OS 6.0, associated software versions, known issues, and changes in default behavior, see PAN-OS 6.0 Release Information.

| Issue Identifier | Description |
|---|---|
| **89962** | An update was made to ensure that firewalls and appliances running PAN-OS 6.0.13 and later PAN-OS 6.0 releases meet the transition requirements for random number generators (RNGs)—such as the X9.31 RNG—provided in SP 800-131A. The X9.31 RNG is replaced by the CTR_DRBG specified in SP 800-90A. |
| **89752** | A security-related fix was made to address a buffer overflow condition. |
| **89750** | A security-related fix was made to address a stack underflow condition. |
| **89717** | A security-related fix was made to ensure the appropriate response to special requests received through the API interface. |
| **89706** | A security-related fix was made to prevent some CLI commands from improperly executing code. |
| **77163** | Fixed an issue where the `/var/log/secure` log file inflated and consumed available disk space. With this fix, PAN-OS uses a log rotation function for this log file to avoid consuming more disk space than is necessary. |
| **67207** | Fixed an issue where an upgrade to a PAN-OS 6.0 release caused the dataplane to stop responding. |

© Palo Alto Networks, Inc.

# PAN-OS 6.0.12 Addressed Issues

The following table lists the issues that are fixed in the PAN-OS 6.0.12 release. For new features introduced in PAN-OS 6.0, associated software versions, known issues, and changes in default behavior, see PAN-OS 6.0 Release Information.

| Issue Identifier | Description |
|---|---|
| **86938** | The client certificate used by PAN-OS and Panorama to authenticate to the PAN-DB cloud service, the WildFire cloud service, and the WF-500 appliance expired on January 21, 2016. The expiration results in an outage of these services. To avoid an outage, either upgrade to content release version 550 (or a later version) or upgrade PAN-OS and Panorama instances running a PAN-OS or Panorama 6.0 release to PAN-OS (or Panorama) 6.0.12 or a later release. |
| **85721** | Fixed an issue where firewalls with a specific OCZ Deneva hard disk (model DENCSTE251M21) configured in a RAID and running PAN-OS 6.0.9 or later releases experienced RAID errors. |
| **85065** | Fixed a CLI input parsing issue that caused a process on the management plane to stop responding when processing unexpected input. |
| **83519** | A security-related fix was made to address CVE-2015-5600. |
| **81367** | A security-related fix was made to address CVE-2015-4024. |

© Palo Alto Networks, Inc.

# PAN-OS 6.0.11 Addressed Issues

The following table lists the issues that are fixed in the PAN-OS 6.0.11 release. For new features introduced in PAN-OS 6.0, associated software versions, known issues, and changes in default behavior, see PAN-OS 6.0 Release Information.

| Issue Identifier | Description |
|---|---|
| **81452** | Fixed an issue where switching context from the Panorama™ web interface to a managed firewall did not indicate whether the administrator was logged in over an encrypted SSL connection; the System log message was always `User admin logged in via Panorama from x.x.x.x using http` regardless whether the connection was encrypted. With this fix, the System log now specifically reports `User admin logged in via Panorama from x.x.x.x using http over an SSL connection` when the administrator is connected through an encrypted SSL connection to differentiate from non-encrypted connections. |
| **79443** | Fixed an issue in the web interface where, in some cases, the PHP session cookie (PHPSESSID) was not marked as secure. |
| **79367** | Fixed an issue in PAN-OS where GlobalProtect™ clients experienced delays and intermittently failed to retrieve the gateway configuration for connecting to a GlobalProtect gateway when the firewall was in a high availability (HA) configuration and under a heavy load. This issue occurred due to an issue with the synchronization of HIP reports between gateways on HA peers when there was a high number of near-simultaneous GlobalProtect connection requests. With this fix, the sync process is modified so that GlobalProtect clients are able to download the configuration and connect to the network as expected even when multiple clients are attempting to connect at the same time. |
| **79104** | Fixed a rare issue on a PA-7050 firewall where the HA1 and HA1 backup links experienced heartbeat failures that caused split brain in a high availability (HA) configuration. |
| **78652** | Fixed a rare issue where a firewall dropped URL requests when the management plane (MP) URL *trie* (data structure) reached 100% capacity. With this fix, when the MP URL trie reaches 90% capacity, URLs in the cache are cleared until the MP URL trie utilizes only 50% of capacity so that the trie cannot reach maximum capacity and cause requests to be dropped. |
| **78413** | Fixed an issue on a PA-7050 firewall with multiple virtual systems where a memory leak was observed related to the First Packet Processor (FPP) management plane process when running the `show session meter` CLI command. |
| **78304** | A security-related fix was made to address a cross-site request forgery (CSRF) issue in the web interface. |
| **77816** | Fixed an intermittent issue where some Windows 7 GlobalProtect clients using two-factor authentication (LDAP and certificate) lost connection to the portal or gateway and could not reconnect due to a failed authentication with the error `Required client certificate is not found` even when the certificate was available. |

| Issue Identifier | Description |
|---|---|
| **77548** | Fixed an issue where changing the **Configuration refresh interval** on the **Tunnel Settings** tab (**Network > GlobalProtect > Gateways > Satellite Configuration**) did not update the Refresh Time as expected. With this fix, you can click **Refresh GW Config** (**Network > IPSec Tunnels > Gateway Info**) to update the Refresh Time without having to **Reconnect to GW**. |
| **76711** | Fixed an issue where the dataplane stopped responding on a device using a shared gateway with Captive Portal in redirect mode. |
| **76615** | Fixed an issue on a PA-7050 firewall where running the `request system private-data-reset` command when there was a faulty disk drive on the Log Processing Card (LPC) caused an LPC failure during reboot. |
| **76561** | Fixed an issue where the DHCP relay agent dropped DHCPDISCOVER packets that the agent could not process due to multiple BOOTP flags. With this fix, the DHCP relay agent recognizes the first BOOTP flag in a DHCPDISCOVER packet and ignores any additional BOOTP flags that may exist (per RFC 1542) so that multiple BOOTP flags do not cause DHCPDISCOVER packets to be dropped. |
| **76083** | Fixed an issue where no System logs were generated for failed login attempts using the CLI over an SSH connection. With this fix, additional System logs now provide visibility for failed logins to the management interface even if those attempts come from a CLI over an SSH connection. |
| **75881** | Fixed an issue on a PA-5000 Series firewall where the management plane and dataplane restarted due to a race condition that occurred when the **Enforce Symmetric Return** option was enabled in the policy-based forwarding (PBF) rules (**Policies > Policy Based Forwarding > Forwarding**). This race condition caused inaccurate PBF `return-mac ager` lists, which caused the restarts. With this fix, the firewall retrieves and checks return MAC entries to avoid this race condition and associated restarts. |
| **74558** | Fixed an issue on a PA-7050 firewall where, after upgrading to a PAN-OS 6.1 release, the post-upgrade autocommit failed when the high availability (HA) peer was still running a PAN-OS 6.0 release. |
| **73878** | Fixed an intermittent issue where BGP failed to redistribute the static Discard routes as expected after a high availability (HA) failover. |
| **71674** | Fixed an issue for firewalls running PAN-OS 6.0 releases where the SSL VPN process (*sslvpn*) restarted with a core dump due to a null pointer. |
| **71611** | Introduced a CLI command in response to an issue on PA-7000 Series firewalls where logs did not always get generated or forwarded as expected when DNS response times were too slow. If you are unable to correct DNS server issues to improve response time on your network, use the `debug management-server report-namelookup` command to work around this issue by disabling DNS name lookups in reports. |
| **70919** | Fixed an issue where the dataplane in a high availability (HA) active/active configuration restarted when a `session update/remove` message was received from the peer while the session was pending an FPGA result. With this fix, FPGA results are ignored if the system receives a `session update/remove` message while waiting for those results. |
| **66681** | Resolved a dataplane restart issue due to race conditions. |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **65370** | Fixed an issue where log queries utilizing DESC order or neq operator would not return expected results on M-100 or PA-7050 |
| **64266** | Fixed a rare issue where certain processes (*l3svc* and *sslvpn*) stopped responding when a Content update and FQDN refresh occurred simultaneously. |
| **62644** | When a copper SFP port was plugged in, the SFP interface's link displayed `unknown/unknown/up`; this has been updated to more accurately display `auto/auto/up`. |
| **59914** | Fixed an issue where the firewall did not remove the pan_task_x.log or .log.old files as expected when executing the `debug dataplane packet-diag clear log log` command. |

© Palo Alto Networks, Inc.

# PAN-OS 6.0.10 Addressed Issues

The following table lists the issues that are fixed in the PAN-OS 6.0.10 release. For new features introduced in PAN-OS 6.0, associated software versions, known issues, and changes in default behavior, see PAN-OS 6.0 Release Information.

| Issue Identifier | Description |
|---|---|
| **78897** | Fixed an issue where excessive ZIP traffic caused a null pointer exception in ZIP processing software, causing the dataplane to stop responding. |
| **78206** | Fixed an issue where a multi-dataplane platform did not properly free SSL proxy memory for SSL session-cache entries that included a username field that was parsed from a client certificate. With this fix, memory is freed up as expected for session-cache entries that include a username field parsed from a client certificate. |
| **77707** | Fixed an issue in PAN-OS 6.0.9 where **Threat Map** and **Traffic Map** were not appearing on the web interface under **Monitor > App Scope > Threat Map** or under **Monitor > App Scope > Traffic Map**. |
| **77237** | Fixed an issue where some PA-200 firewalls failed to boot when rebooted or power-cycled after a single PAN-OS software upgrade. You can work around this issue by performing two complete software upgrades, which corrects both u-boot images in the boot flash. With this fix, PA-200 firewalls can be upgraded to PAN-OS release 6.0.10 or higher releases and then rebooted or power-cycled normally without the need to first perform two consecutive upgrades. |
| **76238** | A security-related fix was made to address CVE-2015-1873. |
| **76099** | Fixed an issue where the dataplane restarted on a PA-7050 firewall when there was a NAT rule configured to use dynamic IP that falls back to dynamic IP and port (DIPP) NAT. |
| **75905** | Fixed an issue where a firewall failed to download the BrightCloud database via proxy after upgrading to either PAN-OS 6.0.8 or PAN-OS 6.0.9. |
| **75740** | Fixed an issue where the log-receiver crashed during a restart that happened at the same time that a NetFlow profile was removed from a security rule that was still processing traffic. |
| **74735** | Fixed an issue where a PA-7050 dataplane restarted when attempting to process jumbo frame packets (larger than 1,500 bytes). |
| **74511** | Fixed an issue where static discard routes did not get redistributed using OSPF; the routes were not injected in the OSPF link-state database (LSDB). With this fix, static discard routes are injected into the LSDB and distributed using OSPF as expected. |
| **74138** | Fixed an issue where some PA-7050 firewalls in high availability (HA) mode experienced packet buffer leaks in PAN-OS 6.0 or higher releases. The leaks occurred when interface tables, configurations, or IDs on the two HA devices lost synchronization and HA session sync messages included interface attributes that did not exist on the receiving device. Leaks also occurred when the HA pair was upgraded from PAN-OS 6.0 to PAN-OS 6.1 and interface IDs were out of sync during the time the two firewalls were not running the same software version. With this fix, packet buffer leaks caused by unsynchronized interface attributes are prevented. |

| Issue Identifier | Description |
|---|---|
| **74049** | Fixed an issue where the dataplane intermittently restarted on a PA-5000 Series firewall under heavy load conditions. This fix raises the priority of system health monitor packets so that they do not get dropped and cause the device to restart when under a heavy traffic load. |
| **73689** | Fixed an issue where traffic interruptions occurred due to nested encoding (ZIP content within chunked encoding), which caused the `SML VM vChecks` buffer pool to overflow. With this fix, new checks have been added to prevent `SML VM vChecks` buffer leaks. |
| **73605** | Fixed an issue where the User-ID process became unresponsive when trying to acquire the same lock twice with the same thread while executing the `idmgr reset` command for type `user`. |
| **73180** | Fixed an issue where, with Strip X-Forwarded-For (XFF) enabled under **Device > Setup > Content-ID**, an XFF IP address was not stripped before the packet was forwarded because the XFF header was split into two TCP segments due to an unusually long HTTP GET request. With this fix, the XFF field is stripped as expected when the header is split across two or more packets. |
| **72737** | Fixed a memory corruption issue that caused the dataplane to restart when SSL decryption was enabled. |
| **70669** | Fixed an issue where the User-ID process crashed due to bulk and incremental updates of terminal server users on the active-secondary device in a high availability (HA) active/active configuration. |
| **69837** | In response to a rare issue where a PA-200 firewall stopped processing traffic, additional troubleshooting information and some modifications to error checking and counter processes were added to help prevent this event and identify the root cause if it reoccurs. |
| **67523** | Fixed an issue where the second pair of Aggregate Ethernet (AE) interface ports did not stay down when both ports on the first AE interface went down. This issue occurred on a virtual wire (vwire) with two AE interfaces that had link-state-pass-through enabled and where both ports on one AE interface went down. With this fix, when both ports on one AE interface go down, the second AE interface ports go down and remain in powered down state until the first AE link recovers. |
| **67458** | Fixed an issue where a dataplane failed to get IP pool information from a dynamic IP and port (DIPP) source network address translation (SNAT) rule with an interface IP address. |
| **66406** | Fixed an issue where the current application version was not displayed correctly for managed firewalls when the firewall did not have a Threat Prevention subscription. |
| **66372** | Fixed an issue where some threat names did not display correctly in threat logs forwarded from the firewall when the logs were viewed on a syslog server. |
| **64887** | Fixed an issue on a PA-7050 firewall where some traffic was dropped after a configuration commit that included a change to the interface configuration. With this fix, the firewall updates current available memory as expected when changes to the interface configuration are committed. Without this fix, you can work around the issue by committing a security policy change following any commit that includes changes to the interface configuration, which prompts the firewall to update current available memory settings. |

© Palo Alto Networks, Inc.

# PAN-OS 6.0.9 Addressed Issues

The following table lists the issues that are fixed in the PAN-OS 6.0.9 release. For new features introduced in PAN-OS 6.0, associated software versions, known issues, and changes in default behavior, see PAN-OS 6.0 Release Information.

| Issue Identifier | Description |
|---|---|
| **76043** | Fixed a memory allocation issue on the PA-7050 firewall that caused intermittent connectivity for sessions inspected using SSL Forward Proxy decryption. An update was made to increase the proxy memory pool for PA-7050 firewalls, to allow for more memory to be allocated for SSL Forward Proxy sessions. |
| **74932** | Fixed an issue where high availability (HA) failovers that occurred with simultaneous route advertisements caused a routing process to restart, which then caused the firewall to restart. |
| **73813** | When using the PAN-OS® CLI in configuration mode, the `show predefined signature` CLI command incorrectly displayed App-ID™ signatures and patterns for some predefined applications. The `signature` command option has been removed and the `show predefined` command now correctly displays application information, but does not display the App-ID signature and pattern. |
| **73790** | Additional security-related enhancements were made to support frame-busting for the firewall web interface, in order to prevent framing of web interface elements. |
| **73757** | A security-related fix was made to enforce character encoding specified in HTTP headers due to CWE-116: Improper Encoding or Escaping of Output. |
| **73638** | A security-related fix was made to address issues related to HTML encoding. |
| **73337** | Fixed an issue where a VM-Series firewall with a VPN configuration restarted due to a buffer overflow caused by a race condition. |
| **73309** | Attempting to use the web interface or CLI to upload a WildFire™ content release to Panorama™ displayed an error (**Device > Dynamic Updates > WildFire**). This issue has been fixed so that WildFire content updates can be uploaded successfully to Panorama. |
| **73071** | Fixed an issue where the firewall incorrectly sent duplicate SYN packets for ftp-data sessions. |
| **72825** | Fixed an issue where traffic interruptions for various traffic patterns occurred when data was not released after packet processing. This caused vChecks to remain allocated for an extended period of time, which depleted the buffer pool. With this fix, the vCheck offset is modified so that data can be released and processed at a later time to avoid traffic interruptions. |
| **72763** | Fixed an issue where HA3 packet forwarding may fail in a high availability (HA) active/active configuration when using an Aggregate Ethernet (AE) subinterface to send and receive traffic. |
| **72737** | Fixed a memory corruption issue that caused the dataplane to restart when SSL decryption was enabled. |

| Issue Identifier | Description |
|---|---|
| **72730** | Fixed an issue where it was possible for a firewall under heavy load conditions to send malformed BGP keep-alive messages to a BGP neighbor, causing the BGP neighbor to flap. |
| **72544** | A security-related fix was made to address CVE-2014-8730. For additional information, refer to the PAN-SA-2014-0224 security advisory on the Palo Alto Networks Security Advisories web site at https://securityadvisories.paloaltonetworks.com. |
| **72536** | Fixed an issue where packet buffers leaked when a firewall with inbound SSL decryption enabled attempted to block a connection and send TCP RST packets to the connection endpoints. With this fix, TCP RST packets sent by the firewall to the connection endpoints no longer cause buffers to leak when SSL Inbound Inspection is enabled. |
| **72285** | New counters have been added to track the upload process for files forwarded to WildFire. |
| **72092** | Addressed an LSVPN issue where routes advertised by GlobalProtect™ satellites were not installed in a GlobalProtect gateway routing table. This issue has been resolved so that the GlobalProtect gateway correctly accepts routes from GlobalProtect satellites. |
| **71262** | When two M-100 appliances were in a high availability (HA) active/passive configuration, memory usage for the passive appliance increased significantly compared to the memory usage for the active appliance. This was due to a management process memory leak on the passive device and the issue is fixed. |
| **71040** | Resolved an issue that caused SFP+ ports to hang following a restart and the ports continued to stay in link down state. |
| **70903** | Fixed an issue where SNMP traps from some firewalls were not parsed correctly by the SNMP manager. |
| **70816** | Fixed an issue where the `Address is not valid` error displayed when running commands that initiate a filtering session based on an IPv6 address (examples of the affected commands include `clear session all`, `set application dump`, and `test decryption-policy-match`). IPv6 address validation now works correctly. |
| **70544** | A dataplane restart occurred when the **SSL Opt-Out** page was enabled (to notify users that SSL connections are decrypted), the RC4 cipher was enforced, and a long URL was accessed. This issue has been fixed so that the dataplane does not restart when SSL decryption is enabled. |
| **70304** | Resolved an issue that was seen with **Rematch Sessions** enabled, where a race condition could occur when new security policies were matched to existing sessions. |
| **70150** | Resolved an issue where Simple Network Management Protocol (SNMP) traps were not correctly sent to the SNMP trap destinations following a software upgrade. This issue is fixed so that SNMP traps are generated and correctly sent to SNMP trap destinations after performing an upgrade. |
| **69900** | Fixed an issue where the tech support file did not contain some expected files, including /var/log files. |
| **69737** | On platforms with multiple dataplanes, stale IPv6 neighbor entries were not removed and replaced with new IPv6 neighbor entries when the IPv6 neighbor table was full. This issue has been fixed so that stale IPv6 neighbor entries are correctly removed when the neighbor table threshold is reached. |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **69242** | When a user failed to authenticate using the web interface, firewall system logs did not display the user's source IP address. Updates have been made so that a failed authentication on the web interface is logged with two entries. One entry is logged as a `general` event and displays only the username of the user who failed authentication. The other entry is logged as an `auth-fail` event and displays both the username and source IP address of the user who failed authentication. |
| **68982** | Fixed an issue where the firewall stops receiving new reports from WildFire when the report ID on the WildFire public cloud exceeds a certain limit. (WildFire continues to generate reports but does not log them as expected on the firewall). |
| **67930** | Fixed an issue where an update to a stale IPv6 neighbor entry could cause a dataplane restart. |
| **67810** | When a PA-5000 Series device initiates sessions on different data planes in an environment with multiple virtual systems, session traffic sometimes failed to span across virtual systems. This issue has been resolved so that inter-virtual system sessions succeed with a dynamic network address translation (NAT) policy configuration. |
| **66217** | Fixed an issue that caused unreliable VoIP communication. The issue occurred for firewalls in a high availability (HA) active/active configuration, and was due to predict session traffic not being installed correctly on the HA peer when the peer was setup to use a dataplane other than DP0 to process the session. |
| **64759** | Fixed an issue where a high availability (HA) failover occurred due to insufficient kernel memory on a PA-5000 Series firewall that was attempting to handle unusually heavy network and system traffic. With this fix, the kernel memory on PA-5000 Series firewalls is increased to ensure sufficient kernel memory is avail-able for ping requests and keep-alive messages even when under an unusually heavy load. |
| **58547** | Policy-based forwarding (PBF) with symmetric return did not work when the traffic was translated with source NAT. Return traffic, which needs to be forwarded using the same interface on which it arrived, was dropped with the message `Symmetric Return: Packet dropped, no return MAC found`. The issue is fixed. |

© Palo Alto Networks, Inc.

# PAN-OS 6.0.8 Addressed Issues

The following table lists the issues that are fixed in the PAN-OS 6.0.8 release. For new features introduced in PAN-OS 6.0, associated software versions, known issues, and changes in default behavior, see PAN-OS 6.0 Release Information.

| Issue Identifier | Description |
|---|---|
| **73111** | Dataplane restarts were caused by a race condition between dataplane packet processes, where the session resource allocation became out of sync between central processing units (CPUs). A fix was added to keep session resource allocation in sync between dataplane processes. |
| **72241** | Following an upgrade, attempting to perform a high availability (HA) configuration sync between two HA peers in an active/passive or active/active deployment did not work correctly. This issue has been fixed so that HA peers will sync correctly following an upgrade. |
| **72068** | If a firewall with Open Shortest Path First (OSPF) enabled was then restarted, a flapping condition was seen between the firewall and the adjacent OSPF neighbor, and a new OSPF election was forced by the firewall. This issue has been fixed so that following a firewall restart, any OSPF adjacency remains established. |
| **71939** | Addressed an issue where enabling a second Network Processing Card (NPC) on a PA-7050 firewall resulted in URL packets being dropped by the second NPC and URL lookups could fail. This issue has been fixed so that URL lookups are performed correctly and web pages load quickly. |
| **71850** | Changing the IP address for a log card interface on a PA-7050 firewall caused an issue where traffic log forwarded to syslog servers stopped until the firewall was restarted. This was due to an issue where the firewall sent out traffic using an internal IP address (which was recognized as an invalid source IP address by devices intermediate to the firewall and the syslog server) following a change to the log card interface IP address. This issue has been fixed so that changing the IP address for a log card interface does not cause the firewall to send out traffic using an internal IP address. |
| **71688** | On a PA-7050 firewall with OSPF enabled, a restart caused OSPF neighbor adjacency states to flap. This issue was caused by an incorrect slot number setting on the Network Processing Card (NPC) for the session owner. With this fix, the NPC slot number for the session owner is properly selected and OSPF neighbor adjacency is established. |
| **71553** | Fixed an issue where dataplane processes restarted when handling SSL decryption sessions during high availability (HA) message updates. The fix for this issue included the addition of a global counter. |
| **71512** | A fix was made to add frame-busting to the firewall web interface to prevent framing of web interface elements. |
| **71503** | Addressed an incorrect file permissions issue in the web interface. |
| **71486** | A fix was made to address an issue with user input sanitization to prevent Cross-site Scripting (XSS) attacks against the web interface. |

| Issue Identifier | Description |
|---|---|
| **71464** | If the firewall initiates a point-to-point protocol over Ethernet (PPPoE) session, an issue was seen when a server responds with a PPPoE Active Discovery Offer (PADO) packet that was greater in size than the maximum transmission unit (MTU) of the firewall interface. In this case, the PADO packet was dropped. This issue has been addressed so that PADO packets are handled correctly by the firewall, including when the size of the packet is greater than the MTU for the firewall interface. |
| **71333** | In a high availability (HA) active/active configuration with an IPSec tunnel configured to terminate on a floating IP address, Encapsulating Security Payload (ESP) was performed by the device that did not own the floating IP address. The encapsulated packets failed the IPSec anti-replay check on the remote end of the IPSec tunnel and were discarded. With this fix, packets are always sent to the owner of the floating IP address to be encapsulated. |
| **71321** | Removed support for SSL 3.0 from the GlobalProtect™ gateway, GlobalProtect portal, and Captive Portal due to CVE-2014-3566 (POODLE). |
| **71320** | Removed support for SSL 3.0 from the web interface due to CVE-2014-3566 (POODLE). |
| **71273** | A security-related fix was made in PAN-OS to address issues related to parsing XML data. |
| **71199** | In a Large Scale VPN (LSVPN) setup, a GlobalProtect satellite reconnecting to a GlobalProtect gateway after receiving a different IP address, changed the GlobalProtect routing metrics when installing the gateway access routes into the satellite routing table. With this fix, the original gateway routing priority is restored when the GlobalProtect satellite reconnects to the GlobalProtect gateway with a different IP address. |
| **71148** | When attempting to add an address to an **Address Group** using the Panorama web interface, filtering for the address returned no results even though the address object did exist and was displayed as configured on the **Objects > Addresses** page. Additionally, filtering for the same address object when attempting to add the address to a security rule displayed different results for the address object name. This issue has been resolved so that filtering for an address correctly displays any configured addressed objects, and address object names are displayed consistently. |
| **70820** | Addressed an issue for PA-7050 firewalls, where Real-time Transport Protocol (RTP) predict sessions remained in the Opened session state and did not become an active session. This caused the RTP packets to not merge correctly with the predict session and the packets were dropped if they did not specifically match to an allow policy. |
| **70499** | Fixed an issue where traffic that matched to a predict session and then converted to a flow session was then being incorrectly matched to security policies where the only matching criteria defined in the policy was a custom application. A fix was made to perform a second policy lookup after predict session traffic is converted to flow session traffic. |
| **70383** | When using the Panorama™ XML API to register an IP address to a Dynamic Address Group on a targeted firewall, an error was displayed that the user was not authorized to perform the operation. This issue has been resolved so that using the XML API to register an IP address to a Dynamic Address Group on the firewall results in the firewall correctly registering the IP address and updating the membership information for the dynamic address group. |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **69934** | Fixed an issue where active File Transfer Protocol (FTP) enabled with Dynamic IP Network Address Translation (NAT) failed. Inconsistent translation was seen for PORT packets sent over the control connection established between the FTP server and the NAT device. |
| **69685** | Updates were made to existing Russian time zones and new Russian time zones were added to the available list of global time zones for a device, to accommodate the 2014 changes to Russian time zones. |
| **69528** | An issue was seen with captive portal enabled in an environment with multiple virtual systems, where two virtual systems were configured as User-ID collectors. When captive portal timed out a User-ID entry in one virtual system, captive portal did not time out for the same User-Id entry in the second virtual system, and the user was not prompted to re-authenticate to the captive portal login page. This issue has been fixed so that if captive portal times out for a User-ID entry in one virtual system, the same User-ID entry correctly times out in the second virtual system and the user is prompted to authenticate to the captive portal login page. |
| **68764** | When a DNS proxy server is configured on the firewall, the proxy settings were not used and DNS resolution was requested to resolve service.brightcloud.com. After the fix, the connection request by the firewall to BrightCloud is always forwarded to the proxy. |
| **68702** | An error was displayed when pushing a policy from Panorama to a managed firewall with a user group defined in the policy. The error displayed was Duplicate group name and this issue has been resolved so that pushing a user group from Panorama to a managed firewall works correctly. |
| **68560** | Addressed an issue where vulnerabilities were logged as unknown when an ampersand character (&) was used in the **Comment** field when creating a custom vulnerability object (**Objects > Custom Objects > Vulnerability**). Using the ampersand character in the **Comment** field when creating a custom vulnerability object is supported, and does not cause the vulnerability to display as unknown. |
| **68430** | The dataplane restarted unexpectedly due to a lack of memory. An update has been made to provide additional debug information for this issue. |
| **68372** | Setting up a static MAC configuration for a tagged interface configured on a VLAN did not work correctly. This occurred when a process that communicates between the dataplane and the management plane restarted, and the issue has been resolved. |
| **68371** | Addressed an issue where you could not install the BrightCloud database when the default url-db was set to PAN url-DB, and you had not downloaded the BrightCloud database previously. |
| **68100** | The Strip X-Forward-For (XFF) feature did not correctly remove the contents of the XFF header field when the HTTP GET request contained encoded URL characters. This issue has been fixed to ensure that the Strip XFF feature removes the contents of the XFF field from the HTTP header, including when the HTTP GET request contains encoded URLs. |
| **67885** | Panorama predefined reports for vulnerabilities were inconsistent with the predefined report for Vulnerabilities on the managed firewall. This issue has been addressed so that reports are correctly synchronized between Panorama and managed devices. |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **67861** | Following an upgrade to a PAN-OS 6.0 release version, in some cases virtual wire interfaces went down after restarting the firewall. This issue has been fixed so that the status for virtual wire interfaces is no longer down after upgrading to a PAN-OS 6.0 release version and restarting the firewall. |
| **67567** | When a new version of the BrightCloud URL database was downloaded and installed, if the category for a URL changed in the new version of the database from the previous version, the change in category was not reflected on the dataplane. With this fix, URL categories on the dataplane are updated correctly after a installing a new version of the BrightCloud database. |
| **65477** | A deadlock issue has been addressed where an inter-process communication (IPC) failed while another IPC operation was in progress. This resulted in the management server restarting with a core dump. |
| **64958** | Resolved an issue displayed on the Panorama web interface, where the **Oldest Log** statistics incorrectly showed no data (**Panorama > Managed Collectors > Collector Statistics**). |
| **64930** | Dynamic objects could be lost if the device server restarted unexpectedly. This has been fixed so that dynamic objects are repopulated if the device server process unexpectedly restarts. |
| **64600** | When a dynamic block list was configured on the firewall to be updated according to a list hosted on a web server, the firewall was configured to access the web server using a proxy server. An issue was seen where the firewall was connecting directly to the web server hosting the block list, instead of using the proxy server to connect to the web server. This issue has been fixed so that when a proxy server is configured, the firewall updates the dynamic block list using the proxy server and does not connect to the server hosting the block list directly. |
| **64040** | The logging partition could become full on a log collector if the total configured quota was larger than 90%. A fix was made to address the way free space is allocated for the logging partition. |
| **62791** | An update was made to reduce the number of TCP stale sessions for PA-5000 Series devices. |
| **61201** | Scheduled email reports were not being delivered, though the reports were generating and displaying correctly on the **Monitor** tab on the web interface. This issue was due to a memory leak for a back-end process that maintains configuration information for the firewall. This issue has been fixed so that scheduled email reports are correctly delivered to email. |
| **58055** | Addressed an issue where a race condition between a high availability (HA) synchronization and a web interface commit caused a management server restart. |
| **55249** | You can now run the `test <feature>` CLI command for the following features: botnet, cp-policy-match, custom-url, data-filtering, decryption-policy-match, dns-proxy, dos-policy-match, global-protect-mdm, global-protect-satellite, nat-policy-match, nd, pbf-policy-match, pppoe, qos-policy-match, routing, scp-server-connection, security-policy-match, stats-service, tag-filter, url, url-info-cloud, url-info-host, user-id, vpn, wildfire. |

© Palo Alto Networks, Inc.

# PAN-OS 6.0.7 Addressed Issues

The following table lists the issues that are fixed in the PAN-OS 6.0.7 release. For new features introduced in PAN-OS 6.0, associated software versions, known issues, and changes in default behavior, see PAN-OS 6.0 Release Information.

| Issue Identifier | Description |
|---|---|
| **70588** | Fixed an issue where a browser with Transport Layer Security (TLS) 1.2 enforced could not access the GlobalProtect™ portal login page. This issue occurred when no client certificate was configured. |
| **70165** | Fixed an issue for PA-7050 firewalls in a high availability (HA) active/active configuration, where IPv6 fragments could cause a Network Processing Card (NPC) to restart. |
| **69956** | Resolved an issue where NetFlow information for some sessions was not being forwarded for PA-5000 Series devices due to a session ID format change. |
| **69035** | When using the **ACC** tab on the Panorama™ web interface to view statistics for a custom application, using applications filters (such as Category, Subcategory, and Technology) to filter the data displayed for the custom application resulted in no data being displayed. This occurred when Panorama was selected as the **Data Source** for the traffic data displayed on the **ACC** tab, and the issue has been resolved. |
| **68836** | In a a high availability (HA) configuration, a path monitoring failure lead to a delayed HA failover. An update has been made to optimize HA failover time. |
| **68588** | Predefined reports for a firewall connected to Panorama were not being displayed correctly if the management server for the firewall was not restarted after connecting to Panorama. This issue has been fixed so that predefined reports on a managed firewall are still displayed correctly after establishing a connection with Panorama. |
| **68472** | Addressed an issue where some expected counters were not returned in the output for the `<show> <interface>` XML API command for loopback, VLAN, and tunnel interfaces. |
| **68389** | The Application subcategory is listed as unknown in the PDF report for custom applications pushed from Panorama. This issue was resolved by correcting the report daemon to properly parse the configuration objects pushed from Panorama. |
| **68055** | Mac clients were incorrectly unable to access certain websites that Windows clients were able to access. This issue occurred when fragmented traffic passed through the firewall and the first fragment did not include the header; this caused packets to be dropped. The issue has been resolved. |
| **67864** | When a rule pushed from Panorama is selected on a managed device, the clone button in a security policy is enabled; however, rules pushed to a managed device from Panorama cannot be cloned on a managed device. With this fix, the clone button for rules pushed from Panorama correctly shows as disabled on the web interface for a managed device. |
| **67856** | When a primary NTP server was down and the secondary NTP server was up, the CLI incorrectly showed the secondary NTP server as down. This has been fixed so that the CLI displays the correct status for both the primary and secondary NTP servers. |

| Issue Identifier | Description |
|---|---|
| **67833** | When a tech support file was generated for Panorama, private information was not being removed correctly from files within a device group if the device group had a space in its name. With this fix, device groups with a space in the device group name are handled correctly when generating a tech support file. |
| **67814** | Panorama displayed the secure-proxy-password in the web interface under **Panorama > Setup > Services** and in the CLI. With this fix, Panorama encrypts the secure-proxy-password and downgrade attempts to versions that show the secure-proxy-password will fail until you remove the secure-proxy-password from the configuration. |
| **67788** | The configuration log on Panorama displayed the secure-proxy-password. With this fix, the configuration log encrypts the secure-proxy-password. |
| **67778** | Fixed an issue where a GlobalProtect Mac client experienced intermittent connectivity with the GlobalProtect portal when running Mac OS X 10.10. |
| **67455** | Made an update to the enforcement for the SSL Inbound Inspection setting `block when resources are unavailable` so that hosts cannot resume an SSL session, when that session has been removed from the SSL-decrypt session cache due to the cache being full. The host must start a new session to continue. |
| **67300** | Addressed an issue on the VM-Series firewalls where enabling packet capture for certain application-level gateway (ALG) traffic causes the system to restart. |
| **67268** | A DNS sinkhole was not responding to DNS queries that contained DNSSEC Header flags, such as the Authenticated Data (AD) bit or Checking Disabled (CD) bit. The DNS sinkhole now correctly responds to DNS queries that contain DNSSEC header flags (AD or CD bit) and the firewall can successfully provide the DNS sinkhole IP address to the client. |
| **67258** | The process (*mprelay*) that communicates between the dataplane and the management plane restarted unexpectedly. A policy-based forwarding (PBF) rule configured with symmetric return but not specifying an IPv6 next hop address resulted in excessive neighbor discovery (ND) update messages that caused a conditional loop, which then caused the mprelay process to restart. With this fix, the IPv6 ND performs correctly and avoids unexpected restarts of the mprelay process even if no IPv6 next hop address is specified. |
| **67187** | The following error was displayed due to an issue that caused a User-ID process to restart: `Abnormal system memory usage detected, restarting userid with virtual memory`. Many GlobalProtect users logging into the system, and the resulting high availability (HA) synchronization of the HIP reports, caused the virtual memory to exceed its limit. |
| **67160** | An issue was fixed where a data port configured on a PA-7050 firewall as a Log Card Interface was restarting when commits were performed. |
| **66924** | When logging in to the Panorama web interface with two-factor RADIUS authentication, Panorama would successfully authenticate an administrator but then immediately log the administrator out of the web interface. With this fix, Panorama no longer logs the administrator out of the web interface following a successful authentication. |
| **66918** | Memory corruption issues related to SSL decryption caused the dataplane to restart and resulted in a flapping condition between firewalls in an HA cluster. |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **66635** | Enabling SSL Forward Proxy decryption with a self-signed certificate could sometimes cause the certificate presented to the client to have a negative serial number, causing an error on the client. |
| **66482** | In some cases, the web interface was not accessible for an M-100 appliance even though the appliance could be accessed through the CLI. This issue is the result of a race condition, where a reporting process attempted to delete session that had been previously deleted. This issue is not addressed so that the web interface and CLI are both accessible for an M-100 appliance. |
| **66364** | Fixed an issue that prevented two certificates with the same subject name from being installed following an upgrade to a PAN-OS 6.0 release version. |
| **66208** | A brute-force attack on an unprotected management interface on the firewall caused the /var/log/btmp log file to inflate and consume available disk space. With this fix, PAN-OS enables a log rotation function for failed SSH logins, such as those from brute-force attacks. |
| **66161** | For a PA-3050 firewall, the next hop MAC address for hardware offload did not update correctly for routes that were learned using multiple dynamic routing protocols. This occurred when the routing protocols were not using the default administrative distance. Packets used the wrong egress interface when the session was offloaded. This issue has been resolved. |
| **65859** | Fixed an issue where the dataplane could restart when SSL Forward Proxy decryption was enabled and a certain packet sequence was received. |
| **65850** | Addressed an issue where a high availability (HA) backup failed due to there being no buffer space available. |
| **65180** | Removed support for the RC4-MD5 and RC4-SHA cipher suites. These ciphers cannot be used to negotiate an SSL/TLS connection to the GlobalProtect portal. |
| **64713** | Removed support for the RC4-MD5 and RC4-SHA cipher suites. These ciphers cannot be used to negotiate an SSL/TLS connection to the management interface of the firewall.. |
| **64606** | When navigating to the GlobalProtect portal using a browser that had Transport Layer Security (TLS) 1.2 enabled, and when using a client certificate for authentication, the SSL connection failed due to issues with fallback to a lower TLS version. With this fix, fallback to a lower TLS version succeeds with Google Chrome and Mozilla Firefox. A specific behavior of Internet Explorer still exhibits issues. |
| **64223** | Fixed an issue where FQDN objects that were added to a dynamic address group were not listed after issuing the `request system fqdn show` command, with the command displaying a message that no FQDN object is used in the policies. |
| **63150** | In an Active/Active HA setup, User Datagram Protocol (UDP) sessions with a certain traffic pattern caused the session state to flap frequently and generate excessive traffic logs. This issue is now fixed and the session state is stable. |
| **61056** | IPSec tunnels could not be established due to the firewall running out of encap/decap context. An enhancement was made to allow more granular debugging for the depletion of encap/decap context for IPSec tunnels, in order to provide further root cause analysis. Restart the firewall as a workaround for this issue. |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **60617** | TCP connectivity issues occurred on a virtual machine when SYN Flood was enabled with the SYN Cookies **Activate Rate** set to zero. This was due to an issue where active and passive FTP were not working under different NAT configurations, and has been addressed so that both active and passive FTP work correctly under different NAT configurations and do not cause TCP connectivity issues. A workaround for this issue is to set the **Activate Rate** to a value greater than zero (**Objects > Security Profiles > DoS Protection > Flood Protection > SYN Flood**). |

© Palo Alto Networks, Inc.

# PAN-OS 6.0.6 Addressed Issues

The following table lists the issues that are fixed in the PAN-OS 6.0.6 release. For new features introduced in PAN-OS 6.0, associated software versions, known issues, and changes in default behavior, see PAN-OS 6.0 Release Information.

| Issue Identifier | Description |
|---|---|
| **68899** | Fixed an issue that affected PA-7050 firewalls. An HSCI port configured as an HA2 interface went down due to a dataplane board restarting. An improvement has been made so that if more than one dataplane board is installed, an HA2 interface on an HSCI port will stay up. |
| **68708** | Addressed the bash vulnerability CVE-2014-7169 that relates to how environment variables are processed when the shell starts up. This fix prevents a user with an account on the firewall, from using the vulnerability to gain escalated privileges. |
| **68286** | An issue was seen where setting up a password for a proxy server caused the management plane to restart (**Device > Setup > Services > Proxy Server**). This was due to a process that was restarting when the password was configured. This issue has been fixed. |
| **67910** | While viewing the **Combined Rules Preview** on the Panorama™ web interface (**Policies > Preview Rules > Combined Rules Preview**), the **Device** drop-down displayed the virtual system number for some virtual systems and not the virtual system name. This issue has been fixed so that the **Device** drop-down in the Combined Rules Preview displayed the names of the virtual systems that you can select. |
| **67873** | Resolved an issue where disabling OSPF and performing a commit caused a routing process to restart. This was due to a race condition related to running the `show route` command during a commit. |
| **67860** | On the Panorama web interface, the **Preview Changes** button could not be clicked when **Group HA Peers** was selected. This has been fixed so that the **Preview Changes** button is correctly enabled when **Group HA Peers** is selected (**Panorama > Templates**). |
| **67723** | Fixed an issue that occurred when an OSPF profile was configured with a tunnel interface and the **Passive** state was disabled for the tunnel interface. In this case, the runtime configuration incorrectly overrode the configured settings, and the tunnel interface was incorrectly enabled as **Passive**. |
| **67516** | Fixed an issue with a high availability (HA) active/active configuration where a physical MAC address was returned for a floating IP address instead of a virtual MAC address. This has been addressed so that the floating IP correctly responds to ARP requests with a virtual MAC address. |
| **67483** | This fixes an issue where a firewall failed to email scheduled reports due to a race condition. |
| **67436** | The `debug software trace reportd` and `debug software core reportd` commands were added to the CLI command structure. |
| **67399** | Fixed an issue that occurred in a high availability (HA) active/active configuration, where log card interfaces were synced to the HA peer and resulted in duplicate IP addresses. |

| Issue Identifier | Description |
|---|---|
| **67344** | Fixed an issue for the M-100 appliance where the `show log-collector detail` command was presenting incorrect information. |
| **67069** | Internal packet path monitoring failure errors caused the dataplane to restart. An enhancement was made to detection and recovery mechanisms to minimize the impacts of these errors. |
| **66959** | Addressed an issue where configuring overlapping IPv6 addresses when adding a **OSPFv3 range** on the **Network > Virtual Routers > OSPFv3 > Area > Ranges** tab caused a restart to occur after attempting to commit. This issue has been fixed so that if an invalid range is entered, an error is displayed; if a valid range is entered, you can continue to commit successfully. |
| **66690** | The dataplane restarted due to a process restart while running traffic in a high availability (HA) configuration. Additional checks have been added to avoid a possible race condition, which had led to the dataplane process restart. |
| **66503** | Addressed an issue where the firewall dataplane experienced an out of memory condition, which could cause the dataplane to restart and the firewall to go into nonfunctional state. |
| **66466** | Addressed an issue for PA-2000 Series firewalls, where a device failed to handle a volume of packets (larger than the MTU) on the management interface. Symptoms of this issue included device unresponsiveness, a random restart, traffic failures or ATA errors on the console. This issue has been resolved. |
| **66220** | An issue was seen in a high availability (HA) active/passive configuration where the secondary device was not able to pass traffic after a failover until a routing process was restarted. This issue has been fixed so that when a failover occurs, the secondary device correctly becomes the Backup Designated Router (BDR). |
| **66168** | Resolved an issue where adding an FQDN to the Servers table to specify an LDAP server in an LDAP server profile caused intermittent connection issues (**Device > Server Profiles > LDAP**). |
| **66025** | Configuration files with names longer than 32 characters were allowed and could be successfully imported, but load and delete operations would fail. With this fix, configuration file names of up to 32 characters can be imported and configuration files with longer names are prevented from being imported with an error. |
| **65607** | If the last remaining user was removed from the **Allow List** for an LDAP authentication profile (meaning no users remained on the list), authd was not notified that the group was empty and retained the last user's information. That user could continue to be authenticated despite no longer being included in the allow list. This has been addressed so when the last user remaining on the allow list is removed, the user can no longer authenticate. |
| **65565** | Fixed an issue where selecting R**eplay attack detection** in the **GlobalProtect gateway satellite** configuration on the web interface did not actually enable replay attack detection. |
| **65488** | Resolved an issue that occurred with a high availability (HA) active/passive configuration, where using the `request -availability state suspend` command to suspend the active peer and perform an HA failover resulted in some packet loss. |
| **65176** | Resolved an issue that caused a dataplane restart on the VM-Series firewall, when using RC4 ciphers to decrypt SSL traffic. This issue is specific to ESXi servers using AMD processors. |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **64647** | Following an upgrade from a PAN-OS 5.0 release version to a PAN-OS 6.0 release version, high availability (HA) synchronizations were failing intermittently. The HA sync failures were due to an issue where the host information profile (HIP) database was not syncing correctly during the HA sync between the peers. This issue has been fixed so that performing a HA synchronization works correctly. |
| **64379** | This fixes an issue where older cached IP address to username mappings on a User-ID agent could overwrite newer IP address to username mappings on the firewall. With this fix, IP address to username mappings with more recent timestamps take precedence over IP address to username mappings with older timestamps. |
| **64309** | A WildFire™ threat log with the severity `Informational` was incorrectly showing the severity `Emergency` when forwarded to a syslog server. This issue has been fixed so that when WildFire logs are forwarded to a syslog server, the log entries show the correct severity for the log. |
| **62768** | Unreliable DNS servers incorrectly provide NXDOMAIN responses. To help prevent incorrect WildFire sample categorization, NXDOMAIN responses are no longer shared across WildFire samples. Each NXDOMAIN response will be evaluated on a sample by sample basis. |
| **61205** | Using the web interface to export traffic logs in CSV format was showing an error that the query job failed. This issue has been addressed so that exporting traffic logs to CSV works correctly. |
| **58820** | On PA-5000 Series firewalls, Static Source NAT, Dynamic IP NAT, and Destination NAT session processing has been enhanced to greatly improve the throughput in these NAT scenarios, allowing the firewall to use multiple CPUs to process NAT sessions, rather than anchoring the sessions to a CPU based on destination IP hash. |

# PAN-OS 6.0.5-h3 Addressed Issues

The following table lists the issues that are fixed in the PAN-OS 6.0.5-h3 release. For new features introduced in PAN-OS 6.0, associated software versions, known issues, and changes in default behavior, see PAN-OS 6.0 Release Information.

Before upgrading to PAN-OS 6.0.5-h3 or subsequent PAN-OS 6.0 release versions, and if you have asymmetric routes in your network or have attached a zone protection profile, first refer to the Important notes in the Upgrade to PAN-OS 6.0 section of the PAN-OS New Features Guide Version 6.0.

| Issue Identifier | Description |
|---|---|
| **69173** | Under certain conditions, unspecified layering of packet-level evasions could be used to bypass signature matching of the session. |

© Palo Alto Networks, Inc.

# PAN-OS 6.0.5 Addressed Issues

The following table lists the issues that are fixed in the PAN-OS 6.0.5 release. For new features introduced in PAN-OS 6.0, associated software versions, known issues, and changes in default behavior, see PAN-OS 6.0 Release Information.

| Issue Identifier | Description |
|---|---|
| **68018** | When configured in high availability (HA) mode, the High Speed Chassis Interconnect (HSCI) ports using QSFP modules on the PA-7050 experienced packet loss. This HSCI link flapping issue has been resolved. |
| **67613** | Resolved an issue where uploading files to Wildfire sometimes failed when the files were uploaded from the client to the server using HTTP. |
| **67565** | For Panorama and PAN-OS, when an Admin Role Profile was set up with Privacy permissions disabled, the administrator was able to search the traffic logs based on username. This issue has been fixed so that an administrator without privacy permissions cannot search traffic logs based on username. |
| **67378** | Resolved an issue where LEDs for copper ports on the PA-7050 firewall that were configured as high availability (HA) ports were not correctly showing active links. |
| **67246** | Resolved an issue where modifying an existing policy caused any tags configured in that policy to be removed. |
| **67073** | Fixed an issue where link flapping was seen during a high availability (HA) failover. |
| **67058** | Resolved an issue where a Vulnerability Protection profile did not match a custom vulnerability signature when the vulnerability name was entered as the **Threat Name** in the vulnerability protection rule. This issue has been resolved so that the Vulnerability Protection profile matches signature when the vulnerability name is entered as the Threat Name in the rule. As a workaround, the **Threat Name** in the Vulnerability Protection profile could be set to **any** so that the profile will match the custom signature. |
| **66910** | With Block Password Change Period enabled to specify an amount of time during which an administrator cannot change a password, an administrator's password could still not be changed after the period had passed. This has been resolved so that when the period has passed, a password for an administrator can be successfully modified. |
| **66692** | Resolved an issue where device administrators with privacy settings disabled were still able to view usernames on the **ACC** tab. |
| **66610** | Scheduled email reports for Panorama were not correctly showing IP addresses resolved to hostnames, and were continuing to display IP addresses for entries. This issue has been resolved so that hostnames are correctly displayed in scheduled email reports instead of the corresponding IP address. |

| Issue Identifier | Description |
|---|---|
| **66342** | Resolved an issue that occurred with Panorama peers in a high availability (HA) configuration. Following an HA failover, a managed device forwarded logs to the secondary Panorama while the primary Panorama was down. When the primary Panorama came back online, the managed device incorrectly continued to forward logs to the secondary Panorama. This has been fixed to ensure that managed devices correctly forward logs to the primary Panorama when both the primary and secondary Panoramas are online. |
| **66215** | Resolved an issue that caused a dataplane restart when a tech support file was being generated and a content update was being performed at the same time. |
| **66199** | When the option **Target to all but these selected devices** was enabled for a Panorama Security policy, the policy was being pushed to the dataplane of managed devices that were explicitly excluded from receiving the policy (the policy should not have been pushed to these devices at all). This issue has been fixed so that when **Target to all but these selected devices** is enabled, the policy is correctly pushed to devices associated with that policy, and is not pushed at all to devices that are explicitly excluded. |
| **66043** | A PA-5050 firewall was showing that it only supported 32,768 device routes when it should support a maximum of 64,000 routes. This issue has been resolved to ensure that the firewall supports 64,000 device routes. |
| **65936** | Addressed an issue where the device server could crash if a configuration referenced different names for a single GlobalProtect gateway entry. |
| **65905** | Addressed an issue where a routing process restarted, causing the firewall to restart. This occurred when configuring virtual routers with both OSPF and BGP enabled with aggregate routes and routes to be redistributed. |
| **65833** | In a high availability (HA) active/active configuration, resolved an issue where the primary HA device did not resume the primary status after being suspended, when the preemptive option was enabled on both firewall peers in the setup. |
| **65828** | On Panorama, with the option to **Share Unused Address and Service Objects with Devices** enabled, certain conditions caused unused objects to still be pushed to managed devices. This issue has been fixed so that unused objects are not pushed to firewalls when the option to **Share Unused Address and Service Objects with Devices** is not selected. |
| **65801** | Traffic for a voice and video application was being dropped because Network Address Translation (NAT) was not correctly translating the application's IP address and the traffic was not able to be routed correctly. This issue has been resolved so that H225 and H245 traffic is handled efficiently by the firewall-NAT is correctly performed for voice and video applications and calls placed using Voice over IP (VoIP) do not fail. |
| **65765** | Addressed an issue related to parsing long URLs which in some cases was causing an infinite loop that could cause the dataplane to restart. |
| **65747** | When one port configured as a virtual wire interface was brought down and then brought back up, both virtual wire interfaces continued to flap before stabilizing. This was an issue for 10G Fiber ports and has been resolved. |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **65678** | After upgrading to Panorama 6.0.0 or a later release version, previously authenticated non-local administrator accounts, like RADIUS authenticated administrators, could not log in using the CLI unless first logging in to the web interface. This issue has been addressed so that, following a Panorama upgrade, an authenticated administrator can successfully log in to the CLI without first logging in to the web interface. |
| **65511** | The Mozilla compatibility user agent headers in Internet Explorer 11 were changed, causing Captive Portal to identify Mozilla as an unsupported browser and NTLM authentication was not performed. This issue has been resolved so that Internet Explorer 11 can perform NTLM authentication. |
| **65496** | The Panorama command line interface (CLI) was displaying an extra line when exiting the CLI when running Panorama 6.0.2 or 6.0.3. The additional line, which indicated that the management session was terminated, was not displayed in releases prior to Panorama 6.0.2 and has been removed. |
| **65340** | A commit failed without a clear error message when a static route statement overlapped an OSPF export statement. Updates have been made to clarify the error message showing conflicts that could lead to a failed commit. |
| **65292** | Safe Search Enforcement was not being enforced when users were logged into either Bing or Google accounts (if users were logged out of their Bing or Google accounts, Safe Search enforcement worked correctly). This issue has been resolved so that Safe Search Enforcement blocks Bing or Google search results correctly, even when users are logged into Google or Bing accounts. |
| **65256** | The system logs on a PA-7050 displayed an error informing the user that an executable file could not be found. This issue has been fixed so that the executable file has a valid file path and the error is no longer displayed. |
| **65068** | Resolved an issue seen while forwarding logs to a syslog server, where the `risk-of-app` field was displayed as an application instead of a risk value. |
| **64990** | Attempting to sort entries for scheduled custom reports according to the **Receive Time** under **Monitor > Reports** was not the correct sorted results. This has been fixed so that these results can be correctly displayed in ascending or descending order by **Receive Time**. |
| **64908** | With both OSPF and BGP enabled, if OSPF was configured to redistribute the default route `0.0.0.0/0`, this caused OSPF to redistribute routes that were configured for BGP route redistribution. Resolved this issue so that OSPF no longer redistributes routes configured for BGP redistribution. |
| **64707** | Fixed an issue where a device server process restarted unexpectedly while processing the URL cache. |
| **64705** | Exporting logs from Panorama and then attempting to import them to a managed device did not display the logs on the managed device. Imported logs were placed in a temporary directory before being added to the main database. An ordering error in this process was cleaning up the temporary directory before the imported logs were correctly merged into the main database. This issue has been resolved. |
| **64664** | Resolved an issue where the Detailed Log View for traffic logs was not displaying the Log Links widget (**Monitor > Logs > Traffic**). |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **64642** | Fixed an issue where an IP address obtained from a DHCP server on a dataplane interface was not binding to the dataplane and an IP address obtained from a PPPoE server on a dataplane interface was not bound to the dataplane. This issue has been resolved. |
| **64596** | A user icon was showing for a group object, when the group object was added to a security policy. This has been fixed so that a group icon is shown for a group object when added to a security policy. |
| **64550** | Resolved an issue where enabling NAT64 resulted in unexpected ARP behavior on Layer 3 interfaces. |
| **64165** | Following a Panorama upgrade to PAN-OS 6.0.2, several duplicated email notifications were being sent for old logs. This was due to an issue with sequence and acknowledgment (SEQ/ACK) numbers. Updates have been made to reduce the duplicated logs. |
| **64076** | When a template with the L3 Forwarding Enabled option selected was created on Panorama running a Panorama 5.1 release version, commits could not be performed after then upgrading to the Panorama to run PAN-OS 6.0.2. This was due to a migration issue that occurred during the upgrade and was related to the L3 Forwarding object. This issue is now resolved. |
| **63854** | Resolved an issue where a virtual systems administrator could not use the XML API to add IP address to username mappings. |
| **63395** | Custom reports configured on Panorama were not being pushed to a PA-7050, and were displaying on the PA-7050 with no data. This has issue has been resolved so that custom reports configured on Panorama are successfully pushed to a PA-7050 and display correctly. |
| **62565** | Resolved an issue where OSPFv3 was not redistributing a default route correctly. |
| **62375** | The GoDaddy root certificate authority (CA) was missing from the list of trusted certificate authorities. When SSL decryption was configured, sites using the GoDaddy root certificate authority were displayed as not trusted. The GoDaddy Root Certificate Authority - G2 has been added to the list of trusted CAs. |
| **61038** | Resolved an issue where the device server would sometimes fail to send a URL request to BrightCloud, and the URL categories would display as not resolved. |
| **60030** | URL Filtering logs now display when a search has been successfully blocked due to Safe Search Enforcement. An entry with a `block-url` action is listed in the URL Filtering logs whenever a user is presented with a block page (**Monitor > Logs > URL Filtering**). |

© Palo Alto Networks, Inc.

# PAN-OS 6.0.4 Addressed Issues

The following table lists the issues that are fixed in the PAN-OS 6.0.4 release. For new features introduced in PAN-OS 6.0, associated software versions, known issues, and changes in default behavior, see PAN-OS 6.0 Release Information.

| Issue Identifier | Description |
|---|---|
| **66157** | Fixed an issue on a PA-7050 firewall, where traffic through an IPSec tunnel failed during tunnel key renegotiation due to a race condition. |
| **65643** | When a firewall was configured with both 1GB and 10GB interfaces, and a 10GB interface went down, a back-end process was not reporting the link down event instantly. An update was made to prevent back-end processes from delaying to report an interface's link status as down. |
| **65612** | Fixed an issue that occurred when Panorama was running a PAN-OS 6.0 release version and a managed firewall was running a PAN-OS 5.0 release version. Reports generated for WildFire private cloud were not accessible on Panorama and showed the error message: `the requested resource does not exist`. |
| **65557** | In certain situations, a firewall in a high availability (HA) configuration could exit a suspended state without user intervention. With this fix, additional checks have been implemented to ensure that a firewall can exit a suspended state only due to an administrator request using the CLI or web interface. |
| **65534** | Resolved an issue that caused a PA-7050 to restart due to a link failure. This was due to an issue where when a link failure occurred, only one side of the link was being reset. Link detection has been updated so that if a link failure occurs, both sides of the link are reset. |
| **65445** | Addressed an issue where the ACC charts on the firewall web interface did not display any data after the order of the columns was modified and the width of the columns was adjusted. |
| **65396** | Fixed an issue that occurred when the option to **Share Unused Address and Service Objects with Devices** was disabled on Panorama. When this option was disabled, attempting to commit a Device Group to a managed firewall failed. |
| **65328** | Addressed an issue with Panorama where logs were not being uploaded. The use of a space character in Log Collector Group names led to this issue. You can no longer include a space character in a Log Collector Group name. |
| **65316** | The firewall web interface would allow you to add an **Exempt IP Address** to a vulnerability from the Threat Logs but did not save the settings and enforce the IP exception unless an **Exempt Profile** was also selected. The web interface has been updated so that you cannot add an **Exempt IP Address** without also selecting an **Exempt Profile**. |
| **65278** | Selecting a service object displayed in the Service column for a Security policy rule and then selecting **Value** did not expand to display the service object's members as expected (**Policies > Security**). This has been updated so that selecting a service object in the Service column correctly displays the service object's **Value** fields. |

| Issue Identifier | Description |
|---|---|
| **65156** | A security-related fix was made to address CVE-2014-0224. For additional information, refer to PAN-SA-2014-0003 on the Security Advisories site (https://securityadvisories.paloaltonetworks.com). |
| **65146** | Resolved an issue that occurred in a high availability (HA) active/active configuration, where HA3 packets could drop for a few seconds on the active-primary device while a content update was running on the active-secondary device. |
| **65098** | Resolved an issue that was seen after a shared policy was pushed from Panorama, where all traffic through a firewall stopped. This was due to an issue where the routing loop configuration between two Virtual Routers was causing incorrect programming to the offload processor on the PA-4000 Series firewall. |
| **64960** | In a high availability (HA) active/active configuration, when a device received Jumbo packets that had been fragmented, it transmitted the packets as fully assembled Jumbo packets. This issue has been resolved so that fragmented Jumbo packets are no longer transmitted as assembled Jumbo packets; both fragmented and assembled packets are transmitted correctly. |
| **64870** | Resolved an issue that was seen in a Panorama high availability (HA) active/passive configuration, where saving the configuration on the active device did not correctly sync the predefined configuration to the passive device. |
| **64795** | Custom application port settings were getting deleted inadvertently by clicking the **OK** button after opening the specific custom application. This issue has been addressed so that clicking the **OK** button after opening a custom application entry does not delete port settings. |
| **64656** | Addressed an issue that occurred on PA-3000 Series firewalls, where the dedicated HA2 port was taking more than 10 seconds to link up when an Ethernet cable was connected. |
| **64591** | The fix in this bug resolves two issues:<br>• PA-3000 Series firewalls could stop passing traffic due to errors in the internal data path. A registry value was changed in the dataplane packet processor to prevent this error.<br>• When highly compressed traffic is passing through PA-7050, PA-5000 Series, or PA-3000 Series firewalls, this caused some additional latency in other traffic passing through the firewall. This fix prevents the latency from being introduced to the traffic by changing the amount of data being handled by the signature matching FPGA. |
| **64553** | When using the PAN-OS integrated User-ID agent, after the mapping has timed out, the firewall continued to send WMI probes to devices that were no longer responding. With this fix, the firewall does not perform WMI probing after the time-to-live (TTL) timer for an IP address to username mapping expires. |
| **64438** | Static DNS proxy entries configured on the DNS Proxy page are set with an initial TTL value of 7 days. For static DNS proxy entries, the TTL counter should always remain at the initial value; however, in this case, the TTL counter for the static DNS proxy entries was counting down to zero. This issue has been resolved so that the TTL value for static DNS proxy entries remains at 7 days. |
| **64322** | Resolved an issue where Panorama was running a PAN-OS 6.0 release version and could not push Dynamic Address Groups to a firewall running a PAN-OS 5.0 release version. This issue has been resolved and was due to migration issues caused by the removal of the Dynamic Address Object functionality in PAN-OS 6.0. |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **64289** | Addressed an issue where SSL Certificate Common Names containing uppercase characters were not parsed properly due to case sensitivity. In certain conditions, this caused the URL Categorization lookup to fail and the issue has been resolved. |
| **64166** | After approximately 388 days of uptime, the firewall lost the IP address to username mappings on the dataplane. This issue has been addressed so that the firewall does not lose IP address to username mappings when it reaches this uptime. |
| **64122** | Addressed an issue where a User-ID process unexpectedly stopped on the passive device in a high availability (HA) active/passive configuration. This was due to an issue caused by a restart of the Windows server that was hosting the Terminal Server Agent. |
| **63971** | Addressed an issue where the Network File System (NFS) process failed intermittently on PA-5000 Series devices configured in a high availability (HA) configuration. This issue occurred because HA session updates were not being processed in the correct order and sessions were stalled. Though the issue was not specific to NFS traffic, it was more prevalent for NFS traffic and other application traffic with long session timeout periods. |
| **63658** | An update was made to support the export of threat packet capture (PCAP) files using the XML API for a role-based user. |
| **63620** | Fixed an issue with PA-3000 Series firewalls where traffic could stop passing through the firewall or the dataplane could restart due to errors seen on the field-programmable gate array (FPGA). |
| **63423** | Resolved an issue with the firewall web interface where attempting to filter traffic logs using the parameter `user in` caused the management plane to stop responding. |
| **63304** | A dataplane process stopped unexpectedly when processing malformed inbound-proxy SSL encrypted handshake packets. Defensive protection logic has been incorporated to gracefully handle these packets and to avoid process failures. |
| **63113** | Resolved an issue where MIB walk counters were showing different information than the output of the `show session info` command on the firewall. |
| **63110** | Changed the level of a User-ID log to show as a debug log instead of a warning log. |
| **62741** | The feature that allows you to configure polymorphic objects in the Panorama web interface was not working in PAN-OS 6.0 release versions (the feature worked as expected in PAN-OS 5.0 release versions). This feature allows you to configure objects that do not exist in policies on Panorama if the following command is configured: `debug skip-policy-address-check yes`. This issue has been fixed so that the polymorphic objects feature works correctly. |
| **62410** | With SSL decryption enabled on the firewall, certain web sites that use Transport Layer Security (TLS) Renegotiation were failing to load because the sites' certificates included renegotiation extensions. An update was made so that the firewall supports TLS Session Renegotiation. |
| **62323** | Made fixes to improve the issue where the firewall went into a non-functional state due to an out of memory condition caused by an internal process. Updates have been made to resolve some of the memory utilization issues. |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **62305** | In a multiple virtual system environment, subsequent commit failures were seen following an upgrade to a PAN-OS 6.0 release version. This occurred when prior to the upgrade, Panorama had pushed security policies that reference tags. This issue has been resolved so that following an upgrade to PAN-OS 6.0.4 or later release version commits are successful and tag objects pushed from Panorama prior to the upgrade are automatically created. |
| **62244** | When trying to add an address object to a policy, the search drop-down failed to display the configured address object. This issue was only seen when the number of address objects available exceeded 500 objects, and has been addressed so that address objects are displayed correctly when using the search drop-down to add the object to a policy. |
| **61972** | When highly compressed traffic passes through a PA-7050, PA-5000 Series, or PA-3000 Series firewall, this caused some additional latency in other traffic passing through the firewall. This fix prevents the latency from being introduced to the traffic by changing the amount of data being handled by the signature matching FPGA. |
| **61846** | The firewall web interface required the field **Peer HA1 IP Address** to be populated in order to disable high availability (HA). This has been addressed so that the field **Peer HA1 IP Address** is not mandatory to disable HA. |
| **61170** | The PAN-OS 6.0 SNMP MIB has been updated to add 42 new system log traps. The new traps are added as follows:<br>• 5 traps added under PAN_ELOG_EVENT_HA<br>• 3 traps added under PAN_ELOG_EVENT_VPN<br>• 2 traps added under PAN_ELOG_EVENT_USERID<br>• 11 traps added for PAN_ELOG_EVENT_MDM (new category)<br>• 21 traps added for PAN_ELOG_EVENT_RAID (new category)<br>• 2 traps added for PAN_ELOG_EVENT_VM (new category)<br>You can download the updated SNMP MIB (PAN-MIB-MODULES-6.0-RevC.zip) from the following location: https://live.paloaltonetworks.com/docs/DOC-6587. |
| **61641** | Addressed an issue where incorrect entries and information were displayed when moving between pages in the **Monitor** tab on the web interface. |
| **61632** | Addressed an issue where a service route was configured for a syslog server using a destination IP address, but the syslog server's traffic was using the management port. |
| **61329** | Using the web interface to add an IP address to a security policy, where a subnet was added without a proper subnet mask (for example, `1.1.1.1/`), was not blocked as an error. The expected behavior would be to block adding an IP address ending with a `/` as that character could translate to a value of any on the dataplane. An update was made to check for the `/` character. |
| **59795** | For administrators that logged into the web interface using RADIUS authentication, configuration changes did not cause the **Commit** button to be lighted (the **Commit** button showed as disabled) and were not displayed on the **Device > Config Audit** page. This issue did not exist for administrators authenticating using the local database. This issue has been resolved for all authentication methods (local user database, RADIUS, and LDAP). |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **59715** | On PA-5000 Series devices, when sessions were initiated on different dataplanes in an environment with multiple virtual systems, sometimes session traffic failed to span across virtual systems. This issue has been resolved so that inter-virtual system sessions succeed with a destination NAT (DNAT) policy setup. |
| **57687** | An update was made to enhance initialization of the PAN-DB cloud lookup process during device startup. |
| **56786** | Security rules with a URL category attribute were not being correctly matched against certain sessions with `set deviceconfig setting ssl-decrypt url-proxy` enabled, which sets a proxy for SSL sessions if the URL category is blocked. An update has been made so that a security policy lookup is performed after the URL category is received for proxy purposes, in order to ensure the information is retrieved correctly. |
| **40883** | Addressed a root partition that was at 100% usage due to an issue where FireMon processes (where FireMon was being used as an external third-party monitoring utility to the Palo Alto Networks firewall) continued to run on a device and did not close correctly, even after the FireMon connection had timed out. |

© Palo Alto Networks, Inc.

# PAN-OS 6.0.3 Addressed Issues

The following table lists the issues that are fixed in the PAN-OS 6.0.3 release. For new features introduced in PAN-OS 6.0, associated software versions, known issues, and changes in default behavior, see PAN-OS 6.0 Release Information.

| Issue Identifier | Description |
|---|---|
| **63862** | A back-end process was using an excessive amount of memory, causing an out of memory condition. An update has been made to improve how out of memory conditions are addressed. When an out of memory condition occurs, the back-end process will be terminated in place of any other critical processes. This ensures that any critical processes will continue to run despite an out of memory condition, and the back-end process will later restart automatically. |
| **63859** | A PA-500 device was not sending out scheduled email reports. This was due to a rare issue where report generation was suspended and a race condition caused it to be unable to resume, resulting in subsequent scheduled reports failing to generate. This issue has been addressed so that the report generation process is able to correctly resume after being suspended. |
| **63635** | Addressed an issue where Panorama restarted unexpectedly due to a back-end reporting process that stopped responding. |
| **63626** | The clear log operational command was not available on the PA-7050 firewall in the first three releases of PAN-OS 6.0 (6.0.0, 6.0.1, and 6.0.2). As of PAN-OS 6.0.3, this command is now available. |
| **63608** | Upgrading from a PAN-OS 5.0 release version to a PAN-OS 6.0 release version failed when the PAN-OS 5.0 configuration included a custom application configuration that included the spyware identification option (CLI command: `spyware-ident`). This was related to the spyware identification option not being supported in PAN-OS 6.0 release versions until PAN-OS 6.0.3. This issue has been addressed so that upgrading to PAN-OS 6.0.3 or higher release versions is successful, even when the PAN-OS 5.0 configuration includes a custom application configuration with the spyware identification option. |
| **63602** | An issue was resolved where a User-ID process on the firewall stopped working when a connected User-ID Agent sent an XML API logout message containing a valid IP address but no entry name. |
| **63587** | Custom signatures added as exceptions to a Vulnerability Protection Profile were not being displayed on the **Exceptions** tab on the Panorama web interface (**Objects > Vulnerability Protection > Exceptions**). This issue has been addressed so that custom signatures added as exceptions to a Vulnerability Protection profile are correctly displayed on the **Exceptions** tab. |
| **63582** | On the Panorama web interface, attempting to filter target devices to which specific security rules have been applied did not display results. This issue has been addressed so that the filter works correctly. |
| **63570** | Addressed a race condition that caused scheduled report generation to stall preventing scheduled reports from generating. |

| Issue Identifier | Description |
|---|---|
| 63551 | Selecting **Sync to Peer** on the **High Availability** widget on the web interface **Dashboard** did not display the expected pop-up to confirm the sync to peer. This issue and another minor display issue were seen using an Internet Explorer 9 or Internet Explorer 10 browser to use the web interface. These display issues have been addressed. |
| 63472 | Smart card authentication for GlobalProtect was displaying the following error message: `Authentication failed: empty password`. This issue has been addressed so that authentication is successful and the password field is correctly populated. |
| 63422 | Scheduled reports were not showing resolved host names. This was caused by an attribute value that was incorrectly set in one of the functions responsible for resolving the hostname for a given IP address. The value for this attribute has been corrected. |
| 63383 | Addressed an issue where DNS Proxy did not use the expected DNS server (according to the configured DNS Proxy rule) to perform a name server lookup. |
| 63316 | Addressed an issue that occurred when attempting to log in to the Panorama web interface. After authenticating login credentials and displaying the message: `Creating administrative session. Please wait…`, a white screen was displayed instead of the Panorama web interface **Dashboard**. This issue has been resolved so that logging in to the Panorama web interface correctly displays the **Dashboard**. |
| 63298 | Addressed an issue where syncing a configuration between Panorama high availability (HA) peers did not work correctly. |
| 63282 | Fixed an issue where a VM-Series firewall on a Citrix SDX server would not reboot into maintenance mode to allow administrators to perform specific tasks, such as reverting images or changing between FIPS and CC mode. |
| 63247 | During Session Initiation Protocol (SIP) registration, if there was no port specified in the SIP payload, the device did not add any NAT information to the SIP payload. This caused some SIP servers to use more aggressive registration intervals using the RTP Control Protocol (RTCP). This has been fixed by adding a new application: `sipviaheader-nat`. An Application Override policy is required to use this new application. |
| 63242 | A field-programmable gate array (FPGA) change was made to handle microbursts of multicast traffic and improve recovery mechanisms in latency conditions. |
| 63161 | Resolved an issue where the NetBIOS name was removed from the IP address to username mapping when the NetBIOS name contained a period punctuation mark. |
| 63147 | Fixed an issue in the migration script for the Routing Information Protocol (RIP) export rules from PAN-OS 5.0 release versions to PAN-OS 6.0 release versions that caused Panorama template commits to fail. |
| 63106 | Addressed an issue that affected an upgrade from a PAN-OS 5.0 release version to a PAN-OS 6.0 release version, where an IPSec validation error occurred when the dynamic peer type on an IKE gateway had the Local and Peer IDs defined. |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **63086** | Resolved an issue that occurred in a high availability (HA) active/active configuration, where the parent application sessions on a HA peer were not updated with traffic from the child application session and the parent applications sessions timed out. This caused the parent applications to close on both devices in the HA pair. This has been updated so that when the parent application session is refreshed on the primary device, it is now also refreshed on the secondary device. |
| **63052** | When attempting to connect to GlobalProtect with token-based authentication configured, and a token could not be found, different error messages were previously displayed depending on the GlobalProtect or PAN-OS release version. This error message has been updated to be consistent across release versions. |
| **62995** | Addressed an issue where the Application usage and Traffic summary by URL Category information in User Activity Reports was not in sync with the information displayed on the **ACC** tab in the web interface, in the **Top Applications** and **URL Filtering** sections. |
| **62985** | An issue with the FPGA code for some PA-3000 Series devices was causing a small amount of VLAN tagged and offloaded packets to be truncated by 4 bytes. |
| **62969** | Online Certificate Status Protocol (OCSP) requests were using the OCSP location in the certificate instead of the location configured on the firewall. This has been adjusted so that the OCSP configuration on the firewall will take precedence. If no OCSP location is configured on the firewall, the certificate OCSP location will be used. |
| **62895** | Addressed an issue where members of groups on non-Active Directory LDAP servers were not displayed as group members on the firewall. |
| **62883** | Addressed an issue where fiber port down detection on SFP ports on a PA-2000 Series device took 10 - 20 seconds. |
| **62876** | A Panorama role-based administrator with privileges for Device Groups and Templates could view devices which were not included in any device groups or templates. An update has been made in the web interface to eliminate visibility into devices that are not a part of a device group for administrators limited to Device Groups and Templates privileges. |
| **62827** | Addressed an upgrade schema issue for Panorama running PAN-OS 6.0.1 where address objects were causing commit errors when attempting to push a configuration from Panorama to managed devices. |
| **62801** | Traffic was blocked during SSL decryption when a certificate was signed with an untrusted CA and when the option to use OCSP to check certificate status was enabled (**Device > Setup > Session > Certificate Revocation Checking**). This has been resolved so that decryption works with untrusted certificates, with the option to use OCSP to check certificate status enabled. |
| **62763** | Group mapping queries failed if the group name, or Active Directory organizational unit (OU) path, contained characters that were used in the standard LDAP query syntax (for example, parenthesis). These characters were not escaped correctly during the query building process causing the query to fail. An update was made so that the special characters are escaped. |
| **62663** | Resolved an issue where the status for Tor was inaccurately reported in the outputs for the `show wildfire status` and `test wildfire tor` CLI commands. |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **62596** | A shadow rule warning message was incorrectly displayed and was not accurate in indicating that a security rule's match criteria was met by a preceding rule (the match criteria had not been met by a preceding rule). The incorrect error messages were being displayed while performing a commit and a fix was made to eliminate the incorrect warning messages. |
| **62595** | Addressed an issue that was seen when using a filter to define search criteria for WildFire logs on the web interface. When adding a log filter for WildFire logs, selecting Category as the Attribute to include in the search displayed URL categories to select from in the **Value** column (**Monitor > Wildfire > Add Log Filter**). The **Value** column should have only displayed the options Malicious or Benign to select from. |
| **62591** | During extremely high rates of logging over an extended period of time, traffic and threat logs could not be displayed on the web interface or the CLI. This was due to the dataplane logging process consuming too much memory when attempting to write very large amounts of traffic logs and has been resolved. |
| **62586** | When upgrading Panorama, commits to device groups would fail if Panorama had Service Groups and Address Groups configured with the same name. This has been resolved so that group objects are independent and unique names are not required. |
| **62573** | Fixed an issue where upgrading a VM-Series firewall with the VM-1000-HV license caused a firewall to go into maintenance mode without any indication of why it did so. This issue occurred because the VM-1000-HV license requires 5GB RAM to support higher capacities but, prior to PAN-OS 6.0.3, the memory requirement was not enforced, making it possible to apply the VM-1000-HV license to a VM-Series firewall without enough memory allocated (default allocated memory is 4GB). With this fix, a memory requirement check is added so that the VM-Series firewall will boot to maintenance mode with an error informing you that you need to increase the allocated memory on the firewall to 5GB or more. |
| **62559** | Resolved an issue where creating or modifying policy rules took a long time for large configurations (for example, a configuration with 3000 rules and 20,000 objects). An update was made to increase the speed for creating and modifying policy rules for large configurations. |
| **62552** | With both SSL Inbound Inspection and virus scanning enabled, the firewall was able to detect a virus being sent, but did not block the virus from being forwarded to the target. With this fix, the virus file is not forwarded to the target. |
| **62545** | An update was made to support the export of threat packet capture (PCAP) files using the XML API. |
| **62391** | When displaying the Detailed Log View of a traffic log entry, the value of the attribute **Receive Time** was incorrect and did not match the value from the **Receive Time** column on the traffic log list. With this fix, the value of the **Receive Time** attribute in the Detailed Log View is shown correctly. |
| **62377** | Following an upgrade to PAN-OS 6.0.1, the following unexpected system log was generated daily: `Got batch event for unknown child acc_rollup`. An update has been made so that the log is no longer generated daily. |
| **62366** | The dataplane restarted with multiple cores due to a race condition caused by updating the aged out session. This issue has been fixed so that the race condition is resolved and will no longer trigger a restart. |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **62315** | Resolved an issue for devices running PAN-OS 5.0 or PAN-OS 6.0 release versions, where the disk quota displayed on the Panorama web interface for a Log Collector group was not reflective of the actual disk quota output. |
| **62291** | An issue was occurring where any type of commit triggered the `syslog-ng` configuration to be reloaded and the connection to be reset. This issue was fixed so that only commits related to the syslog server configurations and syslog-related log forwarding configurations will trigger a `syslog-ng` configuration reload and the connection to be reset. |
| **62219** | Unexpected XML data was present when loading an existing configuration version from the device. This resulted in a commit failure that cited the unexpected text. An update has been made to avoid this condition and to ensure a successful commit when loading an existing configuration version. |
| **62179** | In certain situations, a tunnel interface appeared to be up and was present in the forwarding table, although the underlying IPSec tunnel was down. This issue occurred when the IPSec tunnel had a VPN Monitor profile configured with Fail Over enabled, and the device was restarted while the remote IPSec endpoint was down. With this fix, the status of the tunnel interface matches the state of its corresponding IPSec tunnel when a VPN Monitor profile with Fail Over enabled is configured, and regardless of the initial state of the tunnel. |
| **62113** | Resolved an issue for a PA-7050 device, where TAP Mode traffic did not load balance properly on a Network Processing Card (NPC), and caused a much higher load on one dataplane in comparison to another dataplane. |
| **61987** | Resolved an issue where virtual firewalls running PAN-OS 6.0 release versions did not correctly sinkhole suspicious DNS queries. |
| **61953** | When the IPv6 address `::/0` was configured under the Permitted IP Addresses section in an Interface Management profile, IPv6 communication to the interface was not allowed. Since IPv6 address `::/0` is equivalent to `any`, IPv6 communication should be allowed from any IPv6 host. This has been addressed so that you can add the IPv6 address `::/0` under Permitted IP Addresses for an Interface Management Profile to successfully allow IPv6 communication from any IPv6 host. |
| **61879** | IPSec VPN traffic could not be initiated following a restart of the `sysd` process. This issue has been resolved so that IPSec VPN traffic can be initiated even if `sysd` process is restarted. |
| **61864** | Fixed an issue where a PA-5000 Series firewall was dropping Skinny Call Control Protocol (SCCP) traffic after an upgrade to PAN-OS 6.0.0; SCCP sessions were timing out within 5 seconds due to communication issues between dataplanes. With this fix, the parent session timeout value is set appropriately and SCCP traffic is not dropped. |
| **61855** | Resolved an issue where multiple configuration pushes from Panorama to a managed device could cause that managed device's management server to restart. When this occurred, a system log would be indicating that the management server was restarted due to high memory utilization. This issue is resolved so that commits from Panorama to managed devices succeed for multiple configuration pushes and the management server remains stable. |
| **61827** | Addressed an issue where a virtual wire with **Link State Pass Through** enabled had one interface that remained connected despite the other interface being physically disconnected. |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **61785** | Resolved an issue where an administrator for a single virtual system could delete logs for other virtual systems using the CLI. |
| **61781** | Resolved an issue that occurred when using the Panorama web interface to set up SNMPv3 with a view. Adding a **View** with a space in the view's name caused SNMP polling to fail. This has been resolved so that an error is displayed if a space is used when naming a **View** and a new name can be entered without a space (**Panorama > Setup > Operations > Miscellaneous > SNMP Setup > Views**). |
| **61757** | The `show arp management` command timed out after 30 seconds without returning output if both primary and secondary DNS servers configured on the firewall were unreachable. The timeout has been increased up to 120 seconds to return ARP entries with or without DNS resolved names. The time taken to return the output could vary based on the number of DNS servers configured and the availability of the DNS servers to resolve host names. |
| **61724** | When a custom report was exported to CSV format, the device name in the report was showing the device's serial number instead of the device name. This has been fixed so that exporting a custom report to CSV format correctly shows the device name in the device column. |
| **61643** | Resolved an issue where email alerts were displaying all values on a single line. This occurred when the email alerts were based on custom log formats that were configured with a `\n` or a new line as a separator between fields. |
| **61350** | Following an import of a license key file from the CLI, several checks were performed to verify the certificates validity and an error was seen where the file size of the key file could be misinterpreted and the file incorrectly rejected. This issue has been resolved so that importing a valid license key file is successful. |
| **61329** | Using the web interface to add a an IP address to a security policy, where a subnet was added without a proper subnet mask (for example, `1.1.1.1/`), was not blocked as an error. The expected behavior would be to block adding an IP address ending with a `/` as that character could translate to a value of any on the dataplane. An update was made to check for the `/` character. |
| **61326** | Addressed an issue that occurred in a high availability (HA) configuration, where link monitoring for a 10G port displayed the wrong status for the port when the port was down. |
| **61284** | Traffic using policy-based forwarding (PBF) with symmetric return enforced experienced packet loss due to failed return MAC address lookups. This issue was caused by another change made in PAN-OS 5.0.11 which changed the PBF return MAC learning from the forwarding state to the session start; the PAN-OS 5.0.11 change that caused this issue has been reversed, which fixes the issue. |
| **61276** | Resolved an issue that occurred while replacing a device following an RMA. After issuing the `replace device` CLI command, exporting the device state did not show the appropriate configuration fields to set up the replacement device. |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **61254** | H.323 video calls were getting dropped intermittently when video call traffic was creating a multi-level application-level gateway (ALG) session dependency pattern. The issue was observed when the grandparent session had a low timeout value and then timed out, causing its dependent parent and grandchild sessions to be terminated and the video call was dropped. This has been addressed so that TTL counters of both parent and grandparent sessions refresh and do not time out while the corresponding grandchild session continues to see traffic. |
| **61101** | Resolved an issue where the Address Resolution Protocol (ARP) table was not updated following Spanning Tree Protocol (STP) re-convergence in the network. |
| **61058** | Resolved an issue that occurred when a NAT Policy rule was configured to use a Dynamic IP pool for IP NAT translations and a fall back pool was also configured to perform **Fall Back Dynamic IP Translation** if the Dynamic IP pool ran out of addresses. In certain cases, the fall back pool was being used for translations when the IP pool was not exhausted. |
| **60781** | A Dynamic Block List address object (0.0.0.0) was being added to security rules where that Dynamic Block List was referenced, even though that object did not exist in the Dynamic Block List source file. This was due to issues with EBL Refresh, and has been addressed so that when a Dynamic Block List is referenced in a security policy, the Dynamic Block List objects displayed in the policy are accurate. |
| **60634** | Inter-vsys multicast traffic caused the dataplane to restart. The restart was due to a fragmented packet that was encapsulated into a Protocol Independent Multicast (PIM) packet and routed to another virtual system. The fix prevents this kind of fragmentation of the packets. |
| **59852** | Fixed a high dataplane CPU usage issue seen on PA-5000 Series devices that was caused by FPGA lock-up. |
| **59331** | Syncing a high availability (HA) configuration failed. This occurred when the MTU size on the management interface was set to a value smaller than the default MTU size, and dataplane interfaces were using the MTU size value set on the management interface. This resulted in dataplane interfaces (in this case, including the HA interfaces) to drop packets that were larger than the MTU size set on the management interface. |

# PAN-OS 6.0.2 Addressed Issues

The following table lists the issues that are fixed in the PAN-OS 6.0.2 release. For new features introduced in PAN-OS 6.0, associated software versions, known issues, and changes in default behavior, see PAN-OS 6.0 Release Information.

| Issue Identifier | Description |
|---|---|
| **62578** | A Panorama administrator with privileges to manage Device Groups and Templates was unable to perform management and administrative functions due to several buttons and functionalities appearing to be disabled on the web interface. The issue has been resolved so that a Device Groups and Templates admin can successfully perform management and administrative functions as defined by the admin role. |
| **62567** | An issue was addressed where commits were failing intermittently following an upgrade to PAN-OS 6.0.1. This was due to the management server failing to send the ID request to the client device and has been fixed so that commits are successful following an upgrade. A second issue was addressed with this fix, where high availability (HA) synchronization was showing an error message when there was no URL Filtering license; this occurred when the PAN-DB cache was empty and the passive device treated the empty files as corrupt files. |
| **62386** | The URL category match within a security policy was not enforced, allowing non-HTTP traffic to match the rule. This update ensures proper enforcement of the URL category selection in a security policy. |
| **62352** | Addressed an issue where templates pushed from Panorama were missing BrightCloud to PAN-DB conversion files, resulting in errors when managed devices attempted to translate URL filtering policies pushed from Panorama. |
| **62321** | The Panorama web interface was inaccessible due to a corruption in MongoDB journal files. A fix was made so that if a MongoDB journal file becomes corrupt, Panorama now recovers correctly by removing the journal files and then recreating them. |
| **62244** | When trying to add an address object to a policy, the search field failed to return the address object. This issue was only seen when the number of address objects available exceeded 500 objects. |
| **62218** | Fixed an issue where an administrator with full privileges on Panorama could not delete most of the configuration on the **Network** tab of the Panorama web interface. This issue has been addressed so that all objects on the **Network** tab can be created, modified, and deleted. |
| **62208** | Resolved an issue where service routes for email alerts and SNMP messages did not take precedence if the management interface was disconnected. |
| **62199** | Panorama failed to commit when attempting to push a configuration to a managed device. This occurred when the pushed configuration included a decryption profile; even though there were no decryption port mirroring options selected in the decryption profile, the managed device did not support decryption port mirroring and the commit failed. This was due to Panorama not pruning out the portion of the configuration that was specific to decryption port mirroring and has been fixed to ensure that configuration parameters are removed when pushed to devices that do not support them. |

| Issue Identifier | Description |
|---|---|
| **62084** | Addressed an issue where domain names greater than 63 characters were getting truncated in the resolv.conf file for Linux and Mac OS even when separated by commas. |
| **62076** | After creating an Anti-Spyware profile with the **Action on DNS queries** set to **Block** (**Objects > Security Profiles > Anti-Spyware > Anti-Spyware Profile > DNS Signatures**), the threat logs for a suspicious DNS query displayed the action taken on the threat traffic as `reset-both`. This has been updated so that when the action is set to **Block** for DNS queries in an Anti-Spyware profile, the threat logs will show the action taken on the suspicious DNS traffic as `drop-all-packets` when using UDP (the threat logs will still show the action taken on suspicious DNS traffic as `reset-both` when using TCP). |
| **62057** | FTP log export failed when an explicit destination path was defined. In cases where multiple CSV files were used, the first CSV file was created but subsequent CSV files failed. This was updated to allow the creation of multiple CSV files during file export. |
| **62020** | When a device is configured to use a Time Zone with a name that is abbreviated to more than three characters (for example, America/Anchorage abbreviated to AKST), the web interface displayed an error message on the Dynamic Updates page. This issue did not affect already configured automatic updates. Workarounds for this issue include using the CLI to configure and view dynamic updates and re-setting the Time Zone of the device to a Time Zone with a name that is three characters or less, for example, America/Los Angeles abbreviated to PST. This issue has been addressed so that the Time Zone and the corresponding Time Zone name the device is configured to use do not cause an error on the Dynamic Updates page. |
| **61985** | The GlobalProtect portal became inaccessible using the web interface or the GlobalProtect client after an interface address change. This normally occurred when an interface was DHCP enabled and an address renewal occurred. The issue was caused by an address map change which published incorrect interface data to the SSL VPN component. The address map change operation has been corrected to publish the correct data. |
| **61951** | SSL Inbound Inspection sometimes failed due to SSL session reuse. This issue has been resolved so that SSL Inbound Inspection is successfully enforced according to the configured decryption policy. |
| **61992** | PA-4000 Series firewalls running PAN-OS 6.0 in a high availability (HA) active/active configurations utilizing Virtual or Floating IP addresses experienced intermittent connectivity. (HA active/passive configurations on PA-4000 Series firewalls running PAN-OS 6.0 releases were not affected by this issue.)<br>Workaround (limited): Configure static ARP entries that are bound to the physical interfaces; however, this creates the possibility of losing failover capabilities in HA active/active configurations and force traffic to prefer one firewall over another. |
| **61897** | The following error message displayed when loading Enterprise 6.0 SNMP MIBs using the ManageEngine SNMP MIB Browser: `Could not parse the file PAN-COMMON-MIB. Couldn't resolve these sequence constructs`. This issue has been resolved by fixing capitalization errors on the MIBs. |
| **61844** | Under extremely heavy load with fully Layer 7 traffic, the PA-7050 firewall was experiencing packet loss due to the depletion of the software buffer. |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **61840** | Auth and priv passwords for SNMPV3 setup on managed collector groups were displayed in clear text. With this fix, the passwords are masked and are not shown in clear text. |
| **61828** | TCP SYN cookies were activated sooner than the **Activate Rate** set in the DoS protection profile. Using DoS Protection with SYN cookies now activates correctly according to the configured SYN count. |
| **61747** | The use of a 64-character string as a RADIUS shared secret was not supported. A fix is implemented to ensure a higher value for the buffer to store and encode shared secrets. |
| **61742** | With safe search enabled, when a user was attempting to access a regional site (for example, www.google.co.uk), a block page appeared directing the user to update the preferences page for the main site and not the regional site (for example, the block page directed the user to google.com preferences instead of www.google.co.uk). However, updating the preferences page for the main site did not enforce the preferences on the regional site. This has been fixed so that block pages display the correct preferences page for regional sites. |
| **61714** | Traffic logs were not displayed on a PA-7050 firewall despite traffic being generated. This was due to a disk failure and there was no system log was generated for the disk failure. This has been addressed so that a system log is generated to notify if disk failure event occurs during raid rebuilding. |
| **61696** | When using SSL Forward Proxy decryption with self-signed certificates with Firefox, an error was seen from Firefox regarding conflicting certificate serial numbers: `sec_error_reused_issuer_and_serial`. |
| **61683** | Fixed an issue with configuring SNMPv3, where an SNMPv3 user with a view could not be added. An error was displayed when attempting to add a name for a view, where the error message stated that view is not a valid reference and the SNMPv3 user with a view could not be added (**Panorama > Collector Groups > Collector Group > Monitoring > Views**). |
| **61682** | An M-100 appliance failed to mount the file system for a RAID Disk Pair. There was no system log generated for this mount failure, and disks were shown as `Available`. This issue has been addressed so that a system log is generated when a disk mount fails, and disk is not made `Available`. |
| **61675** | After creating a Log Forwarding profile using the Panorama web interface (**Device Groups > Objects > Log Forwarding**), the Log Forwarding object always defaulted to being shared across device groups, regardless of whether the **Shared** checkbox had been selected when creating the profile. This has been fixed so that only Log Forwarding objects with **Shared** selected are shared across device groups. Log Forwarding objects where **Shared** is not selected correctly belong only to the Device Group displayed in the Device Group drop-down. |
| **61579** | When session offload is disabled, the sequence and acknowledgment (SEQ/ACK) number check dropped ACK packets. This was due to an issue with the sequence and acknowledgment number check and has been fixed. The workaround for releases prior to PAN-OS 6.0.2 is to use the `set deviceconfig setting tcp asymmetric-path bypass` command. |

| Issue Identifier | Description |
|---|---|
| **61471** | Following a restart, an internal path monitoring failure that showed a false positive triggered a second dataplane restart. This issue has been addressed so that when the dataplane restarts, path monitoring stops and a false positive is not generated so that a second dataplane restart does not occur after reboot. |
| **61437** | On a few occasions, a device stopped authenticating any users. This was due to an issue where bind errors were causing an LDAP file descriptor leak and the issue has been resolved. |
| **61396** | When read using SNMP, the value returned for Dataplane CPU utilization was always zero. This was fixed so that the value returned for dataplane CPU utilization matches the true CPU utilization. |
| **61387** | Data connection of FTP in passive mode sometimes failed on PA-5000 Series devices. This has been fixed so that data connection of FTP in passive mode does not fail. |
| **61366** | When loading a report template, the selected time period was being reset automatically. A fix has been implemented to limit this behavior. |
| **61236** | An issue was resolved to prevent the OSPF MD5 sequence number from resetting during a high availability (HA) failover or routed restart. Before this fix, there was a reset when a failover occurred. This reset caused a longer outage than expected. When upgrading from an earlier PAN-OS 6.0 release version to PAN-OS 6.0.2, allow a five minute grace period before a HA failover or routed restart. Following the five minute grace period, this limitation will not apply to further failovers or upgrades. |
| **61174** | Fixed an issue where license retrieval on the device was failing when the option **Verify Update Server Identity** was enabled on the **Device > Setup > Services** page. |
| **61168** | SYN packets were dropped when a session with the same 5-tuple (same source IP address, destination IP address, source port number, destination port number, and protocol) is received by the firewall at the same time the existing session gets aged-out based on the TIME-WAIT period when source NAT (Dynamic-ip-and-port) was used. |
| **61083** | When using URL Filtering with `ssl-decrypt url-proxy` enabled, the block page failed to display on some browsers using SNI (Server Name Indication) because the firewall failed to retrieve the hostname from the SSL session in order to run decryption. With this fix, the process was improved to retrieve this information correctly. |
| **60985** | Fixed an issue with PA-3000 Series devices where traffic could stop passing through the firewall or the dataplane could restart due to an internal path monitoring failure. |
| **60974** | When a colon was used in password field to generate an API key, using that API key displayed the error `Invalid Credentials`. The way that passwords are handled has been updated to allow a colon as part of the API key. |
| **60928** | In certain situations on the Global Protect gateway, the context for an IPSec tunnel to a GlobalProtect client showed the presence of NAT-T, although there is no NAT between the client and the gateway. Traffic through that IPSec tunnel failed. This issue was caused when a tunnel context ID previously used for a tunnel with NAT-T was re-used for a tunnel without NAT-T. With this fix, tunnel contexts are properly cleared before re-use. |
| **60902** | An issue was resolved where subinterface names with length greater than 16 characters were being truncated in the output of some CLI commands, corresponding web interface sections, and system logs. |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **60743** | An untagged subinterface caused stale hardware sessions on a PA-5000 Series device, and traffic failed when a new session was hitting the stale 5 tuple session. This issue has been fixed so that hardware session info is deleted when sessions are closed. |
| **60673** | LDAP groups containing non-ASCII characters in their names could not be processed by the firewall. Policies filtering on these groups were not working properly. With this fix, groups are received by the firewall, regardless of the types of characters used in their names. |
| **60617** | TCP connectivity issues occurred on a virtual machine when SYN Flood protection was enabled with SYN Cookies with the **Activate Rate** set to 0. This was related to an issue where active and passive FTP were not working under different NAT configurations and has been addressed so that both active and passive FTP work correctly under different NAT configurations and do not cause TCP connectivity issues. A workaround for this issue is to set the **Activate Rate** parameter for SYN Flood settings to a value greater than 0 (**Objects > DoS Protection > Flood Protection > SYN Flood**). |
| **60299** | Multicast ICMPv6 traffic was causing a restart after enabling and disabling zone protection profiles multiple times. |
| **60250** | Logging into the Panorama web interface only displayed a blank gray page instead of the Panorama **Dashboard**. This issue has been addressed so that logging into the Panorama web interface correctly displays the Panorama web interface **Dashboard** and management functions. |
| **60036** | Addressed an issue in summary PDF reports where if the **srcuser** field is not in the format of `domain\username`, the **srcuser** field was left empty. |
| **59542** | When sessions were initiated on different dataplanes in a multi-vsys environment, session traffic failed to span across virtual systems. This issue has been resolved so that inter-vsys sessions succeed with a DNAT policy setup. |
| **59289** | An issue has been addressed where dataplane restarts were seen due to PAN-DB becoming unresponsive. New URLs could not be learned and the repeated attempts built up the URL cache and caused an excessive consumption of system resources, making the dataplane unstable. |
| **57736** | Active FTP through NAT (dynamic ip-port) did not work on a virtual machine. This issue has been addressed so that both active and passive FTP work under different NAT configurations. |
| **57600** | Resolved a display issue on the **Monitor > Logs > Configuration** page, where the IPSec pre-shared key was displayed in clear text format in the **After Change** column. The IPSec pre-shared key is no longer displayed in clear text in the Configuration Logs. |
| **57599** | Addressed an issue where the firewall was dropping ARP unicast packets which resulted in incomplete ARP entries and Layer 3 forwarding issues. |
| **57412** | Addressed an issue where User Activity Reports were sometimes not returning any results due to malformed XML output. |

© Palo Alto Networks, Inc.

| Issue Identifier | Description |
|---|---|
| **50798** | Device fans running at lower speeds were sometimes causing a thermal alarm. This occurred when the dataplane restarted while the device was in a temperature alarm state. In this case, the fan's speed control value was set to the default value, causing the fan to run at the incorrect speed. This issue has been addressed so that the fan speed is recalculated based on the device's current temperature following a dataplane restart. |
| **50091** | Management plane services were not performing optimally during peak traffic periods. The size of the ARP table on the management plane was increased to address this issue. |
| **48758** | In some cases, large amounts of compressed HTTP traffic could cause the zip buffer to fill and it would not continue to process additional compressed HTTP traffic. Offload of compressed HTTP traffic now works correctly so that even large amounts of compressed HTTP traffic are processed by the zip buffer. |
| **40883** | Addressed a root partition that was at 100% usage due to an issue where FireMon processes (where FireMon was being used as an external third party monitoring utility to the Palo Alto Networks firewall) continued to run on a device and did not close correctly, even after the FireMon connection had timed out. |
| **24804** | When specifying a default route of 0.0.0.0/0 in an OSPF export rule, the route was advertised with a metric of 255. This was because there was no option to specify a metric when specifying a route in an OSPF export rule. This change removes the metric field from the redistribution profiles, and adds it to the OSPF export rule configuration. |

© Palo Alto Networks, Inc.

# PAN-OS 6.0.1 Addressed Issues

The following table lists the issues that are fixed in the PAN-OS 6.0.1 release. For new features introduced in PAN-OS 6.0, associated software versions, known issues, and changes in default behavior, see PAN-OS 6.0 Release Information.

| Issue Identifier | Issue Description |
|---|---|
| **61193** | A certificate chain error was causing commit failures due to an IKE code change in 6.0.0. The fix changes the error that causes the commit to fail to a warning so that the commit can be successful. |
| **61004** | Addressed an issue where a user in a custom admin role could only view HIP match logs but was unable to view log details. Clicking the spyglass icon on the web interface opened the **Detailed Log View**, but no information was displayed. |
| **60971** | Following an upgrade to PAN-OS 6.0.0, scheduled Dynamic Updates failed to be pushed from Panorama to managed devices. |
| **60826** | Issues relating to Tags with brackets were occurring after upgrading to PAN-OS 6.0.0, and Tags with brackets could not be created, edited or deleted. In PAN-OS 6.0.1, the brackets in existing Tags are replaced with quotes and new Tags that you create cannot include brackets. |
| **60816** | Following an upgrade to PAN-OS 6.0.0, syslog connection status warnings for all defined syslog connections appeared in the system log every hour and were categorized as critical. This was caused by a scheduled hourly rotation of the syslog-ng log file, during which the syslog-ng daemon would restart. This issue has been fixed by adding a condition to the log file rotation process requiring the log file to be 10 MB or more and the connection status warning will only be seen once every few months. |
| **60780** | On PA-5000 Series firewalls, restarts were seen under heavy load conditions and were due to an internal path monitoring failure. Enhancements have been made to avoid such restarts. |
| **60700** | 1GB copper SFP interfaces belonging to an Aggregate Group would sometimes show the link status as down after a reboot of the firewall. |
| **60677** | Group mapping queries failed when nested groups with long group names were searched. The search queries showed group members to be missing. This was due to the query string (groups/nested groups) being truncated at 39 characters. |
| **60650** | When using the web interface to configure SNMPv3 on a high availability (HA) pair, the **EngineID** field should be optional; however, the **OK** button could be clicked when this field was blank. This has been fixed so that the **EngineID** field is optional. |
| **60564** | On Panorama, a system log message was generated when a log file used for internal processing was truncated. This system log message is not relevant for the administrator and will not be displayed in the system log. |
| **60510** | An attempt to revoke SSL certificates generated on Panorama failed. The issue was caused by an internal verification check failure involving shared certificate objects used in device groups that included firewalls enabled for multiple virtual systems. The verification check has been corrected. |

| Issue Identifier | Issue Description |
|---|---|
| **60505** | SYN packets were dropped if a session with the same source and destination IP addresses and port and IP protocols comes to existing session at the timing of aged-out TIME-WAIT period. |
| **60502** | On the Panorama web interface **Monitor**, the maximum number of pages displayed for logs is not consistent depending on the log numbers displayed per page. |
| **60412** | The user was unable to modify custom logo due to an unrecognized `mime-type` option (`Device > Setup > Operations > Custom Logos`). |
| **60347** | Some service route settings could not be configured when the web interface was set to a language other than English. |
| **60337** | Fixed an issue where XML API showed empty hardware counters for `show interface dedicated-ha1`. |
| **60274** | Fixed an issue where the XML API showed an error when running the `show -availability interface ha1` command using the rest API. |
| **60255** | On occasion, the web interface for the Citrix SDX server fails to execute a reboot or shutdown of the VM-Series firewall. To trigger a reboot or shutdown, use the Force Shutdown or Force Reboot options on the SDX web interface. If you need to modify the instance of the VM-Series firewall, make the changes while the instance is shutdown, and then power it on. |
| **60225** | Fixed an issue where the XML API showed an error when running show session rematch using the rest API. |
| **60201** | In a high availability (HA) active/active configuration, an IPSec key renegotiation timing issue caused the new IPSec session to be set to DISCARD until the next key renegotiation. This caused traffic loss until the next tunnel key renegotiation. |
| **60189** | When high availability (HA) active/passive peers lost communication on HA1 and HA2 links, a race condition caused the dataplane to restart. |
| **60070** | In order for Android devices to be able to connect to the Mobile Security Manager's device check-in for enrollment and subsequent check-ins, the Root CA certificate had to be used to sign the server certificate for the device check-in interface in the portal configuration that was being delivered to Android devices. This applied even if you purchased a server certificate from a well-known, trusted CA as recommended. This was because the GlobalProtect Android app does not look in its system store for certificate verification With this fix, GlobalProtect Android app will first look in its system store for certificate verification. If this fails, the app will proceed to verify certificates against the CAs from the portal configuration. |
| **60063** | SSL decryption with Internet Explorer was inconsistent with certificate common names, resulting in name mismatch errors for some sites. |
| **60035** | When an external zone was configured with a Zone Protection profile applied to it, large IPv6 packets were causing dataplane processes to fail when sent through the zone. |
| **60012** | Addressed issues that were causing filtering on the web interface to return incorrect results. |

© Palo Alto Networks, Inc.

| Issue Identifier | Issue Description |
|---|---|
| **60011** | When a User ID Agent Setup template was pushed from Panorama to a managed device, the application content updates were not available for viewing or cloning in the syslog filters list in the web interface (**Device > User Identification > User Mapping > User ID Agent Setup > Syslog Filters**). |
| **59991** | In a shared gateway setup, when the firewall was configured to drop inbound Destination NATed traffic for a particular application, the traffic logs for Destination NATed traffic to be dropped showed the post-translated address instead of the pre-translated address. This issue was fixed by displaying the original source IP address in the traffic logs instead of the translated IP address. |
| **59989** | The Panorama web interface was not displaying data on the **Monitor > Logs > WildFire Submissions** page. A query for the data with no filters continued loading for a significant amount of time and then eventually timed out. This was due to threat logs that were not handled correctly by Panorama running PAN-OS 6.0.0 when received from log collectors running releases previous to PAN-OS 6.0.0. |
| **59973** | For Android devices that were being managed by the GlobalProtect Mobile Security Manager, when authenticating to the GlobalProtect gateway using client certificate authentication, the GlobalProtect app for Android did not look up the identity certificate issued to the device during enrollment. Identity certificates were therefore not being used for gateway authentication as expected. This has been fixed so that Android devices are able to use identity certificates for gateway authentication. |
| **59967** | When the firewall was configured as a GlobalProtect satellite and was receiving access routes from another firewall configured as the GlobalProtect gateway, the routing resource counter for static routes was not incrementing or decrementing correctly. This behavior caused the maximum number of routes to be artificially reached and the firewall stopped accepting routing updates. The fix for this issue readjusts the counters for static routes and total routes when creating a redundant static route or deleting a non-existent one. |
| **59915** | The filter field on the **Policies > Security** page of the web interface returned different results when strings with the same value, but different patterns were entered. For example, xx.xx.xx.0-24 is an address object name which includes the IP/netmask pattern xx.xx.xx.0/24. Entering either string in the filter should return the same search results but one query was showing fewer results than the other. |
| **59890** | When a PA-4050 firewall reached the limit for max supported concurrent decrypted sessions, the dataplane restarted. A fix was added to ensure that device will stop decrypting sessions once the limit is reached and a restart will not occur. |
| **59873** | A TCP session could not be established when SYN Cookies was enabled and when both Aggregate and Classified DoS Protection Profiles were configured. |
| **59772** | Traffic logs from log collectors were not visible on the Panorama web interface. |
| **59707** | NTP information on the firewall was displayed in way that could lead to confusion; for example, stating that the server the device is synced with is not connected (connected: false). NTP information is now displayed more clearly (**Device > Setup > Services**). |
| **59574** | Fixed an issue where an Antivirus profile on Internet Explorer and Firefox browsers was not showing the default action in parenthesis (alert/drop/) for the decoders. |

© Palo Alto Networks, Inc.

| Issue Identifier | Issue Description |
|---|---|
| **59471** | Resolved an issue with registering dynamic tags on the VM-Series firewall. The VM-Series firewall did not allow you to register dynamic tags that included the single quote (') character. |
| **59343** | When a security policy was configured that did not have a URL Filtering profile applied to it, URL Filtering logs were still being generated and were visible on the **Monitor > URL Filtering** page. |
| **59309** | User Activity Reports were showing inconsistent results. This was due to the User Activity Report generation taking too long and timing out. The timeout for User Activity Report generation has been extended so that requested reports will run until all data is completely gathered. |
| **59276** | Fixed an issue where botnet reports failed to use URL Filtering data for report generation. |
| **59256** | Performing an SCP import of the logdb file failed with the error: `failed to verify for logdb import`. |
| **59180** | Session setup between a client and server was not completed in a high availability (HA) active/active configuration when configured with multi-vsys and multi-VR. The client from one virtual system could not reach the server located on a second virtual system because the session in the second virtual system was not set up correctly. |
| **59126** | In a high availability (HA) active/passive configuration, OSPF and BGP neighbors went down on an active device after the passive device unexpectedly restarted. |
| **59031** | When admin users tried to login to the CLI without previously logging into the web interface and there was a RADIUS authentication profile configured, the firewall sent out a request to the RADIUS server with an invalid password that was different from the one submitted by the user. This resulted in valid users being unable to authenticate to the RADIUS server. |
| **59018** | A network outage occurred when the number of active sessions reached 100,000 sessions. This occurred on a PA-3000 Series firewall and Detector Threats have been increased on PA-3000 Series firewalls in order to address this issue. |
| **58971** | The CLI output for the `show routing protocol bgp loc-rib-detail` command displayed the community field incorrectly when certain prefix combinations appeared in the IP addresses of the BGP neighbors. |
| **58736** | WildFire email notifications did not contain a date header. |
| **58586** | Fixed the inability to log into the Panorama web interface. This issue occurred because root partition on an M-100 appliance was at 100% usage due to old reports being incorrectly stored in the /tmp directory. |
| **58268** | Traffic was sometimes blocked during SSL decryption when the option **Use OCSP to check certificate status** was enabled. |
| **58215** | The output of the `show routing protocol ospf area` CLI command was updated to provide greater clarity for the values defined. |
| **58212** | New virtual systems could not be added after applying a virtual systems license and could only be added after restarting the management server. |

© Palo Alto Networks, Inc.

| Issue Identifier | Issue Description |
|---|---|
| **57997** | In a high availability (HA) active/active configuration, the User-ID agent status was displayed as `connected` on the active-secondary device. This issue has been addressed and the active-secondary device will only show a User-ID agent status of `disconnected` as only the active-primary device connects to the User-ID servers. |
| **57660** | The management ports on a PA-2000 Series firewall did not link-up when connected directly using a straight or crossover cable. |
| **57601** | Fixed an issue where Data Filtering logs were showing incorrect file names when the data pattern was matched against the files. |
| **57261** | A denied session was logged with the Action displayed as `Allow`. This occurred when the application denied was on port 80 and triggered the Captive Portal redirect. |
| **56905** | When a PA-5000 Series firewall received more than 3000 BGP prefixes, the web interface showed an error (`op command for client routed timed out`) when displaying the Local RIB for BGP. Also, when executing the `show routing protocol bgp loc-rib-detail` command, the CLI returned an error (`Server error : op command for client routed timed out`). |
| **55318** | The following commit warning message is now included when nested wildcards are used in a URL Filtering configuration: `Warning: Nested wildcards (*) in URLs may severely impact performance. It is recommended to use a single wildcard to cover multiple tokens or a caret (^) to target a single token.` |
| **50932** | In a high availability (HA) active/passive configuration, `seed` was removed from the `PAN-DB sync seed with HA` message because `MP cache` is what is synchronized instead of `seed`. Also fixed an issue where the synchronized `MP cache` is not loaded on the passive device. |
| **47642** | Logs were not being written to disk because the configuration on the Managed Collector and Collector Group was set up before the Managed Collector established a connection to Panorama. This has been fixed so that Panorama allows you to configure the Collector Group only after the Managed Collector has connected at least once. This allows Panorama to verify the availability of the disk(s) and its size, ensuring that logs are written properly to disk. |
| **45529** | In some User-ID implementations, server session reads picked up capitalized special characters, such as Ü. All capital letters should be set to lower case but this operation was not supported for special characters, which caused a mismatch between group mapping and user mapping. |
| **41347** | Packet capture (PCAP) filters were not filtering information accurately. This fix ensures that the PCAP filters match the criteria defined on the device and accurately capture all relevant frames in the session. |

# PAN-OS 6.0.0 Addressed Issues

The following table lists the issues that are fixed in the PAN-OS 6.0.0 release. For new features, associated software versions, known issues, and changes in default behavior, see PAN-OS 6.0 Release Information.

| Issue Identifier | Issue Description |
|---|---|
| **60347** | Some service route settings could not be configured when the web interface was set to a language other than English. |
| **59772** | Traffic logs from log collectors are not visible on the Panorama web interface. |
| **59707** | NTP information on the firewall was displayed in way that could lead to confusion; for example, stating that the server the device is synced with is not connected (connected: false). NTP information is now displayed more clearly. |
| **59407** | NetFlow (type 4) messages were appearing in the traffic log database and reports. |
| **59128** | After logging in to Panorama using the CLI with RADIUS credentials, the following error message was printed: `Server error : show -> system -> setting -> multi-vsys is unexpected`. |
| **59031** | When admin users tried to login to the CLI without previously logging into the web interface and there was a RADIUS authentication profile configured, the firewall sent out a request to the RADIUS server with an invalid password that was different from the one submitted by the user. This resulted in valid users being unable to authenticate to the RADIUS server. |
| **59030** | Certificates generated during SSL decryption were not adhering to the ASN.1 format. This was leading to the SSL connection being dropped by some servers. |
| **58885** | The `test nat-policy-match` command now properly displays results for no-nat rules. |
| **58736** | WildFire email notifications did not contain a date header. |
| **58733** | The fields in the CSV report were displayed incorrectly after performing a CSV export on the **Monitor > HIP Match** page on the Panorama web interface. |
| **58614** | Local users discovered by WMI query were mapped as the local user of the computer, instead of Unknown as is the expected behavior. |
| **58347** | Suppressed extraneous messages (for example, disabling of an interrupt request that occurs within the underlying subsystem) from displaying on the console. These messages are now logged in the system log only. |
| **58264** | Previously, the `debug software virt-limit limit` command showed an incorrect max value: `4294967295`. The max value has been fixed to display in kilobytes. |
| **58223** | Captive portal was not presenting a complete certificate chain to the client. It presented only the end certificate and not the intermediate certificate. |
| **58215** | The output from the `show routing protocol ospf area` CLI command was rearranged to provide greater clarity in the values defined. |

| Issue Identifier | Issue Description |
|---|---|
| **57975** | It was not possible using Panorama to proxy a REST API call for retrieving report information from a firewall. |
| **57960** | When the Palo Alto Networks firewall was configured to support several virtual systems, the firewall administrator could not revert the **Destination Interface** in a NAT Policy Rule back to the option any after an interface had been selected. This was because the any field in the NAT to-interface configuration had an incorrect schema value. The incorrect schema was fixed by adding any as a default NAT to-interface value in the configuration. |
| **57927** | When authenticating through captive portal, there was a delay after the authentication redirect for Firefox and Chrome browsers. This has been corrected by closing the socket after the redirect. |
| **57874** | DNS resolution did not turn off when the **Resolve Hostname** checkbox was cleared in the **Monitor** tab, and the Palo Alto firewall continued to display the hostnames instead of the IP addresses. IP addresses are now displayed when the **Resolve Hostname** checkbox is cleared. |
| **57768** | A DHCP server did not differentiate between DHCP Clients when the DHCP Client Identifier in the DHCP request exceeded 32 bytes. The maximum size of the DHCP Client Identifier has been increased to 312 bytes. |
| **57660** | PA-2000 Series platform management ports did not link-up when connected directly using a straight or cross cable. |
| **57608** | When using multiple NetFlow hosts across multiple profiles, instances of the FlowSequence number were skipped. The expected behavior is that the value is cumulative, and should be used by the Collector to identify whether any Export Packets have been missed. |
| **57535** | Fixed an issue where the user was not able to create a QoS profile with an egress bandwidth greater than 50 Mbps on a virtual firewall (**Network > Network Profiles > QoS Profile**). |
| **57507** | The option **L3 Forwarding Enabled** in the configuration of a VLAN has been removed. In pre-6.0 releases, enabling or disabling this option did not have an effect on traffic forwarding. Enabling or disabling L3 forwarding on a VLAN should be performed by adding or removing an L3 VLAN interface to the VLAN configuration. |
| **57448** | The **IRC** checkbox in the Botnet Configuration window (**Monitor > Botnet**) was not displayed on the web interface when the language was set to Japanese and a Chrome browser was being used. |
| **57360** | CLI help for `show session all filter destination` command is showing `<ip/netmask>` instead of `<ip>`. |
| **57258** | Both HTTP and HTTPS were available when accessed directly from the management interface; however, HTTP was unavailable when accessed using a subinterface. |
| **57159** | The dataplane was passing traffic even though the management plane was rebooted and could not boot. |
| **57154** | On a PA-5000 series firewall, the QoS rate is adjusted slightly to accommodate hardware limitations. The following help message now is displayed on the configuration window on the web interface: `Bandwidth limits shown include hardware adjustment factor`. |

© Palo Alto Networks, Inc.

| Issue Identifier | Issue Description |
|---|---|
| **57098** | In some Layer 2 configurations, multicast traffic passing through the firewall was resulting in both forward and drop counters incrementing due to the packets being broadcast. Additionally, the multicast packet was included in both the transmit and drop stage dataplane packet capture. New global counters were added to clarify the actions being taken by the firewall when processing multicast packets in a Layer 2 configuration. |
| **56905** | When a PA-5000 Series firewall received more than 3000 BGP prefixes, the web interface showed an error when displaying the Local RIB for BGP: `op command for client routed timed out`. Additionally, when the `show routing protocol bgp loc-rib-detail` command was issued, the CLI returned the error: `Server error : op command for client routed timed out`. |
| **56858** | A cache corruption prevented the user from downloading files when clicking the Continue button in the File Blocking Continue page. |
| **56802** | In a single-vsys setup, a Log Forwarding Profile created on the web interface was not displayed after issuing the `show shared log-settings profile` CLI command. |
| **56787** | After an upgrade, the captive portal custom response page shows `::ffff:` before the IP address. |
| **56703** | In the web interface, global timeout values were displayed in addition to the application level timeout values that actually took effect. This has been updated to show only application level timeout values. |
| **56367** | Fixed an issue where NetFlow data could not be exported for all subinterface types. NetFlow records were not picked up by the log-receiver. |
| **56107** | Addressed dataplane restarts that occurred intermittently on the PA-3000 Series devices deployed in a high availability (HA) configuration. |
| **56087** | Log collectors were optimized in PAN-OS 6.0 for quicker failover and failback. |
| **55833** | GRE port information was not mapped correctly on the VM-Series platforms, causing predict sessions to not match and leading to dropped packets. |
| **55774** | On the web interface, setting the value for max-rows-in-csv-export did not work when it was set to more than 65535. |
| **55696** | Misspellings were displayed in the output for the `set session processing-cpu` command. The misspellings have been corrected. |
| **55693** | Added an enhancement to reduce the routed log in order to help reduce OSPF flaps. |
| **55407** | User-ID virtual memory was exceeding its limit in a multi-vsys environment when a large number of LDAP objects were returned to the firewall. With this fix, LDAP queries made by the firewall will filter on groups specified in the include-list. |
| **55387** | When using local user groups to assign users to particular gateways, the connection to the Global Protect server for the users in that local group failed. |
| **55342** | When an LDAP Server Profile was configured with multiple LDAP servers and/or multiple User-ID agents were configured to be used as LDAP proxy servers and the primary server was not connected, the firewall continually attempted to connect to the secondary LDAP server (or LDAP proxy server) but was unable to establish a connection. |

© Palo Alto Networks, Inc.

| Issue Identifier | Issue Description |
|---|---|
| **55111** | Fixed an issue where a FIN packet was dropped when the sequence number was out of sync after traffic triggered session reuse and was offloaded. With this fix, the sequence-number check for offloaded reused sessions is skipped (because the data plane processor cannot track sequence numbers after traffic is offloaded). |
| **54958** | Upon opening a PCAP on the firewall, escape sequences were displayed instead of the special characters in data part. A fix is provided to display the characters correctly. |
| **54949** | A commit failed when DHCPv6 relay was configured on an interface that did not have an IPv4 address. |
| **54755** | An issue was addressed where creating a static route with the next hop set to None and cloning it or going back into it was changing the next hop settings to <IP Address> from None. |
| **54676** | In the web interface, on the **Device > User Identification > Group Mapping Settings > Group Mapping > Group Include List** tab, the list of Available Groups to add to the Included Group list displayed approximately the first 200 groups, with the option to select **more** to view more group entries. However, clicking **more** failed to display more group entries, even when several more groups are defined and should be available. |
| **54547** | Fixed an issue where high availability (HA) peer HA2 IP information was not getting updated after issuing the `show high-availability all` CLI command. |
| **54486** | Added support for both single quote and double quote values when entering options using the Command Line Interface (CLI). |
| **54283** | An auto commit failed during a threat database update, displaying the error `Threat database handler failed`. |
| **54265** | The system log message `Antivirus job failed` has been updated and the following will be reported in the system log instead: `Antivirus update job failed`. |
| **54113** | A Forwarding Information Base (FIB) table entry discrepancy caused SSH packets to be sent back. This only occurred on PA-2000 Series firewalls. |
| **53888** | On PA-5000 Series devices, the DIPP limit was causing the following system error when trying to add more NAT policies to the firewall: `Error: Number of dynamic-ip-and-port rules (251) exceeds vsys capacity (250) Error: Failed to parse nat policy The maximum number of DIPP has now been increased`. |
| **53632** | Fixed a BGP aggregate policy issue where the aggregate route was no longer advertised when a more specific prefix within the aggregate range was learned. |
| **53615** | When enabling IPv6 on an interface, link local IPv6 routes were counted towards the rtm_total/connected/ipv6; however, the Link Local IPv6 routes were not installed to the Forward Information Base (FIB) on the dataplane. |
| **53554** | Disks in a Panorama VM OVF were misaligned with NetApp and caused performance degradation with some storage devices. |
| **53514** | A high availability (HA) active/active configuration for IPv6 using Fibre Channel over Ethernet (FCoE) Initialization Protocol (FIP) did not behave consistently when stateless address autoconfiguration (SLAAC) was also configured. |

© Palo Alto Networks, Inc.

| Issue Identifier | Issue Description |
|---|---|
| **53148** | Output of `debug dataplane packet-diag show setting` command truncates the interface name to 15 characters. |
| **53059** | Role-based admin users without privileges to access logs or the **Monitor** tab were able to view logs using the **Dashboard** widgets. |
| **52847** | Link monitoring and Path monitoring were on hold when a commit started and until one minute after the commit was done. Changes are introduced to remove the hold on the Link and Path monitoring during Phase -1 of commits. |
| **52777** | Link and Path monitoring were not always working properly during the commit process. |
| **52738** | Reset was sent to Captive Portal clients when trying to load multiple pages before logging in to the portal. |
| **52629** | PAN-DB reverted back to BrightCloud due lack of management connection for first reboot. |
| **52567** | The loading icon was not shown when using the list of users to add a source user to a security policy on the web interface. |
| **52214** | Some traffic was getting dropped if the number of routes in the routing table was high. |
| **52184** | Changing the Jumbo Frame settings on the device without restarting the entire device caused the dataplane to experience an unexpected restart. This has since been fixed so that when you change Jumbo Frame settings, an entire device reboot is no longer required and a dataplane restart will work. |
| **52128** | Fixed an issue where a management profile was configured on an interface and the clients were not getting IP addresses from the DHCP server when the device was configured as a DHCP relay agent. |
| **52050** | After manually upgrading PAN-OS, no **Reboot** button was visible, as it was in previous releases. A message was displayed instead that the user must reboot the device by closing the current window and then rebooting. |
| **51955** | The CLI displayed two counters listed under `IPv6 filter`, even though they also applied to IPv4. A change was made to list them under `IPv(4/6) filter`. |
| **51880** | Dynamic role-based device administrators did not have the ability to save, export, load, and revert a configuration on the firewall or Panorama. This fix provides these capabilities to the administrators. |
| **51824** | Device Groups added to multiple virtual systems were not always shown as managed devices on the web interface (**Panorama > Device Groups > Device Group**). |
| **51648** | In a high availability (HA) active/passive configuration, if NAT exists for outbound FTP connections and the interface IP address is used for the NAT, the ftp-data session would not synchronize to the passive device. |
| **51597** | When the XML API was used to push IP address, port range and username information to a firewall deployed in high availability (HA) configuration, the details were not synchronized with the HA peer. |

© Palo Alto Networks, Inc.

| Issue Identifier | Issue Description |
|---|---|
| **51091** | Two-factor authentication (where both a client certificate profile and an authentication profile are configured) was not functioning as expected. The client was not required to provide the login credentials associated with the authentication profile after successfully authenticating with the client certificate. |
| **51089** | Fixed an issue where repeat count in threat logs was resulting in incorrect values. |
| **51062** | Inter-vsys sessions that traverse the firewall and terminate on a firewall interface would fail. This has been fixed. |
| **51042** | Certificates that were generated prior to master key changes could continue to be used. |
| **51000** | On a redundant Power Supply system on a PA-5000 Series device, there was no system log visible when removing or adding redundant Power Supply. Logging for these events has been added. |
| **50963** | Panorama software deployment failed to deploy when the **OK** button was clicked. |
| **50936** | Crypto cores were created when a SIGTERM signal was received while the management plane was starting. |
| **50817** | Fixed an issue for firewalls running PAN-OS 4.1.6 and later releases where GlobalProtect users were unable to connect to the GlobalProtect gateway when the external-facing interface on the gateway was configured with dynamic PPPoE and a loopback interface was configured for the destination interface to the GlobalProtect portal. With this fix, you can configure a loopback interface for GlobalProtect even when the external-facing interface for the gateway is dynamic. |
| **50606** | Captive Portal authentication failed when the username contained the character &. This issue has been addressed so that & is a valid character and Captive Portal authentication is successful when a username contains the character &. |
| **50478** | The certificate signing request (CSR) generated by the firewall had a Challenge Attribute set by default. If configured, the signing entity could use this attribute or ignore it. Since this attribute was not being ignored by some signing entities, the behavior has been updated so that the Challenge Attribute is not set by default. |
| **50310** | A destination based service route for DNS prevented an FQDN query from refreshing. |
| **50091** | A possible memory leak caused management plane services to not perform optimally during peak traffic periods. |
| **50079** | Added logging enhancements in order to help identify root cause. |
| **50048** | The `show session all filter from <zone> to <zone>` CLI command displayed no active sessions when there were active sessions that should have been displayed in the output. |
| **49851** | In PAN-OS 6.0, DoS enforcement is now performed in CPU prior to session installation. |
| **49828** | In custom reports, source and destination country are now available in the Query Builder as grouping options to organize the report. |
| **49727** | Navigating to the **Network > Interface > Ethernet** tab took 12-15 seconds for the screen to populate the interface data. |

© Palo Alto Networks, Inc.

| Issue Identifier | Issue Description |
|---|---|
| **49294** | The **ACC** (Application Command Center) tab on the Panorama web interface failed to display complete sections and appeared to be stalled, showing the error message: `3 requests sent 1 response received`. |
| **49038** | Time zones were not automatically converted for Dynamic Update package release times. |
| **49015** | Fixed a dataplane restart issue that occurred when Jumbo Frames were enabled and the packets received buffer was high. |
| **48896** | In rare cases, abrupt restarting (for example, a power outage) lead to internal system file corruption. This was related to checking OS image integrity and cannot upgrade. Preventative measures were put in place to prevent issues before and after the internal file updating. |
| **48729** | In Panorama, disabling the **Share Unused Address and Service Objects with Devices** feature returned an error stating that the shared address is not a valid reference. This occurred when a non-shared address group—that was assigned to a specific device group—contained a shared address or an address group was pushed. This issue has been fixed so that such a configuration is supported. |
| **48709** | Fixed an issue where setting a packet capture filter in the web interface did not work until the filter was reset by removing the automatically added 0.0.0.0. |
| **48703** | This fixes a NAT pool leak issue when a SYN packet on TCP/443 was sent to an address on an interface on which GlobalProtect was configured but which was not its primary address. A NAT port was allocated, the connection failed, and the session was freed, but the allocated NAT port is not cleared. |
| **48584** | On Panorama, there were long delays committing a policy due to the option **Share Unused Address and Service Objects with Devices** being cleared in large configurations. The delay was introduced as the system performs a calculation of the unused objects on commit. Commit times have been improved for large configurations. |
| **48093** | Configured address objects were not displayed as resolved on the Panorama web interface. On both the **ACC** tab and the **Monitor > Logs > Traffic** tab, host names defined in the address objects were not displayed, and the IP address was shown in the Host Name columns. |
| **47616** | Devices which were no longer managed devices (had been managed devices previously but were not anymore) were displayed on the **Panorama > Device Deployment > Licenses** page on the Panorama web interface. |
| **47461** | Fixed an issue where SIP sessions were going into offload state after a content installation causing SIP connectivity issues. |
| **47071** | In PAN-OS 6.0.0, you can now rename and push a shared object from Panorama to a managed firewall if you used that shared object in a local policy. |
| **47007** | An enhanced mechanism to hold control session packets being sent out before predict session is now installed on the master dataplane. |
| **46535** | When using an Internet Explorer browser and a Block / Continue page appears when attempting to download a file, clicking the Continue option did not download the file. |

© Palo Alto Networks, Inc.

| Issue Identifier | Issue Description |
|---|---|
| **46308** | The full User-ID Mapping table is now synchronized between peers in a high availability (HA) cluster. |
| **46134** | On the Panorama web interface, DHCP server settings displayed for entries on the **Network > DHCP** page were not displayed on the DHCP Server window that is displayed when clicking on one of the specific DHCP server entries. |
| **45529** | In some User-ID implementations, server session reads picked up capitalized special characters such as Ü. Normally all capitals are set to lower case, but this operation was not supported for special characters, causing a mismatch between group mapping and ip mapping. |
| **44925** | When a Virtual Router interface was deleted, added, or updated with a new IP/mask, all local Virtual Router interfaces on the management plane were uninstalled and then reinstalled. With this fix, the management plan will assess if all Virtual Router interfaces change before automatically uninstalling and reinstalling them all; the management plane will not continue to uninstall and reinstall all Virtual Router interfaces unless they have all been changed. |
| **43280** | Prior to PAN-OS 6.0.0, NetFlow data could not be exported on a per subinterface basis. Starting in PAN-OS 6.0.0, NetFlow data can be exported on a per subinterface basis. |
| **41472** | When a DNS Proxy object was configured with static entries, hostnames assigned to the DNS Proxy were resolved as expected to the IP addresses listed on the Static Entries tab (**Network > DNS Proxy**). However, when setting the DNS Proxy Object as the DNS Service on the **Device > Setup > Services** dialog, all DNS queries from the management interface ignored the defined static entries. |
| **40648** | Validation logic has been added to PAN-OS software image files to prevent upgrade failures due to file corruption. |
| **39368** | Enhancements have been made to the web interface so that high availability (HA) link status is displayed with green or red indicators on the **High Availability** widget on the **Dashboard** tab. A green indicator signifies that the link is up on the HA port and heartbeats (keep-alive messages) are being sent and received. A red indicator signifies that the link on the HA port is down or that heartbeats (keep-alive messages) are not being received at all. (For HA3 interfaces, the green and red indicators signify only whether the link is up or down.) |

# Getting Help

The following topics provide information on where to find out more about our products and how to request support:

- Related Documentation
- Requesting Support

## Related Documentation

Refer to the following documents on the Technical Documentation portal at https://www.paloaltonetworks.com/documentation for more information on our products:

- New Features Guide—Detailed information on configuring the features introduced in this release.
- PAN-OS Administrator's Guide—Provides the concepts and solutions to get the most out of your Palo Alto Networks next-generation firewalls. This includes taking you through the initial configuration and basic set up on your Palo Alto Networks firewalls.
- Panorama Administrator's Guide—Provides the basic framework to quickly set up the Panorama virtual appliance or the M-100 appliance for centralized administration of the Palo Alto Networks firewalls.
- WildFire Administrator's Guide—Provides information on deploying, operating, and maintaining the WildFire cloud and the WildFire WF-500 appliance and the Palo Alto Networks firewalls.
- VM-Series Deployment Guide—Provides details on deploying and licensing the VM-Series firewall on all supported hypervisors. It includes example of supported topologies on each hypervisor.
- GlobalProtect Administrator's Guide—Takes you through the configuration and maintenance of your GlobalProtect infrastructure.
- Online Help System—Detailed, context-sensitive help system integrated with the firewall web interface.
- Open Source Software (OSS) Listings—OSS licenses used with Palo Alto Networks products and software:
  - PAN-OS 6.0
  - Panorama 6.0
  - WildFire 6.0

# Getting Started

The following sections provide detailed steps to help you deploy a new Palo Alto Networks next-generation firewall. They provide details for integrating a new firewall into your network and configuring basic security policies and threat prevention features.

After you perform the basic configuration steps required to integrate the firewall into your network, you can use the rest of the topics in this guide to help you deploy the comprehensive enterprise security platform features as necessary to address your network security needs.

- Integrate the Firewall into Your Management Network
- Create the Security Perimeter
- Enable Basic Threat Prevention Features
- Best Practices for Completing the Firewall Deployment

# Integrate the Firewall into Your Management Network

All Palo Alto Networks firewalls provide an out-of-band management port (MGT) that you can use to perform the firewall administration functions. By using the MGT port, you separate the management functions of the firewall from the data processing functions, safeguarding access to the firewall and enhancing performance. When using the web interface, you must perform all initial configuration tasks from the MGT port even if you plan to use an in-band port for managing your device going forward.

Some management tasks, such as retrieving licenses and updating the threat and application signatures on the firewall require access to the Internet. If you do not want to enable external access to your MGT port, you will need to either set up a data port to provide access to required external services or plan to manually upload updates regularly.

The following topics describe how to perform the initial configuration steps that are necessary to integrate a new firewall into the management network and deploy it in a basic security configuration.

- Determine Your Management Strategy
- Perform Initial Configuration
- Set Up Network Access for External Services
- Register the Firewall
- Activate Licenses and Subscriptions
- Manage Content Updates
- Install Software Updates

The following topics describe how to integrate a single Palo Alto Networks next-generation firewall into your network. However, for redundancy, consider deploying a pair of firewalls in a High Availability configuration.

## Determine Your Management Strategy

The Palo Alto Networks firewall can be configured and managed locally or it can be managed centrally using Panorama, the Palo Alto Networks centralized security management system. If you have six or more firewalls deployed in your network, use Panorama to achieve the following benefits:

- Reduce the complexity and administrative overhead in managing configuration, policies, software and dynamic content updates. Using device groups and templates on Panorama, you can effectively manage device specific configuration locally on a device and enforce shared policies across all devices or device groups.
- Aggregate data from all managed firewalls and gain visibility across all the traffic on your network. The Application Command Center (**ACC**) on Panorama provides a single glass pane for unified reporting across all the firewalls, allowing you to centrally analyze, investigate and report on network traffic, security incidents and administrative modifications.

 © Palo Alto Networks, Inc.

The procedures in this document describe how to manage the firewall using the local web interface. If you want to use Panorama for centralized management, after you complete the instructions in the Perform Initial Configuration section of this guide and verify that the firewall can establish a connection to Panorama. From that point on you can use Panorama to configure your firewall centrally.

## Perform Initial Configuration

By default, the firewall has an IP address of 192.168.1.1 and a username/password of admin/admin. For security reasons, you must change these settings before continuing with other firewall configuration tasks. You must perform these initial configuration tasks either from the MGT interface, even if you do not plan to use this interface for your firewall management, or using a direct serial connection to the console port on the device.

| **Set Up Network Access to the Firewall** | | |
|---|---|---|
| Step 1 | Gather the required information from your network administrator. | ❑ IP address for MGT port<br>❑ Netmask<br>❑ Default gateway<br>❑ DNS server address |
| Step 2 | Connect your computer to the firewall. | You can connect to the firewall in one of the following ways:<br>• Connect a serial cable from your computer to the Console port and connect to the firewall using terminal emulation software (9600-8-N-1). Wait a few minutes for the boot-up sequence to complete; when the device is ready, the prompt changes to the name of the firewall, for example `PA-500 login`.<br>• Connect an RJ-45 Ethernet cable from your computer to the MGT port on the firewall. From a browser, go to `https://192.168.1.1`. Note that you may need to change the IP address on your computer to an address in the 192.168.1.0 network, such as 192.168.1.2, in order to access this URL. |
| Step 3 | When prompted, log in to the firewall. | You must log in using the default username and password (admin/admin). The firewall will begin to initialize. |
| Step 4 | Configure the MGT interface. | 1. Select **Device > Setup > Management** and then edit the Management Interface Settings.<br>2. Enter the **IP Address**, **Netmask**, and **Default Gateway**.<br>3. Set the **Speed** to **auto-negotiate**.<br>4. Select which management services to allow on the interface.<br> Make sure **Telnet** and **HTTP** are not selected because these services use plaintext and are not as secure as the other services.<br>5. Click **OK**. |

| Set Up Network Access to the Firewall (Continued) | | |
|---|---|---|
| Step 5 | (Optional) Configure general firewall settings. | 1. Select **Device > Setup > Management** and edit the General Settings.<br>2. Enter a **Hostname** for the firewall and enter your network **Domain** name. The domain name is just a label; it will not be used to join the domain.<br>3. Enter the **Latitude** and **Longitude** to enable accurate placement of the firewall on the world map.<br>4. Click **OK**. |
| Step 6 | Configure DNS, time and date settings.<br>You must manually configure at least one DNS server on the firewall or it will not be able to resolve hostnames; it will not use DNS server settings from another source, such as an ISP. | 1. Select **Device > Setup > Services** and edit the Services.<br>2. On the **Services** tab, enter the IP address of the **Primary DNS Server** and optionally a **Secondary DNS Server**.<br>3. To use the virtual cluster of time servers on the Internet, enter the hostname **pool.ntp.org** as the **Primary NTP Server** or add the IP address of your **Primary NTP Server** and optionally a **Secondary NTP Server**.<br>4. To authenticate time updates from an NTP server, select the **NTP** tab, enter the **NTP Server Address**, and select the **Authentication Type** for the firewall to use.<br>5. Click **OK** to save your settings. |
| Step 7 | Set a secure password for the admin account. | 1. Select **Device > Administrators.**<br>2. Select the **admin** role.<br>3. Enter the current default password and the new password.<br>4. Click **OK** to save your settings. |
| Step 8 | Commit your changes.<br>When the configuration changes are saved, you will lose connectivity to the web interface because the IP address will have changed. | Click **Commit**. The device may take up to 90 seconds to save your changes.<br> |
| Step 9 | Connect the firewall to your network. | 1. Disconnect the firewall from your computer.<br>2. Connect the MGT port to a switch port on your management network using an RJ-45 Ethernet cable. Make sure that the switch port you cable the firewall to is configured for auto-negotiation. |
| Step 10 | Open an SSH management session to the firewall. | Using a terminal emulation software, such as PuTTY, launch an SSH session to the firewall using the new IP address you assigned to it. |

 © Palo Alto Networks, Inc.

| Set Up Network Access to the Firewall (Continued) | | |
|---|---|---|
| Step 11 | Verify network access to external services required for firewall management, such as the Palo Alto Networks Update Server, in one of the following ways:<br>• If you do not want to allow external network access to the MGT interface, you will need to set up a data port to retrieve required service updates. Continue to Set Up Network Access for External Services.<br>• If you do plan to allow external network access to the MGT interface, verify that you have connectivity and then proceed to Register the Firewall and Activate Licenses and Subscriptions. | If you cabled your MGT port for external network access, verify that you have access to and from the firewall by using the ping utility from the CLI. Make sure you have connectivity to the default gateway, DNS server, and the Palo Alto Networks Update Server as shown in the following example:<br>`admin@PA-200> ping host updates.paloaltonetworks.com`<br>`PING updates.paloaltonetworks.com (67.192.236.252) 56(84) bytes of data.`<br>`64 bytes from 67.192.236.252 : icmp_seq=1 ttl=243 time=40.5 ms`<br>`64 bytes from 67.192.236.252 : icmp_seq=1 ttl=243 time=53.6 ms`<br>`64 bytes from 67.192.236.252 : icmp_seq=1 ttl=243 time=79.5 ms`<br>After you have verified connectivity, press Ctrl+C to stop the pings. |

## Set Up Network Access for External Services

By default, the firewall uses the MGT interface to access remote services, such as DNS servers, content updates, and license retrieval. If you do not want to enable external network access to your management network, you must set up a data port to provide access to these required external services.

This task requires familiarity with firewall interfaces, zones, and policies. For more information on these topics, see Create the Security Perimeter.

| Set Up a Data Port for Access to External Services | | |
|---|---|---|
| Step 1 | Decide which port you want to use for access to external services and connect it to your switch or router port. | The interface you use will need to have a static IP address. |
| Step 2 | Log in to the web interface. | Using a secure connection (https) from your web browser, log in using the new IP address and password you assigned during initial configuration (https://<IP address>). You will see a certificate warning; that is okay. Continue to the web page. |

| Set Up a Data Port for Access to External Services (Continued) | | |
|---|---|---|
| Step 3 | (Optional) The firewall comes preconfigured with a default virtual wire interface between ports Ethernet 1/1 and Ethernet 1/2 (and a corresponding default security policy and zones). If you do not plan to use this virtual wire configuration, you must manually delete the configuration to prevent it from interfering with other interface settings you define. | You must delete the configuration in the following order:<br>1. To delete the default security policy, select **Policies > Security**, select the rule, and click **Delete**.<br>2. Next, delete the default virtual wire by selecting **Network > Virtual Wires**, selecting the virtual wire and clicking **Delete**.<br>3. To delete the default trust and untrust zones, select **Network > Zones**, select each zone and click **Delete**.<br>4. Finally, delete the interface configurations by selecting **Network > Interfaces** and then select each interface (ethernet1/1 and ethernet1/2) and click **Delete**.<br>5. **Commit** the changes. |
| Step 4 | Configure the interface. | 1. Select **Network > Interfaces** and select the interface that corresponds to the port you cabled in Step 1.<br>2. Select the **Interface Type**. Although your choice here depends on your network topology, this example shows the steps for **Layer3**.<br>3. On the **Config** tab, expand the **Security Zone** drop-down and select **New Zone**.<br>4. In the Zone dialog, define a **Name** for new zone, for example L3-trust, and then click **OK**.<br>5. Select the **IPv4** tab, select the **Static** radio button, and click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 192.168.1.254/24.<br>6. Select **Advanced > Other Info**, expand the **Management Profile** drop-down, and select **New Management Profile**.<br>7. Enter a **Name** for the profile, such as allow_ping, and then select the services you want to allow on the interface. These services provide management access to the device, so only select the services that correspond to the management activities you want to allow on this interface. For example, if you plan to use the MGT interface for device configuration tasks through the web interface or CLI, you would not want to enable HTTP, HTTPS, SSH, or Telnet so that you could prevent unauthorized access through this interface. For the purposes of allowing access to the external services you probably only need to enable **Ping** and then click **OK**.<br>8. To save the interface configuration, click **OK**. |

 © Palo Alto Networks, Inc.

**Set Up a Data Port for Access to External Services (Continued)**

| | |
|---|---|
| Step 5 Because the firewall uses the MGT interface by default to access the external services it requires, you must change the interface the firewall uses to send these requests by editing the service routes. | 1. Select **Device > Setup > Services > Service Route Configuration**.<br>  <br>For the purposes of activating your licenses and getting the most recent content and software updates, you will want to change the service route for **DNS**, **Palo Alto Updates**, **URL Updates**, and **WildFire**.<br>2. Click the **Customize** radio button, and select one of the following:<br>• For a predefined service, select **IPv4** or **IPv6** and click the link for the service for which you want to modify the **Source Interface** and select the interface you just configured.<br>If more than one IP address is configured for the selected interface, the **Source Address** drop-down allows you select an IP address.<br>• To create a service route for a custom destination, select **Destination**, and click **Add**. Enter a **Destination** name and select a **Source Interface**. If more than one IP address is configured for the selected interface, the **Source Address** drop-down allows you select an IP address.<br>3. Click **OK** to save the settings.<br>4. Repeat steps 2-3 above for each service route you want to modify.<br>5. **Commit** your changes. |

**Set Up a Data Port for Access to External Services (Continued)**

| | | |
|---|---|---|
| Step 6 | Configure an external-facing interface and an associated zone and then create security and NAT policy rules to allow the firewall to send service requests from the internal zone to the external zone. | 1. Select **Network > Interfaces** and then select your external-facing interface. Select **Layer3** as the **Interface Type**, **Add** the **IP** address (on the **IPv4** or **IPv6** tab), and create the associated **Security Zone** (on the **Config** tab), such as l3-untrust. You do not need to set up management services on this interface.<br>2. To set up a security rule that allows traffic from your internal network to the Palo Alto Networks update server and external DNS servers, select **Policies > Security** and click **Add**. For the purposes of initial configuration, you can create a simple rule that allows all traffic from l3-trust to l3-untrust as follows:<br> <br>3. If you are using a private IP address on the internal-facing interface, you will need to create a Source NAT rule to translate the address to a publicly routable address. Select **Policies > NAT** and then click **Add**. At a minimum you must define a name for the rule (**General** tab), specify a source and destination zone, l3-trust to l3-untrust in this case (**Original Packet** tab), and define the source address translation settings (**Translated Packet** tab) and then click **OK**.<br> <br>4. **Commit** your changes. |
| Step 7 | Verify that you have connectivity from the data port to the external services, including the default gateway, DNS server, and the Palo Alto Networks Update Server.<br><br>After you verify you have the required network connectivity, continue to Register the Firewall and Activate Licenses and Subscriptions. | Launch the CLI and use the ping utility to verify that you have connectivity. Keep in mind that by default pings are sent from the MGT interface, so in this case you must specify the source interface for the ping requests as follows:<br>`admin@PA-200> ping source 192.168.1.254 host updates.paloaltonetworks.com`<br>`PING updates.paloaltonetworks.com (67.192.236.252) from 192.168.1.254 : 56(84) bytes of data.`<br>`64 bytes from 67.192.236.252: icmp_seq=1 ttl=242 time=56.7 ms`<br>`64 bytes from 67.192.236.252: icmp_seq=2 ttl=242 time=47.7 ms`<br>`64 bytes from 67.192.236.252: icmp_seq=3 ttl=242 time=47.6 ms`<br>`^C`<br>After you have verified connectivity, press Ctrl+C to stop the pings. |

 © Palo Alto Networks, Inc.

## Register the Firewall

| Register the Firewall | | |
|---|---|---|
| Step 1 | Log in to the web interface. | Using a secure connection (https) from your web browser, log in using the new IP address and password you assigned during initial configuration (https://<IP address>). You will see a certificate warning; that is okay. Continue to the web page. |
| Step 2 | Locate your serial number and copy it to the clipboard. | On the **Dashboard**, locate your **Serial Number** in the General Information section of the screen. |
| Step 3 | Go to the Palo Alto Networks Support site. | In a new browser tab or window, go to https://support.paloaltonetworks.com. |
| Step 4 | Register the device. The way you register depends on whether you already have a login to the support site. | • If this is the first Palo Alto Networks device you are registering and you do not yet have a login, click **Register** on the right side of the page. To register, you must provide your sales order number or customer ID, and the serial number of your firewall (which you can paste from your clipboard) or the authorization code you received with your order. You will also be prompted to set up a username and password for access to the Palo Alto Networks support community.<br> <br>• If you already have a support account, log in and then click **My Devices**. Scroll down to Register Device section at the bottom of the screen and enter the serial number of your firewall (which you can paste from your clipboard), your city and postal code and then click **Register Device**. |

## Activate Licenses and Subscriptions

Before you can start using your firewall to secure the traffic on your network, you must activate the licenses for each of the services you purchased. Available licenses and subscriptions include the following:

- Threat Prevention—Provides antivirus, anti-spyware, and vulnerability protection.
- Decryption Port Mirroring—Provides the ability to create a copy of decrypted traffic from a firewall and send it to a traffic collection tool that is capable of receiving raw packet captures—such as NetWitness or Solera—for archiving and analysis.
- URL Filtering—In order to create policy rules based on dynamic URL categories, you must purchase and install a subscription for one of the supported URL filtering databases: PAN-DB or BrightCloud. For more information about URL filtering, see Control Access to Web Content.

© Palo Alto Networks, Inc.

- Virtual Systems—This license is required to enable support for multiple virtual systems on PA-2000 and PA-3000 Series firewalls. In addition, you must purchase a Virtual Systems license if you want to increase the number of virtual systems beyond the base number provided by default on PA-4000 Series, PA-5000 Series, and PA-7050 firewalls (the base number varies by platform). The PA-500, PA-200, and VM-Series firewalls do not support virtual systems.
- WildFire—Although basic WildFire support is included as part of the Threat Prevention license, the WildFire subscription service provides enhanced services for organizations that require immediate coverage for threats, enabling sub-hourly WildFire signature updates, advanced file type forwarding (APK, PDF, Microsoft Office, and Java Applet), as well as the ability to upload files using the WildFire API. A WildFire subscription is also required if your firewalls will be forwarding files to a private WF-500 WildFire appliance.
- GlobalProtect—Provides mobility solutions and/or large-scale VPN capabilities. By default, you can deploy a single GlobalProtect portal and gateway (without HIP checks) without a license. However, if you want to deploy multiple gateways, you must purchase a portal license (one-time, permanent license). If you want to use host checks you will also need gateway licenses (subscription) for each gateway.

| **Activate Licenses** | | |
|---|---|---|
| Step 1 | Locate the activation codes for the licenses you purchased. | When you purchased your subscriptions you should have received an email from Palo Alto Networks customer service listing the activation code associated with each subscription. If you cannot locate this email, contact customer support to obtain your activation codes before you proceed. |
| Step 2 | Launch the web interface and go to the license page. | Select **Device > Licenses**. |
| Step 3 | Activate each license you purchased. | After purchasing your licenses/subscriptions activate them in one of the following ways:<br>• **Retrieve license keys from license server**—Use this option if you activated your license on the support portal.<br>• **Activate feature using authorization code**—Use this option to enable purchased subscriptions using an authorization code for licenses that have not been previously activated on the support portal. When prompted, enter the **Authorization Code** and then click **OK**.<br>• **Manually upload license key**—Use this option if your device does not have connectivity to the Palo Alto Networks support site. In this case, you must download a license key file from the support site on an Internet connected computer and then upload to the device. |
| Step 4 | Verify that the license was successfully activated | On the **Device > Licenses** page, verify that the license was successfully activated. For example, after activating the WildFire license, you should see that the license is valid:<br> |

 © Palo Alto Networks, Inc.

| Activate Licenses (Continued) | |
|---|---|
| Step 5 (WildFire subscriptions only) Perform a commit to complete WildFire subscription activation. | After activating a WildFire subscription, a commit is required for the firewall to begin forwarding advanced file types:<br>• Commit any pending changes.<br>• Make a minor change and perform a commit. For example, update a rule description and commit the change.<br> Check the file blocking profile rule used for WildFire forwarding includes the advanced file types that are now supported with the WildFire subscription. If the rule is already set to forward **Any** file type, or no change to the rule is required, make a minor edit to the rule description and perform a commit. |

## Manage Content Updates

In order to stay ahead of the changing threat and application landscape, Palo Alto Networks maintains a Content Delivery Network (CDN) infrastructure for delivering content updates to the Palo Alto Networks devices. The devices access the web resources in the CDN to perform various App-ID and Content-ID functions. By default, the devices use the management port to access the CDN infrastructure for application updates, threat and antivirus signature updates, BrightCloud and PAN-DB database updates and lookups, and access to the Palo Alto Networks WildFire Cloud. To ensure that you are always protected from the latest threats (including those that have not yet been discovered), you must ensure that you keep your devices up-to-date with the latest updates published by Palo Alto Networks.

The following content updates are available, depending on which subscriptions you have:

Although you can manually download and install content updates at any time, as a best practice you should Schedule each update. Scheduled updates occur automatically.

- **Antivirus**—Includes new and updated antivirus signatures, including signatures discovered by the WildFire cloud service. You must have a Threat Prevention subscription to get these updates. New antivirus signatures are published daily.
- **Applications**—Includes new and updated application signatures. This update does not require any additional subscriptions, but it does require a valid maintenance/support contract. New application updates are published weekly.
- **Applications and Threats**—Includes new and updated application and threat signatures. This update is available if you have a Threat Prevention subscription (and you get it instead of the Applications update). New Applications and Threats updates are published weekly.
- **GlobalProtect Data File**—Contains the vendor-specific information for defining and evaluating host information profile (HIP) data returned by GlobalProtect agents. You must have a GlobalProtect portal and GlobalProtect gateway license in order to receive these updates. In addition, you must create a schedule for these updates before GlobalProtect will function.

- **BrightCloud URL Filtering**—Provides updates to the BrightCloud URL Filtering database only. You must have a BrightCloud subscription to get these updates. New BrightCloud URL database updates are published daily. If you have a PAN-DB license, scheduled updates are not required as devices remain in-sync with the servers automatically.
- **WildFire**—Provides near real-time malware and antivirus signatures created as a result of the analysis done by the WildFire cloud service. Without the subscription, you must wait 24 to 48 hours for the signatures to roll into the Applications and Threat update.

If your firewall does not have Internet access from the management port, you can download content updates from the Palo Alto Networks Support portal and then Upload them to your firewall.

If your firewall is deployed behind existing firewalls or proxy servers, access to these external resources might be restricted using access control lists that allow the firewall to only access a hostname or an IP address. In such cases, to allow access to the CDN, set the update server address to use the hostname `staticupdates.paloaltonetworks.com` or the IP address `199.167.52.15`.

| **Download the Latest Databases** | |
|---|---|
| Step 1 Verify that the firewall points to the CDN infrastructure. | Select **Device > Setup > Services**.<br>• As a best practice, set the **Update Server** to access `updates.paloaltonetworks.com`. This allows the firewall to receive content updates from the server to which it is closest in the CDN infrastructure.<br>• (Optional) If the firewall has restricted access to the Internet, set the update server address to use the hostname `staticupdates.paloaltonetworks.com` or the IP address `199.167.52.15`.<br>• For additional security, select **Verify Update Server Identity**. The firewall verifies that the server from which the software or content package is download has an SSL certificate signed by a trusted authority. |
| Step 2 Launch the web interface and go to the Dynamic Updates page. | Select **Device > Dynamic Updates**. |

 © Palo Alto Networks, Inc.

**Download the Latest Databases (Continued)**

Step 3 Check for the latest updates.

Click **Check Now** (located in the lower left-hand corner of the window) to check for the latest updates. The link in the **Action** column indicates whether an update is available:

- **Download**—Indicates that a new update file is available. Click the link to begin downloading the file directly to the firewall. After successful download, the link in the **Action** column changes from **Download** to **Install**.

You cannot download the antivirus database until you have installed the Application and Threats database.

- **Upgrade**—Indicates that there is a new version of the BrightCloud database available. Click the link to begin the download and installation of the database. The database upgrade begins in the background; when completed a check mark displays in the **Currently Installed** column. Note that if you are using PAN-DB as your URL filtering database you will not see an upgrade link because the PAN-DB database automatically stays in sync with the server.

To check the status of an action, click **Tasks** (on the lower right-hand corner of the window).

- **Revert**—Indicates that the corresponding software version has been downloaded previously. You can choose to revert to the previously installed version of the update.

Step 4 Install the updates.

Installation can take up to 20 minutes on a PA-200, PA-500, or PA-2000 device and up to two minutes on a PA-3000 Series, PA-4000 Series, PA-5000 Series, PA-7050, or VM-Series firewall.

Click the **Install** link in the **Action** column. When the installation completes, a check mark displays in the **Currently Installed** column.

| Download the Latest Databases (Continued) | | |
|---|---|---|
| Step 5 | Schedule each update.<br><br>Repeat this step for each update you want to schedule.<br><br>Stagger the update schedules because the firewall can only download one update at a time. If you schedule the updates to download during the same time interval, only the first download will succeed. | 1. Set the schedule of each update type by clicking the **None** link.<br> <br>2. Specify how often you want the updates to occur by selecting a value from the **Recurrence** drop-down. The available values vary by content type (WildFire updates are available **Every 15 minutes**, **Every 30 minutes** or **Every Hour** whereas all other content types can be scheduled for **Daily** or **Weekly** update).<br>3. Specify the **Time** and (or, minutes past the hour in the case of WildFire), if applicable depending on the **Recurrence** value you selected, **Day** of the week that you want the updates to occur.<br>4. Specify whether you want the system to **Download Only** or, as a best practice, **Download And Install** the update.<br>5. In rare instances, errors in content updates may be found. For this reason, you may want to delay installing new updates until they have been released for a certain number of hours. You can specify how long after a release to wait before performing a content update by entering the number of hours to wait in the **Threshold (Hours)** field.<br>6. Click **OK** to save the schedule settings.<br>7. Click **Commit** to save the settings to the running configuration. |

## Install Software Updates

When installing a new firewall, it is a good idea to upgrade to the latest software update (or to the update version recommended by your reseller or Palo Alto Networks Systems Engineer) to take advantage of the latest fixes and security enhancements. Note that before updating the software, you should first make sure you have the latest content updates as detailed in the previous section (the Release Notes for a software update specify the minimum Content Release version supported in the release).

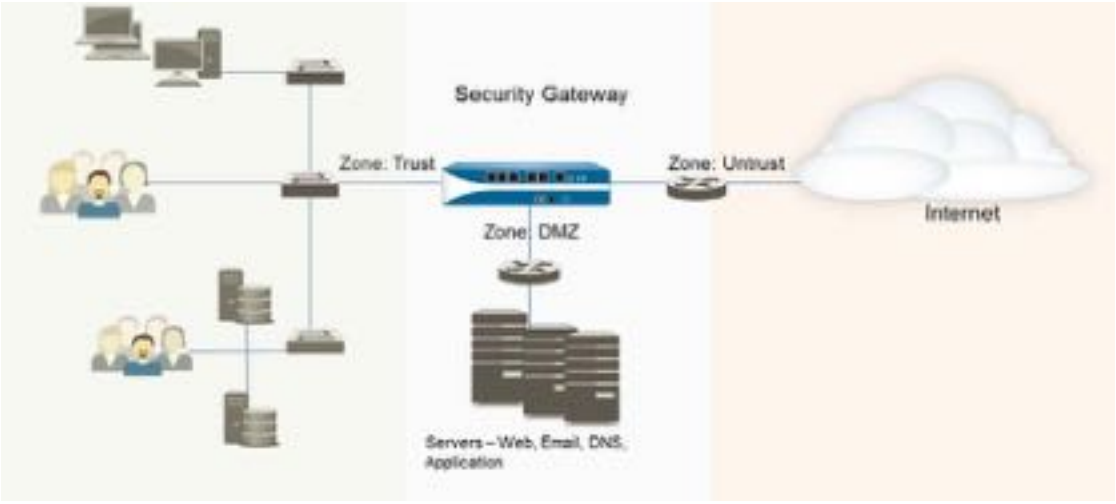
| Update PAN-OS | | |
|---|---|---|
| Step 1 | Launch the web interface and go to the Software page. | Select **Device > Software**. |
| Step 2 | Check for software updates. | Click **Check Now** to check for the latest updates. If the value in the **Action** column is **Download** it indicates that an update is available. |

 © Palo Alto Networks, Inc.

| Update PAN-OS (Continued) | |
|---|---|
| Step 3 Download the update.<br><br>If your firewall does not have Internet access from the management port, you can download the software update from the Palo Alto Networks Support portal. You can then manually **Upload** them to your firewall. | Locate the version you want and then click **Download**. When the download completes, the value in the Action column changes to **Install**.<br>  <br> |
| Step 4 Install the update. | 1. Click **Install**.<br>2. Reboot the firewall:<br>• If you are prompted to reboot, click **Yes**.<br> <br><br>• If you are not prompted to reboot, select **Device > Setup > Operations** and click **Reboot Device** in the Device Operations section of the screen.<br> <br> |

# Create the Security Perimeter

Traffic must pass through the firewall in order for the firewall to manage and control it. Physically, traffic enters and exits the firewall through *interfaces*. The firewall determines how to act on a packet based on whether the packet matches a *security policy rule*. At the most basic level, each security policy rule must identify where the traffic came from and where it is going. On a Palo Alto Networks next-generation firewall, security policy rules are applied between zones. A *zone* is a grouping of interfaces (physical or virtual) that provides an abstraction for an area of trust for simplified policy enforcement. For example, in the following topology diagram, there are three zones: Trust, Untrust, and DMZ. Traffic can flow freely within a zone, but traffic will not be able to flow between zones until you define a security policy rule that allows it.



The following topics describe the components of the security perimeter and provide steps for configuring the firewall interfaces, defining zones, and setting up a basic security policy that allows traffic from your internal zone to the Internet and to the DMZ. By initially creating a basic security policy rulebase like this, you will be able to analyze the traffic running through your network and use this information to define more granular policies for safely enabling applications while preventing threats.

- Basic Interface Deployments
- About Security Policy
- Plan the Deployment
- Configure Interfaces and Zones
- Set Up Basic Security Policies

If you use private IP addresses in your internal networks, you will also need to configure network address translation (NAT); see Networking for NAT concepts and configuration tasks.

## Basic Interface Deployments

All Palo Alto Networks next-generation firewalls provide a flexible networking architecture that includes support for dynamic routing, switching, and VPN connectivity, enabling you to deploy the firewall into nearly any networking environment. When configuring the Ethernet ports on your firewall, you can choose from

 © Palo Alto Networks, Inc.

virtual wire, Layer 2, or Layer 3 interface deployments. In addition, to allow you to integrate into a variety of network segments, you can configure different types of interfaces on different ports. The following sections provide basic information on each type of deployment.

- Virtual Wire Deployments
- Layer 2 Deployments
- Layer 3 Deployments

For more detailed deployment information, refer to Designing Networks with Palo Alto Networks Firewalls.

## Virtual Wire Deployments

In a virtual wire deployment, the firewall is installed transparently on a network segment by binding two ports together. By using a virtual wire, you can install the firewall in any network environment without reconfiguring adjacent devices. If necessary, a virtual wire can block or allow traffic based on the virtual LAN (VLAN) tag values. You can also create multiple subinterfaces and classify traffic according to an IP Address (address, range, or subnet), VLAN, or a combination of the two.

By default, the virtual wire (named **default-vwire**) binds Ethernet ports 1 and 2 and allows all untagged traffic. Choose this deployment to simplify installation and configuration and/or avoid configuration changes to surrounding network devices.

A virtual wire is the default configuration, and should be used only when no switching or routing is needed. If you do not plan to use the default virtual wire, you should manually delete the configuration before proceeding with interface configuration to prevent it from interfering with other interface settings you define. For instructions on how to delete the default virtual wire and its associated security policy and zones, see Step 3 in Set Up a Data Port for Access to External Services.

## Layer 2 Deployments

In a Layer 2 deployment, the firewall provides switching between two or more interfaces. Each group of interfaces must be assigned to a VLAN object in order for the firewall to switch between them. The firewall will perform VLAN tag switching when Layer 2 subinterfaces are attached to a common VLAN object. Choose this option when switching is required.

For more information on Layer 2 deployments, refer to the Layer 2 Networking Tech Note and/or the Securing Inter VLAN Traffic Tech Note.

## Layer 3 Deployments

In a Layer 3 deployment, the firewall routes traffic between ports. An IP address must be assigned to each interface and a virtual router must be defined to route the traffic. Choose this option when routing is required.

You must assign an IP address to each physical Layer 3 interface you configure. You can also create logical subinterfaces for each physical Layer 3 interface that allows you to segregate the traffic on the interface based on VLAN tag (when VLAN trunking is in use) or by IP address, for example for multi-tenancy.

In addition, because the firewall must route traffic in a Layer 3 deployment, you must configure a virtual router. You can configure the virtual router to participate with dynamic routing protocols (BGP, OSPF, or RIP) as well as adding static routes. You can also create multiple virtual routers, each maintaining a separate set of routes that are not shared between virtual routers, enabling you to configure different routing behaviors for different interfaces.

The configuration example in this chapter illustrates how to integrate the firewall into your Layer 3 network using static routes. For information on other types of routing integrations, refer to the following documents:

- How to Configure OSPF Tech Note
- How to Configure BGP Tech Note

## About Security Policy

Security Policy protects network assets from threats and disruptions and aids in optimally allocating network resources for enhancing productivity and efficiency in business processes. On the Palo Alto Networks firewall, security policy rules determine whether to block or allow a session based on traffic attributes such as the source and destination security zone, the source and destination IP address, the application, user, and the service.

For traffic that doesn't match any defined rules, the default rules apply. The default rules—displayed at the bottom of the security rulebase—are predefined to allow all intrazone (within the zone) traffic and deny all interzone (between zones) traffic. Although these rules are part of the pre-defined configuration and are read-only by default, you can override them and change a limited number of settings, including the tags, action (allow or deny), log settings, and security profiles.

Security policies rules are evaluated left to right and from top to bottom. A packet is matched against the first rule that meets the defined criteria; after a match is triggered the subsequent rules are not evaluated. Therefore, the more specific rules must precede more generic ones in order to enforce the best match criteria. Traffic that matches a rule generates a log entry at the end of the session in the traffic log, if logging is enabled for that rule. The logging options are configurable for each rule, and can for example be configured to log at the start of a session instead of, or in addition to, logging at the end of a session.

▲ About Policy Objects
▲ About Security Profiles

### About Policy Objects

A *policy object* is a single object or a collective unit that groups discrete identities such as IP addresses, URLs, applications, or users. With Policy Objects that are a collective unit, you can reference the object in security policy instead of manually selecting multiple objects one at a time. Typically, when creating a policy object, you group objects that require similar permissions in policy. For example, if your organization uses a set of server IP addresses for authenticating users, you can group the set of server IP addresses as an *address group* policy object and reference the address group in the security policy. By grouping objects, you can significantly reduce the administrative overhead in creating policies.

Some examples of address and application policy objects are shown in the security policies that are included in Create Security Rules. For information on the other policy objects, see Enable Basic Threat Prevention Features.

 © Palo Alto Networks, Inc.

## About Security Profiles

While security policies enable you to allow or deny traffic on your network, security profiles help you define an *allow but scan* rule, which scan allowed applications for threats. When traffic matches the allow rule defined in the security policy, the Security Profiles that are attached to the rule are applied for further content inspection rules such as antivirus checks and data filtering.

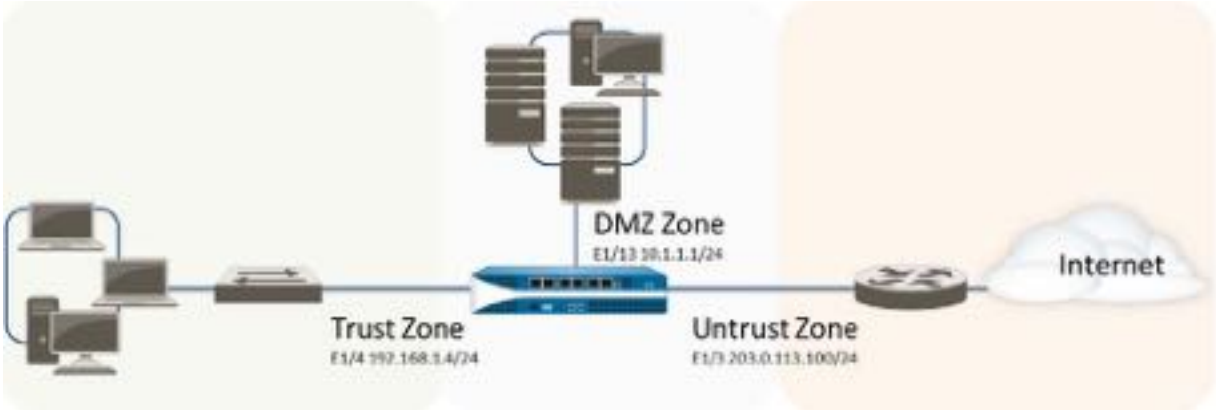
Security profiles are not used in the match criteria of a traffic flow. The security profile is applied to scan traffic after the application or category is allowed by the security policy.

The different types of security profiles that can be attached to security policies are: Antivirus, Anti-spyware, Vulnerability Protection, URL Filtering, File Blocking, and Data Filtering. The firewall provides default security profiles that you can use out of the box to begin protecting your network from threats. See Create Security Rules for information on using the default profiles in your security policy. As you get a better understanding about the security needs on your network, you can create custom profiles. See Scan Traffic for Threats for more information.

# Plan the Deployment

Before you begin configuring interfaces and zones, take some time to plan the zones you will need based on the different usage requirements within your organization. In addition, you should gather all of the configuration information you will need ahead of time. At a basic level, you should plan which interfaces will belong to which zones. For Layer 3 deployments you'll also need to obtain the required IP addresses and network configuration information from your network administrator, including information on how to configure the routing protocol or static routes required for the virtual router configuration. The example in this chapter will be based on the following topology:

**Figure: Layer 3 Topology Example**



The following table shows the information we will use to configure the Layer 3 interfaces and their corresponding zones as shown in the sample topology.

| Zone | Deployment Type | Interface(s) | Configuration Settings |
|---|---|---|---|
| Untrust | L3 | Ethernet1/3 | **IP address:** 203.0.113.100/24<br>**Virtual router:** default<br>**Default route:** 0.0.0.0/0<br>**Next hop:** 203.0.113.1 |
| Trust | L3 | Ethernet1/4 | **IP address:** 192.168.1.4/24<br>**Virtual router:** default |
| DMZ | L3 | Ethernet1/13 | **IP address:** 10.1.1.1/24<br>**Virtual router:** default |

## Configure Interfaces and Zones

After you plan your zones and the corresponding interfaces, you can configure them on the device. The way you configure each interface depends on your network topology.

The following procedure shows how to configure a Layer 3 deployment as depicted in Figure: Layer 3 Topology Example.

The firewall comes preconfigured with a default virtual wire interface between ports Ethernet 1/1 and Ethernet 1/2 (and a corresponding default security policy and virtual router). If you do not plan to use the default virtual wire, you must manually delete the configuration and commit the change before proceeding to prevent it from interfering with other settings you define. For instructions on how to delete the default virtual wire and its associated security policy and zones, see Step 3 in Set Up a Data Port for Access to External Services.

| Set Up Interfaces and Zones | |
|---|---|
| Step 1 Configure a default route to your Internet router. | 1. Select **Network > Virtual Router** and then select the **default** link to open the Virtual Router dialog.<br>2. Select the **Static Routes** tab and click **Add**. Enter a **Name** for the route and enter the route in the **Destination** field (for example, 0.0.0.0/0).<br>3. Select the **IP Address** radio button in the **Next Hop** field and then enter the IP address and netmask for your Internet gateway (for example, 203.00.113.1).<br>4. Click **OK** twice to save the virtual router configuration. |

 © Palo Alto Networks, Inc.

| Set Up Interfaces and Zones (Continued) | | |
|---|---|---|
| Step 2 | Configure the external interface (the interface that connects to the Internet). | 1. Select **Network > Interfaces** and then select the interface you want to configure. In this example, we are configuring Ethernet1/3 as the external interface.<br>2. Select the **Interface Type**. Although your choice here depends on your network topology, this example shows the steps for **Layer3**.<br>3. On the **Config** tab, select **New Zone** from the **Security Zone** drop-down. In the Zone dialog, define a **Name** for new zone, for example Untrust, and then click **OK**.<br>4. In the **Virtual Router** drop-down, select **default**.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 208.80.56.100/24.<br>6. To enable you to ping the interface, select **Advanced > Other Info**, expand the **Management Profile** drop-down, and select **New Management Profile**. Enter a **Name** for the profile, select **Ping** and then click **OK**.<br>7. To save the interface configuration, click **OK**. |
| Step 3 | Configure the interface that connects to your internal network.<br> In this example, the interface connects to a network segment that uses private IP addresses. Because private IP addresses cannot be routed externally, you will have to configure NAT. | 1. Select **Network > Interfaces** and select the interface you want to configure. In this example, we are configuring Ethernet1/4 as the internal interface.<br>2. Select **Layer3** from the **Interface Type** drop-down.<br>3. On the **Config** tab, expand the **Security Zone** drop-down and select **New Zone**. In the Zone dialog, define a **Name** for new zone, for example Trust, and then click **OK**.<br>4. Select the same Virtual Router you used in Step 2, default in this example.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 192.168.1.4/24.<br>6. To enable you to ping the interface, select the management profile that you created in Step 2-6.<br>7. To save the interface configuration, click **OK**. |

| Set Up Interfaces and Zones (Continued) | | |
|---|---|---|
| Step 4 | Configure the interface that connects to the DMZ. | 1. Select the interface you want to configure.<br>2. Select **Layer3** from the **Interface Type** drop-down. In this example, we are configuring Ethernet1/13 as the DMZ interface.<br>3. On the **Config** tab, expand the **Security Zone** drop-down and select **New Zone**. In the Zone dialog, define a **Name** for new zone, for example DMZ, and then click **OK**.<br>4. Select the Virtual Router you used in Step 2, default in this example.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 10.1.1.1/24.<br>6. To enable you to ping the interface, select the management profile that you created in Step 2-6.<br>7. To save the interface configuration, click **OK**. |
| Step 5 | Save the interface configuration. | Click **Commit**. |
| Step 6 | Cable the firewall. | Attach straight through cables from the interfaces you configured to the corresponding switch or router on each network segment. |
| Step 7 | Verify that the interfaces are active. | From the web interface, select **Network > Interfaces** and verify that icon in the Link State column is green. You can also monitor link state from the **Interfaces** widget on the **Dashboard**.<br>  |

## Set Up Basic Security Policies

Policies allow you to enforce rules and take action. The different types of policy rules that you can create on the firewall are: Security, NAT, Quality of Service (QoS), Policy Based Forwarding (PBF), Decryption, Application Override, Captive Portal, Denial of Service, and Zone protection policies. All these different policies work together to allow, deny, prioritize, forward, encrypt, decrypt, make exceptions, authenticate access, and reset connections as needed to help secure your network. This section covers basic security policies and the default security profiles:

- Create Security Rules
- Test Your Security Policies
- Monitor the Traffic on Your Network

 © Palo Alto Networks, Inc.

## Create Security Rules

Security policies reference security zones and enable you to allow, restrict, and track traffic on your network. Because each zone implies a level of trust, the implicit rule for passing traffic between two different zones is deny, and the traffic within a zone is permitted. To allow traffic between two different zones, you must create a security rule that allows traffic to flow between them.

While setting up the basic framework for securing the enterprise perimeter, it's good idea to start with a simple security policy that allows traffic between the different zones without being too restrictive. As illustrated in the following section, our objective is to minimize the likelihood of breaking applications that users on the network need access to, while providing visibility into the applications and the potential threats for your network.

When defining policies make sure that you do not create a policy that denies all traffic from *any* source zone to *any* destination zone as this will break intra-zone traffic that is implicitly allowed. By default, intra-zone traffic is permitted because the source and destination zones are the same and therefore share the same level of trust.

## Define Basic Security Rules

**Step 1** Permit Internet access for all users on the enterprise network.

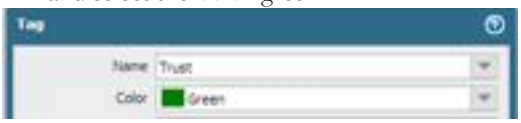
Zone: Trust to Untrust

By default, the firewall includes a security rule named *rule1* that allows all traffic from Trust zone to Untrust zone. You can either delete the rule or modify the rule to reflect your zone-naming convention.

To safely enable applications that are required for day-to-day business operations we will create a simple rule that allows access to the Internet. To provide basic threat protection, we will attach the default security profiles available on the firewall.

1. Select **Policies > Security** and click **Add.**
2. Give the rule a descriptive name in the **General** tab.
3. In the **Source** tab, set the **Source Zone** to Trust.
4. In the **Destination** tab, Set the **Destination Zone** to Untrust.

   To scan policy rules and visually identify the zones on each rule, create a tag with the same name as the zone. For example, to color code the Trust zone as green, select **Objects > Tags,** click **Add** and **Name** the tag Trust, and select the **Color** green.



5. In the **Service/ URL Category** tab, select service-http and service-https.
6. In the **Actions** tab, complete these tasks:
   a. Set the **Action Setting** to **Allow**.
   b. Attach the default profiles for antivirus, anti-spyware, vulnerability protection and URL filtering, under **Profile Setting.**
7. Verify that logging is enabled at the end of a session under **Options**. Only traffic that matches a security rule will be logged.

**Step 2** Permit users on the internal network to access the servers in the DMZ.

Zone: Trust to DMZ

If using IP addresses for configuring access to the servers in the DMZ, always refer to the original IP addresses in the packet (i.e. the pre-NAT addresses), and the post-NAT zone.

1. Click **Add** in the **Policies > Security** section.
2. Give the rule a descriptive name in the **General** tab.
3. In the **Source** tab, set the **Source Zone** to Trust.
4. In the **Destination** tab, set the **Destination Zone** to DMZ.
5. In the **Service/ URL Category** tab, make sure the **Service** is set to **application-default**.
6. In the **Actions** tab, set the **Action Setting** to Allow.
7. Leave all the other options at the default values.

 © Palo Alto Networks, Inc.

**Define Basic Security Rules (Continued)**

Step 3 Restrict access from the Internet to the servers on the DMZ to specific server IP addresses only.

For example, you might only allow users to access the webmail servers from outside.

Zone: Untrust to DMZ

To restrict inbound access to the DMZ from the Internet, configure a rule that allows access only to specific servers IP addresses and on the default ports that the applications use.

1. Click **Add** to add a new rule, and give it a descriptive name.
2. In the **Source** tab, set the **Source Zone** to Untrust.
3. In the **Destination** tab, set the **Destination Zone** to DMZ.
4. Set the **Destination Address** to the **Public web server** address object you created earlier. The public web server address object references the public IP address—208.80.56.11/24—of the web server that is accessible on the DMZ.
5. Select the webmail application in the **Application** tab.

   The **Service** is set to **application-default** by default.

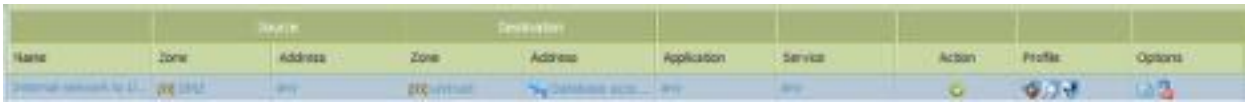
6. Set the **Action Setting** to **Allow**.

Step 4 Allow access from the DMZ to your internal network (Trust zone). To minimize risk, you will allow traffic only between specific servers and destination addresses. For example, if you have an application server on the DMZ that needs to communicate with a specific database server in your Trust zone, create a rule to allow traffic between a specific source to a specific destination.

Zone: DMZ to Trust

1. Click **Add** to add a new rule, and give it a descriptive name.
2. Set the **Source Zone** to DMZ.
3. Set the **Destination Zone** to Trust.
4. Create a an address object that specifies the server(s) on your Trust zone that can be accessed from the DMZ.

5. In the **Destination** tab on the Security Policy rule, set the **Destination Address** to the Address object you created above.
6. In the **Actions** tab, complete these tasks:
   a. Set the **Action Setting** to **Allow**.
   b. Attach the default profiles for antivirus, anti-spyware, vulnerability protection, under **Profile Setting.**
   c. In the Other Settings section, select the option to **Disable Server Response Inspection**. This setting disables the antivirus and anti-spyware scanning on the server-side responses, and thus reduces the load on the firewall.



| Define Basic Security Rules (Continued) | |
|---|---|
| Step 5 Enable the servers on the DMZ to obtain updates and hot fixes from the Internet. Say, for example, you would like to allow the Microsoft Update service.<br><br>Zone: DMZ to Untrust | 1. Add a new rule and give it a descriptive label.<br>2. Set the **Source Zone** to DMZ.<br>3. Set the **Destination Zone** to Untrust.<br>4. Create an application group to specify the applications that you would like to allow. In this example, we allow Microsoft updates (ms-updates) and dns.<br><br>  <br><br>The **Service** is set to **application-default** by default. This allows the firewall to permit the applications only when they use the standard ports associated with these applications.<br>5. Set the **Action Setting** to **Allow**.<br>6. Attach the default profiles for antivirus, anti-spyware, and vulnerability protection, under **Profiles**. |

| | |
|---|---|
| Step 6 Save your policies to the running configuration on the device. | Click **Commit**. |

 © Palo Alto Networks, Inc.

## Test Your Security Policies

To verify that you have set up your basic policies effectively, test whether your security policies are being evaluated and determine which security rule applies to a traffic flow.

| **Verify Policy Match Against a Flow** | |
|---|---|
| To verify the policy rule that matches a flow, use the following CLI command:<br>**`test security-policy-match source`** `<IP_address>` **`destination`** `<IP_address>` **`destination port`** `<port_number>` **`protocol`** `<protocol_number>`<br>The output displays the best rule that matches the source and destination IP address specified in the CLI command. | For example, to verify the policy rule that will be applied for a server on the DMZ with the IP address 208.90.56.11 when it accesses the Microsoft update server, you will try the following command:<br>`test security-policy-match source 208.80.56.11 destination 176.9.45.70 destination-port 80 protocol 6`<br><br>`"Updates-DMZ to Internet" {`<br>`from dmz;`<br>`source any;`<br>`source-region any;`<br>`to untrust;`<br>`destination any;`<br>`destination-region any;`<br>`user any;`<br>`category any;`<br>`application/service[ dns/tcp/any/53 dns/udp/any/53 dns/udp/any/5353 ms-update/tcp/any/80 ms-update/tcp/any/443];`<br>`action allow;`<br>`terminal yes;` |

## Monitor the Traffic on Your Network

Now that you have a basic security policy in place, you can review the statistics and data in the Application Command Center (ACC), traffic logs, and the threat logs to observe trends on your network, to identify where you need to create more granular policies.

Unlike traditional firewalls that use port or protocol to identify applications, the Palo Alto Networks firewalls use the application signature (the App-ID technology) to monitor applications. The application signature is based on unique application properties and related transaction characteristics in combination with the port or protocol. Therefore, even when the traffic uses the right port/protocol, the firewall can deny access to content because the application signature is not a match. This feature allows you to safely enable applications by allowing parts of the application while blocking or controlling functions within the same application. For example, if you allow the application *web-browsing* a user will be able to access content on the Internet. Then, if a user goes to Facebook and then goes on to play Scrabble on Facebook, the firewall will identify the application shifts and recognize Facebook as an *application* and Scrabble as a *Facebook-app*. Therefore, if you create a specific rule that blocks Facebook applications, the user will be denied access to Scrabble while still being able to access Facebook.

| Monitor Network Traffic | |
|---|---|
| • Use the Application Command Center. | In the ACC, review the most used applications and the high-risk applications on your network. The ACC graphically summarizes the log information to highlight the applications traversing the network, who is using them (with User-ID enabled), and the potential security impact of the content to help you identify what is happening on the network in real time. You can then use this information to create appropriate security policies that block unwanted applications, while allowing and enabling applications in a secure manner. |
| • Determine what updates/modifications are required for your network security rules and implement the changes. | For example:<br>• Evaluate whether to allow content based on schedule, users, or groups<br>• Allow or control certain applications or functions within an application<br>• Decrypt and inspect content<br>• Allow but scan for threats and exploits<br>For information on refining your security policies and for attaching custom security profiles, see Enable Basic Threat Prevention Features. |
| • View the Log Files. | Specifically, view the traffic and threat logs (**Monitor > Logs**).<br>Traffic logs are dependent on how your security policies are defined and setup to log traffic. The ACC tab, however, records applications and statistics regardless of policy configuration; it shows all traffic that is allowed on your network, therefore it includes the inter zone traffic that is allowed by policy and the same zone traffic that is allowed implicitly |
| • Interpret the URL Filtering Logs | Review the URL filtering logs to scan through alerts, denied categories/URL. URL logs are generated when a traffic matches a security rule that has a URL filtering profile attached with an action of alert, continue, override or block. |

 © Palo Alto Networks, Inc.

# Enable Basic Threat Prevention Features

The Palo Alto Networks next-generation firewall has unique threat prevention capabilities that allow it to protect your network from attack despite evasive, tunneled, or circumvention techniques. The threat prevention features on the firewall include the WildFire service, the Security Profiles that support Antivirus, Anti-spyware, Vulnerability Protection, URL Filtering, File Blocking and Data Filtering capabilities and the Denial of Service (DoS) and Zone protection functionality.

Before you can apply threat prevention features, you must first configure zones—to identify one or more source or destination interfaces—and security policies. To configure interfaces, zones, and the policies that are needed to apply threat prevention features, see Configure Interfaces and Zones and Set Up Basic Security Policies.

To begin protecting your network from threats start here:

- Enable WildFire
- Scan Traffic for Threats
- Control Access to Web Content

## Enable WildFire

The WildFire service is included as part of the base product. The WildFire service enables the firewall to forward attachments to a sandbox environment where applications are run to detect any malicious activity. As new malware is detected by the WildFire system, malware signatures are automatically generated and are made available within 24-48 hours in the antivirus daily downloads. Your threat prevention subscription entitles you for antivirus signature updates that include signatures discovered by WildFire.

Consider purchasing the WildFire subscription service for these additional benefits:

- Sub-hourly (as often as every 15 minutes) WildFire signature updates
- Advanced file type forwarding (APK, Flash, PDF, Microsoft Office, and Java Applet)
- Ability to upload files using the WildFire API
- Ability to forward files to a private WF-500 WildFire appliance

  While the ability to configure a file blocking profile to forward Portable Executable (PE) files to the WildFire cloud for analysis is free, in order to forward files to a private WildFire appliance, a WildFire subscription is required.

| **Enable WildFire** | | |
|---|---|---|
| Step 1 | Confirm that your device is registered and that you have a valid support account as well as any subscriptions you require. | 1. Go to the Palo Alto Networks Support Site, log in, and select **My Devices**.<br>2. Verify that the firewall is listed. If it is not listed, see Register the Firewall.<br>3. (Optional) Activate Licenses and Subscriptions. |

| Enable WildFire (Continued) | | |
|---|---|---|
| Step 2 | Set the WildFire forwarding options.<br><br> If you do not have a WildFire subscription you can only forward executables. | 1. Select **Device > Setup > WildFire** and edit the General Settings.<br>2. (Optional) Specify the **WildFire Server** to which to forward files. By default, the firewall will forward files to the public WildFire cloud hosted in the United States. To forward files to a different WildFire cloud, enter a new value as follows:<br>• To forward to a private WildFire cloud, enter the IP address or FQDN of your WF-500 WildFire appliance.<br>• To forward files to the public WildFire cloud running in Japan, enter `wildfire.paloaltonetworks.jp`.<br>3. (Optional) If you want to change the maximum file size that the firewall can forward for a specific type of file, modify the value in the corresponding field.<br>4. Click **OK** to save your changes. |
| Step 3 | Set up a file blocking profile to forward files to WildFire. | 1. Select **Objects > Security Profiles > File Blocking** and click **Add**.<br>2. Enter a **Name** and optionally a **Description** for the profile.<br>3. Click **Add** to create a forwarding rule and enter a name.<br>4. In the **Action** column, select **forward**.<br>5. Leave the other fields set to **any** to forward any supported file type from any application.<br>6. Click **OK** to save the profile. |
| Step 4 | Attach the file blocking profile to the security policies that allow access to the Internet. | 1. Select **Policies > Security** and either select an existing policy or create a new policy as described in Create Security Rules.<br>2. Click the **Actions** tab within the security policy.<br>3. In the Profile Settings section, click the drop-down and select the file blocking profile you created for WildFire forwarding. (If you don't see a drop-down for selecting a profile, select **Profiles** from the **Profile Type** drop-down. |
| Step 5 | Save the configuration. | Click **Commit**. |

 © Palo Alto Networks, Inc.

| Enable WildFire (Continued) | |
|---|---|
| Step 6 Verify that the firewall is forwarding files to WildFire. | 1. Select **Monitor > Logs > Data Filtering**.<br>2. Check the **Action** column for the following actions:<br>• **Forward**— Indicates that the file was successfully forwarded by the file blocking profile attached to the security policy.<br>• **Wildfire-upload-success**—Indicates that the file was sent to WildFire. This means the file is not signed by a trusted file signer and it has not been previously analyzed by WildFire.<br>• **Wildfire-upload-skip**—Indicates that the file was identified as eligible to be sent to WildFire by a file blocking profile/security policy, but did not need to be analyzed by WildFire because it has already been analyzed previously. In this case, the action will display as **forward** in the Data Filtering log because it was a valid forward action, but it was not sent to WildFire and analyzed because the file has already been sent to the WildFire cloud from another session, possibly from another firewall.<br>3. View the WildFire logs by selecting **Monitor > Logs > WildFire Submissions**. If new WildFire logs appear, the firewall is successfully forwarding files to WildFire and WildFire is returning file analysis reports. |

## Scan Traffic for Threats

Security Profiles provide threat protection in security policies. For example, you can apply an antivirus profile to a security policy and all traffic that matches the security policy will be scanned for viruses.

The following sections provide steps for setting up a basic threat prevention configuration:

▲ Set Up Antivirus, Anti-Spyware, and Vulnerability Protection

▲ Set Up File Blocking

### Set Up Antivirus, Anti-Spyware, and Vulnerability Protection

Every Palo Alto Networks next-generation firewall comes with predefined Antivirus, Anti-Spyware, and Vulnerability Protection profiles that you can attach to security policies. There is one predefined Antivirus profile, **default**, which uses the default action for each protocol (block HTTP, FTP, and SMB traffic and alert on SMTP, IMAP, and POP3 traffic). There are two predefined Anti-spyware and Zone Protection profiles:

- **default**—Applies the default action to all client and server critical, high, and medium severity spyware/vulnerability protection events. It does not detect low and informational events.
- **strict**—Applies the block response to all client and server critical, high and medium severity spyware/vulnerability protection events and uses the default action for low and informational events.

To ensure that the traffic entering your network is free from threats, attach the predefined profiles to your basic web access policies. As you monitor the traffic on your network and expand your policy rulebase, you can then design more granular profiles to address your specific security needs.

| Set up Antivirus/Anti-Spyware/Vulnerability Protection | | |
|---|---|---|
| Step 1 | Verify that you have a Threat Prevention license. | • The Threat Prevention license bundles the Antivirus, Anti-Spyware, and the Vulnerability Protection features in one license.<br>• Select **Device > Licenses** to verify that the **Threat Prevention** license is installed and valid (check the expiration date). |
| Step 2 | Download the latest antivirus threat signatures. | 1. Select **Device > Dynamic Updates** and click **Check Now** at the bottom of the page to retrieve the latest signatures.<br>2. In the **Actions** column, click **Download** to install the latest Antivirus, and Applications and Threats signatures. |
| Step 3 | Schedule signature updates.<br> Perform a **download-and-install** on a daily basis for antivirus updates and weekly for applications and threats updates. | 1. From **Device > Dynamic Updates**, click the text to the right of **Schedule** to automatically retrieve signature updates for **Antivirus** and **Applications and Threats**.<br>2. Specify the frequency and timing for the updates and whether the update will be downloaded and installed or only downloaded. If you select **Download Only**, you would need to manually go in and click the **Install** link in the **Action** column to install the signature. When you click **OK**, the update is scheduled. No commit is required.<br>3. (Optional) You can also enter the number of hours in the **Threshold** field to indicate the minimum age of a signature before a download will occur. For example, if you entered **10**, the signature must be at least 10 hours old before it will be downloaded, regardless of the schedule.<br>4. In an HA configuration, you can also click the **Sync To Peer** option to synchronize the content update with the HA peer after download/install. This will not push the schedule settings to the peer device, you need to configure the schedule on each device. |

Recommendations for HA Configurations:

- **Active/Passive HA**—If the MGT port is used for antivirus signature downloads, you should configure a schedule on both devices and both devices will download/install independently. If you are using a data port for downloads, the passive device will not perform downloads while it is in the passive state. In this case you would set a schedule on both devices and then select the **Sync To Peer** option. This will ensure that whichever device is active, the updates will occur and will then push to the passive device.
- **Active/Active HA**—If the MGT port is used for antivirus signature downloads on both devices, then schedule the download/install on both devices, but do not select the **Sync To Peer** option. If you are using a data port, schedule the signature downloads on both devices and select **Sync To Peer**. This will ensure that if one device in the active/active configuration goes into the active-secondary state, the active device will download/install the signature and will then push it to the active-secondary device.

 © Palo Alto Networks, Inc.

| Set up Antivirus/Anti-Spyware/Vulnerability Protection (Continued) | |
|---|---|
| Step 4 Attach the security profiles to a security policy.<br><br>Attach a clone of a predefined security profile to your basic security policies. That way, if you want to customize the profile you can do so without deleting the read-only predefined **strict** or **default** profile and attaching a customized profile. | 1. Select **Policies > Security**, select the desired policy to modify it and then click the **Actions** tab.<br>2. In **Profile Settings**, click the drop-down next to each security profile you would like to enable. In this example we choose default for **Antivirus, Vulnerability Protection,** and **Anti-Spyware**.<br><br>If you don't see drop-downs for selecting profiles, select **Profiles** from the **Profile Type** drop-down.<br><br>  |
| Step 5 Save the configuration. | Click **Commit**. |

## Set Up File Blocking

File Blocking Profiles allow you to identify specific file types that you want to want to block or monitor. The following workflow shows how to set up a basic file blocking profile that prevents users from downloading executable files from the Internet.

| Configure File Blocking | | |
|---|---|---|
| Step 1 | Create the file blocking profile. | 1. Select **Objects > Security Profiles > File Blocking** and click **Add**.<br>2. Enter a **Name** for the file blocking profile, for example `Block_EXE`.<br>3. Optionally enter a **Description**, such as `Block users from downloading exe files from websites`. |
| Step 2 | Configure the file blocking options.<br><br>The **forward** and **continue-and-forward** actions are for forwarding files to WildFire only. | 1. Click **Add** to define the profile settings.<br>2. Enter a **Name**, such as `BlockEXE`.<br>3. Set the **Applications** to which to apply file blocking, or leave it set to **any**.<br>4. Set **File Types** to block. For example, to block download of executables, you would select **exe**.<br>5. Specify the **Direction** in which to block files: **download**, **upload**, or **both**.<br>6. Set the **Action** to one of the following:<br>• **continue**—(web traffic only) Files matching the selected criteria will trigger a customizable response page that requires users to click **Continue** in order to proceed with the download/upload. You must enable response pages on the associated interfaces if you plan to use this option (Step 4).<br>• **block**—Files matching the selected criteria will be blocked from download/upload.<br>• **alert**—Files matching the selected criteria will be allowed, but will generate a log entry in the data filtering log.<br> <br>7. Click **OK** to save the profile. |
| Step 3 | Attach the file blocking profile to the security policies that allow access to content. | 1. Select **Policies > Security** and either select an existing policy or create a new policy as described in Create Security Rules.<br>2. Click the **Actions** tab within the security policy.<br>3. In the Profile Settings section, click the drop-down and select the file blocking profile you created.<br>If you don't see drop-downs for selecting profiles, select **Profiles** from the **Profile Type** drop-down. |

 © Palo Alto Networks, Inc.

| Configure File Blocking (Continued) | | |
|---|---|---|
| Step 4 | Enable response pages in the management profile for each interface on which you are attaching file blocking profile with a **continue** action. | 1. Select **Network > Network Profiles > Interface Mgmt** and then select an interface profile to edit or click **Add** to create a new profile.<br>2. Select **Response Pages**, as well as any other management services required on the interface.<br>3. Click **OK** to save the interface management profile.<br>4. Select **Network > Interfaces** and select the interface to which to attach the profile.<br>5. On the **Advanced > Other Info** tab, select the interface management profile you just created.<br>6. Click **OK** to save the interface settings. |
| Step 5 | Test the file blocking configuration. | Access a client PC in the trust zone of the firewall and attempt to download an.exe file from a website in the untrust zone. Make sure the file is blocked as expected based on the action you defined in the file blocking profile:<br>• If you selected **alert** as the action, check the data filtering log to make sure you see a log entry for the request.<br>• If you selected **block** as the action, the File Blocking Block Page response page should display.<br>• If you selected the **continue** action, the File Blocking Continue Page response page should display. Click **Continue** to download the file. The following shows the default File Blocking Continue Page.<br> |

## Control Access to Web Content

URL Filtering provides visibility and control over web traffic on your network. With URL filtering enabled, the firewall can categorize web traffic into one or more (from approximately 60) categories. You can then create policies that specify whether to allow, block, or log (alert) traffic based on the category to which it belongs. The following workflow shows how to enable PAN-DB for URL filtering, create security profiles, and attach them to security policies to enforce a basic URL filtering policy.

| Configure URL Filtering | | |
|---|---|---|
| Step 1 | Confirm license information for URL Filtering. | 1. Obtain and install a URL Filtering license. See Activate Licenses and Subscriptions for details.<br>2. Select **Device > Licenses** and verify that the URL Filtering license is valid.<br> |
| Step 2 | Download the seed database and activate the license. | 1. To download the seed database, click **Download** next to **Download Status** in the PAN-DB URL Filtering section of the Licenses page.<br>2. Choose a region (North America, Europe, APAC, Japan) and then click **OK** to start the download.<br>3. After the download completes, click **Activate**.<br> |
| Step 3 | Create a URL filtering profile.<br> Because the default URL filtering profile blocks risky and threat-prone content, clone this profile when creating a new profile in order to preserve the default settings. | 1. Select **Objects > Security Profiles > URL Filtering**.<br>2. Select the default profile and then click **Clone**. The new profile will be named default-1.<br>3. Select the new profile and rename it. |

 © Palo Alto Networks, Inc.

| Configure URL Filtering (Continued) | |
|---|---|
| Step 4 Define how to control access to web content.<br><br>If you are not sure what traffic you want to control, consider setting the categories (except for those blocked by default) to alert. You can then use the visibility tools on the firewall, such as the ACC and App Scope, to determine which web categories to restrict to specific groups or to block entirely. You can then go back and modify the profile to block and allow categories as desired.<br><br>You can also define specific sites to always allow or always block regardless of category and enable the safe search option to filter search results when defining the URL Filtering profile. | 1. For each category that you want visibility into or control over, select a value from the **Action** column as follows:<br>• If you do not care about traffic to a particular category (that is you neither want to block it nor log it), select **allow**.<br>• For visibility into traffic to sites in a category, select **alert**.<br>• To present a response page to users attempting to access a particular category to alert them to the fact that the content they are accessing might not be work appropriate, select **continue**.<br>• To prevent access to traffic that matches the associated policy, select **block** (this also generates a log entry).<br> <br>2. Click **OK** to save the URL filtering profile. |
| Step 5 Attach the URL filtering profile to a security policy. | 1. Select **Policies > Security**.<br>2. Select the desired policy to modify it and then click the **Actions** tab.<br>3. If this is the first time you are defining a security profile, select **Profiles** from the **Profile Type** drop-down.<br>4. In the **Profile Settings** list, select the profile you just created from the **URL Filtering** drop-down. (If you don't see drop-downs for selecting profiles, select **Profiles** from the **Profile Type** drop-down.)<br>5. Click **OK** to save the profile.<br>6. **Commit** the configuration. |

| Configure URL Filtering (Continued) | | |
|---|---|---|
| Step 6 | Enable Response Pages in the management profile for each interface on which you are filtering web traffic. | 1. Select **Network > Network Profiles > Interface Mgmt** and then select an interface profile to edit or click **Add** to create a new profile.<br>2. Select **Response Pages**, as well as any other management services required on the interface.<br>3. Click **OK** to save the interface management profile.<br>4. Select **Network > Interfaces** and select the interface to which to attach the profile.<br>5. On the **Advanced > Other Info** tab, select the interface management profile you just created.<br>6. Click **OK** to save the interface settings. |
| Step 7 | Save the configuration. | Click **Commit**. |
| Step 8 | Test the URL filtering configuration. | Access a client PC in the trust zone of the firewall and attempt to access a site in a blocked category. Make sure URL filtering is applied based on the action you defined in the URL filtering profile:<br>• If you selected **alert** as the action, check the data filtering log to make sure you see a log entry for the request.<br>• If you selected the **continue** action, the URL Filtering Continue and Override Page response page should display. **Continue** to the site.<br>• If you selected **block** as the action, the URL Filtering and Category Match Block Page response page should display as follows:<br> |

## For More Information

For more detailed information on how to protect your enterprise from threats, see Threat Prevention. For details on how to scan encrypted (SSH or SSL) traffic for threats, see Decryption.

For information about the threats and applications that Palo Alto Networks products can identify, visit the following links:

- Applipedia—Provides details on the applications that Palo Alto Networks can identify.
- Threat Vault—Lists threats that Palo Alto Networks products can identify. You can search by Vulnerability, Spyware, or Virus. Click the Details icon next to the ID number for more information about a threat.

 © Palo Alto Networks, Inc.

# Best Practices for Completing the Firewall Deployment

Now that you have integrated the firewall into your network and enabled the basic security features, you can begin configuring more advanced features. Here are some things to consider next:

- Learn about the different Management Interfaces that are available to you and how to access and use them.
- Set up High Availability—High availability (HA) is a configuration in which two firewalls are placed in a group and their configuration is synchronized to prevent a single point to failure on your network. A heartbeat connection between the firewall peers ensures seamless failover in the event that a peer goes down. Setting up the firewalls in a two-device cluster provides redundancy and allows you to ensure business continuity.
- Configure the Master Key—Every Palo Alto Networks firewall has a default master key that encrypts private keys that are used to authenticate administrators when they access management interfaces on the firewall. As a best practice to safeguard the keys, configure the master key on each firewall to be unique.
- Manage Firewall Administrators—Every Palo Alto Networks firewall and appliance is preconfigured with a default administrative account (admin) that provides full read-write access (also known as superuser access) to the device. As a best practice, create a separate administrative account for each person who needs access to the administrative or reporting functions of the firewall. This allows you to better protect the device from unauthorized configuration (or modification) and to enable logging of the actions of each individual administrator.
- Enable User Identification (User-ID)—User-ID is a Palo Alto Networks next-generation firewall feature that allows you to create policies and perform reporting based on users and groups rather than individual IP addresses.
- Enable Decryption—Palo Alto Networks firewalls provide the capability to decrypt and inspect traffic for visibility, control, and granular security. Use decryption on a firewall to prevent malicious content from entering your network or sensitive content from leaving your network concealed as encrypted or tunneled traffic.
- Enable Passive DNS Collection for Improved Threat Intelligence—Enable this opt-in feature to enable the firewall to act as a passive DNS sensor and send select DNS information to Palo Alto Networks for analysis in order to improve threat intelligence and threat prevention capabilities.
- Follow the Best Practices for Securing Your Network from Layer 4 and Layer 7 Evasions.

© Palo Alto Networks, Inc.

 © Palo Alto Networks, Inc.

# Device Management

Administrators can configure, manage, and monitor the Palo Alto Networks firewalls using the web interface, the CLI, and the API management interfaces. Role-based administrative access to the management interfaces can be customized in order to delegate specific tasks or permissions to certain administrators. See the following topics for information on device management options, including how to begin using the management interfaces and how to customize administrator roles:

- Management Interfaces
- Manage Firewall Administrators
- Reference: Web Interface Administrator Access
- Reference: Port Numbers Used by Palo Alto Networks Devices
- Reset the Firewall to Factory Default Settings

# Management Interfaces

PAN-OS firewalls and Panorama provide three user interfaces: a web interface, a command line interface (CLI), and a XML-based management API. See the following topics for how to access and begin using each of the device management interfaces:

- Use the Web Interface to complete administrative tasks and generate reports from the web interface with relative ease. This graphical interface allows you to access the firewall using HTTPS and it is the best way to perform administrative tasks.
- Use the Command Line Interface (CLI) to type through the commands in rapid succession to complete a series of tasks. The CLI is a no-frills interface that supports two command modes and each mode has its own hierarchy of commands and statements. When you get familiar with the nesting structure and the syntax of the commands, the CLI allows quick response times and offers administrative efficiency.
- Use the XML API to streamline your operations and integrate with existing, internally developed applications and repositories. The XML API is provided as a web service that is implemented using HTTP/HTTPS requests and responses.

 © Palo Alto Networks, Inc.

# Use the Web Interface

The following topics describes how to begin using the firewall web interface. For detailed information about the tabs and fields that are available in the web interface, refer to the Web Interface Reference Guide.

- Launch the Web Interface
- Navigate the Web Interface
- Commit Changes
- Use Configuration Pages
- Required Fields
- Lock Transactions

## Launch the Web Interface

The following web browsers are supported for access to the web interface for PAN-OS firewalls and Panorama:

- Internet Explorer 7+
- Firefox 3.6+
- Safari 5+
- Chrome 11+

Launch an Internet browser and enter the firewall's IP address. Enter your user credentials. If logging in to the firewall for the first time, type the default **admin** into both the **Name** and **Password** fields.

To view information on how to use a specific page and an explanation of the fields and options on the page, click the **Help** icon

in the upper right area of the page to open the online help system. In addition to displaying context-sensitive help for a page, clicking the **Help** icon displays a help navigation pane with options to browse and search all help content.

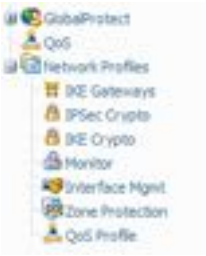
## Navigate the Web Interface

The following conventions apply when using the web interface.

- To display the menu items for a general functional category, click the tab, such as **Objects** or **Device**, near the top of the browser window.

- Click an item on the side menu to display a panel.

- To display submenu items, click the ⊞ icon to the left of an item. To hide submenu items, click the ⊟ icon to the left of the item.

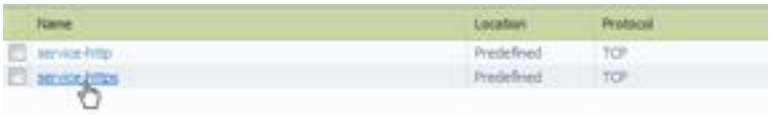


- On most configuration pages, you can click **Add** to create a new item.

- To delete one or more items, select their check boxes and click **Delete**. In most cases, the system prompts you to confirm by clicking **OK** or to cancel the deletion by clicking **Cancel**.

- On some configuration pages, you can select the check box for an item and click **Clone** to create a new item with the same information as the selected item.

- To modify an item, click its underlined link.

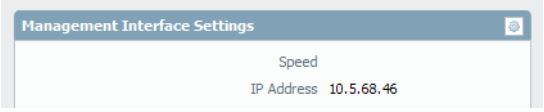


- To view the current list of tasks, click the **Tasks** icon in the lower right corner of the page. The Task Manager window opens to show the list of tasks, along with status, start times, associated messages, and actions. Use the **Show** drop-down to filter the list of tasks.

 © Palo Alto Networks, Inc.

- The web interface language is controlled by the current language of the computer that is managing the device if a specific language preference has not been defined. For example, if the computer you use to manage the firewall has a locale of Spanish, when you log in to the firewall, the web interface will be in Spanish.
- To specify a language that will always be used for a given account regardless of the locale of the computer, click the **Language** icon in the lower right corner of the page and the Language Preference window opens. Click the drop-down to select the desired language and then click **OK** to save your change.

- On pages that list information you can modify (for example, the **Setup** page on the **Devices** tab), click the icon in the upper right corner of a section to edit the settings.



- After you configure settings, you must click **OK** or **Save** to store the changes. When you click **OK**, the current *candidate* configuration is updated.

## Commit Changes

Click **Commit** at the top of the web interface to open the Commit dialog box, which displays the following options. Certain options only display if you click **Advanced**.

If dependencies between the configuration changes you included and excluded cause a validation error, perform the commit with all the changes included. For example, if your changes introduce a new Log Forwarding profile (an object) that references a new Syslog server profile (a device setting), the commit must include both policy and object configurations and device and network configurations.

- **Include Device and Network configuration**—Include the device and network configuration changes in the commit operation.
- **Include Shared Object configuration**—(Multi-virtual system firewalls only) Include the shared object configuration changes in the commit operation.
- **Include Policy and Objects**—(Non-multi-virtual system firewalls only) Include the policy and object configuration changes in the commit operation.
- **Include virtual system configuration**—Include all virtual systems or choose **Select one or more virtual systems**.

- **Preview Changes**—Click this button to bring up a two-pane window that shows proposed changes in the candidate configuration compared to the current running configuration. You can choose the number of lines of context to display, or show all lines. Changes are color coded based on items that you and other administrators added (green), modified (yellow), or deleted (red) since the last commit.

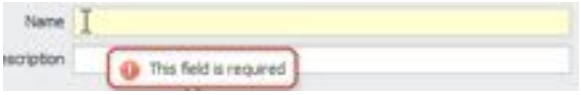
Because the preview results display in a new window, your browser must allow pop-ups. If the preview window does not open, refer to your browser documentation for the steps to unblock pop-ups.

## Use Configuration Pages

The tables on configuration pages include sorting and column chooser options. Click a column header to sort on that column, and click again to change the sort order. Click the arrow to the right of any column and select check boxes to choose the columns to display.

## Required Fields

Required fields are shown with a light yellow background. A message indicating that the field is required appears when you hover over or click in the field entry area.



## Lock Transactions

The web interface provides support for multiple administrators by allowing an administrator to lock a current set of transactions, thereby preventing configuration changes or commit operations by another administrator until the lock is removed. The following types of locks are supported:

- **Config lock**—Blocks other administrators from making changes to the configuration. This type of lock can be set globally or for a virtual system. It can be removed only by the administrator who set it or by a superuser on the system.

 © Palo Alto Networks, Inc.

- **Commit Lock**—Blocks other administrators from committing changes until all of the locks have been released. This type of lock prevents collisions that can occur when two administrators are making changes at the same time and the first administrator finishes and commits changes before the second administrator has finished. The lock is released when the current changes are committed by the administrator who applied the lock, or it can be released manually.

Any administrator can open the lock window to view the current transactions that are locked, along with a time stamp for each.

To lock a transaction, click the unlocked icon on the top bar to open the Locks dialog box. Click **Take a Lock**, select the scope of the lock from the drop-down, and click **OK**. Add additional locks as needed, and then click **Close** to close the Lock dialog box.

The transaction is locked, and the icon on the top bar changes to a locked icon that shows the number of locked items in parentheses.

To unlock a transaction, click the locked icon on the top bar to open the Locks window. Click the icon for the lock that you want to remove, and click **Yes** to confirm. Click **Close** to close the Lock dialog box.

You can arrange to automatically acquire a commit lock by selecting the **Automatically acquire commit lock** check box in the Management area of the **Device Setup** page.

# Use the Command Line Interface (CLI)

The PAN-OS CLI allows you to access Firewall and Panorama devices, view status and configuration information, and modify configurations. Access to the PAN-OS CLI is provided through SSH, Telnet, or direct console access.

The following topics describe how to access and begin using the PAN-OS CLI:

- Access the PAN-OS CLI
- Operational and Configuration Modes

For more information on the CLI, refer to the *PAN-OS Command Line Interface Reference Guide*.

## Access the PAN-OS CLI

You can connect to the CLI on the firewall either directly using a serial cable from your management computer to the Console port, or by opening a Secure Shell (SSH) connection to the firewall MGT port as follows:

| **Access the PAN-OS CLI** | |
|---|---|
| Step 1 | Launch a terminal emulator, such as PuTTY, and open a connection to the firewall using one of the following methods:<br>• **Console Connection**—Connect a serial cable from your computer to the Console port and connect use the terminal emulation software to open a Serial connection to the firewall. The firewall requires that you configure the terminal emulation software with the following settings:<br>  • Data rate: 9600<br>  • Data bits: 8<br>  • Parity: none<br>  • Stop bits: 1<br>  • Flow control: None<br>• **SSH Connection**—Use the terminal emulation software to open an SSH connection (default port 22) to the IP address you assigned to the MGT port during initial configuration. |
| Step 2 | Enter the administrative username. The default is admin. |
| Step 3 | Enter the administrative password. The default is admin. |
| Step 4 | The PAN-OS CLI opens in Operational mode, and the CLI prompt is displayed: |
| Step 5 | `username@hostname>` |

 © Palo Alto Networks, Inc.

## Operational and Configuration Modes

When you log in, the PAN-OS CLI opens in Operational mode. You can move between Operational and Configuration modes at any time. Use Operational mode to view the state of the system, navigate the PAN-OS CLI, and enter configuration mode. Use Configuration mode to view and modify the configuration hierarchy.

- To enter Configuration mode from Operational mode, use the `configure` command:

```
username@hostname> configure
Entering configuration mode
[edit]
username@hostname#
```

- To leave Configuration mode and return to Operational mode, use the `quit` or `exit` command:

```
username@hostname# quit
Exiting configuration mode
username@hostname>
```

- To enter an Operational mode command while in Configuration mode, use the `run` command, for example:

```
username@hostname# run ping host 1.1.1.2
PING 1.1.1.1 (1.1.1.1) 56(84) bytes of data
...
username@hostname#
```

- To direct an Operational mode command to a particular VSYS, specify the target VSYS with the following command:

```
username@hostname# set system setting target-vsys <vsys_name>
```

## Use the XML API

Palo Alto Networks XML API uses standard HTTP requests to send and receive data, allowing access to several types of data on the device so the data can be easily integrated with and used in other systems. Use the XML-based Management API to view a firewall or Panorama's configuration, extract report data in XML format, and execute operational commands. API calls can be made directly from command line utilities such as cURL or wget, or using any scripting or application framework that supports RESTful services. When using the API with command lines tools, both HTTP GET and POST methods are supported.

You must generate an API key in order to use the XML API. The API key authenticates the user to the firewall, application, or Panorama. After you have generated an API key, you can use the key to perform device configuration and operational tasks, retrieve reports and logs, and import and export files. See Generate an API Key for steps to generate an API key.

The following table shows the URL structure for API requests:

| PAN-OS Version | XML API URL Structure |
|---|---|
| Prior to PAN-OS 4.1.0 | http(s)://hostname/esp/restapi.esp?request-parameters-values |
| PAN-OS 4.1.0 and later | http(s)://hostname/api/?request-parameters-values |

URL structure item definitions:

- **hostname**—Device's IP address or Domain name.
- **request-parameters-values**—A series of multiple 'parameter=value' pairs separated by the ampersand character (&). These values can either be keywords or data-values in standard or XML format (response data is always in XML format).

There are APIs for PAN-OS, User-ID, and WildFire products. For more information on how to use the API interface, refer to the PAN-OS XML API Usage Guide. To access the online community for developing scripts, visit: https://live.paloaltonetworks.com/community/devcenter.

### Generate an API Key

In order to use the API to manage a firewall or application, an API key is required to authenticate all API calls. Admin account credentials are used to generate API keys.

As a best practice, create a separate admin account for XML-based administration.

| Generate an API key | |
|---|---|
| Step 1 Create an administrator account. | 1. In the web interface, on the **Device > Administrators** tab, click **Add**.<br>2. Enter a login **Name** for the admin.<br>3. Enter and confirm a **Password** for the admin.<br>4. Click **OK** and **Commit**. |

 © Palo Alto Networks, Inc.

| Generate an API key (Continued) | | |
|---|---|---|
| Step 2 | Request an API key. | Replace the hostname, username and password parameters in the following URL with the appropriate values from your administrator account credentials:<br>http(s)://hostname/api/?type=keygen&user=username&password=password<br>The API key is displayed in an XML block. For example:<br><response status="success"><br><result><br><key>0RgWc42Oi0vDx2WRUIUM6A</key><br></result><br></response> |
| Step 3 | (Optional) Revoke or change an API key.<br>For PAN-OS 4.1.0 and later releases, generating an API key using the same administrator account credentials returns unique API keys every time, and all of the keys are valid.<br>You can choose to revoke and then change an API key associated with an administrator account by changing the password associated with the administrator account. Any API keys that were generated using the previous credentials would no longer be valid. | 1. On the **Device > Adminstrators** tab, open the administrator account associated with the API key.<br>2. Enter and confirm a new **Password** for the administrator account.<br>3. Click **OK** and **Commit**.<br>Any API keys associated with the admin account prior to the password change are revoked upon Commit.<br>4. (Optional) Use the updated administrator account credentials to generate a new API key. See Step 2. |

Example work flow using an API key:

Request an API key by entering the URL with the appropriate values in a web browser:

```
https://10.xx.10.50/esp/restapi.esp?type=keygen&user=admin&password=admin
```

Entering the URL displays an XML block that contains the API key:

```
<response status="success">
  <result>
    <key>0RgWc42Oi0vDx2WRUIUM6A</key>
  </result>
</response>
```

Continue to use the API key to create API requests. For example, to generate a report:

```
https://10.xx.10.50/esp/restapi.esp?type=report&reporttype=dynamic&reportname
=top-app-summary&period=last-hour&topn=5&key=0RgWc42Oi0vDx2WRUIUM6A=
```

# Manage Firewall Administrators

Every Palo Alto Networks firewall and appliance is preconfigured with a default administrative account (admin) that provides full read-write access (also known as superuser access) to the device.

As a best practice, create a separate administrative account for each person who needs access to the administrative or reporting functions of the firewall. This allows you to better protect the device from unauthorized configuration (or modification) and to enable logging of the actions of each individual administrator.

The following topics describe the various ways you can set up administrative accounts and provides procedures for setting up basic administrative access:

- Administrative Roles
- Administrative Authentication
- Create an Administrative Account

## Administrative Roles

The way you configure administrator accounts depends on the security requirements within your organization, whether you have existing authentication services you want to integrate with, and how many different administrative roles you require. A *role* defines the type of access the associated administrator has to the system. There are two types of roles you can assign:

- **Dynamic Roles**—These are built-in roles that provide access to the firewall. When new features are added, the firewall automatically updates the definitions of dynamic roles; you never need to manually update them. The following table lists the access privileges associated with dynamic roles.

| Dynamic Role | Privileges |
|---|---|
| Superuser | Full access to the firewall, including defining new administrator accounts and virtual systems. You must have superuser privileges to create an administrative user with superuser privileges. |
| Superuser (read-only) | Read-only access to the firewall. |
| Virtual system administrator | Full access to a selected virtual system (vsys) on the firewall. |
| Virtual system administrator (read-only) | Read-only access to a selected vsys on the firewall. |
| Device administrator | Full access to all firewall settings except for defining new accounts or virtual systems. |
| Device administrator (read-only) | Read-only access to all firewall settings except password profiles (no access) and administrator accounts (only the logged in account is visible). |

- **Admin Role Profiles**—Custom roles you can configure for more granular access control over the functional areas of the web interface, CLI, and XML API. For example, you can create an Admin Role profile for your operations staff that provides access to the firewall and network configuration areas of the web interface and a separate profile for your security administrators that provides access to security policy definitions, logs, and reports. On a multi-vsys firewall, you can select whether the role defines access for all

 © Palo Alto Networks, Inc.

virtual systems or for a specific vsys. When new features are added to the product, you must update the roles with corresponding access privileges: the firewall does not automatically add new features to custom role definitions. For details on the privileges you can configure for custom administrator roles, see Reference: Web Interface Administrator Access.

## Administrative Authentication

There are four ways you can authenticate administrative users:

- **Local administrator account with local authentication**—Both the administrator account credentials and the authentication mechanisms are local to the firewall. You can further secure the local administrator account by creating a password profile that defines a validity period for passwords and by setting device-wide password complexity settings.
- **Local administrator account with SSL-based authentication**—With this option, you create the administrator accounts on the firewall, but authentication is based on SSH certificates (for CLI access) or client certificates/common access cards (for the web interface). Refer to the article How to Configure Certificate-based Authentication for the WebUI for details on how to configure this type of administrative access.
- **Local administrator account with external authentication**—The administrator accounts are managed on the local firewall, but the authentication functions are offloaded to an existing LDAP, Kerberos, or RADIUS service. To configure this type of account, you must first create an authentication profile that defines how to access the external authentication service and then create an account for each administrator that references the profile.
- **External administrator account and authentication**—Account administration and authentication are handled by an external RADIUS server. To use this option, you must define Vendor Specific Attributes (VSAs) on your RADIUS server that map to the admin role and, optionally, the virtual system objects you have defined on the Palo Alto Networks device. Refer to the Radius Vendor Specific Attributes (VSA) article for details on how to configure this type of administrative access.

## Create an Administrative Account

Create administrative accounts to define access and administrative privileges for firewall administrators. Because it is common to delegate specific administrative tasks to specific administrators with varying roles, Palo Alto Networks recommends that you create admin role profiles that allow administrators access only to the areas of the management interface that are required to perform their jobs. You can assign the various roles you create to individual administrator accounts and specify access privileges to each management interface: the web interface, the Command Line Interface (CLI), and the XML-based Management API. By creating admin roles with very granular access privileges, you can ensure that sensitive company data is protected and end user privacy is ensured.

The following procedure describes how to create a local administrator account with local authentication, including how to set administrator access for each management interface.

© Palo Alto Networks, Inc.

| Create a Local Administrator | |
|---|---|
| Step 1 Create the Admin Role Profiles that you plan to assign to your administrators (this does not apply if you plan to use Dynamic Roles). The Admin Role Profiles define what type of access to give to the different sections of the web interface, CLI, and XML API for each administrator that you assign a role to.<br><br>You can use this step to set particularly granular access privileges for web interface users. For details on what a specific option enables on the **Web UI** tab, see Web Interface Access Privileges. | Complete the following steps for each role you want to create:<br>1. Select **Device > Admin Roles** and then click **Add**.<br>2. Enter a **Name** and optionally a **Description** for the role.<br>3. On the Web UI, Command Line and/or XML API tabs, specify the access to allow for each management interface:<br>• On the **Web UI** and/or **XML API** tabs, set the access levels for each functional area of the interface by clicking the icon to toggle it to the desired setting: Enable, Read Only, or Disable.<br>• On the **Command Line** tab, specify the type of access to allow to the CLI: **superreader**, **deviceadmin**, or **devicereader** (for Device roles); **vsysadmin** or **vsysreader** (for Virtual System roles); or **None** to disable CLI access entirely.<br>4. Click **OK** to save the profile.<br><br>For example, allow an admin full access to a device using the XML API, with the exception of importing or exporting files:<br> |

 © Palo Alto Networks, Inc.

| Create a Local Administrator (Continued) | | |
|---|---|---|
| Step 2 | (Optional) Set requirements for local user-defined passwords. | • **Create Password Profiles**—Define how often administrators must change their passwords. You can create multiple password profiles and apply them to administrator accounts as needed to enforce the desired security. To create a password profile, select **Device > Password Profiles** and then click **Add**.<br>• **Configure minimum password complexity settings**—Define rules that govern password complexity, allowing you to force administrators to create passwords that are harder to guess, crack, or compromise. Unlike password profiles, which can be applied to individual accounts, these rules are device-wide and apply to all passwords. To configure the settings, select **Device > Setup** and then Edit in the Minimum Password Complexity section. |
| Step 3 | Create an account for each administrator. | 1. Select **Device > Administrators** and then click **Add**.<br>2. Enter a user **Name** and **Password** for the administrator, or create an **Authentication Profile** to use for validating an administrative user's credentials to an external authentication server. See Step 4 for details on setting up an authentication profile.<br>3. Select the **Role** to assign to this administrator. You can either select one of the predefined Dynamic roles or a custom Role Based profile if you created one in Step 1.<br>4. (Optional) Select a **Password Profile**.<br>5. Click **OK** to save the account. |

| Create a Local Administrator (Continued) | | |
|---|---|---|
| Step 4 | (Optional) Set up authentication to an external server—LDAP, RADIUS or Kerberos.<br><br>The server profile specifies how the firewall can connect to the authentication service you plan to use. | 1. Select **Device > Authentication Profile** and then click **Add**.<br>2. Enter a user **Name** to identify the authentication profile.<br>3. Define the conditions for locking out the administrative user.<br>a. Enter the **Lockout Time**. This is the number of minutes that a user is locked out upon reaching the maximum number of failed attempts (0-60 minutes; default 0). 0 means that the lockout is in effect until it is manually unlocked.<br>b. Enter the **Failed Attempts** count. This is the number of failed login attempts that are allowed before the account is locked out (1-10; default 0). By default, the failed attempt count is 0 and the user is not locked out despite repeated failure to authenticate.<br>4. Specify the users and groups that are explicitly allowed to authenticate. By adding an **Allow List** to an authentication profile, you can limit access to specific users in a user group/directory.<br>• Select the **All** check box to allow all users.<br>• Click **Add** and enter the first few characters of a name in the field to list all the users and user groups that start with those characters. Repeat to add as many users/user groups as required.<br>5. In the **Authentication** drop-down, select the type of authentication you plan to use on your network.<br>If you plan to use local database authentication, you must create the local database. Select **Device > Local User Database** and add the users and groups to be authenticated.<br>6. For access to an external authentication server (not local database), select the appropriate server profile in the **Server Profile** drop-down. To create a new server profile, click the link next to New and continue with configuring access to the **LDAP**, **RADIUS** or **Kerberos** server.<br>7. Click **OK**. |
| Step 5 | Commit your changes. | 1. Click **Commit**. |

© Palo Alto Networks, Inc.

# Reference: Web Interface Administrator Access

While the privileges associated with dynamic administrator roles are fixed, you can configure privileges at a granular level for custom administrator roles. Configuring privileges at a granular level ensures that lower level administrators cannot access certain information. You can create custom roles for firewall administrators (see Create an Administrative Account), Panorama administrators, or Device Group and Template administrators (refer to the Panorama Administrator's Guide). The following topics describe the privileges you can configure for custom administrator roles.

- Web Interface Access Privileges
- Panorama Web Interface Access

## Web Interface Access Privileges

If you want to prevent a role-based administrator from accessing specific tabs on the web interface, you can disable the tab and the administrator will not even see it when logging in using the associated role-based administrative account. For example, you could create an Admin Role Profile for your operations staff that provides access to the **Device** and **Network** tabs only and a separate profile for your security administrators that provides access to the **Object**, **Policy**, and **Monitor** tabs.

The following table describes the tab-level access privileges you can assign to the admin role profile. It also provides cross-references to additional tables that detail granular privileges within a tab. For specific information on how to set the admin role profile to protect end user privacy, see Define User Privacy Settings in the Admin Role Profile.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Dashboard | Controls access to the **Dashboard** tab. If you disable this privilege, the administrator will not see the tab and will not have access to any of the Dashboard widgets. | Yes | No | Yes |
| ACC | Controls access to the Application Command Center (ACC). If you disable this privilege, the **ACC** tab will not display in the web interface. Keep in mind that if you want to protect the privacy of your users while still providing access to the ACC, you can disable the **Privacy > Show Full Ip Addresses** option and/or the **Show User Names In Logs And Reports** option. | Yes | No | Yes |
| Monitor | Controls access to the **Monitor** tab. If you disable this privilege, the administrator will not see the **Monitor** tab and will not have access to any of the logs, packet captures, session information, reports or to App Scope. For more granular control over what monitoring information the admin can see, leave the Monitor option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Monitor Tab. | Yes | No | Yes |

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Policies | Controls access to the **Policies** tab. If you disable this privilege, the administrator will not see the **Policies** tab and will not have access to any policy information. For more granular control over what policy information the admin can see, for example to enable access to a specific type of policy or to enable read-only access to policy information, leave the **Policies** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Policy Tab. | Yes | No | Yes |
| Objects | Controls access to the **Objects** tab. If you disable this privilege, the administrator will not see the **Objects** tab and will not have access to any objects, security profiles, log forwarding profiles, decryption profiles, or schedules. For more granular control over what objects the admin can see, leave the **Objects** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Objects Tab. | Yes | No | Yes |
| Network | Controls access to the **Network** tab. If you disable this privilege, the administrator will not see the **Network** tab and will not have access to any interface, zone, VLAN, virtual wire, virtual router, IPsec tunnel, DHCP, DNS Proxy, GlobalProtect, or QoS configuration information or to the network profiles. For more granular control over what objects the admin can see, leave the **Network** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Network Tab. | Yes | No | Yes |
| Device | Controls access to the **Device** tab. If you disable this privilege, the administrator will not see the **Device** tab and will not have access to any device-wide configuration information, such as User-ID, High Availability, server profile or certificate configuration information. For more granular control over what objects the admin can see, leave the **Objects** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Device Tab.<br> You cannot enable access to the **Admin Roles** or **Administrators** nodes for a role-based administrator even if you enable full access to the **Device** tab. | Yes | No | Yes |

 © Palo Alto Networks, Inc.

## Provide Granular Access to the Monitor Tab

In some cases you might want to enable the administrator to view some but not all areas of the Monitor tab. For example, you may want to restrict operations admins to the configuration and system logs only, because they do not contain sensitive user data. Although this section of the admin role definition specifies what areas of the Monitor tab the admin can see, you can also couple privileges in this section with privacy privileges, such as disabling the ability to see user names in logs and reports. One thing to keep in mind, however, is that any system-generated reports will still show user names and IP addresses even if you disable that functionality in the role. For this reason, if you do not want the admin to see any of the private user information, you should disable access to the specific reports as detailed in the following table.

The following table lists the **Monitor** tab access levels and the administrator roles for which they are available.

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Monitor | Enables or disables access to the **Monitor** tab. If disabled, the admin will not see this tab or any of the associated logs or reports. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Logs | Enables or disables access to all log files. You can also leave this privilege enabled and then disable specific logs that you do not want the admin to see. Keep in mind that if you want to protect the privacy of your users while still providing access to one or more of the logs, you can disable the **Privacy > Show Full Ip Addresses** option and/or the **Show User Names In Logs And Reports** option. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Traffic | Specifies whether the admin can see the traffic logs. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Threat | Specifies whether the admin can see the threat logs. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| URL Filtering | Specifies whether the admin can see the URL filtering logs. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| WildFire Submissions | Specifies whether the admin can see the WildFire logs. These logs are only available if you have a WildFire subscription. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Data Filtering | Specifies whether the admin can see the data filtering logs. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| HIP Match | Specifies whether the admin can see the HIP Match logs. HIP Match logs are only available if you have a GlobalProtect portal license and gateway subscription. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Configuration | Specifies whether the admin can see the configuration logs. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| System | Specifies whether the admin can see the system logs. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| Alarms | Specifies whether the admin can see system-generated alarms. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Packet Capture | Specifies whether the admin can see packet captures (pcaps) from the **Monitor** tab. Keep in mind that packet captures are raw flow data and as such may contain user IP addresses. Disabling the **Show Full IP Addresses** privileges will not obfuscate the IP address in the pcap and you should therefore disable the Packet Capture privilege if you are concerned about user privacy. | Firewall: Yes<br>Panorama: No<br>Device Group/Template: No | Yes | Yes | Yes |
| App Scope | Specifies whether the admin can see the App Scope visibility and analysis tools. Enabling App Scope enables access to all of the **App Scope** charts. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Session Browser | Specifies whether the admin can browse and filter current running sessions on the firewall. Keep in mind that the session browser shows raw flow data and as such may contain user IP addresses. Disabling the **Show Full IP Addresses** privileges will not obfuscate the IP address in the session browser and you should therefore disable the **Session Browser** privilege if you are concerned about user privacy. | Firewall: Yes<br>Panorama: No<br>Device Group/Template: No | Yes | No | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Botnet | Specifies whether the admin can generate and view botnet analysis reports or view botnet reports in read-only mode. Disabling the **Show Full IP Addresses** privileges will not obfuscate the IP address in scheduled botnet reports and you should therefore disable the **Botnet** privilege if you are concerned about user privacy. | Firewall: Yes<br>Panorama: No<br>Device Group/Template: No | Yes | Yes | Yes |
| PDF Reports | Enables or disables access to all PDF reports. You can also leave this privilege enabled and then disable specific PDF reports that you do not want the admin to see. Keep in mind that if you want to protect the privacy of your users while still providing access to one or more of the reports, you can disable the **Privacy > Show Full Ip Addresses** option and/or the **Show User Names In Logs And Reports** option. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| Manage PDF Summary | Specifies whether the admin can view, add or delete PDF summary report definitions. With read-only access, the admin can see PDF summary report definitions, but not add or delete them. If you disable this option, the admin can neither view the report definitions nor add/delete them. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| PDF Summary Reports | Specifies whether the admin can see the generated PDF Summary reports in **Monitor > Reports**. If you disable this option, the **PDF Summary Reports** category will not display in the **Reports** node. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| User Activity Report | Specifies whether the admin can view, add or delete User Activity report definitions and download the reports. With read-only access, the admin can see User Activity report definitions, but not add, delete, or download them. If you disable this option, the admin cannot see this category of PDF report. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Report Groups | Specifies whether the admin can view, add or delete report group definitions. With read-only access, the admin can see report group definitions, but not add or delete them. If you disable this option, the admin cannot see this category of PDF report. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Email Scheduler | Specifies whether the admin can schedule report groups for email. Because the generated reports that get emailed may contain sensitive user data that is not removed by disabling the **Privacy > Show Full Ip Addresses** option and/or the **Show User Names In Logs And Reports** options and because they may also show log data to which the admin does not have access, you should disable the **Email Scheduler** option if you have user privacy requirements. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Manage Custom Reports | Enables or disables access to all Custom report functionality. You can also leave this privilege enabled and then disable specific custom report categories that you do not want the admin to be able to access. Keep in mind that if you want to protect the privacy of your users while still providing access to one or more of the reports, you can disable the **Privacy > Show Full Ip Addresses** option and/or the **Show User Names In Logs And Reports** option.<br> Reports that are scheduled to run rather than run on demand will show IP address and user information. In this case, be sure to restrict access to the corresponding report areas. In addition, the custom report feature does not restrict the ability to generate reports that contain log data contained in logs that are excluded from the admin role. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| Application Statistics | Specifies whether the admin can create a custom report that includes data from the application statistics database. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| Data Filtering Log | Specifies whether the admin can create a custom report that includes data from the data filtering log. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| Threat Log | Specifies whether the admin can create a custom report that includes data from the threat log. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Threat Summary | Specifies whether the admin can create a custom report that includes data from the threat summary database. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| Traffic Log | Specifies whether the admin can create a custom report that includes data from the traffic log. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| Traffic Summary | Specifies whether the admin can create a custom report that includes data from the traffic summary database. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| Url Log | Specifies whether the admin can create a custom report that includes data from the URL filtering log. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| Hipmatch | Specifies whether the admin can create a custom report that includes data from the HIP match log. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| View Scheduled Custom Reports | Specifies whether the admin can view a custom report that has been scheduled to generate. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| View Predefined Application Reports | Specifies whether the admin can view Application Reports. Privacy privileges do not impact reports available on the **Monitor > Reports** node and you should therefore disable access to the reports if you have user privacy requirements. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| View Predefined Threat Reports | Specifies whether the admin can view Threat Reports. Privacy privileges do not impact reports available on the **Monitor > Reports** node and you should therefore disable access to the reports if you have user privacy requirements. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| View Predefined URL Filtering Reports | Specifies whether the admin can view URL Filtering Reports. Privacy privileges do not impact reports available on the **Monitor > Reports** node and you should therefore disable access to the reports if you have user privacy requirements. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| View Predefined Traffic Reports | Specifies whether the admin can view Traffic Reports. Privacy privileges do not impact reports available on the **Monitor > Reports** node and you should therefore disable access to the reports if you have user privacy requirements. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |

## Provide Granular Access to the Policy Tab

If you enable the Policy option in the admin role profile, you can then enable, disable, or provide read-only access to specific nodes within the tab as necessary for the admin role you are defining. By enabling access to a specific policy type, you enable the ability to view, add, or delete policy rules. By enabling read-only access to a specific policy, you enable the admin to view the corresponding policy rule base, but not add or delete rules. Disabling access to a specific type of policy prevents the admin from seeing the policy rule base.

Because policy that is based on specific users (by user name or IP address) must be explicitly defined, privacy settings that disable the ability to see full IP addresses or user names do not apply to the Policy tab. Therefore, you should only allow access to the Policy tab to administrators that are excluded from user privacy restrictions.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Security | Enable this privilege to allow the admin to view, add, and/or delete security policy rules. Set the privilege to read only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the security policy rule base, disable this privilege. | Yes | Yes | Yes |
| NAT | Enable this privilege to allow the admin to view, add, and/or delete NAT policy rules. Set the privilege to read only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the NAT policy rule base, disable this privilege. | Yes | Yes | Yes |
| QoS | Enable this privilege to allow the admin to view, add, and/or delete QoS policy rules. Set the privilege to read only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the QoS policy rule base, disable this privilege. | Yes | Yes | Yes |
| Policy Based Forwarding | Enable this privilege to allow the admin to view, add, and/or delete Policy-Based Forwarding (PBF) policy rules. Set the privilege to read only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the PBF policy rule base, disable this privilege. | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Decryption | Enable this privilege to allow the admin to view, add, and/or delete decryption policy rules. Set the privilege to read only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the decryption policy rule base, disable this privilege. | Yes | Yes | Yes |
| Application Override | Enable this privilege to allow the admin to view, add, and/or delete application override policy rules. Set the privilege to read only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the application override policy rule base, disable this privilege. | Yes | Yes | Yes |
| Captive Portal | Enable this privilege to allow the admin to view, add, and/or delete captive portal policy rules. Set the privilege to read only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the captive portal policy rule base, disable this privilege. | Yes | Yes | Yes |
| DoS Protection | Enable this privilege to allow the admin to view, add, and/or delete DoS protection policy rules. Set the privilege to read only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the DoS protection policy rule base, disable this privilege. | Yes | Yes | Yes |

## Provide Granular Access to the Objects Tab

An *object* is a container that groups specific policy filter values—such as IP addresses, URLs, applications, or services—for simplified rule definition. For example, an address object might contain specific IP address definitions for the web and application servers in your DMZ zone.

When deciding whether to allow access to the objects tab as a whole, determine whether the admin will have policy definition responsibilities. If not, the admin probably does not need access to the tab. If, however, the admin will need to create policy, you can enable access to the tab and then provide granular access privileges at the node level.

By enabling access to a specific node, you give the admin the privilege to view, add, and delete the corresponding object type. Giving read-only access allows the admin to view the already defined objects, but not create or delete any. Disabling a node prevents the admin from seeing the node in the web interface.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Addresses | Specifies whether the admin can view, add, or delete address objects for use in security policy. | Yes | Yes | Yes |
| Address Groups | Specifies whether the admin can view, add, or delete address group objects for use in security policy. | Yes | Yes | Yes |

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Regions | Specifies whether the admin can view, add, or delete regions objects for use in security, decryption, or DoS policy. | Yes | Yes | Yes |
| Applications | Specifies whether the admin can view, add, or delete application objects for use in policy. | Yes | Yes | Yes |
| Application Groups | Specifies whether the admin can view, add, or delete application group objects for use in policy. | Yes | Yes | Yes |
| Application Filters | Specifies whether the admin can view, add, or delete application filters for simplification of repeated searches. | Yes | Yes | Yes |
| Services | Specifies whether the admin can view, add, or delete service objects for use in creating policies that limit the port numbers an application can use. | Yes | Yes | Yes |
| Service Groups | Specifies whether the admin can view, add, or delete service group objects for use in security policy. | Yes | Yes | Yes |
| Tags (Panorama only) | Specifies whether the admin can view, add, or delete tags that have been defined on the device. | Yes | Yes | Yes |
| GlobalProtect | Specifies whether the admin can view, add, or delete HIP objects and profiles. You can restrict access to both types of objects at the GlobalProtect level, or provide more granular control by enabling the GlobalProtect privilege and restricting HIP Object or HIP Profile access. | Yes | No | Yes |
| HIP Objects | Specifies whether the admin can view, add, or delete HIP objects, which are used to define HIP profiles. HIP Objects also generate HIP Match logs. | Yes | Yes | Yes |
| HIP Profiles | Specifies whether the admin can view, add, or delete HIP Profiles for use in security policy and/or for generating HIP Match logs. | Yes | Yes | Yes |
| Dynamic Block Lists | Specifies whether the admin can view, add, or delete dynamic block lists for use in security policy. | Yes | Yes | Yes |
| Custom Objects | Specifies whether the admin can see the custom spyware and vulnerability signatures. You can restrict access to either enable or disable access to all custom signatures at this level, or provide more granular control by enabling the Custom Objects privilege and then restricting access to each type of signature. | Yes | No | Yes |
| Data Patterns | Specifies whether the admin can view, add, or delete custom data pattern signatures for use in creating custom vulnerability protection profiles. | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Spyware | Specifies whether the admin can view, add, or delete custom spyware signatures for use in creating custom vulnerability protection profiles. | Yes | Yes | Yes |
| Vulnerability | Specifies whether the admin can view, add, or delete custom vulnerability signatures for use in creating custom vulnerability protection profiles. | Yes | Yes | Yes |
| URL Category | Specifies whether the admin can view, add, or delete custom URL categories for use in policy. | Yes | Yes | Yes |
| Security Profiles | Specifies whether the admin can see security profiles. You can restrict access to either enable or disable access to all security profiles at this level, or provide more granular control by enabling the Security Profiles privilege and then restricting access to each type of profile. | Yes | No | Yes |
| Antivirus | Specifies whether the admin can view, add, or delete antivirus profiles. | Yes | Yes | Yes |
| Anti-Spyware | Specifies whether the admin can view, add, or delete anti-spyware profiles. | Yes | Yes | Yes |
| Vulnerability Protection | Specifies whether the admin can view, add, or delete vulnerability protection profiles. | Yes | Yes | Yes |
| URL Filtering | Specifies whether the admin can view, add, or delete URL filtering profiles. | Yes | Yes | Yes |
| File Blocking | Specifies whether the admin can view, add, or delete file blocking profiles. | Yes | Yes | Yes |
| Data Filtering | Specifies whether the admin can view, add, or delete data filtering profiles. | Yes | Yes | Yes |
| DoS Protection | Specifies whether the admin can view, add, or delete DoS protection profiles. | Yes | Yes | Yes |
| Security Profile Groups | Specifies whether the admin can view, add, or delete security profile groups. | Yes | Yes | Yes |
| Log Forwarding | Specifies whether the admin can view, add, or delete log forwarding profiles. | Yes | Yes | Yes |
| Decryption Profile | Specifies whether the admin can view, add, or delete decryption profiles. | Yes | Yes | Yes |
| Schedules | Specifies whether the admin can view, add, or delete schedules for limiting a security policy to a specific date and/or time range. | Yes | Yes | Yes |

## Provide Granular Access to the Network Tab

When deciding whether to allow access to the **Network** tab as a whole, determine whether the admin will have network administration responsibilities, including GlobalProtect administration. If not, the admin probably does not need access to the tab.

You can also define access to the **Network** tab at the node level. By enabling access to a specific node, you give the admin the privilege to view, add, and delete the corresponding network configurations. Giving read-only access allows the admin to view the already-defined configuration, but not create or delete any. Disabling a node prevents the admin from seeing the node in the web interface.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Interfaces | Specifies whether the admin can view, add, or delete interface configurations. | Yes | Yes | Yes |
| Zones | Specifies whether the admin can view, add, or delete zones. | Yes | Yes | Yes |
| VLANs | Specifies whether the admin can view, add, or delete VLANs. | Yes | Yes | Yes |
| Virtual Wires | Specifies whether the admin can view, add, or delete virtual wires. | Yes | Yes | Yes |
| Virtual Routers | Specifies whether the admin can view, add, modify or delete virtual routers. | Yes | Yes | Yes |
| IPSec Tunnels | Specifies whether the admin can view, add, modify, or delete IPSec Tunnel configurations. | Yes | Yes | Yes |
| DHCP | Specifies whether the admin can view, add, modify, or delete DHCP server and DHCP relay configurations. | Yes | Yes | Yes |
| DNS Proxy | Specifies whether the admin can view, add, modify, or delete DNS proxy configurations. | Yes | Yes | Yes |
| GlobalProtect | Specifies whether the admin can view, add, modify GlobalProtect portal and gateway configurations. You can disable access to the GlobalProtect functions entirely, or you can enable the GlobalProtect privilege and then restrict the role to either the portal or gateway configuration areas. | Yes | No | Yes |
| Portals | Specifies whether the admin can view, add, modify, or delete GlobalProtect portal configurations. | Yes | Yes | Yes |
| Gateways | Specifies whether the admin can view, add, modify, or delete GlobalProtect gateway configurations. | Yes | Yes | Yes |
| MDM | Specifies whether the admin can view add, modify, or delete GlobalProtect MDM server configurations. | Yes | Yes | Yes |
| QoS | | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Network Profiles | Sets the default state to enable or disable for all of the Network settings described below. | Yes | No | Yes |
| IKE Gateways | Controls access to the **Network Profiles > IKE Gateways** node. If you disable this privilege, the administrator will not see the **IKE Gateways** node or define gateways that include the configuration information necessary to perform IKE protocol negotiation with peer gateway.<br>If the privilege state is set to read only, you can view the currently configured IKE Gateways but cannot add or edit gateways. | Yes | Yes | Yes |
| IPSec Crypto | Controls access to the **Network Profiles > IPSec Crypto** node. If you disable this privilege, the administrator will not see the **Network Profiles > IPSec Crypto** node or specify protocols and algorithms for identification, authentication, and encryption in VPN tunnels based on IPSec SA negotiation.<br>If the privilege state is set to read only, you can view the currently configured IPSec Crypto configuration but cannot add or edit a configuration. | Yes | Yes | Yes |
| IKE Crypto | Controls how devices exchange information to ensure secure communication. Specify the protocols and algorithms for identification, authentication, and encryption in VPN tunnels based on IPsec SA negotiation (IKEv1 Phase-1). | Yes | Yes | Yes |
| Monitor | Controls access to the **Network Profiles > Monitor** node. If you disable this privilege, the administrator will not see the **Network Profiles > Monitor** node or be able to create or edit a monitor profile that is used to monitor IPSec tunnels and monitor a next-hop device for policy-based forwarding (PBF) rules.<br>If the privilege state is set to read only, you can view the currently configured monitor profile configuration but cannot add or edit a configuration. | Yes | Yes | Yes |
| Interface Mgmt | Controls access to the **Network Profiles > Interface Mgmt** node. If you disable this privilege, the administrator will not see the **Network Profiles > Interface Mgmt** node or be able to specify the protocols that are used to manage the firewall.<br>If the privilege state is set to read only, you can view the currently configured Interface management profile configuration but cannot add or edit a configuration. | Yes | Yes | Yes |

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Zone Protection | Controls access to the **Network Profiles > Zone Protection** node. If you disable this privilege, the administrator will not see the **Network Profiles > Zone Protection** node or be able to configure a profile that determines how the firewall responds to attacks from specified security zones.<br>If the privilege state is set to read only, you can view the currently configured Zone Protection profile configuration but cannot add or edit a configuration. | Yes | Yes | Yes |
| QoS Profile | Controls access to the **Network Profiles > QoS** node. If you disable this privilege, the administrator will not see the **Network Profiles > QoS** node or be able to configure a profile QoS profile that determines how QoS traffic classes are treated.<br>If the privilege state is set to read only, you can view the currently configured QoS profile configuration but cannot add or edit a configuration. | Yes | Yes | Yes |

## Provide Granular Access to the Device Tab

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Setup | Controls access to the **Setup** node. If you disable this privilege, the administrator will not see the **Setup** node or have access to device-wide setup configuration information, such as Management, Operations, Service, Content-ID, Wildfire or Session setup information.<br>If the privilege state is set to read only, you can view the current configuration but cannot make any changes. | Yes | Yes | Yes |
| Config Audit | Controls access to the **Config Audit** node. If you disable this privilege, the administrator will not see the **Config Audit** node or have access to any device-wide configuration information. | Yes | No | Yes |
| Admin Roles | Controls access to the **Admin Roles** node. This function can only be allowed for read only access.<br>If you disable this privilege, the administrator will not see the **Admin Roles** node or have access to any device-wide information concerning admin roles configuration.<br>If you set this privilege to read only, you can view the configuration information for all admin roles configured on the device. | No | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Administrators | Controls access to the **Administrators** node. This function can only be allowed for read only access.<br>If you disable this privilege, the administrator will not see the **Administrators** node or have access to information about their own admin account.<br>If you set this privilege to read only, the administrator can view the configuration information for their own admin account. They will not see any information about other admin accounts configured on the device. | No | Yes | Yes |
| Virtual Systems | Controls access to the **Virtual Systems** node. If you disable this privilege, the administrator will not see or be able to configure virtual systems.<br>If the privilege state is set to read only, you can view the currently configured virtual systems but cannot add or edit a configuration. | Yes | Yes | Yes |
| Shared Gateways | Controls access to the **Shared Gateways** node. Shared gateways allow virtual systems to share a common interface for external communications.<br>If you disable this privilege, the administrator will not see or be able to configure shared gateways.<br>If the privilege state is set to read only, you can view the currently configured shared gateways but cannot add or edit a configuration. | Yes | Yes | Yes |
| User Identification | Controls access to the **User Identification** node. If you disable this privilege, the administrator will not see the **User Identification** node or have access to device-wide User Identification configuration information, such as User Mapping, User-ID Agents, Service, Terminal Services Agents, Group Mappings Settings or Captive Portal Settings.<br>If you set this privilege to read only, the administrator can view configuration information for the device but is not allowed to perform any configuration procedures. | Yes | Yes | Yes |
| VM Information Source | Controls access to the **VM Information Source** node that allows you to configure the firewall/Windows User-ID agent to collect VM inventory automatically. If you disable this privilege, the administrator will not see the **VM Information Source** node.<br>If you set this privilege to read only, the administrator can view the VM information sources configured but cannot add, edit, or delete any sources.<br>This privilege is not available to Device Group and Template administrators. | Yes | Yes | Yes |

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| High Availability | Controls access to the **High Availability** node. If you disable this privilege, the administrator will not see the **High Availability** node or have access to device-wide high availability configuration information such as General setup information or Link and Path Monitoring.<br>If you set this privilege to read only, the administrator can view High Availability configuration information for the device but is not allowed to perform any configuration procedures. | Yes | Yes | Yes |
| Certificate Management | Sets the default state to enable or disable for all of the Certificate settings described below. | Yes | No | Yes |
| Certificates | Controls access to the **Certificates** node. If you disable this privilege, the administrator will not see the **Certificates** node or be able to configure or access information regarding Device Certificates or Default Trusted Certificate Authorities.<br>If you set this privilege to read only, the administrator can view Certificate configuration information for the device but is not allowed to perform any configuration procedures. | Yes | Yes | Yes |
| Certificate Profile | Controls access to the **Certificate Profile** node. If you disable this privilege, the administrator will not see the **Certificate Profile** node or be able to create certificate profiles.<br>If you set this privilege to read only, the administrator can view Certificate Profiles that are currently configured for the device but is not allowed to create or edit a certificate profile. | Yes | Yes | Yes |
| OCSP Responder | Controls access to the **OCSP Responder** node. If you disable this privilege, the administrator will not see the **OCSP Responder** node or be able to define a server that will be used to verify the revocation status of certificates issues by the PAN-OS device.<br>If you set this privilege to read only, the administrator can view the **OCSP Responder** configuration for the device but is not allowed to create or edit an OCSP responder configuration. | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Response Pages | Controls access to the **Response Pages** node. If you disable this privilege, the administrator will not see the **Response Page** node or be able to define a custom HTML message that is downloaded and displayed instead of a requested web page or file.<br>If you set this privilege to read only, the administrator can view the **Response Page** configuration for the device but is not allowed to create or edit a response page configuration. | Yes | Yes | Yes |
| Log Settings | Sets the default state to enable or disable for all of the Log settings described below. | Yes | No | Yes |
| System | Controls access to the **Log Settings > System** node. If you disable this privilege, the administrator will not see the **Log Settings > System** node or be able to specify the severity levels of the system log entries that are logged remotely with Panorama and sent as SNMP traps, syslog messages, and/or email notifications.<br>If you set this privilege to read only, the administrator can view the **Log Settings > System** configuration for the device but is not allowed to create or edit a configuration. | Yes | Yes | Yes |
| Config | Controls access to the **Log Settings > Config** node. If you disable this privilege, the administrator will not see the **Log Settings > Config** node or be able to specify the configuration log entries that are logged remotely with Panorama, and sent as syslog messages and/or email notification.<br>If you set this privilege to read only, the administrator can view the **Log Settings > Config** configuration for the device but is not allowed to create or edit a configuration. | Yes | Yes | Yes |
| HIP Match | Controls access to the **Log Settings > HIP Match** node. If you disable this privilege, the administrator will not see the **Log Settings > HIP Match** node or be able to specify the Host Information Profile (HIP) match log settings that are used to provide information on security policies that apply to GlobalProtect clients<br>If you set this privilege to read only, the administrator can view the **Log Settings > HIP** configuration for the device but is not allowed to create or edit a configuration. | Yes | Yes | Yes |

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Alarms | Controls access to the **Log Settings > Alarms** node. If you disable this privilege, the administrator will not see the **Log Settings > Alarms** node or be able to configure notifications that are generated when a security rule (or group of rules) has been hit repeatedly in a set period of time.<br>If you set this privilege to read only, the administrator can view the **Log Settings > Alarms** configuration for the device but is not allowed to create or edit a configuration. | Yes | Yes | Yes |
| Manage Logs | Controls access to the **Log Settings > Manage Logs** node. If you disable this privilege, the administrator will not see the **Log Settings > Manage Logs** node or be able to clear the indicated logs.<br>If you set this privilege to read only, the administrator can view the **Log Settings > Manage Logs** information but cannot clear any of the logs. | Yes | Yes | Yes |
| Server Profiles | Sets the default state to enable or disable for all of the Server Profiles settings described below. | Yes | No | Yes |
| SNMP Trap | Controls access to the **Server Profiles > SNMP Trap** node. If you disable this privilege, the administrator will not see the **Server Profiles > SNMP Trap** node or be able to specify one or more SNMP trap destinations to be used for system log entries.<br>If you set this privilege to read only, the administrator can view the **Server Profiles > SNMP Trap Logs** information but cannot specify SNMP trap destinations. | Yes | Yes | Yes |
| Syslog | Controls access to the **Server Profiles > Syslog** node. If you disable this privilege, the administrator will not see the **Server Profiles > Syslog** node or be able to specify one or more syslog servers.<br>If you set this privilege to read only, the administrator can view the **Server Profiles > Syslog** information but cannot specify syslog servers. | Yes | Yes | Yes |
| Email | Controls access to the **Server Profiles > Email** node. If you disable this privilege, the administrator will not see the **Server Profiles > Email** node or be able to configure an email profile that can be used to enable email notification for system and configuration log entries<br>If you set this privilege to read only, the administrator can view the **Server Profiles > Email** information but cannot configure and email profile. | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Netflow | Controls access to the **Server Profiles > Netflow** node. If you disable this privilege, the administrator will not see the **Server Profiles > Netflow** node or be able to define a NetFlow server profile, which specifies the frequency of the export along with the NetFlow servers that will receive the exported data.<br>If you set this privilege to read only, the administrator can view the **Server Profiles > Netflow** information but cannot define a Netflow profile. | Yes | Yes | Yes |
| RADIUS | Controls access to the **Server Profiles > RADIUS** node. If you disable this privilege, the administrator will not see the **Server Profiles > RADIUS** node or be able to configure settings for the RADIUS servers that are identified in authentication profiles.<br>If you set this privilege to read only, the administrator can view the **Server Profiles > RADIUS** information but cannot configure settings for the RADIUS servers. | Yes | Yes | Yes |
| LDAP | Controls access to the **Server Profiles > LDAP** node. If you disable this privilege, the administrator will not see the **Server Profiles > LDAP** node or be able to configure settings for the LDAP servers to use for authentication by way of authentication profiles.<br>If you set this privilege to read only, the administrator can view the **Server Profiles > LDAP** information but cannot configure settings for the LDAP servers. | Yes | Yes | Yes |
| Kerberos | Controls access to the **Server Profiles > Kerberos** node. If you disable this privilege, the administrator will not see the **Server Profiles > Kerberos** node or configure a Kerberos server that allows users to authenticate natively to a domain controller.<br>If you set this privilege to read only, the administrator can view the **Server Profiles > Kerberos** information but cannot configure settings for Kerberos servers. | Yes | Yes | Yes |
| Local User Database | Sets the default state to enable or disable for all of the Local User Database settings described below. | Yes | No | Yes |
| Users | Controls access to the **Local User Database > Users** node. If you disable this privilege, the administrator will not see the **Local User Database > Users** node or set up a local database on the firewall to store authentication information for remote access users, device administrators, and captive portal users.<br>If you set this privilege to read only, the administrator can view the **Local User Database > Users** information but cannot set up a local database on the firewall to store authentication information. | Yes | Yes | Yes |

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| User Groups | Controls access to the **Local User Database > Users** node. If you disable this privilege, the administrator will not see the **Local User Database > Users** node or be able to add user group information to the local database.<br>If you set this privilege to read only, the administrator can view the **Local User Database > Users** information but cannot add user group information to the local database. | Yes | Yes | Yes |
| Authentication Profile | Controls access to the **Authentication Profile** node. If you disable this privilege, the administrator will not see the **Authentication Profile** node or be able to create or edit authentication profiles that specify local database, RADIUS, LDAP, or Kerberos settings that can be assigned to administrator accounts.<br>If you set this privilege to read only, the administrator can view the **Authentication Profile** information but cannot create or edit an authentication profile. | Yes | Yes | Yes |
| Authentication Sequence | Controls access to the **Authentication Sequence** node. If you disable this privilege, the administrator will not see the **Authentication Sequence** node or be able to create or edit an authentication sequence.<br>If you set this privilege to read only, the administrator can view the **Authentication Profile** information but cannot create or edit an authentication sequence. | Yes | Yes | Yes |
| Access Domain | Controls access to the **Access Domain** node. If you disable this privilege, the administrator will not see the **Access Domain** node or be able to create or edit an access domain.<br>If you set this privilege to read only, the administrator can view the **Access Domain** information but cannot create or edit an access domain. | Yes | Yes | Yes |
| Scheduled Log Export | Controls access to the **Scheduled Log Export** node. If you disable this privilege, the administrator will not see the **Scheduled Log Export** node or be able schedule exports of logs and save them to a File Transfer Protocol (FTP) server in CSV format or use Secure Copy (SCP) to securely transfer data between the device and a remote host.<br>If you set this privilege to read only, the administrator can view the **Scheduled Log Export Profile** information but cannot schedule the export of logs. | Yes | No | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Software | Controls access to the **Software** node. If you disable this privilege, the administrator will not see the **Software** node or view the latest versions of the PAN-OS software available from Palo Alto Networks, read the release notes for each version, and select a release to download and install.<br>If you set this privilege to read only, the administrator can view the **Software** information but cannot download or install software. | Yes | Yes | Yes |
| GlobalProtect Client | Controls access to the **GlobalProtect Client** node. If you disable this privilege, the administrator will not see the **GlobalProtect Client** node or view available GlobalProtect releases, download the code or activate the GlobalProtect agent.<br>If you set this privilege to read only, the administrator can view the available **GlobalProtect Client** releases but cannot download or install the agent software. | Yes | Yes | Yes |
| Dynamic Updates | Controls access to the **Dynamic Updates** node. If you disable this privilege, the administrator will not see the **Dynamic Updates** node or be able to view the latest updates, read the release notes for each update, or select an update to upload and install.<br>If you set this privilege to read only, the administrator can view the available **Dynamic Updates** releases, read the release notes but cannot upload or install the software. | Yes | Yes | Yes |
| Licenses | Controls access to the **Licenses** node. If you disable this privilege, the administrator will not see the **Licenses** node or be able to view the licenses installed or activate licenses.<br>If you set this privilege to read only, the administrator can view the installed **Licenses**, but cannot perform license management functions. | Yes | Yes | Yes |
| Support | Controls access to the **Support** node. If you disable this privilege, the administrator will not see the **Support** node or be able to access product and security alerts from Palo Alto Networks or generate tech support or stats dump files.<br>If you set this privilege to read only, the administrator can view the **Support** node and access product and security alerts but cannot generate tech support or stats dump files. | Yes | Yes | Yes |

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Master Key and Diagnostics | Controls access to the **Master Key and Diagnostics** node. If you disable this privilege, the administrator will not see the **Master Key and Diagnostics** node or be able to specify a master key to encrypt private keys on the firewall.<br>If you set this privilege to read only, the administrator can view the **Master Key and Diagnostics** node and view information about master keys that have been specified but cannot add or edit a new master key configuration. | Yes | Yes | Yes |

## Define User Privacy Settings in the Admin Role Profile

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Privacy | Sets the default state to enable or disable for all of the privacy settings described below. | Yes | N/A | Yes |
| Show Full IP addresses | When set to disable, full IP addresses obtained by traffic running through the Palo Alto firewall are not shown in logs or reports. In place of the IP addresses that are normally displayed, the relevant subnet is displayed.<br>Scheduled reports that are displayed in the interface through **Monitor > Reports** and reports that are sent via scheduled emails will still display full IP addresses. Because of this exception, we recommend that the following settings within the **Monitor** tab be set to disable: Custom Reports, Application Reports, Threat Reports, URL Filtering Reports, Traffic Reports and Email Scheduler. | Yes | N/A | Yes |
| Show User Names in Logs and Reports | When set to disable, user names obtained by traffic running through the Palo Alto Networks firewall are not shown in logs or reports. Columns where the user names would normally be displayed are empty.<br>Scheduled reports that are displayed in the interface through **Monitor > Reports** or reports that are sent via the email scheduler will still display user names. Because of this exception, we recommend that the following settings within the Monitor tab be set to disable: Custom Reports, Application Reports, Threat Reports, URL Filtering Reports, Traffic Reports and Email Scheduler. | Yes | N/A | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| View Pcap Files | When set to disable, packet capture files that are normally available within the Traffic, Threat and Data Filtering logs are not displayed. | Yes | N/A | Yes |

## Restrict Admin Access to Commit Functions

**Restrict User Access Using the Commit Setting**

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Commit | When set to disable, an admin cannot commit any changes to a configuration. | Yes | N/A | Yes |

## Provide Granular Access to Global Settings

**Restrict User Access Using the Global Settings**

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Global | Sets the default state to enable or disable for all of the global settings described below. In effect, this setting is only for System Alarms at this time. | Yes | N/A | Yes |
| System Alarms | When set to disable, an admin cannot view or acknowledge alarms that are generated. | Yes | N/A | Yes |

## Provide Granular Access to the Panorama Tab

The following table lists the **Panorama** tab access levels and the custom Panorama administrator roles for which they are available. Firewall administrators cannot access any of these privileges.

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Setup | Specifies whether the administrator can view or edit Panorama setup information, such as **Management**, **Operations**, **Services**, **WildFire**, or **HSM**.<br>If you set the privilege to read only, the administrator can see the information but cannot edit it.<br>If you disable this privilege, the administrator cannot see or edit the information. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Templates | Specifies whether the administrator can view, edit, add, or delete templates.<br>If you set the privilege to read only, the administrator can see template configurations but cannot manage them.<br>If you disable this privilege, the administrator cannot see or manage template configurations. | Panorama: Yes<br>Device Group/Template: Yes | Yes<br>(No for Device Group and Template admins) | Yes | Yes |
| Config Audit | Specifies whether the administrator can run Panorama configuration audits. If you disable this privilege, the administrator cannot run Panorama configuration audits. | Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| Managed Devices | Specifies whether the administrator can view, add, edit, tag, or delete firewalls as managed devices, and install software or content updates on them.<br>If you set this privilege to read only, the administrator can see managed firewalls but cannot add, delete, tag, or install updates on them.<br>If you disable this privilege, the administrator cannot view, add, edit, tag, delete, or install updates on managed firewalls.<br>This privilege applies only to the **Panorama > Managed Devices** page. An administrator with Device Deployment privileges can still use the **Panorama > Device Deployment** pages to install updates on managed firewalls. | Panorama: Yes<br>Device Group/Template: Yes | Yes<br>(No for Device Group and Template roles) | Yes | Yes |
| Device Groups | Specifies whether the administrator can view, edit, add, or delete device groups.<br>If you set this privilege to read only, the administrator can see device group configurations but cannot manage them.<br>If you disable this privilege, the administrator cannot see or manage device group configurations. | Panorama: Yes<br>Device Group/Template: Yes | Yes<br>(No for Device Group and Template roles) | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Managed Collectors | Specifies whether the administrator can view, edit, add, or delete Managed Collectors.<br>If you set this privilege to read only, the administrator can see Managed Collector configurations but cannot manage them.<br>If you disable this privilege, the administrator cannot view, edit, add, or delete Managed Collector configurations.<br>This privilege applies only to the **Panorama > Managed Collectors** page. An administrator with Device Deployment privileges can still use the **Panorama > Device Deployment** pages to install updates on Log Collectors. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Collector Groups | Specifies whether the administrator can view, edit, add, or delete Collector Groups.<br>If you set this privilege to read only, the administrator can see Collector Groups but cannot manage them.<br>If you disable this privilege, the administrator cannot see or manage Collector Groups. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Admin Roles | Specifies whether the administrator can view Panorama administrator roles.<br>You cannot enable full access to this function: just read only access. (Only Panorama administrators with a dynamic role can add, edit, or delete custom Panorama roles.) With read only access, the administrator can see Panorama administrator role configurations but cannot manage them.<br>If you disable this privilege, the administrator cannot see or manage Panorama administrator roles. | Panorama: Yes<br>Device Group/Template: No | No | Yes | Yes |

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Administrators | Specifies whether the administrator can view Panorama administrator account details.<br>You cannot enable full access to this function: just read only access. (Only Panorama administrators with a dynamic role can add, edit, or delete Panorama administrators.) With read only access, the administrator can see information about his or her own account but no other Panorama administrator accounts.<br>If you disable this privilege, the administrator cannot see information about any Panorama administrator account, including his or her own. | Panorama: Yes<br>Device Group/Template: No | No | Yes | Yes |
| High Availability | Specifies whether the administrator can view and manage high availability (HA) settings for the Panorama management server.<br>If you set this privilege to read only, the administrator can view HA configuration information for the Panorama management server but cannot manage the configuration.<br>If you disable this privilege, the administrator cannot see or manage HA configuration settings for the Panorama management server. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| VMware Service Manager | Specifies whether the administrator can view and edit VMware Service Manager settings.<br>If you set this privilege to read only, the administrator can see the settings but cannot perform any related configuration or operational procedures.<br>If you disable this privilege, the administrator cannot see the settings or perform any related configuration or operational procedures. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Certificate Management | Sets the default state, enabled or disabled, for all of the Panorama certificate management privileges. | Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Certificates | Specifies whether the administrator can view, edit, generate, delete, revoke, renew, or export certificates. This privilege also specifies whether the administrator can import or export HA keys.<br>If you set this privilege to read only, the administrator can see Panorama certificates but cannot manage the certificates or HA keys.<br>If you disable this privilege, the administrator cannot see or manage Panorama certificates or HA keys. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Certificate Profile | Specifies whether the administrator can view, add, edit, delete or clone Panorama certificate profiles.<br>If you set this privilege to read only, the administrator can see Panorama certificate profiles but cannot manage them.<br>If you disable this privilege, the administrator cannot see or manage Panorama certificate profiles. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Log Settings | Sets the default state, enabled or disabled, for all the log setting privileges. | Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| System | Specifies whether the administrator can see and configure the settings that control the forwarding of system logs to external services (Syslog, email, or SNMP trap servers).<br>If you set this privilege to read only, the administrator can see the system log forwarding settings but cannot manage them.<br>If you disable this privilege, the administrator cannot see or manage the settings.<br>On a Panorama M-100 appliance, this privilege pertains only to system logs that Panorama generates for itself. On a Panorama virtual appliance, this privilege applies to system logs that Panorama generates and to system logs that Panorama collects from firewalls. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Config | Specifies whether the administrator can see and configure the settings that control the forwarding of configuration logs to external services (Syslog, email, or SNMP trap servers).<br>If you set this privilege to read only, the administrator can see the configuration log forwarding settings but cannot manage them.<br>If you disable this privilege, the administrator cannot see or manage the settings.<br> On a Panorama M-100 appliance, this privilege pertains only to configuration logs that Panorama generates for itself. On a Panorama virtual appliance, this privilege applies to configuration logs that Panorama generates and to configuration logs that Panorama collects from firewalls. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| HIP Match | Specifies whether the administrator can see and configure the settings that control the forwarding of HIP match logs from a Panorama virtual appliance to external services (Syslog, email, or SNMP trap servers).<br> The **Panorama > Collector Groups** page controls the forwarding of HIP match logs from a Panorama M-100 appliance. The **Device > Log Settings > HIP Match** page controls the forwarding of HIP match logs directly from firewalls to external services (without aggregation on Panorama).<br>If you set this privilege to read only, the administrator can see the forwarding settings of HIP match logs but cannot manage them.<br>If you disable this privilege, the administrator cannot see or manage the settings. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Master Key and Diagnostics | Specifies whether the administrator can view and configure a master key by which to encrypt private keys on Panorama.<br>If you set this privilege to read only, the administrator can view the Panorama master key configuration but cannot change it.<br>If you disable this privilege, the administrator cannot see or edit the Panorama master key configuration. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |

## Panorama Web Interface Access

The custom Panorama administrator roles allow you to define access to the options on Panorama and the ability to only allow access to Device Groups and Templates (**Policies**, **Objects**, **Network**, **Device** tabs).

The admin roles you can create are **Panorama** and **Device Group and Template**. You cannot assign CLI access privileges to a **Device Group and Template** admin role. If you assign superuser privileges for the CLI to a **Panorama** admin role, administrators with that role can access all features regardless of the web interface privileges you assign.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Dashboard | Controls access to the **Dashboard** tab. If you disable this privilege, the administrator will not see the tab and will not have access to any of the Dashboard widgets. | Yes | No | Yes |
| ACC | Controls access to the Application Command Center (ACC). If you disable this privilege, the **ACC** tab will not display in the web interface. Keep in mind that if you want to protect the privacy of your users while still providing access to the ACC, you can disable the **Privacy > Show Full Ip Addresses** option and/or the **Show User Names In Logs And Reports** option. | Yes | No | Yes |
| Monitor | Controls access to the **Monitor** tab. If you disable this privilege, the administrator will not see the **Monitor** tab and will not have access to any of the logs, packet captures, session information, reports or to App Scope. For more granular control over what monitoring information the admin can see, leave the Monitor option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Monitor Tab. | Yes | No | Yes |

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Policies | Controls access to the **Policies** tab. If you disable this privilege, the administrator will not see the **Policies** tab and will not have access to any policy information. For more granular control over what policy information the admin can see, for example to enable access to a specific type of policy or to enable read-only access to policy information, leave the **Policies** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Policy Tab. | Yes | No | Yes |
| Objects | Controls access to the **Objects** tab. If you disable this privilege, the administrator will not see the **Objects** tab and will not have access to any objects, security profiles, log forwarding profiles, decryption profiles, or schedules. For more granular control over what objects the admin can see, leave the **Objects** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Objects Tab. | Yes | No | Yes |
| Network | Controls access to the **Network** tab. If you disable this privilege, the administrator will not see the **Network** tab and will not have access to any interface, zone, VLAN, virtual wire, virtual router, IPsec tunnel, DHCP, DNS Proxy, GlobalProtect, or QoS configuration information or to the network profiles. For more granular control over what objects the admin can see, leave the **Network** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Network Tab. | Yes | No | Yes |
| Device | Controls access to the **Device** tab. If you disable this privilege, the administrator will not see the **Device** tab and will not have access to any device-wide configuration information, such as User-ID, High Availability, server profile or certificate configuration information. For more granular control over what objects the admin can see, leave the **Device** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Device Tab.<br> You cannot enable access to the **Admin Roles** or **Administrators** nodes for a role-based administrator even if you enable full access to the **Device** tab. | Yes | No | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Panorama | Controls access to the **Panorama** tab. If you disable this privilege, the administrator will not see the **Panorama** tab and will not have access to any Panorama-wide configuration information, such as Managed Devices, Managed Collectors, or Collector Groups.<br>For more granular control over what objects the admin can see, leave the **Panorama** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Panorama Tab. | Yes | No | Yes |

# Reference: Port Numbers Used by Palo Alto Networks Devices

The following tables list the ports that Palo Alto Networks devices use to communicate with each other, or with other services on the network.

- Ports Used for Management Functions
- Ports Used for HA
- Ports Used for Panorama
- Ports Used for User-ID

## Ports Used for Management Functions

| Destination Port | Protocol | Description |
|---|---|---|
| 22 | TCP | Used for communication from a client system to the firewall CLI interface. |
| 80 | TCP | The port the firewall listens on for Online Certificate Status Protocol (OCSP) updates when acting as an OCSP responder. |
| 123 | UDP | Port the firewall uses for NTP updates. |
| 443 | TCP | Used for communication from a client system to the firewall web interface. This is also the port the firewall and/or the User-ID agent listens on for VM Information source updates. For monitoring an AWS environment, this is the only port that is used. For monitoring a VMware vCenter/ESXi environment, the listening port defaults to 443, but it is configurable. |
| 162 | UDP | Port the firewall, Panorama, or the log collector use to send SNMP traps to a SNMP trap receiver.<br> This port does not need to be open on the Palo Alto Networks device. The SNMP trap receiver must be configured to listen on this port. |
| 161 | UDP | Port the firewall listens on for SNMP polling requests from the NMS. |
| 514<br>514<br>6514 | TCP<br>UDP<br>SSL | Port the firewall, Panorama, or the log collector use to send logs to a Syslog server and the ports the User-ID agent (on the firewall or on a Windows server) listens on for authentication Syslog messages for use with User-ID. |
| 2055 | UDP | Default port the firewall uses to send NetFlow records, but this is configurable. |
| 5008 | TCP | Port the GlobalProtect Mobile Security Manager listens on for HIP requests from the GlobalProtect gateways.<br>If you are using a third-party MDM system, you can configure the gateway to use a different port as required by the MDM vendor. |

 © Palo Alto Networks, Inc.

| Destination Port | Protocol | Description |
|---|---|---|
| 6081<br>6082 | TCP<br>TCP | Ports used for Captive Portal. |

## Ports Used for HA

Firewalls configured as High Availability (HA) peers must be able to communicate with each other to maintain state information (HA1 control link) and synchronize data (HA2 data link). In Active/Active HA deployments the peer firewalls must also forward packets to the HA peer that owns the session. The HA3 link is a Layer 2 (MAC-in-MAC) link and it does not support Layer 3 addressing or encryption.

| Destination Port | Protocol | Description |
|---|---|---|
| 28769<br>28260 | TCP<br>TCP | Used for the HA1 control link for clear text communication between the HA peer firewalls. The HA1 link is a Layer 3 link and requires an IP address. |
| 28 | TCP | Used for the HA1 control link for encrypted communication (SSH over TCP) between the HA peer firewalls. |
| 28770 | TCP | Listening port for HA1 backup links. |
| 28771 | TCP | Used for heartbeat backups. Palo Alto Networks recommends enabling heartbeat backup on the MGT interface if you use an in-band port for the HA1 or the HA1 backup links. |
| 99<br>29281 | IP<br>UDP | Used for the HA2 link to synchronize sessions, forwarding tables, IPSec security associations and ARP tables between firewalls in an HA pair. Data flow on the HA2 link is always unidirectional (except for the HA2 keep-alive); it flows from the active device (Active/Passive) or active-primary (Active/Active) to the passive device (Active/Passive) or active-secondary (Active/Active). The HA2 link is a Layer 2 link, and it uses ether type 0x7261 by default.<br>The HA data link can also be configured to use either IP (protocol number 99) or UDP (port 29281) as the transport, and thereby allow the HA data link to span subnets. |

## Ports Used for Panorama

| Destination Port | Protocol | Description |
|---|---|---|
| 22 | TCP | Used for communication from a client system to the Panorama CLI interface. |
| 443 | TCP | Used for communication from a client system to the Panorama web interface. |
| 3978 | TCP | Used for communication between Panorama and managed devices and/or managed log collectors as well as for communication between log collectors in a collector group as follows:<br>• For communication between Panorama and managed devices, this is a bi-directional connection on which the managed firewalls forward logs to Panorama and for Panorama to push configuration changes to the managed devices. Context switching commands are sent over the same connection.<br>• Log collectors use this destination port to forward logs to Panorama.<br>• For communication between the default log collector on a Panorama in Panorama mode, and for communicating with log collectors in a DLC architecture mode. |
| 28769 (5.1 and later)<br>28260 (5.0 and later)<br>49160 (5.0 and earlier) | TCP<br>TCP<br>TCP | Used for the HA connectivity and synchronization between Panorama HA peers using clear text communication. Communication can be initiated by either peer. |
| 28 | TCP | Used for the HA connectivity and synchronization between Panorama HA peers using encrypted communication (SSH over TCP). Communication can be initiated by either peer. |
| 28270 (6.0 and later)<br>49190 (5.1 and earlier) | TCP | Used for communication between log collectors in a collector group for log distribution. |
| 2049 | TCP | Used by the Panorama virtual appliance to write logs to the NFS datastore. |

 © Palo Alto Networks, Inc.

## Ports Used for User-ID

User-ID is a feature that enables mapping of user IP addresses to usernames and group memberships, enabling user- or group-based policy and visibility into user activity on your network (for example, to be able to quickly track down a user who may be the victim of a threat). To perform this mapping, the firewall, the User-ID agent (either installed on a Windows-based system or the PAN-OS integrated agent running on the firewall), and/or the Terminal Services agent must be able to connect to directory services on your network to perform Group Mapping and User Mapping. Additionally, if the agents are running on systems external to the firewall, they must be able to connect to the firewall to communicate the IP address to username mappings to the firewall. The following table lists the communication requirements for User-ID along with the port numbers required to establish connections.

| Destination Port | Protocol | Description |
|---|---|---|
| 389 | TCP | Port the firewall uses to connect to the LDAP server (plaintext or StartTLS) in order to Map Users to Groups. |
| 636 | TCP | Port the firewall uses to connect to the LDAP server (LDAP over SSL) in order to Map Users to Groups. Used for LDAP over SSL connections. |
| 514<br>514<br>6514 | TCP<br>UDP<br>SSL | Ports the User-ID agent (on the firewall or on a Windows server) listens on for authentication Syslog messages for use with User-ID. |
| 5007 | TCP | Port the firewall listens on for user mapping information from the User-ID or Terminal Server agent. The agent sends the IP address and username mapping along with a timestamp whenever it learns of a new or updated mapping. In addition, it connects to the firewall at regular intervals to refresh known mappings. |
| 5006 | TCP | Port the User-ID agent listens on for User-ID XML API requests. The source for this communication is typically the system running a script that invokes the API. |
| 88 | UDP | Port the User-ID agent uses to authenticate to a Kerberos server. |
| 1812 | UDP | Port the User-ID agent uses to authenticate to a RADIUS server. |
| 135 | TCP | Port the User-ID agent uses to establish TCP-based WMI connections with the Microsoft Remote Procedure Call (RPC) Endpoint Mapper. The Endpoint Mapper then assigns the agent a randomly assigned port in the 49152-65535 port range. The agent uses this connection to make RPC queries for Exchange Server or AD server security logs, session tables. This is also the port used to access Terminal Services.<br>The User-ID agent also uses this port to connect to client systems to perform WMI probes. |
| 139 | TCP | Port the User-ID agent uses to establish TCP-based NetBIOS connections to the AD server so that it can send RPC queries for security logs and session information.<br>The User-ID agent also uses this port to connect to client systems for NetBIOS probing (supported on the Windows-based User-ID agent only). |
| 445 | TCP | Port the User-ID agent uses to connect to the Active Directory (AD) using TCP-based SMB connections to the AD server for access to user logon information (print spooler and Net Logon). |

# Reset the Firewall to Factory Default Settings

Resetting the firewall to factory defaults will result in the loss of all configuration settings and logs.

| Reset the Firewall to Factory Default Settings | |
|---|---|
| Step 1 Set up a console connection to the firewall. | 1. Connect a serial cable from your computer to the Console port and connect to the firewall using terminal emulation software (9600-8-N-1).<br>If your computer does not have a 9-pin serial port, use a USB-to-serial port connector.<br>2. Enter your login credentials.<br>3. Enter the following CLI command:<br>`debug system maintenance-mode`<br>The firewall will reboot in the maintenance mode. |
| Step 2 Reset the system to factory default settings. | 1. When the device reboots, press `Enter` to continue to the maintenance mode menu.<br> <br>2. Select `Factory Reset` and press `Enter`.<br>3. Select `Factory Reset` and press `Enter` again.<br>The firewall will reboot without any configuration settings. The default username and password to log in to the firewall is admin/admin.<br>To perform initial configuration on the firewall and to set up network connectivity, see Integrate the Firewall into Your Management Network. |

 © Palo Alto Networks, Inc.

# Certificate Management

The following topics describe the different keys and certificates that Palo Alto Networks devices use, and how to obtain and manage them:

- Keys and Certificates
- Certificate Revocation
- Certificate Deployment
- Set Up Verification for Certificate Revocation Status
- Configure the Master Key
- Obtain Certificates
- Configure a Certificate Profile
- Configure the Key Size for SSL Forward Proxy Server Certificates
- Revoke and Renew Certificates
- Secure Keys with a Hardware Security Module

# Keys and Certificates

To ensure trust between parties in a secure communication session, Palo Alto Networks devices use digital certificates. Each certificate contains a cryptographic key to encrypt plaintext or decrypt cyphertext. Each certificate also includes a digital signature to authenticate the identity of the issuer. The issuer must be in the list of trusted certificate authorities (CAs) of the authenticating party. Optionally, the authenticating party verifies the issuer did not revoke the certificate (see Certificate Revocation).

Palo Alto Networks devices use certificates in the following applications:

- User authentication for Captive Portal, GlobalProtect, Mobile Security Manager, and firewall/Panorama web interface access.
- Device authentication for GlobalProtect VPN (remote user-to-site or large scale).
- Device authentication for IPSec site-to-site VPN with Internet Key Exchange (IKE).
- Decrypting inbound and outbound SSL traffic. A firewall decrypts the traffic to apply security policies and rules, then re-encrypts it before forwarding the traffic to the final destination. For outbound traffic, the firewall acts as a forward proxy server, establishing an SSL/TLS connection to the destination server. To secure a connection between itself and the client, the firewall uses a *signing certificate* to automatically generate a copy of the destination server certificate.

The following table describes the keys and certificates that Palo Alto Networks devices use. As a best practice, use different keys/certificates for each usage.

**Table: Palo Alto Networks Device Keys/Certificates**

| Key/Certificate Usage | Description |
|---|---|
| Administrative Access | Secure access to device administration interfaces (HTTPS access to the web interface) requires a server certificate for the MGT interface (or a designated interface on the dataplane if the device does not use MGT) and, optionally, a certificate to authenticate the administrator. |
| Captive Portal | In deployments where Captive Portal identifies users who access HTTPS resources, designate a server certificate for the Captive Portal interface. If you configure Captive Portal to use certificates (instead of, or in addition to, username/password credentials) for user identification, designate a user certificate also. For more information on Captive Portal, see Map IP Addresses to User Names Using Captive Portal. |
| Forward Trust | For outbound SSL/TLS traffic, if a firewall acting as a forward proxy trusts the CA that signed the certificate of the destination server, the firewall uses the forward trust CA certificate to generate a copy of the destination server certificate to present to the client. To set the key size, see Configure the Key Size for SSL Forward Proxy Server Certificates. For added security, store the key on a hardware security module (for details, see Secure Keys with a Hardware Security Module). |
| Forward Untrust | For outbound SSL/TLS traffic, if a firewall acting as a forward proxy does not trust the CA that signed the certificate of the destination server, the firewall uses the forward untrust CA certificate to generate a copy of the destination server certificate to present to the client. |

 © Palo Alto Networks, Inc.

| Key/Certificate Usage | Description |
|---|---|
| SSL Inbound Inspection | The keys that decrypt inbound SSL/TLS traffic for inspection and policy enforcement. For this application, import onto the firewall a private key for each server that is subject to SSL/TLS inbound inspection. See Configure SSL Inbound Inspection. |
| SSL Exclude Certificate | Certificates for servers to exclude from SSL/TLS decryption. For example, if you enable SSL decryption but your network includes servers for which the firewall should not decrypt traffic (for example, web services for your HR systems), import the corresponding certificates onto the firewall and configure them as SSL Exclude Certificates. See Configure Decryption Exceptions. |
| GlobalProtect | All interaction among GlobalProtect components occurs over SSL/TLS connections. Therefore, as part of the GlobalProtect deployment, deploy server certificates for all GlobalProtect portals, gateways, and Mobile Security Managers. Optionally, deploy certificates for authenticating users also.<br>Note that the GlobalProtect Large Scale VPN (LSVPN) feature requires a CA signing certificate. |
| Site-to-Site VPNs (IKE) | In a site-to-site IPSec VPN deployment, peer devices use Internet Key Exchange (IKE) gateways to establish a secure channel. IKE gateways use certificates or preshared keys to authenticate the peers to each other. You configure and assign the certificates or keys when defining an IKE gateway on a firewall. See Site-to-Site VPN Overview. |
| Master Key | The firewall uses a master key to encrypt all private keys and passwords. If your network requires a secure location for storing private keys, you can use an encryption (wrapping) key stored on a hardware security module (HSM) to encrypt the master key. For details, see Encrypt a Master Key Using an HSM. |
| Secure Syslog | The certificate to enable secure connections between the firewall and a syslog server. See Configure the Firewall to Authenticate to the Syslog Server. |
| Trusted Root CA | The designation for a root certificate issued by a CA that the firewall trusts. The firewall can use a self-signed root CA certificate to automatically issue certificates for other applications (for example, SSL Forward Proxy).<br>Also, if a firewall must establish secure connections with other firewalls, the root CA that issues their certificates must be in the list of trusted root CAs on the firewall. |

© Palo Alto Networks, Inc.

# Certificate Revocation

Palo Alto Networks devices use digital certificates to ensure trust between parties in a secure communication session. Configuring a device to check the revocation status of certificates provides additional security. A party that presents a revoked certificate is not trustworthy. When a certificate is part of a chain, the device checks the status of every certificate in the chain except the root CA certificate, for which the device cannot verify revocation status.

Various circumstances can invalidate a certificate before the expiration date. Some examples are a change of name, change of association between subject and certificate authority (for example, an employee terminates employment), and compromise (known or suspected) of the private key. Under such circumstances, the certificate authority that issued the certificate must revoke it.

Palo Alto Networks devices support the following methods for verifying certificate revocation status. If you configure both, the devices first try the OCSP method; if the OCSP server is unavailable, the devices use the CRL method.

- Certificate Revocation List (CRL)
- Online Certificate Status Protocol (OCSP)

In PAN-OS, certificate revocation status verification is an optional feature. It is a best practice to enable it for certificate profiles, which define user and device authentication for Captive Portal, GlobalProtect, site-to-site IPsec VPN, and firewall/Panorama web interface access.

## Certificate Revocation List (CRL)

Each certificate authority (CA) periodically issues a certificate revocation list (CRL) to a public repository. The CRL identifies revoked certificates by serial number. After the CA revokes a certificate, the next CRL update will include the serial number of that certificate.

The Palo Alto Networks firewall downloads and caches the last-issued CRL for every CA listed in the trusted CA list of the firewall. Caching only applies to validated certificates; if a firewall never validated a certificate, the firewall cache does not store the CRL for the issuing CA. Also, the cache only stores a CRL until it expires.

The firewall supports CRLs only in Distinguished Encoding Rules (DER) format. If the firewall downloads a CRL in any other format—for example, Privacy Enhanced Mail (PEM) format—any revocation verification process that uses that CRL will fail when a user performs an activity that triggers the process (for example, sending outbound SSL data). The firewall will generate a system log for the verification failure. If the verification was for an SSL certificate, the firewall will also display the SSL Certificate Errors Notify response page to the user.

To use CRLs for verifying the revocation status of certificates used for the decryption of inbound and outbound SSL/TLS traffic, see Configure Revocation Status Verification of Certificates Used for SSL/TLS Decryption.

To use CRLs for verifying the revocation status of certificates that authenticate users and devices, configure a certificate profile and assign it to the interfaces that are specific to the application: Captive Portal, GlobalProtect (remote user-to-site or large scale), site-to-site IPSec VPN, or firewall/Panorama web interface access. For details, see Configure Revocation Status Verification of Certificates Used for User/Device Authentication.

 © Palo Alto Networks, Inc.

## Online Certificate Status Protocol (OCSP)

When establishing an SSL/TLS session, clients can use Online Certificate Status Protocol (OCSP) to check the revocation status of the authentication certificate. The authenticating client sends a request containing the serial number of the certificate to the OCSP responder (server). The responder searches the database of the certificate authority (CA) that issued the certificate and returns a response containing the status (*good*, *revoked* or *unknown*) to the client. The advantage of the OCSP method is that it can verify status in real-time, instead of depending on the issue frequency (hourly, daily, or weekly) of CRLs.

The Palo Alto Networks firewall downloads and caches OCSP status information for every CA listed in the trusted CA list of the firewall. Caching only applies to validated certificates; if a firewall never validated a certificate, the firewall cache does not store the OCSP information for the issuing CA. If your enterprise has its own public key infrastructure (PKI), you can configure the firewall as an OCSP responder (see Configure an OCSP Responder).

To use OCSP for verifying the revocation status of certificates when the firewall functions as an SSL forward proxy, perform the steps under Configure Revocation Status Verification of Certificates Used for SSL/TLS Decryption.

The following applications use certificates to authenticate users and/or devices: Captive Portal, GlobalProtect (remote user-to-site or large scale), site-to-site IPSec VPN, and firewall/Panorama web interface access. To use OCSP for verifying the revocation status of the certificates:

- Configure an OCSP responder.
- Enable the HTTP OCSP service on the firewall.
- Create or obtain a certificate for each application.
- Configure a certificate profile for each application.
- Assign the certificate profile to the relevant application.

To cover situations where the OCSP responder is unavailable, configure CRL as a fall-back method. For details, see Configure Revocation Status Verification of Certificates Used for User/Device Authentication.

# Certificate Deployment

The basic approaches to deploy certificates for Palo Alto Networks devices are:

- **Obtain certificates from a trusted third-party CA**—The benefit of obtaining a certificate from a trusted third-party certificate authority (CA) such as VeriSign or GoDaddy is that end clients will already trust the certificate because common browsers include root CA certificates from well-known CAs in their trusted root certificate stores. Therefore, for applications that require end clients to establish secure connections with a Palo Alto Network device, purchase a certificate from a CA that the end clients trust to avoid having to pre-deploy root CA certificates to the end clients. (Some such applications are a GlobalProtect portal or GlobalProtect Mobile Security Manager.) However, note that most third-party CAs cannot issue signing certificates. Therefore, this type of certificate is not appropriate for applications (for example, SSL/TLS decryption and large-scale VPN) that require the firewall to issue certificates. See Obtain a Certificate from an External CA.

- **Obtain certificates from an enterprise CA**—Enterprises that have their own internal CA can use it to issue certificates for firewall applications and import them onto the firewall. The benefit is that end clients probably already trust the enterprise CA. You can either generate the needed certificates and import them onto the firewall, or generate a certificate signing request (CSR) on the firewall and send it to the enterprise CA for signing. The benefit of this method is that the private key does not leave the firewall. An enterprise CA can also issue a signing certificate, which the firewall uses to automatically generate certificates (for example, for GlobalProtect large-scale VPN or sites requiring SSL/TLS decryption). See Import a Certificate and Private Key.

- **Generate self-signed certificates**—You can Create a Self-Signed Root CA Certificate on the firewall and use it to automatically issue certificates for other firewall applications. Note that if you use this method to generate certificates for an application that requires an end client to trust the certificate, end users will see a certificate error because the root CA certificate is not in their trusted root certificate store. To prevent this, deploy the self-signed root CA certificate to all end user systems. You can deploy the certificates manually or use a centralized deployment method such as an Active Directory Group Policy Object (GPO).

 © Palo Alto Networks, Inc.

# Set Up Verification for Certificate Revocation Status

To verify the revocation status of certificates, the firewall uses Online Certificate Status Protocol (OCSP) and/or certificate revocation lists (CRLs). For details on these methods, see Certificate Revocation If you configure both methods, the firewall first tries OCSP and only falls back to the CRL method if the OCSP responder is unavailable. If your enterprise has its own public key infrastructure (PKI), you can configure the firewall to function as the OCSP responder.

The following topics describe how to configure the firewall to verify certificate revocation status:

- Configure an OCSP Responder
- Configure Revocation Status Verification of Certificates Used for User/Device Authentication
- Configure Revocation Status Verification of Certificates Used for SSL/TLS Decryption

## Configure an OCSP Responder

To use Online Certificate Status Protocol (OCSP) for verifying the revocation status of certificates, you must configure the firewall to access an OCSP responder (server). The entity that manages the OCSP responder can be a third-party certificate authority (CA) or, if your enterprise has its own public key infrastructure (PKI), the firewall itself. For details on OCSP, see Certificate Revocation

| **Configure an OCSP Responder** | |
|---|---|
| Step 1 Define an OCSP responder. | 1. In a firewall, select **Device > Certificate Management > OCSP Responder** and click **Add**.<br>In Panorama, select **Device > Certificate Management > OCSP Responder**, select a **Template** and click **Add**.<br>2. Enter a **Name** to identify the responder (up to 31 characters). The name is case-sensitive. It must be unique and use only letters, numbers, spaces, hyphens, and underscores.<br>3. If the firewall supports multiple virtual systems, the dialog displays a **Location** drop-down. Select the virtual system where the responder will be available or select **Shared** to enable availability on all the virtual systems.<br>4. In the **Host Name** field, enter the host name (recommended) or IP address of the OCSP responder. From this value, PAN-OS automatically derives a URL and adds it to the certificate being verified.<br>If you configure the firewall itself as an OCSP responder, the host name must resolve to an IP address in the interface that the firewall uses for OCSP services (specified in Step 3).<br>5. Click **OK**. |

| Configure an OCSP Responder | | |
|---|---|---|
| Step 2 | Enable OCSP communication on the firewall. | 1. In a firewall, select **Device > Setup > Management**.<br>In Panorama, select **Device > Setup > Management** and select a **Template**.<br>2. In the Management Interface Settings section, edit to select the **HTTP OCSP** check box, then click **OK**. |
| Step 3 | Optionally, to configure the firewall itself as an OCSP responder, add an Interface Management Profile to the interface used for OCSP services. | 1. Select **Network > Network Profiles > Interface Mgmt**.<br>2. Click **Add** to create a new profile or click the name of an existing profile.<br>3. Select the **HTTP OCSP** check box and click **OK**.<br>4. Select **Network > Interfaces** and click the name of the interface that the firewall will use for OCSP services. The OCSP **Host Name** specified in Step 1 must resolve to an IP address in this interface.<br>5. Select **Advanced > Other info** and select the Interface Management Profile you configured.<br>6. Click **OK** and **Commit**. |

## Configure Revocation Status Verification of Certificates Used for User/Device Authentication

The firewall uses certificates to authenticate users and devices for such applications as Captive Portal, GlobalProtect, site-to-site IPSec VPN, and firewall/Panorama web interface access. To improve security, it is a best practice to configure the firewall to verify the revocation status of certificates that it uses for device/user authentication.

| Configure Revocation Status Verification of Certificates Used for User/Device Authentication | | |
|---|---|---|
| Step 1 | Configure a Certificate Profile for each application. | Assign one or more root CA certificates to the profile and select how the firewall verifies certificate revocation status. The common name (FQDN or IP address) of a certificate must match an interface to which you apply the profile in Step 2.<br>For details on the certificates that various applications use, see Keys and Certificates |
| Step 2 | Assign the certificate profiles to the relevant applications. | The steps to assign a certificate profile depend on the application that requires it. |

 © Palo Alto Networks, Inc.

# Configure Revocation Status Verification of Certificates Used for SSL/TLS Decryption

The firewall decrypts inbound and outbound SSL/TLS traffic to apply security policies and rules, then re-encrypts the traffic before forwarding it. (For details, see SSL Inbound Inspection and SSL Forward Proxy.) You can configure the firewall to verify the revocation status of certificates used for decryption as follows.

Enabling revocation status verification for SSL/TLS decryption certificates will add time to the process of establishing the session. The first attempt to access a site might fail if the verification does not finish before the session times out. For these reasons, verification is disabled by default.

| **Configure Revocation Status Verification of Certificates Used for SSL/TLS Decryption** | | |
|---|---|---|
| Step 1 | Access the Decryption Certificate Revocation Settings page. | In a firewall, select **Device > Setup > Session** and, in the Session Features section, select **Decryption Certificate Revocation Settings**.<br>In Panorama, select **Device > Setup > Session**, select a **Template** and, in the Session Features section, select **Decryption Certificate Revocation Settings**. |
| Step 2 | Define the service-specific timeout intervals for revocation status requests. | Perform one or both of the following steps, depending on whether the firewall will use Online Certificate Status Protocol (OCSP) or the Certificate Revocation List (CRL) method to verify the revocation status of certificates. If the firewall will use both, it first tries OCSP; if the OCSP responder is unavailable, the firewall then tries the CRL method.<br>1. In the CRL section, select the **Enable** check box and enter the **Receive Timeout**. This is the interval (1-60 seconds) after which the firewall stops waiting for a response from the CRL service.<br>2. In the OCSP section, select the **Enable** check box and enter the **Receive Timeout**. This is the interval (1-60 seconds) after which the firewall stops waiting for a response from the OCSP responder.<br>Depending on the **Certificate Status Timeout** value you specify in Step 3, the firewall might register a timeout before either or both of the **Receive Timeout** intervals pass. |

| Configure Revocation Status Verification of Certificates Used for SSL/TLS Decryption (Continued) | | |
|---|---|---|
| Step 3 | Define the total timeout interval for revocation status requests. | Enter the **Certificate Status Timeout**. This is the interval (1-60 seconds) after which the firewall stops waiting for a response from any certificate status service and applies the session-blocking logic you optionally define in Step 4. The **Certificate Status Timeout** relates to the OCSP/CRL **Receive Timeout** as follows:<br>• If you enable both OCSP and CRL—The firewall registers a request timeout after the lesser of two intervals passes: the **Certificate Status Timeout** value or the aggregate of the two **Receive Timeout** values.<br>• If you enable only OCSP—The firewall registers a request timeout after the lesser of two intervals passes: the **Certificate Status Timeout** value or the OCSP **Receive Timeout** value.<br>• If you enable only CRL—The firewall registers a request timeout after the lesser of two intervals passes: the **Certificate Status Timeout** value or the CRL **Receive Timeout** value. |
| Step 4 | Define the blocking behavior for *unknown* certificate status or a revocation status request timeout. | If you want the firewall to block SSL/TLS sessions when the OCSP or CRL service returns a certificate revocation status of *unknown*, select the **Block Session With Unknown Certificate Status** check box. Otherwise, the firewall proceeds with the session.<br>If you want the firewall to block SSL/TLS sessions after it registers a request timeout, select the **Block Session On Certificate Status Check Timeout** check box. Otherwise, the firewall proceeds with the session. |
| Step 5 | Save and apply your entries. | Click **OK** and **Commit**. |

© Palo Alto Networks, Inc.

# Configure the Master Key

Every firewall has a default master key that encrypts private keys and other secrets (such as passwords and shared keys). The private keys authenticate users when they access administrative interfaces on the firewall. As a best practice to safeguard the keys, configure the master key on each firewall to be unique and periodically change it. For added security, use a *wrapping key* stored on a hardware security module (HSM) to encrypt the master key. For details, see Encrypt a Master Key Using an HSM.

In a high availability (HA) configuration, ensure both devices in the pair use the same master key to encrypt private keys and certificates. If the master keys differ, HA configuration synchronization will not work properly.

When you export a firewall configuration, the master key encrypts the passwords of users managed on external servers. For locally managed users, the firewall hashes the passwords but the master key does not encrypt them.

**Configure a Master Key**

1. In a firewall, select **Device > Master Key and Diagnostics** and, in the Master Key section, click the Edit icon.
   In Panorama, select **Panorama > Master Key and Diagnostics** and, in the Master Key section, click the Edit icon.
2. Enter the **Current Master Key** if one exists.
3. Define a new **New Master Key** and then **Confirm New Master Key**. The key must contain exactly 16 characters.
4. (Optional) To specify the master key **Life Time**, enter the number of **Days** and/or **Hours** after which the key will expire. If you set a life time, create a new master key before the old key expires.
5. (Optional) If you set a key life time, enter a **Time for Reminder** that specifies the number of **Days** and **Hours** preceding master key expiration when the firewall emails you a reminder.
6. (Optional) Select whether to use an **HSM** to encrypt the master key. For details, see Encrypt a Master Key Using an HSM.
7. Click **OK** and **Commit**.

# Obtain Certificates

- Create a Self-Signed Root CA Certificate
- Generate a Certificate on the Firewall
- Import a Certificate and Private Key
- Obtain a Certificate from an External CA

© Palo Alto Networks, Inc.

## Create a Self-Signed Root CA Certificate

A self-signed root certificate authority (CA) certificate is the top-most certificate in a certificate chain. A firewall can use this certificate to automatically issue certificates for other uses. For example, the firewall issues certificates for SSL/TLS decryption and for satellite devices in a GlobalProtect large-scale VPN.

When establishing a secure connection with the firewall, the remote client must trust the root CA that issued the certificate. Otherwise, the client browser will display a warning that the certificate is invalid and might (depending on security settings) block the connection. To prevent this, after generating the self-signed root CA certificate, import it into the client systems.

**Generate a Self-signed Root CA Certificate**

1. In a firewall, select **Device > Certificate Management > Certificates > Device Certificates**.
   In Panorama, select **Device > Certificate Management > Certificates > Device Certificates** and select a **Template**.
2. If the device supports multiple virtual systems, the tab displays a **Location** drop-down. Select a virtual system for the certificate. To make the certificate available to all virtual systems, select the shared option described in Step 6.
3. Click **Generate**.
4. Enter a **Certificate Name**, such as *GlobalProtect_CA*. The name is case-sensitive and can have up to 31 characters. It must be unique and use only letters, numbers, hyphens, and underscores.
5. In the **Common Name** field, enter the FQDN (recommended) or IP address of the interface where you will configure the service that will use this certificate.
6. To make the certificate available to all virtual systems, select the **Shared** check box. This check box appears only if the device supports multiple virtual systems.
7. Leave the **Signed By** field blank to designate the certificate as self-signed.
8. Select the **Certificate Authority** check box.
9. Do *not* select an **OCSP Responder**. Certificate revocation status verification does not apply to root CA certificates.
10. Click **Generate** and **Commit**.

## Generate a Certificate on the Firewall

The firewall uses certificates to authenticate clients, servers, users and devices in several applications, including SSL/TLS decryption, Captive Portal, GlobalProtect, site-to-site IPSec VPN, and firewall/Panorama web interface access. Generate certificates for each usage. For details on application-specific certificates, see Keys and Certificates

To generate a certificate, you must first create or import a root CA certificate to sign it. For details, see Create a Self-Signed Root CA Certificate or Import a Certificate and Private Key.

To use Online Certificate Status Protocol (OCSP) for verifying certificate revocation status, Configure an OCSP Responder *before* generating the certificate. For details on status verification, see Certificate Revocation

**Generate a Certificate on the Firewall**

1. In a firewall, select **Device > Certificate Management > Certificates > Device Certificates**.
   In Panorama, select **Device > Certificate Management > Certificates > Device Certificates** and select a **Template**.
2. If the device supports multiple virtual systems, the tab displays a **Location** drop-down. Select a virtual system for the certificate. To make the certificate available to all virtual systems, select the shared option described in Step 6.
3. Click **Generate**.
4. Enter a **Certificate Name**. The name is case-sensitive and can have up to 31 characters. It must be unique and use only letters, numbers, hyphens, and underscores.
5. In the **Common Name** field, enter the FQDN (recommended) or IP address of the interface where you will configure the service that will use this certificate.
6. To make the certificate available to all virtual systems, select the **Shared** check box. This check box appears only if the device supports multiple virtual systems.
7. In the **Signed By** field, select the root CA certificate that will issue the certificate.
8. If applicable, select an **OCSP Responder**.
9. (Optional) Define the **Cryptographic Settings** as necessary to create a certificate that will work with the devices that must authenticate to it. The default and recommended key size (**Number of Bits**) is 2048 bits. The default and recommended encryption algorithm (**Digest**) is SHA256.
10. (Optional) **Add** the **Certificate Attributes** to uniquely identify the firewall and the service that will use the certificate.
    If you add a **Host Name** (DNS name) attribute, it is a best practice for it to match the **Common Name**. The host name populates the Subject Alternative Name field of the certificate.
11. Click **Generate** and, in the Device Certificates tab, click the certificate **Name**.
    Regardless of the time zone on the firewall, it always displays the corresponding Greenwich Mean Time (GMT) for certificate validity and expiration dates/times.
12. Select the check boxes that correspond to the intended use of the certificate on the firewall. For example, if the firewall will use this certificate to authenticate user access to its web interface, select the **Certificate for Secure Web GUI** check box.
13. Click **OK** and **Commit**.

 © Palo Alto Networks, Inc.

## Import a Certificate and Private Key

If your enterprise has its own public key infrastructure (PKI), you can import a certificate and private key into the firewall from your enterprise certificate authority (CA). Enterprise CA certificates (unlike most certificates purchased from a trusted, third-party CA) can automatically issue CA certificates for applications such as SSL/TLS decryption or large-scale VPN.

Instead of importing a self-signed root CA certificate into all the client systems, it is a best practice to import a certificate from the enterprise CA because the clients will already have a trust relationship with the enterprise CA, which simplifies the deployment.

If the certificate you will import is part of a certificate chain, it is a best practice to import the entire chain.

**Import a Certificate and Private Key**

1. From the enterprise CA, export the certificate and private key that the firewall will use for authentication.

   When exporting a private key, you must enter a passphrase to encrypt the key for transport. Ensure the management system can access the certificate and key files. When importing the key onto the firewall, you must enter the same passphrase to decrypt it.

2. In a firewall, select **Device > Certificate Management > Certificates > Device Certificates**.

   In Panorama, select **Device > Certificate Management > Certificates > Device Certificates** and select a **Template**.

3. If the device supports multiple virtual systems, the tab displays a **Location** drop-down. Select a virtual system for the certificate. To make the certificate available to all virtual systems, select the shared option described in Step 6.

4. Click **Import**.

5. Enter a **Certificate Name**. The name is case-sensitive and can have up to 31 characters. It must be unique and use only letters, numbers, hyphens, and underscores.

6. To make the certificate available to all virtual systems, select the **Shared** check box. This check box appears only if the device supports multiple virtual systems.

7. Enter the path and name of the **Certificate File** received from the CA, or **Browse** to find the file.

8. Select a **File Format**:

   - **Encrypted Private Key and Certificate (PKCS12)**—This is the default and most common format, in which the key and certificate are in a single container (**Certificate File**). If a hardware security module (HSM) will store the private key for this certificate, select the **Private key resides on Hardware Security Module** check box.
   - **Base64 Encoded Certificate (PEM)**—You must import the key separately from the certificate. If a hardware security module (HSM) stores the private key for this certificate, select the **Private key resides on Hardware Security Module** check box and skip Step 9. Otherwise, select the **Import Private Key** check box, enter the **Key File** or **Browse** to it, then perform Step 9.

9. Enter and re-enter (confirm) the **Passphrase** used to encrypt the private key.

10. Click **OK**. The Device Certificates tab displays the imported certificate.

## Obtain a Certificate from an External CA

The advantage of obtaining a certificate from an external certificate authority (CA) is that the private key does not leave the firewall. To obtain a certificate from an external CA, generate a certificate signing request (CSR) and submit it to the CA. After the CA issues a certificate with the specified attributes, import it onto the firewall. The CA can be a well-known, public CA or an enterprise CA.

To use Online Certificate Status Protocol (OCSP) for verifying the revocation status of the certificate, Configure an OCSP Responder *before* generating the CSR.

| **Obtain a Certificate from an External CA** | | |
|---|---|---|
| Step 1 | Request the certificate from an external CA. | 1. In a firewall, select **Device > Certificate Management > Certificates > Device Certificates**.<br>In Panorama, select **Device > Certificate Management > Certificates > Device Certificates** and select a **Template**.<br>2. If the device supports multiple virtual systems, the tab displays a **Location** drop-down. Select a virtual system for the certificate. To make the certificate available to all virtual systems, select the shared option described in sub-step 6.<br>3. Click **Generate**.<br>4. Enter a **Certificate Name**. The name is case-sensitive and can have up to 31 characters. It must be unique and use only letters, numbers, hyphens, and underscores.<br>5. In the **Common Name** field, enter the FQDN (recommended) or IP address of the interface where you will configure the service that will use this certificate.<br>6. To make the certificate available to all virtual systems, select the **Shared** check box. This check box appears only if the device supports multiple virtual systems.<br>7. In the **Signed By** field, select **External Authority (CSR)**.<br>8. If applicable, select an **OCSP Responder**.<br>9. (Optional) **Add** the **Certificate Attributes** to uniquely identify the firewall and the service that will use the certificate.<br> If you add a **Host Name** attribute, it is a best practice for it to match the **Common Name** (this is mandatory for GlobalProtect). The host name populates the Subject Alternative Name field of the certificate.<br>10. Click **Generate**. The Device Certificates tab displays the CSR with a Status of *pending*. |
| Step 2 | Submit the CSR to the CA. | 1. Select the CSR and click **Export** to save the .csr file to a local computer.<br>2. Upload the .csr file to the CA. |

© Palo Alto Networks, Inc.

| Obtain a Certificate from an External CA | |
|---|---|
| Step 3 Import the certificate. | 1. After the CA sends a signed certificate in response to the CSR, return to the **Device Certificates** tab and click **Import**.<br>2. Enter the **Certificate Name** used to generate the CSR in Step 1-4.<br>3. Enter the path and name of the PEM **Certificate File** that the CA sent, or **Browse** to it.<br>4. Click **OK**. The **Device Certificates** tab displays the certificate with a Status of *valid*. |
| Step 4 Configure the certificate. | 1. Click the certificate **Name**.<br>2. Select the check boxes that correspond to the intended use of the certificate on the firewall. For example, if the firewall will use this certificate to authenticate administrators who access the web interface, select the **Certificate for Secure Web GUI** check box.<br>3. Click **OK** and **Commit**. |

# Configure a Certificate Profile

Certificate profiles define user and device authentication for Captive Portal, GlobalProtect, site-to-site IPSec VPN, Mobile Security Manager, and firewall/Panorama web interface access. The profiles specify which certificates to use, how to verify certificate revocation status, and how that status constrains access. Configure a certificate profile for each application.

It is a best practice to enable Online Certificate Status Protocol (OCSP) and/or Certificate Revocation List (CRL) status verification for certificate profiles. For details on these methods, see Certificate Revocation.

| Configure a Certificate Profile | | |
|---|---|---|
| Step 1 | Obtain the certificate authority (CA) certificates you will assign. | Perform one of the following steps to obtain the CA certificates you will assign to the profile. You must assign at least one.<br>• Generate a Certificate on the Firewall.<br>• Export a certificate from your enterprise CA and then import it onto the firewall (see Step 3). |
| Step 2 | Identify the certificate profile. | 1. In a firewall, select **Device > Certificate Management > Certificates Profile** and click **Add**.<br>In Panorama, select **Device > Certificate Management > Certificates Profile**, select a **Template** and click **Add**.<br>2. Enter a **Name** to identify the profile. The name is case-sensitive. It must be unique and use only letters, numbers, spaces, hyphens, and underscores. It can have up to 31 characters.<br>3. If the firewall supports multiple virtual systems, the dialog displays a **Location** drop-down. Select the virtual system where the profile will be available or select **Shared** to enable availability on all the virtual systems. |

© Palo Alto Networks, Inc.

| Configure a Certificate Profile | |
|---|---|
| Step 3 Assign one or more certificates. | Perform the following steps for each certificate:<br>1. In the CA Certificates table, click **Add**.<br>2. Select a **CA Certificate** from Step 1, or click **Import** and perform the following sub-steps:<br>a. Enter a **Certificate Name**.<br>b. Enter the path and name of the **Certificate File** you exported from your enterprise CA, or **Browse** to find the file.<br>c. Click **OK**.<br>3. Optionally, if the firewall uses OCSP to verify certificate revocation status, configure the following fields to override the default behavior. For most deployments, these fields do not apply.<br>• By default, the firewall uses the OCSP responder URL that you set in the procedure Configure an OCSP Responder. To override that setting, enter a **Default OCSP URL** (starting with *http://* or *https://*).<br>• By default, the firewall uses the certificate selected in the **CA Certificate** field to validate OCSP responses. To use a different certificate for validation, select it in the **OCSP Verify CA Certificate** field.<br>4. Click **OK**. The CA Certificates table displays the assigned certificate. |

| Configure a Certificate Profile | |
|---|---|
| Step 4 Define the methods for verifying certificate revocation status and the associated blocking behavior. | 1. Select **Use CRL** and/or **Use OCSP**. If you select both, the firewall first tries OCSP and falls back to the CRL method only if the OCSP responder is unavailable.<br>2. Depending on the verification method, enter the **CRL Receive Timeout** and/or **OCSP Receive Timeout**. These are the intervals (1-60 seconds) after which the firewall stops waiting for a response from the CRL/OCSP service.<br>3. Enter the **Certificate Status Timeout**. This is the interval (1-60 seconds) after which the firewall stops waiting for a response from any certificate status service and applies any session-blocking logic you define. The **Certificate Status Timeout** relates to the OCSP/CRL **Receive Timeout** as follows:<br>• If you enable both OCSP and CRL—The firewall registers a request timeout after the lesser of two intervals passes: the **Certificate Status Timeout** value or the aggregate of the two **Receive Timeout** values.<br>• If you enable only OCSP—The firewall registers a request timeout after the lesser of two intervals passes: the **Certificate Status Timeout** value or the OCSP **Receive Timeout** value.<br>• If you enable only CRL—The firewall registers a request timeout after the lesser of two intervals passes: the **Certificate Status Timeout** value or the CRL **Receive Timeout** value.<br>4. If you want the firewall to block sessions when the OCSP or CRL service returns a certificate revocation status of *unknown*, select the **Block session if certificate status is unknown** check box. Otherwise, the firewall proceeds with the session.<br>5. If you want the firewall to block sessions after it registers an OCSP or CRL request timeout, select the **Block session if certificate status cannot be retrieved within timeout** check box. Otherwise, the firewall proceeds with the session. |
| Step 5 Save and apply your entries. | Click **OK** and **Commit**. |

© Palo Alto Networks, Inc.

# Configure the Key Size for SSL Forward Proxy Server Certificates

When responding to a client in an SSL Forward Proxy session, the firewall creates a copy of the certificate that the destination server presents and uses the copy to establish a connection with the client. By default, the firewall generates certificates with the same key size as the certificate that the destination server presented. However, you can change the key size for the firewall-generated certificate as follows:

| Configure the Key Size for SSL Forward Proxy Server Certificates | |
|---|---|
| Step 1 | Select **Device > Setup > Session** and, in the Decryption Settings section, click **Forward Proxy Server Certificate Settings**. |
| Step 2 | Select a **Key Size**:<br>• **Defined by destination host**—The firewall determines the key size for the certificates it generates to establish SSL proxy sessions with clients based on the key size of the destination server certificate. If the destination server uses a 1,024-bit RSA key, the firewall generates a certificate with that key size and an SHA-1 hashing algorithm. If the destination server uses a key size larger than 1,024 bits (for example, 2,048 bits or 4,096 bits), the firewall generates a certificate that uses a 2,048-bit RSA key and SHA-256 algorithm. This is the default setting.<br>• **1024-bit RSA**—The firewall generates certificates that use a 1,024-bit RSA key and SHA-1 hashing algorithm regardless of the key size of the destination server certificates. As of December 31, 2013, public certificate authorities (CAs) and popular browsers have limited support for X.509 certificates that use keys of fewer than 2,048 bits. In the future, depending on security settings, when presented with such keys the browser might warn the user or block the SSL/TLS session entirely.<br>• **2048-bit RSA**—The firewall generates certificates that use a 2,048-bit RSA key and SHA-256 hashing algorithm regardless of the key size of the destination server certificates. Public CAs and popular browsers support 2,048-bit keys, which provide better security than the 1,024-bit keys.<br> Changing the key size setting clears the current certificate cache. |
| Step 3 | Click **OK** and **Commit**. |

# Revoke and Renew Certificates

▲ Revoke a Certificate
▲ Renew a Certificate

## Revoke a Certificate

Various circumstances can invalidate a certificate before the expiration date. Some examples are a change of name, change of association between subject and certificate authority (for example, an employee terminates employment), and compromise (known or suspected) of the private key. Under such circumstances, the certificate authority (CA) that issued the certificate must revoke it. The following task describes how to revoke a certificate for which the firewall is the CA.

| **Revoke a Certificate** |
|---|
| 1. Select **Device > Certificate Management > Certificates > Device Certificates**. |
| 2. If the device supports multiple virtual systems, the tab displays a **Location** drop-down. Select the virtual system to which the certificate belongs. |
| 3. Select the certificate to revoke. |
| 4. Click **Revoke**. PAN-OS immediately sets the status of the certificate to revoked and adds the serial number to the Online Certificate Status Protocol (OCSP) responder cache or certificate revocation list (CRL). You need not perform a commit. |

## Renew a Certificate

If a certificate expires, or soon will, you can reset the validity period. If an external certificate authority (CA) signed the certificate and the firewall uses the Online Certificate Status Protocol (OCSP) to verify certificate revocation status, the firewall uses the OCSP responder information to update the certificate status (see Configure an OCSP Responder). If the firewall is the CA that issued the certificate, the firewall replaces it with a new certificate that has a different serial number but the same attributes as the old certificate.

| **Renew a Certificate** |
|---|
| 1. In a firewall, select **Device > Certificate Management > Certificates > Device Certificates**.<br>In Panorama, select **Device > Certificate Management > Certificates > Device Certificates** and select a **Template**. |
| 2. If the device supports multiple virtual systems, the tab displays a **Location** drop-down. Select the virtual system to which the certificate belongs. |
| 3. Select a certificate to renew and click **Renew**. |
| 4. Enter a **New Expiration Interval** (in days). |
| 5. Click **OK** and **Commit**. |

 © Palo Alto Networks, Inc.

# Secure Keys with a Hardware Security Module

A hardware security module (HSM) is a physical device that manages digital keys. An HSM provides secure storage and generation of digital keys. It provides both logical and physical protection of these materials from non-authorized use and potential adversaries.

HSM clients integrated with Palo Alto Networks devices enable enhanced security for the private keys used in SSL/TLS decryption (both SSL forward proxy and SSL inbound inspection). In addition, you can use the HSM to encrypt device master keys.

The following topics describe how to integrate an HSM with your Palo Alto Networks devices:

- Set up Connectivity with an HSM
- Encrypt a Master Key Using an HSM
- Store Private Keys on an HSM
- Manage the HSM Deployment

# Set up Connectivity with an HSM

HSM clients are integrated with PA-3000 Series, PA-4000 Series, PA-5000 Series, PA-7050, and VM-Series firewalls and on Panorama (virtual appliance and M-100 appliance) for use with the following HSMs:

- SafeNet Network 5.2.1 or later
- Thales Nshield Connect 11.62 or later

The HSM server version must be compatible with these client versions. Refer to the HSM vendor documentation for the client-server version compatibility matrix.

The following topics describe how to set up connectivity between the firewall/Panorama and one of the supported HSMs:

▲ Set Up Connectivity with a SafeNet Network HSM

▲ Set Up Connectivity with a Thales Nshield Connect HSM

## Set Up Connectivity with a SafeNet Network HSM

To set up connectivity between the Palo Alto Networks device and a SafeNet Network HSM, you must specify the address of the HSM server and the password for connecting to it in the firewall configuration. In addition, you must register the firewall with the HSM server. Prior to beginning the configuration, make sure you have created a partition for the Palo Alto Networks devices on the HSM server.

HSM configuration is not synced between high availability firewall peers. Consequently, you must configure the HSM module separately on each of the peers.

In Active-Passive HA deployments, you must manually perform one failover to configure and authenticate each HA peer individually to the HSM. After this manual failover has been performed, user interaction is not required for the failover function.

| **Set up a Connectivity with a SafeNet Network HSM** | | |
|---|---|---|
| Step 1 | Configure the firewall to communicate with the SafeNet Network HSM. | 1. Log in to the firewall web interface and select **Device > Setup > HSM**.<br>2. Edit the Hardware Security Module Provider section and select **Safenet Luna SA** (SafeNet Network) as the **Provider Configured**.<br>3. Click **Add** and enter a **Module Name**. This can be any ASCII string up to 31 characters in length.<br>4. Enter the IPv4 address of the HSM module as the **Server Address**.<br>If you are configuring a high availability HSM configuration, enter module names and IP addresses for the additional HSM devices.<br>5. (Optional) If configuring a high availability HSM configuration, select the **High Availability** check box and add the following: a value for **Auto Recovery Retry** and a **High Availability Group Name**.<br>If two HSM servers are configured, you should configure high availability. Otherwise the second HSM server is not used.<br>6. Click **OK** and **Commit.** |

 © Palo Alto Networks, Inc.

| Set up a Connectivity with a SafeNet Network HSM (Continued) | | |
|---|---|---|
| Step 2 | (Optional) Configure a service route to enable the firewall to connect to the HSM.<br><br>By default, the firewall uses the Management Interface to communicate with the HSM. To use a different interface, you must configure a service route. | 1. Select **Device > Setup > Services.**<br>2. Select **Service Route Configuration** from the Services Features area.<br>3. Select **Customize** from the Service Route Configuration area.<br>4. Select the **IPv4** tab.<br>5. Select **HSM** from the **Service** column.<br>6. Select an interface to use for HSM from the **Source Interface** drop-down.<br><br>If you select a dataplane connected port for HSM, issuing the `clear session all` CLI command will clear all existing HSM sessions, causing all HSM states to be brought down and then up. During the several seconds required for HSM to recover, all SSL/TLS operations will fail.<br>7. Click **OK** and **Commit.** |
| Step 3 | Configure the firewall to authenticate to the HSM. | 1. Select **Device > Setup > HSM**.<br>2. Select **Setup Hardware Security Module** in the Hardware Security Operations area.<br>3. Select the HSM **Server Name** from the drop-down.<br>4. Enter the **Administrator Password** to authenticate the firewall to the HSM.<br>5. Click **OK.**<br>The firewall attempts to perform an authentication with the HSM and displays a status message.<br>6. Click **OK.** |
| Step 4 | Register the firewall (the HSM client) with the HSM and assign it to a partition on the HSM.<br><br>If the HSM already has a firewall with the same `<cl-name>` registered, you must remove the duplicate registration using the following command before registration will succeed:<br><br>`client delete -client <cl-name>`<br><br>where `<cl-name>` is the name of the client (firewall) registration you want to delete. | 1. Log in to the HSM from a remote system.<br>2. Register the firewall using the following command:<br>`client register -c <cl-name> -ip <fw-ip-addr>`<br>where `<cl-name>` is a name that you assign to the firewall for use on the HSM and `<fw-ip-addr>` is the IP address of the firewall that is being configured as an HSM client.<br>3. Assign a partition to the firewall using the following command:<br>`client assignpartition -c <cl-name> -p <partition-name>`<br>where `<cl-name>` is the name assigned to the firewall in the `client register` command and `<partition-name>` is the name of a previously configured partition that you want to assign to the firewall. |

| Set up a Connectivity with a SafeNet Network HSM (Continued) | | |
|---|---|---|
| Step 5 | Configure the firewall to connect to the HSM partition. | 1. Select **Device > Setup > HSM**.<br>2. Click the **Refresh** icon.<br>3. Select the **Setup HSM Partition** in the Hardware Security Operations area.<br>4. Enter the **Partition Password** to authenticate the firewall to the partition on the HSM.<br>5. Click **OK**. |
| Step 6 | (Optional) Configure an additional HSM for high availability (HA). | 1. Follow Step 1 through Step 5 to add an additional HSM for high availability (HA).<br>This process adds a new HSM to the existing HA group.<br>2. If you remove an HSM from your configuration, repeat Step 5.<br>This will remove the deleted HSM from the HA group. |
| Step 7 | Verify connectivity with the HSM. | 1. Select **Device > Setup > HSM**.<br>2. Check the **Status** of the HSM connection:<br>Green—HSM is authenticated and connected.<br>Red—HSM was not authenticated or network connectivity to the HSM is down.<br>3. View the following columns in Hardware Security Module Status area to determine authentication status:<br>**Serial Number**—The serial number of the HSM partition if the HSM was successfully authenticated.<br>**Partition—**The partition name on the HSM that was assigned on the firewall.<br>**Module State**—The current operating state of the HSM. It always has the value Authenticated if the HSM is displayed in this table. |

## Set Up Connectivity with a Thales Nshield Connect HSM

The following workflow describes how to configure the firewall to communicate with a Thales Nshield Connect HSM. This configuration requires that you set up a remote filesystem (RFS) to use as a *hub* to sync key data for all firewalls in your organization that are using the HSM.

HSM configuration is not synced between high availability firewall peers. Consequently, you must configure the HSM module separately on each of the peers.

If the high availability firewall configuration is in Active-Passive mode, you must manually perform one failover to configure and authenticate each HA peer individually to the HSM. After this manual failover has been performed, user interaction is not required for the failover function.

 © Palo Alto Networks, Inc.

| Set up Connectivity with a Thales Nshield Connect HSM | | |
|---|---|---|
| Step 1 | Configure the Thales Nshield Connect server as the firewall's HSM provider. | 1. From the firewall web interface, select **Device > Setup > HSM** and edit the Hardware Security Module Provider section.<br>2. Select **Thales Nshield Connect** as the **Provider Configured**.<br>3. Click **Add** and enter a **Module Name**. This can be any ASCII string up to 31 characters in length.<br>4. Enter the IPv4 address as the **Server Address** of the HSM module.<br>If you are configuring a high availability HSM configuration, enter module names and IP addresses for the additional HSM devices.<br>5. Enter the IPv4 address of the **Remote Filesystem Address**.<br>6. Click **OK** and **Commit**. |
| Step 2 | (Optional) Configure a service route to enable the firewall to connect to the HSM.<br>By default, the firewall uses the Management Interface to communicate with the HSM. To use a different interface, you must configure a service route. | 1. Select **Device > Setup > Services.**<br>2. Select **Service Route Configuration** from the Services Features area.<br>3. Select **Customize** from the Service Route Configuration area.<br>4. Select the **IPv4** tab.<br>5. Select **HSM** from the **Service** column.<br>6. Select an interface to use for HSM from the **Source Interface** drop-down.<br>If you select a dataplane connected port for HSM, issuing the `clear session all` CLI command will clear all existing HSM sessions, causing all HSM states to be brought down and then up. During the several seconds required for HSM to recover, all SSL/TLS operations will fail.<br>7. Click **OK** and **Commit.** |
| Step 3 | Register the firewall (the HSM client) with the HSM server.<br>This step briefly describes the procedure for using the front panel interface of the Thales Nshield Connect HSM. For more details, consult the Thales documentation. | 1. Log in to the front panel display of the Thales Nshield Connect HSM unit.<br>2. On the unit front panel, use the right-hand navigation button to select **System > System configuration > Client config > New client**.<br>3. Enter the IP address of the firewall.<br>4. Select **System > System configuration > Client config > Remote file system** and enter the IP address of the client computer where you set up the remote file system. |

| Set up Connectivity with a Thales Nshield Connect HSM (Continued) | | |
|---|---|---|
| Step 4 | Set up the remote filesystem to accept connections from the firewall. | 1. Log in to the remote filesystem (RFS) from a Linux client.<br>2. Obtain the electronic serial number (ESN) and the hash of the $K_{NETI}$ key. The $K_{NETI}$ key authenticates the module to clients:<br>`anonkneti <ip-address>`<br>where `<ip-address>` is the IP address of the HSM.<br>The following is an example:<br>`anonkneti 192.0.2.1`<br>`B1E2-2D4C-E6A2 5a2e5107e70d525615a903f6391ad72b1c03352c`<br>In this example, **`B1E2-2D4C-E6A2`** is the ESM and 5a2e5107e70d525615a903f6391ad72b1c03352c is the hash of the $K_{NETI}$ key.<br>3. Use the following command from a superuser account to perform the remote filesystem setup:<br>`rfs-setup --force <ip-address> <ESN> <hash-Kneti-key>`<br>where `<ip-address>` is the IP address of the HSM,<br>`<ESN>` is the electronic serial number (ESN) and<br>`<hash-Kneti-key>` is the hash of the KNETI key.<br>The following example uses the values obtained in this procedure:<br>`rfs-setup --force <192.0.2.1> <B1E2-2D4C-E6A2>`<br>`<5a2e5107e70d525615a903f6391ad72b1c03352c>`<br>4. Use the following command to permit client submit on the Remote Filesystem:<br>`rfs-setup --gang-client --write-noauth <FW-IPaddress>`<br>where `<FW-IPaddress>` is the IP address of the firewall. |
| Step 5 | Configure the firewall to authenticate to the HSM. | 1. From the firewall web interface, select **Device > Setup > HSM**.<br>2. Select **Setup Hardware Security Module** in the Hardware Security Operations area.<br>3. Click **OK.**<br>The firewall attempts to perform an authentication with the HSM and displays a status message.<br>4. Click **OK.** |
| Step 6 | Synchronize the firewall with the remote filesystem. | 1. Select the **Device > Setup > HSM**.<br>2. Select **Synchronize with Remote Filesystem** in the Hardware Security Operations section. |

© Palo Alto Networks, Inc.

| Set up Connectivity with a Thales Nshield Connect HSM (Continued) | | |
|---|---|---|
| Step 7 | Verify that the firewall can connect to the HSM. | 1. Select **Device > Setup > HSM**.<br>2. Check the Status indicator to verify that the firewall is connected to the HSM:<br>Green—HSM is authenticated and connected.<br>Red—HSM was not authenticated or network connectivity to the HSM is down.<br>3. View the following columns in Hardware Security Module Status section to determine authentication status.<br>**Name**: The name of the HSM attempting to be authenticated.<br>**IP address:** The IP address of the HSM that was assigned on the firewall.<br>**Module State**: The current operating state of the HSM: **Authenticated** or **Not Authenticated**. |

# Encrypt a Master Key Using an HSM

A master key is configured on a Palo Alto Networks firewall to encrypt all private keys and passwords. If you have security requirements to store your private keys in a secure location, you can encrypt the master key using an encryption key that is stored on an HSM. The firewall then requests the HSM to decrypt the master key whenever it is required to decrypt a password or private key on the firewall. Typically, the HSM is located in a highly secure location that is separate from the firewall for greater security.

The HSM encrypts the master key using a wrapping key. To maintain security, this encryption key must occasionally be changed. For this reason, a command is provided on the firewall to rotate the wrapping key which changes the master key encryption. The frequency of this wrapping key rotation depends on your application.

Master key encryption using an HSM is not supported on firewalls configured in FIPS or CC mode.

The following topics describe how to encrypt the master key initially and how to refresh the master key encryption:

- Encrypt the Master Key
- Refresh the Master Key Encryption

## Encrypt the Master Key

If you have not previously encrypted the master key on a device, use the following procedure to encrypt it. Use this procedure for first time encryption of a key, or if you define a new master key and you want to encrypt it. If you want to refresh the encryption on a previously encrypted key, see Refresh the Master Key Encryption.

| Encrypt a Master Key Using an HSM | |
|---|---|
| Step 1 | Select **Device > Master Key and Diagnostics.** |
| Step 2 | Specify the key that is currently used to encrypt all of the private keys and passwords on the firewall in the **Master Key** field. |
| Step 3 | If changing the master key, enter the new master key and confirm. |
| Step 4 | Select the **HSM** check box.<br>**Life Time:** The number of days and hours after which the master key expires (range 1-730 days).<br>**Time for Reminder:** The number of days and hours before expiration when the user is notified of the impending expiration (range 1-365 days). |
| Step 5 | Click **OK**. |

## Refresh the Master Key Encryption

As a best practice, refresh the master key encryption on a regular basis by rotating the master key wrapping key on the HSM. This command is the same for both the SafeNet Network and Thales Nshield Connect HSMs.

 © Palo Alto Networks, Inc.

**Refresh the Master Key Encryption**

1. Use the following CLI command to rotate the wrapping key for the master key on an HSM:

   ```
   > request hsm mkey-wrapping-key-rotation
   ```

   If the master key is encrypted on the HSM, the CLI command will generate a new wrapping key on the HSM and encrypt the master key with the new wrapping key.

   If the master key is not encrypted on the HSM, the CLI command will generate new wrapping key on the HSM for future use.

   The old wrapping key is not deleted by this command.

## Store Private Keys on an HSM

For added security, the private keys used to enable SSL/TLS decryption—both SSL forward proxy and SSL inbound inspection—can be secured with an HSM as follows:

- **SSL forward proxy**—The private key in the CA certificate that is used to sign certificates in SSL/TLS forward proxy operations can be stored on the HSM. The firewall will then send the certificates it generates during SSL/TLS forward proxy operations to the HSM for signing before forwarding them on to the client.
- **SSL inbound inspection**—The private keys for the internal servers for which you are doing SSL/TLS inbound inspection can be stored on the HSM.

For instructions on importing the private keys onto the HSM, refer to the documentation from your HSM provider. After the required keys are on the HSM, you can configure the firewall to locate the keys as follows:

| **Store Private Keys on an HSM** | | |
|---|---|---|
| Step 1 | Import the private keys used in your SSL forward proxy and/or SSL inbound inspection deployments onto the HSM. | For instructions on importing the private keys onto the HSM, refer to the documentation from your HSM provider. |
| Step 2 | (Thales Nshield Connect only) Sync the key data from the HSM remote file system to the firewall. | 1. From the firewall web interface, select **Device > Setup > HSM**.<br>2. Select **Synchronize with Remote Filesystem** in the Hardware Security Operations section. |
| Step 3 | Import the certificate(s) that correspond to the private key(s) you are storing on the HSM onto the firewall. | 1. From the firewall web interface, select **Device > Certificate Management > Certificates > Device Certificates**.<br>2. Click **Import**.<br>3. Enter the **Certificate Name**.<br>4. Enter filename of the **Certificate File** you imported to the HSM.<br>5. Select the appropriate **File Format** from the drop-down.<br>6. Select the **Private Key resides on Hardware Security Module** check box.<br>7. Click **OK** and **Commit**. |
| Step 4 | (Forward trust certificates only) Enable the certificate for use in SSL/TLS Forward Proxy. | 1. Select the **Device > Certificate Management > Certificates > Device Certificates**.<br>2. Locate the certificate you imported in Step 3.<br>3. Select the **Forward Trust Certificate** check box.<br>4. Click **OK** and **Commit**. |

 © Palo Alto Networks, Inc.

| Store Private Keys on an HSM (Continued) | | |
|---|---|---|
| Step 5 | Verify that the certificate has been successfully imported to the firewall. | 1. Select **Device > Certificate Management > Certificates > Device Certificates**.<br>2. Locate the certificate you imported in Step 3.<br>3. In the Key column, notice the following:<br>If a Lock icon is displayed, the private key for the certificate can be found on the HSM.<br>If an Error icon is displayed, the private key is not imported to the HSM or the HSM is not properly authenticated or connected. |

## Manage the HSM Deployment

| Manage HSM | |
|---|---|
| • View the HSM configuration settings. | Select **Device > Setup > HSM**. |
| • Display detailed HSM information. | Select **Show Detailed Information** from the Hardware Security Operations section.<br>Information regarding the HSM servers, HSM HA status, and HSM hardware is displayed. |
| • Export Support file. | Select **Export Support File** from the Hardware Security Operations section.<br>A test file is created to help customer support when addressing a problem with an HSM configuration on the firewall. |
| • Reset HSM configuration. | Select **Reset HSM Configuration** from the Hardware Security Operations section.<br>Selecting this option removes all HSM connections. All authentication procedures must be repeated after using this option. |

 © Palo Alto Networks, Inc.

# High Availability

High availability (HA) is a configuration in which two firewalls are placed in a group and their configuration is synchronized to prevent a single point to failure on your network. A heartbeat connection between the firewall peers ensures seamless failover in the event that a peer goes down. Setting up the firewalls in HP pairs provides redundancy and allows you to ensure business continuity.

The Palo Alto Networks firewalls support stateful active/passive or active/active high availability with session and configuration synchronization. Some models of the firewall, such as the VM-Series firewall and the PA-200, only support HA lite without session synchronization capability. The following topics provide more information about high availability and how to configure it in your environment.

- HA Overview
- HA Concepts
- Set Up Active/Passive HA
- HA Resources

# HA Overview

On Palo Alto Networks firewalls, you can set up two firewalls as an HA pair. HA allows you to minimize downtime by making sure that an alternate firewall is available in the event that the peer firewall fails. The firewalls in an HA pair use dedicated or in-band HA ports on the firewall to synchronize data—network, object, and policy configurations—and to maintain state information. Firewall-specific configuration such as management interface IP address or administrator profiles, HA specific configuration, log data, and the Application Command Center (ACC) information is not shared between peers. For a consolidated application and log view across the HA pair, you must use Panorama, the Palo Alto Networks centralized management system.

When a failure occurs on one firewall in the pair and the other firewall takes over the task of securing traffic, the event is called a *failover*. The conditions that trigger a failover are:

- One or more of the monitored interfaces fail. (Link Monitoring)
- One or more of the destinations specified on the firewall cannot be reached. (Path Monitoring)
- The firewall does not respond to heartbeat polls. (Heartbeat Polling and Hello messages)

After you understand the HA Concepts, continue to Set Up Active/Passive HA.

 © Palo Alto Networks, Inc.

# HA Concepts

The following topics provide conceptual information about how HA works on a Palo Alto Networks firewall:

- HA Modes
- HA Links and Backup Links
- Device Priority and Preemption
- Failover Triggers
- HA Timers

## HA Modes

You can set up the firewalls for HA in two modes:

- **Active/Passive**— One firewall actively manages traffic while the other is synchronized and ready to transition to the active state, should a failure occur. In this configuration, both firewalls share the same configuration settings, and one actively manages traffic until a path, link, system, or network failure occurs. When the active firewall fails, the passive firewall takes over seamlessly and enforces the same policies to maintain network security. Active/passive HA is supported in the virtual wire, Layer 2 and Layer 3 deployments. For information on setting up your firewall in an active/passive configuration, see Configure Active/Passive HA.

The PA-200 and the VM-Series firewalls support a lite version of active/passive HA. HA lite provides configuration synchronization and some runtime data synchronization such as IPSec security associations. It does not support any session synchronization, and therefore, HA Lite does not offer stateful failover.

- **Active/Active**— Both the firewalls in the pair are active and processing traffic, and work synchronously to handle session setup and session ownership. The active/active deployment is supported in virtual wire and Layer 3 deployments, and is only recommended for networks with asymmetric routing. For information on setting up the firewalls in an active/active configuration, refer to the Active/Active High Availability Tech Note.

## HA Links and Backup Links

The firewalls in an HA pair use HA links to synchronize data and maintain state information. Some models of the firewall have dedicated HA ports—Control link (HA1) and Data link (HA2), while others require you to use the in-band ports as HA links.

On firewalls with dedicated HA ports such as the PA-3000 Series, PA-4000 Series, PA-5000 Series, and PA-7050 firewalls (see HA Ports on the PA-7050 Firewall), use the dedicated HA ports to manage communication and synchronization between the firewalls. For firewalls without dedicated HA ports such as the PA-200, PA-500, and PA-2000 Series firewalls, as a best practice use the management port for the HA1 link to allow for a direct connection between the management planes on the firewalls, and an in-band port for the HA2 link.

The HA1 and HA2 links provide synchronization for functions that reside on the management plane. Using the dedicated HA interfaces on the management plane is more efficient than using the in-band ports as this eliminates the need to pass the synchronization packets over the dataplane.

- **Control Link**: The HA1 link is used to exchange hellos, heartbeats, and HA state information, and management plane sync for routing, and User-ID information. This link is also used to synchronize configuration changes on either the active or passive firewall with its peer. The HA1 link is a Layer 3 link and requires an IP address.

  **Ports used for HA1**: TCP port 28769 and 28260 for clear text communication; port 28 for encrypted communication (SSH over TCP).

- **Data Link**: The HA2 link is used to synchronize sessions, forwarding tables, IPSec security associations and ARP tables between firewalls in an HA pair. Data flow on the HA2 link is always unidirectional (except for the HA2 keep-alive); it flows from the active firewall to the passive firewall. The HA2 link is a Layer 2 link, and it uses ether type 0x7261 by default.

  **Ports used for HA2:** The HA data link can be configured to use either IP (protocol number 99) or UDP (port 29281) as the transport, and thereby allow the HA data link to span subnets.

  Additionally, an HA3 link is used in Active/Active HA deployments. When there is an asymmetric route, the HA3 link is used for forwarding packets to the HA peer that owns the session. The HA3 link is a Layer 2 link and it does not support Layer 3 addressing or encryption.

- **Backup Links**: Provide redundancy for the HA1 and the HA2 links. In-band ports are used as backup links for both HA1 and HA2. Consider the following guidelines when configuring backup HA links:
  - The IP addresses of the primary and backup HA links must not overlap each other.
  - HA backup links must be on a different subnet from the primary HA links.
  - HA1-backup and HA2-backup ports must be configured on separate physical ports. The HA1-backup link uses port 28770 and 28260.

Palo Alto Networks recommends enabling heartbeat backup (uses port 28771 on the MGT interface) if you use an in-band port for the HA1 or the HA1 backup links.

- **Packet-Forwarding Link**: In addition to the HA1 and HA2 links, an active/active deployment also requires a dedicated HA3 link. The firewalls use this link for forwarding packets to the peer during session setup and asymmetric traffic flow. The HA3 link is a Layer 2 link that uses MAC-in-MAC encapsulation; it does not support Layer 3 addressing or encryption. You can configure aggregate interfaces on the PA-3000 Series, PA-4000 Series, PA-5000 Series and PA-7000 Series firewalls as an HA3 link. The aggregate interfaces can also provide redundancy for the HA3 link; you cannot configure backup links for the HA3 link.

## HA Ports on the PA-7050 Firewall

For HA connectivity on the PA-7050, use the following table for details on which ports on the Switch Management Card (SMC) are mandated and where ports on the Network Processing Card (NPC) are suitable.

 © Palo Alto Networks, Inc.

| HA Links and Backup Links | Ports on the SMC | Description |
|---|---|---|
| **Control Link** | HA1-A<br>Speed: Ethernet 10/100/1000 | Used for HA control and synchronization. Connect this port directly from the HA1-A port on the first firewall to the HA1-A on the second firewall in the pair, or connect them together through a switch or router.<br>HA1 cannot be configured on NPC data ports or the MGT port. |
| **Control Link Backup** | HA1-B<br>Speed: Ethernet 10/100/1000 port | Used for HA control and synchronization as a backup for HA1-A. Connect this port directly from the HA1-B port on the first firewall to the HA1-B on the second firewall in the pair, or connect them together through a switch or router.<br>HA1 Backup cannot be configured on NPC data ports or the MGT port. |
| **Data Link**<br><br>**Data Link Backup** | HSCI-A<br><br>HSCI-B | The High Speed Chassis Interconnect (HSCI) ports are Quad Port SFP (QSFP) interfaces which are used to connect two PA-7000 Series firewalls in an HA configuration. Each port is comprised of four 10 gigabit links internally for a combined speed of 40 gigabits.<br>The HSCI ports are not routable and must be connected directly to each other. The HSCI-A on the first chassis connects directly to HSCI-A on the second chassis and HSCI-B on the first chassis connects to HSCI-B on the second chassis. This will provide full 80 gigabit transfer rates. In software, both ports (HSCI-A and HSCI-B) are treated as one HA interface.<br>Palo Alto Networks recommends using the dedicated HSCI ports for the HA2 link; the HA3 link must use the HSCI port. If the firewalls are deployed in:<br>• an active/active configuration, the HA3 link must use the HSCI port. The HA2 link and HA2 backup links can use the HSCI port or data ports on the NPC.<br>• an active/passive configuration, you can configure a data port on the NPC for the HA2 link or the HA2 backup link, if needed. |

For an overview of the Modules and Interface cards on the PA-7050 firewall, refer to the PA-7050 Hardware Reference Guide.

## Device Priority and Preemption

The firewalls in an HA pair can be assigned a *device priority* value to indicate a preference for which firewall should assume the active role and manage traffic. If you need to use a specific firewall in the HA pair for actively securing traffic, you must enable the preemptive behavior on both the firewalls and assign a device priority value for each firewall. The firewall with the lower numerical value, and therefore *higher priority*, is designated as active and manages all traffic on the network. The other firewall is in a passive state, and synchronizes configuration and state information with the active firewall so that it is ready to transition to an active state should a failure occur.

By default, preemption is disabled on the firewalls and must be enabled on both firewalls. When enabled, the preemptive behavior allows the firewall with the *higher priority* (lower numerical value) to resume as active after it recovers from a failure. When preemption occurs, the event is logged in the system logs.

## Failover Triggers

When a failure occurs on one firewall and the peer takes over the task of securing traffic, the event is called a *failover*. A failover is triggered when a monitored metric on a firewall in an HA pair fails. The metrics that are monitored for detecting a device failure are:

- **Heartbeat Polling and Hello messages**

  The firewalls use hello message and heartbeats to verify that the peer firewall is responsive and operational. Hello messages are sent from one peer to the other at the configured *Hello Interval* to verify the state of the firewall. The heartbeat is an ICMP ping to the HA peer over the control link, and the peer responds to the ping to establish that the firewalls are connected and responsive. By default, the interval for the heartbeat is 1000 milliseconds. For details on the HA timers that trigger a failover, see HA Timers.

- **Link Monitoring**

  The physical interfaces to be monitored are grouped into a link group and their state (link up or link down) is monitored. A link group can contain one or more physical interfaces. A firewall failure is triggered when any or all of the interfaces in the group fail. The default behavior is failure of any one link in the link group will cause the firewall to change the HA state to non-functional to indicate a failure of a monitored object.

- **Path Monitoring**

  Monitors the full path through the network to mission-critical IP addresses. ICMP pings are used to verify reachability of the IP address. The default interval for pings is 200ms. An IP address is considered unreachable when 10 consecutive pings (the default value) fail, and a firewall failure is triggered when any or all of the IP addresses monitored become unreachable. The default behavior is any one of the IP addresses becoming unreachable will cause the firewall to change the HA state to non-functional to indicate a failure of a monitored object.

In addition to the failover triggers listed above, a failover also occurs when the administrator places the firewall is a suspended state or if preemption occurs.

On the PA-3000 Series, PA-5000 Series, and PA-7050 firewalls, a failover can occur when an internal health check fails. This health check is not configurable and is enabled to verify the operational status for all the components within the firewall.

## HA Timers

High Availability (HA) timers are used to detect a firewall failure and trigger a failover. To reduce the complexity in configuring HA timers, you can select from three profiles have been added: **Recommended**, **Aggressive** and **Advanced**. These profiles auto-populate the optimum HA timer values for the specific firewall platform to enable a speedier HA deployment.

 © Palo Alto Networks, Inc.

Use the **Recommended** profile for typical failover timer settings and the **Aggressive** profile for faster failover timer settings. The **Advanced** profile allows you to customize the timer values to suit your network requirements.

The following table describes each timer included in the profiles and the current preset values across the different hardware models; these values are for current reference only and can change in a subsequent release.

**Recommended/Aggressive HA Timer Values by Platform**

| Timers | Description | PA-7050<br>PA-5000 Series<br>PA-4000 Series<br>PA-3000 Series | PA-2000 Series<br>PA-500 Series<br>PA-200 Series<br>VM-Series | Panorama VM<br>M-100 |
|---|---|---|---|---|
| Monitor fail hold up time | Interval during which the firewall will remain active following a path monitor or link monitor failure. This setting is recommended to avoid an HA failover due to the occasional flapping of neighboring devices. | 0/0 | 0/0 | 0/0 |
| Preemption hold time | Time a passive or active-secondary firewall will wait before taking over as the active or active-primary firewall. | 1/1 | 1/1 | 1/1 |
| Heartbeat interval | Frequency at which the HA peers exchange heartbeat messages in the form of an ICMP ping. | 1000/1000 | 2000/1000 | 2000/1000 |
| Promotion hold time | Time that the passive firewall (in active/passive mode) or the active-secondary firewall (in active/active mode) will wait before taking over as the active or active-primary firewall after communications with the HA peer have been lost. This hold time will begin only after the peer failure declaration has been made. | 2000/500 | 2000/500 | 2000/500 |

| Timers | Description | PA-7050<br>PA-5000 Series<br>PA-4000 Series<br>PA-3000 Series | PA-2000 Series<br>PA-500 Series<br>PA-200 Series<br>VM-Series | Panorama VM<br>M-100 |
|---|---|---|---|---|
| Additional master hold up time | This time interval is applied to the same event as Monitor Fail Hold Up Time (range 0-60000 ms, default 500 ms). The additional time interval is applied only to the active firewall in active/passive mode and to the active-primary firewall in active/active mode. This timer is recommended to avoid a failover when both firewalls experience the same link/path monitor failure simultaneously. | 500/500 | 500/500 | 7000/5000 |
| Hello interval | Interval in milliseconds between the hello packets that are sent to verify that the HA functionality on the other firewall is operational. The range is 8000-60000 ms with a default of 8000 ms for all platforms. | 8000/8000 | 8000/8000 | 8000/8000 |
| Maximum no. of flaps | A flap is counted when the firewall leaves the active state within 15 minutes after it last left the active state. This value indicates the maximum number of flaps that are permitted before the firewall is determined to be suspended and the passive firewall takes over (range 0-16, default 3). | 3/3 | 3/3 | Not Applicable |

# Set Up Active/Passive HA

- Prerequisites for Active/Passive HA
- Configuration Guidelines for Active/Passive HA
- Configure Active/Passive HA
- Define HA Failover Conditions
- Verify Failover

## Prerequisites for Active/Passive HA

To set up high availability on your Palo Alto Networks firewalls, you need a pair of firewalls that meet the following requirements:

- **The same model**—Both the firewalls in the pair must be of the same hardware model or virtual machine model.
- **The same PAN-OS version**—Both the firewalls must be running the same PAN-OS version and must each be up-to-date on the application, URL, and threat databases. They must also both have the same multiple virtual systems capability (single or multi vsys).
- **The same type of interfaces**—Dedicated HA links, or a combination of the management port and in-band ports that are set to *interface type* HA.
  - Determine the IP address for the HA1 (control) connection between the HA peers. The HA1 IP address for both peers must be on the same subnet if they are directly connected or are connected to the same switch.

    For firewall without dedicated HA ports, you can use the management port for the control connection. Using the management port provides a direct communication link between the management planes on both firewalls. However, because the management ports will not be directly cabled between the firewalls, make sure that you have a route that connects these two interfaces across your network.
  - If you use Layer 3 as the transport method for the HA2 (data) connection, determine the IP address for the HA2 link. Use Layer 3 *only* if the HA2 connection must communicate over a routed network. The IP subnet for the HA2 links must not overlap with that of the HA1 links or with any other subnet assigned to the data ports on the firewall.
- **The same set of licenses**—Licenses are unique to each firewall and cannot be shared between the firewalls. Therefore, you must license both firewalls identically. If both firewalls do not have an identical set of licenses, they cannot synchronize configuration information and maintain parity for a seamless failover.

If you have an existing firewall and you want to add a new firewall for HA purposes and the new firewall has an existing configuration, it is recommended that you Reset the Firewall to Factory Default Settings on the new firewall. This will ensure that the new firewall has a clean configuration. After HA is configured, you will then sync the configuration on the primary firewall to the newly introduced firewall with the clean config.

 © Palo Alto Networks, Inc.

## Configuration Guidelines for Active/Passive HA

To set up an active (PeerA) passive (PeerB) pair in HA, you must configure some options identically on both firewalls and some independently (non-matching) on each firewall. These HA settings are not synchronized between the firewalls. For details on what is/is not synchronized, refer to HA Synchronization.

To proceed with the instructions on configuring the firewalls in HA, see Configure Active/Passive HA.

The following table lists the settings that you must configure identically on both firewalls:

| Identical Configuration Settings on PeerA and PeerB |
|---|
| • HA must be enabled on both firewalls.<br>• Both firewall must have the same Group ID value. The Group ID value is used to create a virtual MAC address for all the configured interfaces. The format of the virtual MAC is 00-1B-17:00: xx: yy where<br>00-1B-17: vendor ID; 00: fixed; xx: HA group ID; yy: interface ID.<br>When a new active firewall takes over, Gratuitous ARPs are sent from each of the connected interfaces of the new active member to inform the connected Layer 2 switches of the virtual MAC address' new location.<br>• If using in-band ports, the interfaces for the HA1 and HA2 links must be set to type HA.<br>• The HA mode must be set to Active Passive.<br>• If required, preemption must be enabled on both firewalls. The device priority value, however, must not be identical.<br>• If required, encryption on the HA1 link (for communication between the HA peers) must be configured on both firewalls.<br>• Based on the combination of HA1 and HA1 Backup ports you are using, use the following recommendations to decide whether you should enable heartbeat backup:<br>• HA1: Dedicated HA1 port<br>HA1 Backup: In-band port<br>Recommendation: Enable Heartbeat Backup<br>• HA1: Dedicated HA1 port<br>HA1 Backup: Management port<br>Recommendation: Do not enable Heartbeat Backup<br>• HA1: In-band port<br>HA1 Backup: In-band port<br>Recommendation: Enable Heartbeat Backup<br>• HA1: Management port<br>HA1 Backup: In-band port<br>Recommendation: Do not enable Heartbeat Backup |

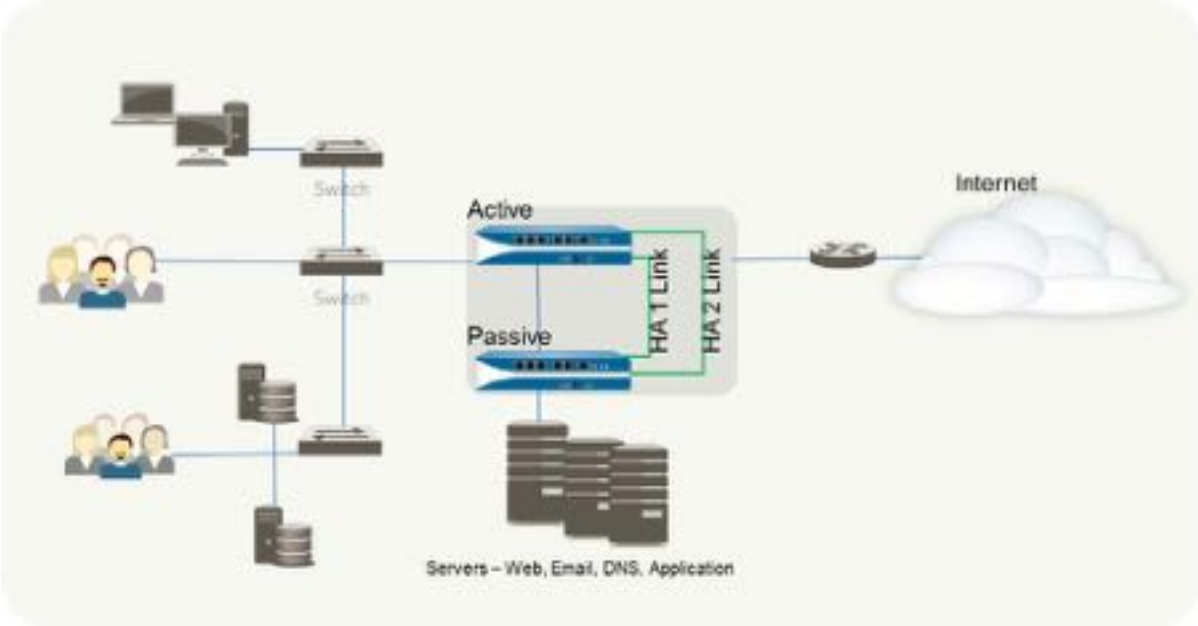
The following table lists the settings that must be configured independently on each firewall:

| Independent Configuration Settings | PeerA | PeerB |
|---|---|---|
| Control Link | IP address of the HA1 link configured on this firewall (PeerA). | IP address of the HA1 link configured on this firewall (PeerB). |
| | For firewalls without dedicated HA ports, use the management port IP address for the control link. | |
| Data Link<br>The data link information is synchronized between the firewalls after HA is enabled and the control link is established between the firewalls. | By default, the HA2 link uses Ethernet/Layer 2.<br>If using a Layer 3 connection, configure the IP address for the data link on this firewall (PeerA). | By default, the HA2 link uses Ethernet/Layer 2.<br>If using a Layer 3 connection, configure the IP address for the data link on this firewall (PeerB). |
| Device Priority (required, if preemption is enabled) | The firewall you plan to make active must have a lower numerical value than its peer. So, if Peer A is to function as the active firewall, keep the default value of 100 and increment the value on PeerB. | If PeerB is passive, set the device priority value to a number larger than that on PeerA. For example, set the value to 110. |
| Link Monitoring—Monitor one or more physical interfaces that handle vital traffic on this firewall and define the failure condition. | Select the physical interfaces on the firewall that you would like to monitor and define the failure condition (all or any) to trigger a failover. | Pick a similar set of physical interfaces that you would like to monitor on this firewall and define the failure condition (all or any) to trigger a failover. |
| Path Monitoring—Monitor one or more destination IP addresses that the firewall can use ICMP pings to ascertain responsiveness. | Define the failure condition (all or any), ping interval and the ping count. This is particularly useful for monitoring the availability of other interconnected networking devices. For example, monitor the availability of a router that connects to a server, connectivity to the server itself, or some other vital device that is in the flow of traffic.<br>Make sure that the node/device that you are monitoring is not likely to be unresponsive, especially when it comes under load, as this could cause a a path monitoring failure and trigger a failover. | Pick a similar set of devices or destination IP addresses that can be monitored for determining the failover trigger for PeerB. Define the failure condition (all or any), ping interval and the ping count. |

 © Palo Alto Networks, Inc.

## Configure Active/Passive HA

The following procedure shows how to configure a pair of firewalls in an active/passive deployment as depicted in the following example topology.



| Connect and Configure the Firewalls | |
|---|---|
| Step 1 Connect the HA ports to set up a physical connection between the firewalls. | • For firewalls with dedicated HA ports, use an Ethernet cable to connect the dedicated HA1 ports and the HA2 ports on the HA firewalls. Use a crossover cable if the firewalls are directly connected to each other.<br>• For firewalls without dedicated HA ports, select two data interfaces for the HA2 link and the backup HA1 link. Then, use an Ethernet cable to connect these in-band HA interfaces across both firewalls.<br>Use the management port for the HA1 link and ensure that the management ports can connect to each other across your network. |
| Pick a firewall in the pair and complete the following steps: | |
| Step 2 Enable ping on the management port.<br>Enabling ping allows the management port to exchange heartbeat backup information. | 1. Select **Device > Setup > Management** and edit the Management Interface Settings.<br>2. Select **Ping** as a service that is permitted on the interface. |

| Connect and Configure the Firewalls (Continued) | | |
|---|---|---|
| Step 3 | If the firewall does not have dedicated HA ports, set up the data ports to function as HA ports.<br><br>For firewalls with dedicated HA ports continue to the next step. | 1. Select **Network > Interfaces.**<br>2. Confirm that the link is up on the ports that you want to use.<br>3. Select the interface and set the interface type to HA.<br>  <br>4. Set the **Link Speed** and **Link Duplex** settings, as appropriate. |
| Step 4 | Set the HA mode and group ID. | 1. Select **Device > High Availability > General** and edit the Setup section.<br>2. Set a **Group ID** and optionally a **Description** for the pair. The Group ID uniquely identifies each HA pair on your network. If you have have multiple HA pairs that share the same broadcast domain you must set a unique Group ID for each pair.<br>3. Set the mode to **Active Passive**. |
| Step 5 | Set up the control link connection.<br><br>This example shows an in-band port that is set to interface type HA.<br><br>For firewalls that use the management port as the control link, the IP address information is automatically pre-populated. | 1. In **Device > High Availability > General**, edit the Control Link (HA1) section.<br>2. Select the Port that you have cabled for use as the HA1 link.<br>3. Set the IPv4/IPv6 Address and Netmask.<br>4. If the HA1 interfaces are on separate subnets, enter the IP address of the Gateway. Do not add a gateway address if the firewalls are directly connected.<br> |
| Step 6 | (Optional) Enable encryption for the control link connection.<br><br>This is typically used to secure the link if the two firewalls are not directly connected, that is if the ports are connected to a switch or a router. | 1. Export the HA key from a firewall and import it into the peer firewall.<br>a. Select **Device > Certificate Management > Certificates**.<br>b. Select **Export HA key**. Save the HA key to a network location that the peer can access.<br>c. On the peer, select **Device > Certificate Management > Certificates,** and select **Import HA key** to browse to the location that you saved the key and import it in to the peer.<br>2. Select **Device > High Availability > General**, edit the Control Link (HA1) section.<br>3. Select **Encryption Enabled**. |

 © Palo Alto Networks, Inc.

| Connect and Configure the Firewalls (Continued) | |
|---|---|
| Step 7 Set up the backup control link connection. | 1. In **Device > High Availability > General**, edit the Control Link (HA1 Backup) section.<br>2. Select the HA1 backup interface and set the **IPv4/IPv6 Address** and **Netmask**.<br> |
| Step 8 Set up the data link connection (HA2) and the backup HA2 connection between the firewalls. | 1. In **Device > High Availability > General**, edit the Data Link (HA2) section.<br>2. Select the **Port** to use for the data link connection.<br>3. Select the **Transport** method. The default is **ethernet**, and will work when the HA pair is connected directly or through a switch. If you need to route the data link traffic through the network, select **IP** or **UDP** as the transport mode.<br>4. If you use IP or UDP as the transport method, enter the **IPv4/IPv6 Address** and **Netmask**.<br>  <br>5. Verify that **Enable Session Synchronization** is selected.<br>6. Select **HA2 Keep-alive** to enable monitoring on the HA2 data link between the HA peers. If a failure occurs based on the threshold that is set (default is 10000 ms), the defined action will occur. For active/passive configuration, a critical system log message is generated when an HA2 keep-alive failure occurs.<br>You can configure the HA2 keep-alive option on both firewalls, or just one firewall in the HA pair. If you only enable the option on one peer, only that firewall will send the keep-alive messages. The other firewall will be notified if a failure occurs.<br>7. Edit the Data Link (HA2 Backup) section, select the interface, and add the **IPv4/IPv6 Address** and **Netmask**. |

| Connect and Configure the Firewalls (Continued) | |
|---|---|
| Step 9 Enable heartbeat backup if your control link uses a dedicated HA port or an in-band port.<br><br>You do not need to enable heartbeat backup if you are using the management port for the control link. | 1. In **Device > High Availability > General**, edit the Election Settings.<br>2. Select **Heartbeat Backup**.<br>To allow the heartbeats to be transmitted between the firewalls, you must verify that the management port across both peers can route to each other.<br><br>Enabling heartbeat backup also allows you to prevent a split-brain situation. Split brain occurs when the HA1 link goes down causing the firewall to miss heartbeats, although the firewall is still functioning. In such a situation, each peer believes that the other is down and attempts to start services that are running, thereby causing a split brain. When the heartbeat backup link is enabled, split brain is prevented because redundant heartbeats and hello messages are transmitted over the management port. |
| Step 10 Set the device priority and enable preemption.<br><br>This setting is only required if you want to make sure that a specific firewall is the preferred active firewall. For information, see Device Priority and Preemption. | 1. In **Device > High Availability > General**, edit the Election Settings.<br>2. Set the numerical value in **Device Priority**. Make sure to set a lower numerical value on the firewall that you want to assign a higher priority to.<br><br>If both firewalls have the same device priority value, the firewall with the lowest MAC address on the HA1 control link will become the active firewall.<br>3. Select **Preemptive**.<br>You must enable preemptive on both the active firewall and the passive firewall. |
| Step 11 (Optional) Modify the failover timers.<br><br>By default, the HA timer profile is set to the **Recommended** profile and is suited for most HA deployments. | 1. In **Device > High Availability > General**, edit the Election Settings.<br>2. Select the **Aggressive** profile for triggering failover faster; select **Advanced** to define custom values for triggering failover in your set up.<br><br>To view the preset value for an individual timer included in a profile, select **Advanced** and click **Load Recommended** or **Load Aggressive**. The preset values for your hardware model will be displayed on screen. |

 © Palo Alto Networks, Inc.

| Connect and Configure the Firewalls (Continued) | |
|---|---|
| Step 12 (Optional, only configured on the passive firewall) Modify the link status of the HA ports on the passive firewall.<br><br>The passive link state is **shutdown**, by default. After you enable HA, the link state for the HA ports on the active firewall will be green and those on the passive firewall will be down and display as red. | Setting the link state to **Auto** allows for reducing the amount of time it takes for the passive firewall to take over when a failover occurs and it allows you to monitor the link state.<br><br>To enable the link status on the passive firewall to stay up and reflect the cabling status on the physical interface:<br>1. In **Device > High Availability > General**, edit the Active Passive Settings.<br>2. Set the **Passive Link State** to **Auto**.<br>The auto option decreases the amount of time it takes for the passive firewall to take over when a failover occurs.<br><br>Although the interface displays green (as cabled and up) it continues to discard all traffic until a failover is triggered.<br><br>When you modify the passive link state, make sure that the adjacent devices do not forward traffic to the passive firewall based only on the link status of the firewall. |
| Step 13 Enable HA. | 1. In **Device > High Availability > General**, edit the Setup section.<br>2. Select **Enable HA**.<br>3. Select **Enable Config Sync**. This setting enables the synchronization of the configuration settings between the active and the passive firewall and should always be enabled.<br>4. Enter the IP address assigned to the control link of the peer firewall in **Peer HA1 IP Address**.<br> <br>For firewalls without dedicated HA ports, if the peer uses the management port for the HA1 link, enter the management port IP address of the peer.<br>5. Enter the **Backup HA1 IP Address**. |
| Step 14 Save your configuration changes. | Click **Commit**. |
| Step 15 Complete Step 2 through Step 14 on the other firewall in the HA pair. | |

| Connect and Configure the Firewalls (Continued) | |
|---|---|
| Step 16 After you finish configuring both firewalls, verify that the firewalls are paired in active/passive HA. | 1. Access the **Dashboard** on both firewalls, and view the High Availability widget.<br>2. On the active firewall, click the **Sync to peer** link.<br>3. Confirm that the firewalls are paired and synced, as shown below: |
| On the passive firewall: the state of the local firewall should display **passive** and the Running Config should show as **synchronized**. | On the active firewall: The state of the local firewall should display **active** and the Running Config should show as **synchronized**. |
| | |

© Palo Alto Networks, Inc.

# Define HA Failover Conditions

| Configure the Failover Triggers | | |
|---|---|---|
| Step 1 | To configure link monitoring, define the interfaces that you would like to monitor. A change in the link state of these interface will trigger a failover. | 1. Select **Device > High Availability > Link and Path Monitoring.**<br>2. In the **Link Group** section, click **Add.**<br>3. Name the **Link Group, Add** the interfaces to monitor, and select the **Failure Condition** for the group. The Link group you define is added to the **Link Group** section.<br> |
| Step 2 | (Optional) Modify the failure condition for the Link Groups that you configured (in the preceding step) on the firewall.<br>By default, the firewall will trigger a failover when any monitored link fails. | 1. Select the **Link Monitoring** section.<br>2. Set the **Failure Condition** to **All.**<br>The default setting is **Any**. |
| Step 3 | To configure path monitoring, define the destination IP addresses that the firewall should ping to verify network connectivity. | 1. In the **Path Group** section of the **Device > High Availability > Link and Path Monitoring** tab, pick the **Add option for your set up:** Virtual Wire, VLAN, or Virtual Router.<br>2. Select the appropriate item from the drop-down for the **Name** and **Add** the IP addresses (source and/or destination, as prompted) that you wish to monitor. Then select the **Failure Condition** for the group. The path group you define is added to the **Path Group** section.<br> |
| Step 4 | (Optional) Modify the failure condition for all Path Groups configured on the firewall.<br>By default, the firewall will trigger a failover when any monitored path fails. | Set the **Failure Condition** to **All.**<br>The default setting is **Any**. |
| Step 5 | Save your changes. | Click **Commit**. |

If you are using SNMPv3 to monitor the firewalls, note that the SNMPv3 Engine ID is unique to each firewall; the EngineID is not synchronized between the HA pair and, therefore, allows you to independently monitor each firewall in the HA pair. For information on setting up SNMP, see Set Up SNMP Trap Destinations.

Because the EngineID is generated using the firewall's unique serial number, on the VM-Series firewall you must apply a valid license in order to obtain a unique EngineID for each firewall.

## Verify Failover

To test that your HA configuration works properly, trigger a manual failover and verify that the firewalls transition states successfully.

| Verify Failover | | |
|---|---|---|
| Step 1 | Suspend the active firewall. | Click the **Suspend local device** link on the **Device > High Availability > Operational Commands** tab.<br>  |
| Step 2 | Verify that the passive firewall has taken over as active. | On the **Dashboard**, verify that the state of the passive firewall changes to **active** in the **High Availability** widget.<br> |
| Step 3 | Restore the suspended firewall to a functional state. Wait for a couple minutes, and then verify that preemption has occurred, if preemptive is enabled. | 1. On the firewall you previously suspended, select the **Make local device functional** link on the **Device > High Availability > Operational Commands** tab.<br>  <br>2. In the **High Availability** widget on the **Dashboard,** confirm that the firewall has taken over as the active firewall and that the peer is now in a passive state.<br> |

 © Palo Alto Networks, Inc.

# Reports and Logging

The firewall provides reports and logs that are useful for monitoring activity on your network. You can monitor the logs and filter the information to generate reports with predefined or customized views. You can, for example, use the predefined templates to generate reports on a user's activity or analyze the reports and logs to interpret unusual behavior on your network and generate a custom report on the traffic pattern. The following topics describe how to view, manage, customize, and generate the reports and logs on the firewall:

- Use the Dashboard
- Use the Application Command Center
- Use App-Scope
- Take Packet Captures
- Monitor the Firewall
- Forward Logs to External Services
- Monitor the Firewall Using SNMP
- Monitor the Firewall Using NetFlow
- NetFlow Templates
- Identify Firewall Interfaces in External Monitoring Systems
- Manage Reporting
- Syslog Field Descriptions

# Use the Dashboard

The **Dashboard** tab widgets show general device information, such as the software version, the operational status of each interface, resource utilization, and up to 10 of the most recent entries in the threat, configuration, and system logs. All of the available widgets are displayed by default, but each administrator can remove and add individual widgets, as needed.

Click the refresh icon to update the Dashboard or an individual widget. To change the automatic refresh interval, select an interval from the drop-down (**1 min**, **2 mins**, **5 mins**, or **Manual**). To add a widget to the Dashboard, click the widget drop-down, select a category and then the widget name. To delete a widget, click in the title bar.

The following table describes the Dashboard widgets.

| Dashboard Charts | Descriptions |
|---|---|
| Top Applications | Displays the applications with the most sessions. The block size indicates the relative number of sessions (mouse-over the block to view the number), and the color indicates the security risk—from green (lowest) to red (highest). Click an application to view its application profile. |
| Top High Risk Applications | Similar to Top Applications, except that it displays the highest-risk applications with the most sessions. |
| General Information | Displays the device name, model, PAN-OS software version, the application, threat, and URL filtering definition versions, the current date and time, and the length of time since the last restart. |
| Interface Status | Indicates whether each interface is up (green), down (red), or in an unknown state (gray). |
| Threat Logs | Displays the threat ID, application, and date and time for the last 10 entries in the Threat log. The threat ID is a malware description or URL that violates the URL filtering profile. |
| Config Logs | Displays the administrator username, client (Web or CLI), and date and time for the last 10 entries in the Configuration log. |
| Data Filtering Logs | Displays the description and date and time for the last 60 minutes in the Data Filtering log. |
| URL Filtering Logs | Displays the description and date and time for the last 60 minutes in the URL Filtering log. |
| System Logs | Displays the description and date and time for the last 10 entries in the System log.<br> A `Config installed` entry indicates configuration changes were committed successfully. |
| System Resources | Displays the Management CPU usage, Data Plane usage, and the Session Count, which displays the number of sessions established through the firewall. |
| Logged In Admins | Displays the source IP address, session type (Web or CLI), and session start time for each administrator who is currently logged in. |

 © Palo Alto Networks, Inc.

| Dashboard Charts | Descriptions |
|---|---|
| ACC Risk Factor | Displays the average risk factor (1 to 5) for the network traffic processed over the past week. Higher values indicate higher risk. |
| High Availability | If high availability (HA) is enabled, indicates the HA status of the local and peer device—green (active), yellow (passive), or black (other). For more information about HA, see High Availability. |
| Locks | Shows configuration locks taken by administrators. |

# Use the Application Command Center

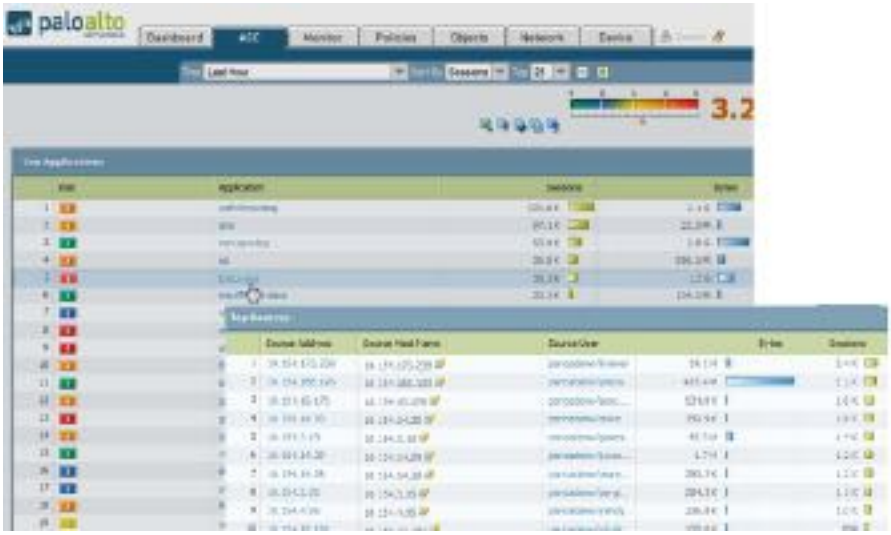
The **ACC** tab visually depicts trends and historic view of traffic on your network.

- ACC Risk Level
- ACC Charts
- ACC Detail Pages
- Use the ACC

 © Palo Alto Networks, Inc.

## ACC Risk Level

The **ACC** tab displays the overall risk level for all network traffic, the risk levels and number of threats detected for the most active and highest-risk applications on your network, and the number of threats detected from the busiest application categories and from all applications at each risk level. Use the ACC to view application data for the past hour, day, week, month, or any custom-defined time frame. **Risk** levels (1=lowest to 5=highest) indicate the application's relative security risk based on criteria such as whether the application can share files, is prone to misuse, or tries to evade firewalls.



## ACC Charts

There are five charts displayed on the **Application Command Center (ACC)** tab:

- Application
- URL Filtering
- Threat Prevention
- Data Filtering
- HIP Matches

| ACC Chart | Description |
|---|---|
| Application | Displays application information grouped by the following attributes:<br>• Applications<br>• High risk applications<br>• Categories<br>• Sub Categories<br>• Technology<br>• Risk<br>Each chart can include the number of sessions, bytes transmitted and received, number of threats, application category, application subcategories, application technology, and risk level, as applicable. |
| URL Filtering | Displays URL/category information grouped by the following attributes:<br>• URL Categories<br>• URLs<br>• Blocked URL Categories<br>• Blocked URLs<br>Each chart can include the URL, URL category, repeat count (number of times access was attempted, as applicable). |
| Threat Prevention | Displays threat information grouped by the following attributes:<br>• Threats<br>• Types<br>• Spyware<br>• Spyware Phone Home<br>• Spyware Downloads<br>• Vulnerability<br>• Virus<br>Each chart can include the threat ID, count (number of occurrences), number of sessions, and subtype (such as vulnerability), as applicable. |

 © Palo Alto Networks, Inc.

| ACC Chart | Description |
|---|---|
| Data Filtering | Displays information on data filtered by the firewall grouped by the following attributes:<br>• Content/File Types<br>• Types<br>• File Names |
| HIP Matches | Displays the host information collected by the firewall grouped by:<br>• HIP Objects<br>• HIP Profiles |

## ACC Detail Pages

To view additional details, click any of the links on the ACC charts. A details page opens to show information about the item at the top and additional lists for related items. For example, click on the web-browsing link on the Application chart opens the Application Information page for web-browsing:

 © Palo Alto Networks, Inc.

## Use the ACC

The following procedure describes how to use the **ACC** tab and how to customize your view:

| Use the ACC | |
|---|---|
| Step 1 | On the **ACC**, change one or more of the settings at the top of the page.<br>• Use the drop-down to select Applications, URL Categories, Threats, Content/File Types, and HIP Objects to view.<br>• Select a virtual system, if virtual systems are defined.<br>• Select a time period from the **Time** drop-down. The default is Last Hour.<br>• Select a sorting method from the **Sort By** drop-down. You can sort the charts in descending order by number of sessions, bytes, or threats. The default is by number of sessions.<br>• For the selected sorting method, select the top number of applications and application categories shown in each chart from the **Top** drop-down. Click the Submit icon to apply the selected settings. |
| Step 2 | To open log pages associated with the information on the page, use the log links in the upper-right corner of the page, as shown here. The context for the logs matches the information on the page.<br> |
| Step 3 | To filter the list, click an item in one of the columns, this will add that item to the filter bar located above the log column names. After adding the desired filters, click the Apply Filter icon.<br>  |

# Use App-Scope

The App-Scope reports provide visibility and analysis tools to help pinpoint problematic behavior, helping you understand changes in application usage and user activity, users and applications that take up most of the network bandwidth, and identify network threats.

With the App-Scope reports, you can quickly see if any behavior is unusual or unexpected. Each report provides a dynamic, user-customizable window into the network; hovering the mouse over and clicking either the lines or bars on the charts opens detailed information about the specific application, application category, user, or source on the ACC. The App-Scope charts give you the ability to:

- Toggle the attributes in the legend to only view chart details that you want to review. The ability to include or exclude data from the chart allows you to change the scale and review details more closely.
- Click into an attribute in a bar chart and drill down to the related sessions in the ACC. Click into an Application name, Application Category, Threat Name, Threat Category, Source IP address or Destination IP address on any bar chart to filter on the attribute and view the related sessions in the ACC.
- Export a chart or map to PDF or as an image. For portability and offline viewing, you can Export charts and maps as PDFs or PNG images.

The following App-Scope reports are available:

- Summary Report
- Change Monitor Report
- Threat Monitor Report
- Threat Map Report
- Network Monitor Report
- Traffic Map Report

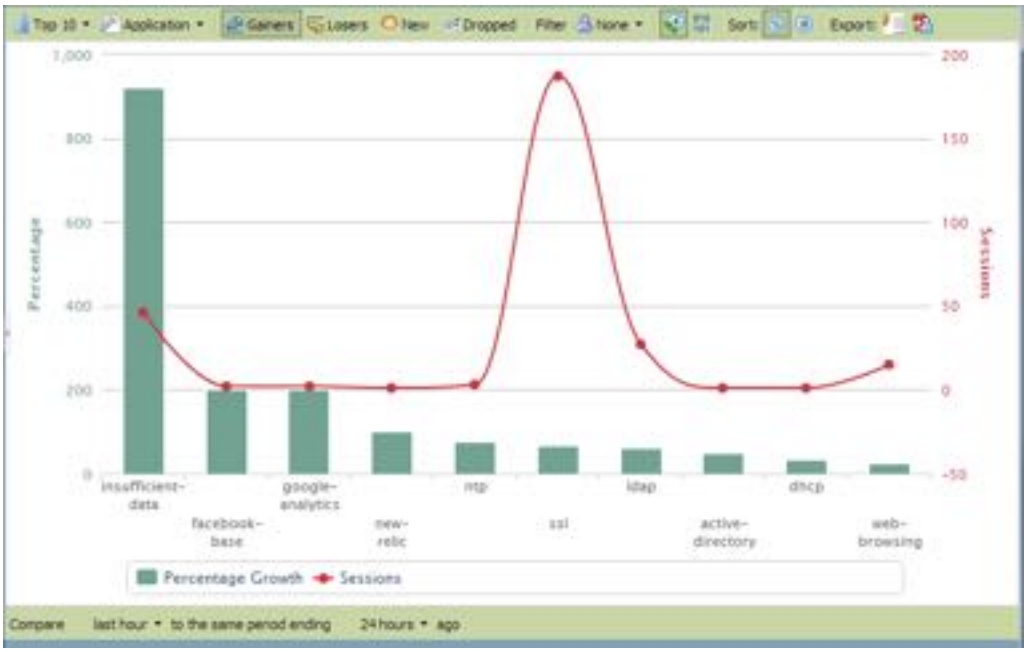
 © Palo Alto Networks, Inc.

## Summary Report

The App-Scope Summary report displays charts for the top five gainers, losers, and bandwidth consuming applications, application categories, users, and sources.

## Change Monitor Report

The App-Scope Change Monitor report displays changes over a specified time period. For example, the following chart displays the top applications that gained in use over the last hour as compared with the last 24-hour period. The top applications are determined by session count and sorted by percent.



The Change Monitor Report contains the following buttons and options.

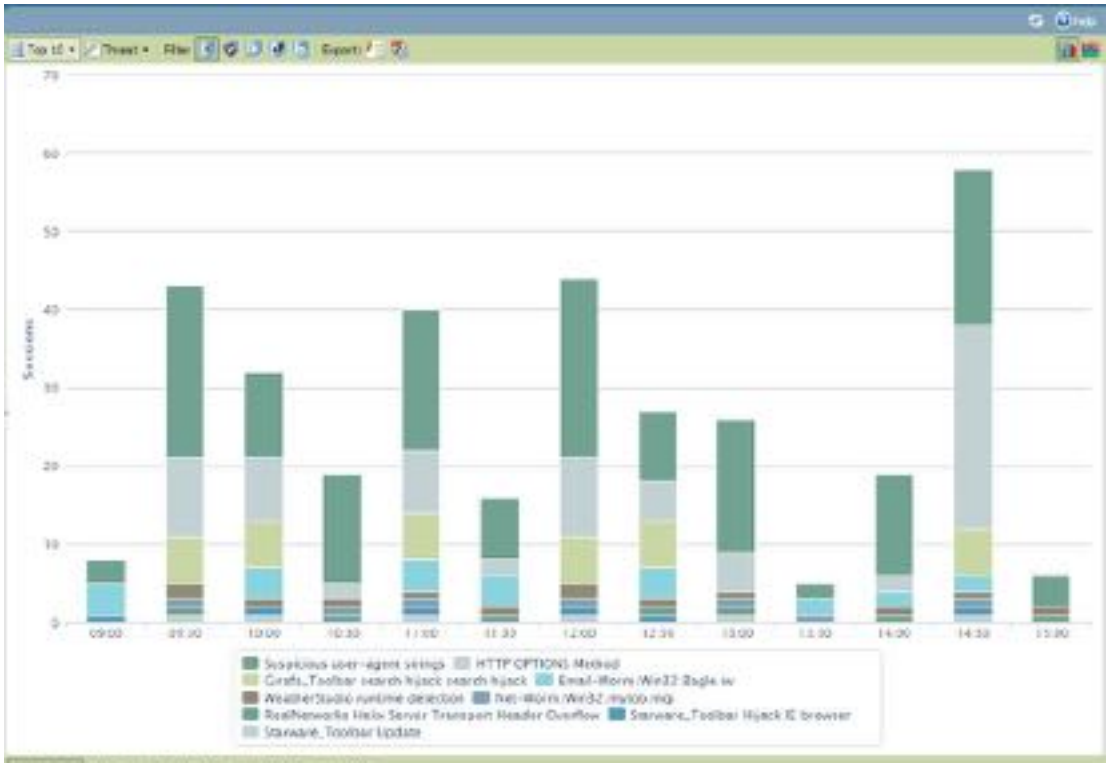
| Button | Description |
|---|---|
| Top 10 | Determines the number of records with the highest measurement included in the chart. |
| Application | Determines the type of item reported: Application, Application Category, Source, or Destination. |
| Gainers | Displays measurements of items that have increased over the measured period. |
| Losers | Displays measurements of items that have decreased over the measured period. |
| New | Displays measurements of items that were added over the measured period. |
| Dropped | Displays measurements of items that were discontinued over the measured period. |

 © Palo Alto Networks, Inc.

| Button | Description |
|---|---|
|  | Applies a filter to display only the selected item. **None** displays all entries. |
| | Determines whether to display session or byte information. |
|  | Determines whether to sort entries by percentage or raw growth. |
|  | Exports the graph as a .png image or as a PDF. |
|  | Specifies the period over which the change measurements are taken. |

## Threat Monitor Report

The App-Scope Threat Monitor report displays a count of the top threats over the selected time period. For example, the following figure shows the top 10 threat types over the last 6 hours.



Each threat type is color-coded as indicated in the legend below the chart. The Threat Monitor report contains the following buttons and options.

| Button | Description |
|---|---|
| | Determines the number of records with the highest measurement included in the chart. |
| | Determines the type of item measured: Threat, Threat Category, Source, or Destination. |
| | Applies a filter to display only the selected type of items. |
| | Determines whether the information is presented in a stacked column chart or a stacked area chart. |
|  | Exports the graph as a .png image or as a PDF. |
| | Specifies the period over which the measurements are taken. |

 © Palo Alto Networks, Inc.

## Threat Map Report

The App-Scope Threat Map report shows a geographical view of threats, including severity. Each threat type is color-coded as indicated in the legend below the chart.

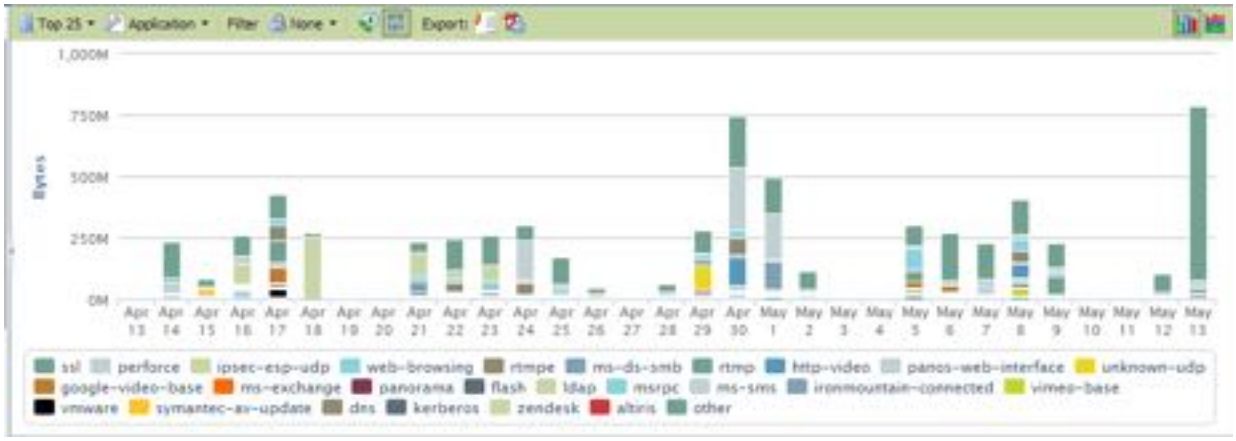
The firewall uses geolocation for creating threat maps. The firewall is placed at the bottom of the threat map screen, if you have not specified the geolocation coordinates (**Device > Setup > Management,** General Settings section) on the firewall.

The Threat Map report contains the following buttons and options.

| Button | Description |
|---|---|
| | Determines the number of records with the highest measurement included in the chart. |
|  | Displays incoming threats. |
|  | Displays outgoing threats. |
| | Applies a filter to display only the selected type of items. |
|  | Zoom in and zoom out of the map. |
| | Exports the graph as a .png image or as a PDF. |
| | Indicates the period over which the measurements are taken. |

## Network Monitor Report

The App-Scope Network Monitor report displays the bandwidth dedicated to different network functions over the specified period of time. Each network function is color-coded as indicated in the legend below the chart. For example, the image below shows application bandwidth for the past 7 days based on session information.



The Network Monitor report contains the following buttons and options.

| Button | Description |
|---|---|
| | Determines the number of records with the highest measurement included in the chart. |
|   | Determines the type of item reported: Application, Application Category, Source, or Destination. |
|   | Applies a filter to display only the selected item. **None** displays all entries. |
| | Determines whether to display session or byte information. |
|   | Exports the graph as a .png image or as a PDF. |
| | Determines whether the information is presented in a stacked column chart or a stacked area chart. |
| | Indicates the period over which the change measurements are taken. |

 © Palo Alto Networks, Inc.

## Traffic Map Report

The App-Scope Traffic Map report shows a geographical view of traffic flows according to sessions or flows.

The firewall uses geolocation for creating traffic maps. The firewall is placed at the bottom of the traffic map screen, if you have not specified the geolocation coordinates (**Device > Setup > Management,** General Settings section) on the firewall.

Each traffic type is color-coded as indicated in the legend below the chart. The Traffic Map report contains the following buttons and options.

| Buttons | Description |
|---|---|
| | Determines the number of records with the highest measurement included in the chart. |
|  | Displays incoming threats. |
|  | Displays outgoing threats. |
| | Determines whether to display session or byte information. |
|  | Zoom in and zoom out of the map. |
| | Exports the graph as a .png image or as a PDF. |
| | Indicates the period over which the change measurements are taken. |

# Take Packet Captures

PAN-OS supports packet capture for troubleshooting or detecting unknown applications. You can define filters such that only the packets that match the filters are captured. The packet captures are locally stored on the device and are available for download to your local computer.

Packet Capture is for troubleshooting only. This feature can cause the system performance to degrade and should be used only when necessary. Remember to disable the feature after you complete the packet capture.

The following table describes the packet capture settings on **Monitor > Packet Capture**.

| Field | Description |
|---|---|
| **Manage Filters** | Click **Manage Filters**, click **Add** to add a new filter, and specify the following information:<br>• **Id**—Enter or select an identifier for the filter.<br>• **Ingress Interface**—Select the firewall interface.<br>• **Source**—Specify the source IP address.<br>• **Destination**—Specify the destination IP address.<br>• **Src Port**—Specify the source port.<br>• **Dest Port**—Specify the destination port.<br>• **Proto**—Specify the protocol to filter.<br>• **Non-IP**—Choose how to treat non-IP traffic (exclude all IP traffic, include all IP traffic, include only IP traffic, or do not include an IP filter).<br>• **IPv6**—Select the check box to include IPv6 packets in the filter. |
| **Filtering** | Click to toggle the filtering selections on or off. |
| **Pre-Parse Match** | Click to toggle the pre-parse match option on or off.<br>The pre-parse-match option is added for advanced troubleshooting purposes. After a packet enters the ingress port, it proceeds through several processing steps before it is parsed for matches against pre-configured filters.<br>It is possible for a packet, due to a failure, to not reach the filtering stage. This can occur, for example, if a route lookup fails.<br>Set the pre-parse-match setting to **ON** to emulate a positive match for every packet entering the system. This allows the firewall to capture even the packets that do not reach the filtering process. If a packet is able to reach the filtering stage, it is then processed according to the filter configuration and discarded if it fails to meet filtering criteria. |

 © Palo Alto Networks, Inc.

| Field | Description |
|---|---|
| **Packet Capture** | Click to toggle packet capturing on or off.<br>For anti-spyware and vulnerability protection profiles, you can enable extended packet captures for rules and exceptions defined in the profile. This functionality allows the firewall to capture from 1 to 50 packets and provides more context when analyzing the threat logs.<br>To define the extended packet capture length:<br>1. Select **Device > Setup > Content-ID.**<br>2. Edit the Threat Detection Settings section to specify the **Capture Length** for the number of packets to capture.<br>  <br>3. View the packet capture in **Monitor > Logs > Threat**.<br>Locate the threat log entry and click the green arrow (Packet Capture) icon in the corresponding row to view the capture. |
| **Packet Capture Stage** | Select **Add** and specify the following:<br>• **Stage**—Indicate the point at which to capture the packet:<br>• **drop**—When packet processing encounters an error and the packet is to be dropped.<br>• **firewall**—When the packet has a session match or a first packet with a session is successfully created.<br>• **receive**—When the packet is received on the dataplane processor.<br>• **transmit**—When the packet is to be transmitted on the dataplane processor.<br>• **File**—Specify the capture file name. The file name should begin with a letter and can include letters, digits, periods, underscores, or hyphens.<br>• **Packet Count**—Specify the number of packets after which capturing stops.<br>• **Byte Count**—Specify the number of bytes after which capturing stops. |
| **Captured Files** | Select **Delete** to remove a packet capture file from the list displaying captured files. |
| **Clear All Settings** | Select **Clear All Settings** to clear all packet capture settings. |

# Monitor the Firewall

The following sections describe the methods you can use to monitor the firewall and provide basic setup instructions:

- Monitor Applications and Threats
- Monitor Log Data
- Monitor the Dashboard
- View Reports

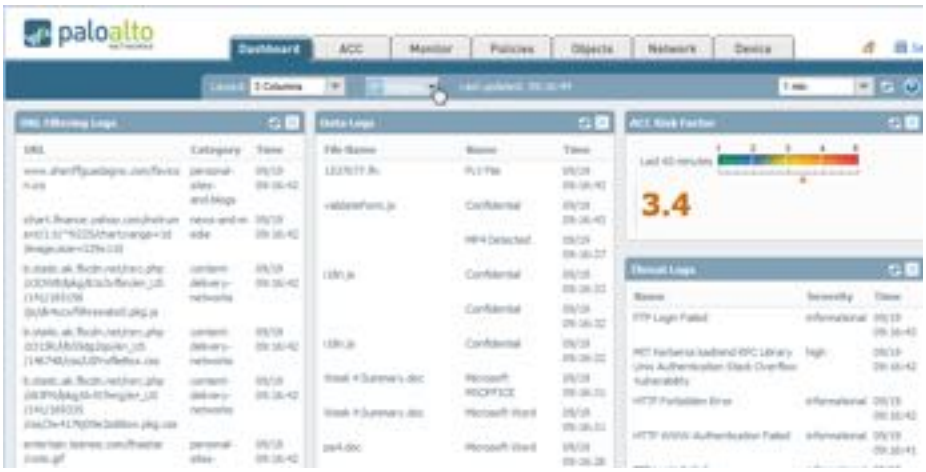
You can also configure the firewall (excluding PA-4000 Series and PA-7050 firewalls) to export flow data to a NetFlow collector for analysis and reporting. To configure NetFlow Settings, refer to the PAN-OS Web Interface Reference Guide.

© Palo Alto Networks, Inc.

## Monitor Applications and Threats

All Palo Alto Networks next-generation firewalls come equipped with the App-ID technology, which identifies the applications traversing your network, irrespective of protocol, encryption, or evasive tactic. You can then Use the Application Command Center to monitor the applications. ACC graphically summarizes the log database to highlight the applications traversing your network, who is using them, and their potential security impact. ACC is dynamically updated, using the continuous traffic classification that App-ID performs; if an application changes ports or behavior, App-ID continues to see the traffic, displaying the results in ACC.

You can quickly investigate new, risky, or unfamiliar applications that appear in ACC with a single click that displays a description of the application, its key features, its behavioral characteristics, and who is using it. Additional visibility into URL categories, threats, and data provides a complete and well-rounded picture of network activity. With ACC, you can very quickly learn more about the traffic traversing the network and then translate that information into a more informed security policy.



# Monitor Log Data

All Palo Alto Networks next-generation firewalls can generate log files that provide an audit trail of the activities and events on the firewall. There are separate logs for separate types of activities and events. For example, the Threat logs record all traffic that causes the firewall to generate a security alarm, URL Filtering logs record all traffic that matches a URL Filtering profile attached to a security policy, and Config logs record all changes to the firewall configuration.

You can either Forward Logs to External Services or you can view logs locally on the device as follows:

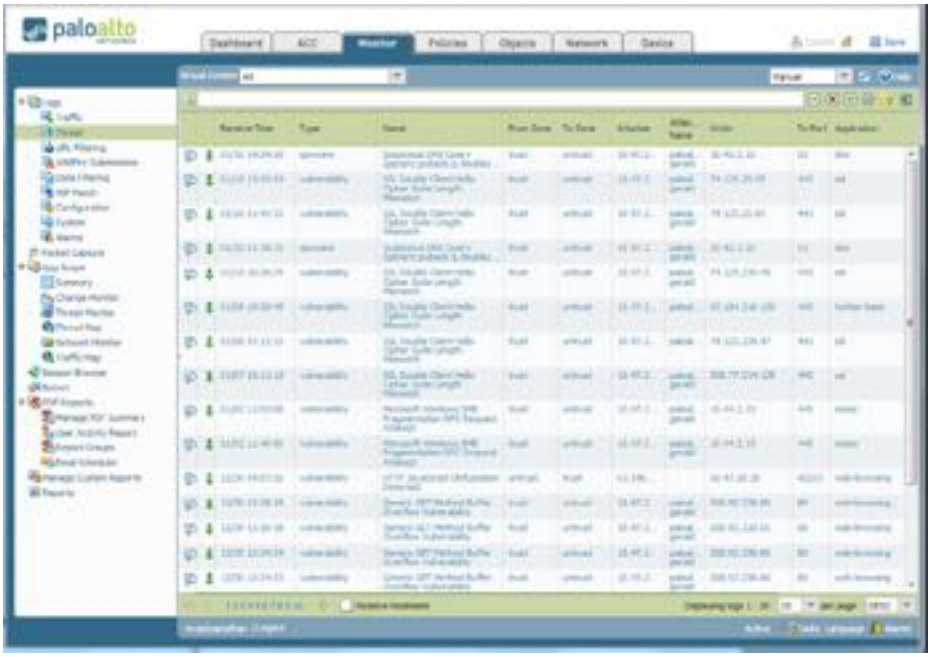
- View the Log Files
- Filter Log Data

## View the Log Files

The firewall maintains logs for WildFire, configurations, system, alarms, traffic flows, threats, URL filtering, data filtering, and Host Information Profile (HIP) matches. You can view the current logs at any time. To locate specific entries, you can apply filters to most of the log fields.

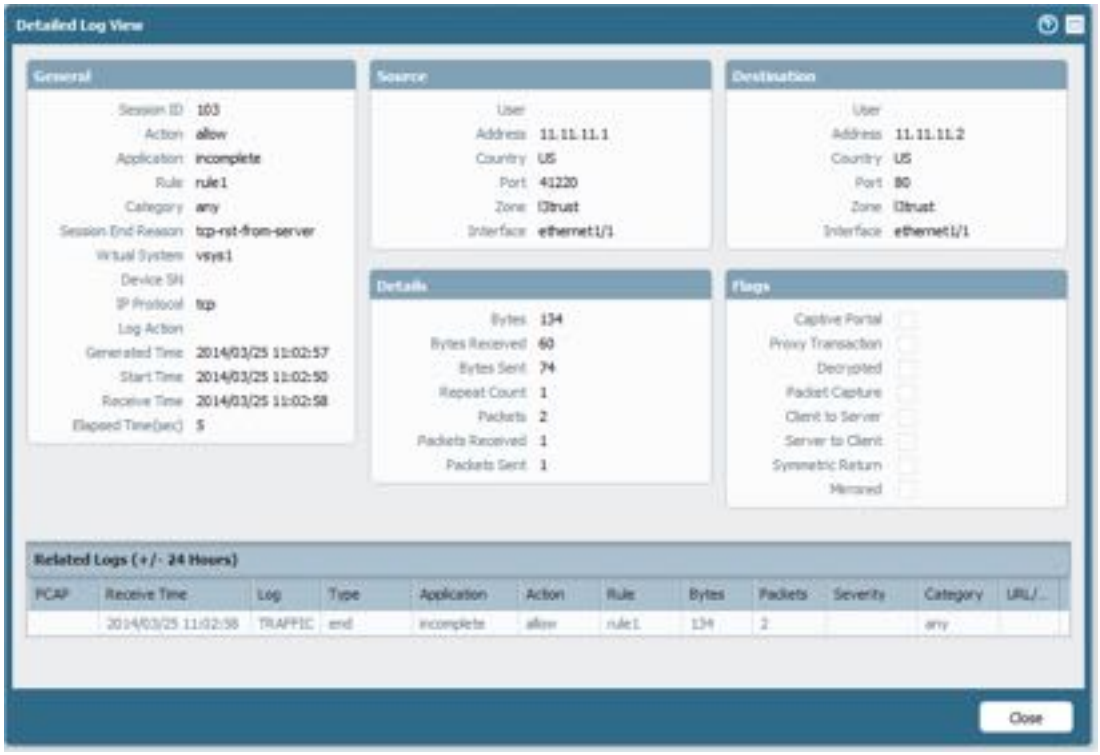
The firewall displays the information in logs so that role-based administration permissions are respected. When you display logs, only the information that you have permission to see is included. For information on administrator permissions, see Administrative Roles.

By default all log files are generated and stored locally on the firewall. You can view these log files directly (**Monitor > Logs**):



To display additional details, click the spyglass icon for an entry.

 © Palo Alto Networks, Inc.



The following table includes information on each log type:

| Log Description Charts | Description |
|---|---|
| Traffic | Displays an entry for the start and end of each session. Each entry includes the date and time, source and destination zones, addresses and ports, application name, security rule name applied to the flow, rule action (**allow**, **deny**, or **drop**), ingress and egress interface, number of bytes, and session end reason.<br>Click next to an entry to view additional details about the session, such as whether an ICMP entry aggregates multiple sessions between the same source and destination (the **Count** value will be greater than one).<br>The **Type** column indicates whether the entry is for the start or end of the session, or whether the session was denied or dropped. A **drop** indicates that the security rule that blocked the traffic specified **any** application, while a **deny** indicates the rule identified a specific application.<br>If traffic is dropped before the application is identified, such as when a rule drops all traffic for a specific service, the application is shown as **not-applicable**. |

| Log Description Charts | Description |
|---|---|
| Threat | Displays an entry when traffic matches a Security Profile (Antivirus, Anti-spyware, Vulnerability, URL Filtering, File Blocking, Data Filtering, or DoS Protection) that is attached to a security policy on the firewall. Each entry includes the date and time, a threat name or URL, the source and destination zones, addresses, and ports, the application name, and the alarm action (**allow** or **block**) and severity.<br>Click next to an entry to view additional details about the threat, such as whether the entry aggregates multiple threats of the same type between the same source and destination (the **Count** value will be greater than one).<br>The **Type** column indicates the type of threat, such as "virus" or "spyware." The Name column is the threat description or URL, and the **Category** column is the threat category (such as "keylogger") or URL category.<br>If local packet captures are enabled, click next to an entry to access the captured packets. To enable local packet captures, see Take Packet Captures. |
| URL Filtering | Displays logs for all traffic that matches a URL Filtering profile attached to a security policy. For example, if policy blocks access to specific web sites and web site categories or if policy is configured to generate an alert when a web site is accessed. For information on defining URL filtering profiles, see URL Filtering. |
| WildFire Submissions | Displays logs for files that are uploaded and analyzed by the WildFire cloud; log data is sent back to the device after analysis, along with the analysis results. |
| Data Filtering | Displays logs for the security policies that help prevent sensitive information such as credit card or social security numbers from leaving the area protected by the firewall. See Set Up Data Filtering for information on defining data filtering profiles.<br>This log also shows information for file-blocking profiles. For example, if you are blocking *.exe* files, the log will show the files that were blocked. If you forward files to WildFire, you will see the results of that action. In this case, if you are forwarding PE files to WildFire, for example, the log will show that the file was forwarded and will also show the status on whether or not it was uploaded to WildFire successfully. |
| Configuration | Displays an entry for each configuration change. Each entry includes the date and time, the administrator username, the IP address from where the change was made, the type of client (XML, Web or CLI), the type of command executed, whether the command succeeded or failed, the configuration path, and the values before and after the change. |
| System | Displays an entry for each system event. Each entry includes the date and time, the event severity, and an event description. |
| HIP Match | Displays traffic flows that match a HIP Object or HIP Profile that you have configured. |

## Filter Log Data

Each log page has a filter area at the top of the page.

Use the filter area as follows:

 © Palo Alto Networks, Inc.

- Click any of the underlined links in the log listing to add that item as a log filter option. For example, if you click the **Host** link in the log entry for 10.0.0.252 and **Web Browsing**, both items are added, and the search will find entries that match both (AND search).
- To define other search criteria, click **Add Log Filter**. Select the type of search (and/or), the attribute to include in the search, the matching operator, and the values for the match, if appropriate. Click **Add** to add the criterion to the filter area on the log page, and then click **Close** to close the pop-up window. Click **Apply Filter** to display the filtered list.

If the **Value** string matches an **Operator** (such as **has** or **in**), enclose the string in quotation marks to avoid a syntax error. For example, if you filter by destination country and use `IN` as a **Value** to specify INDIA, enter the filter as `( dstloc eq "IN" )`.

You can combine filter expressions added on the log page with those you define in the Add Log Filter dialog. The filter field on the log page displays each filter as an entry.

If you add a **Receive Time** filter with the **Operator** set to **in** and the **Value** set to **Last 60 seconds**, some of the page links on the log viewer might not show results because the number of pages might grow or shrink due to the dynamic nature of the selected time.

- To clear filters and redisplay the unfiltered list, click **Clear Filter**.
- To save your selections as a new filter, click **Save Filter**, enter a name for the filter, and click **OK**.
- To export the current log listing (as shown on the page, including any applied filters) click **Save Filter**. Select whether to open the file or save it to disk, and select the check box if you want to always use the same option. Click **OK**.
- To export the current log listing in CSV Format, select the **Export to CSV** icon. By default, exporting the log listing to CSV format generates a CSV report with up to 2,000 rows of logs. To change the limit for rows displayed in CSV reports, use the **Max Rows in CSV Export** field on the **Log Export and Reporting** tab (select **Device > Setup > Management > Logging and Reporting Settings**).

To change the automatic refresh interval, select an interval from the drop-down (**1 min**, **30 seconds**, **10 seconds**, or **Manual**).

To change the number of log entries per page, select the number of rows from the **Rows** drop-down.

Log entries are retrieved in blocks of 10 pages. Use the paging controls at the bottom of the page to navigate through the log list. Select the **Resolve Hostname** check box to begin resolving external IP addresses to domain names.

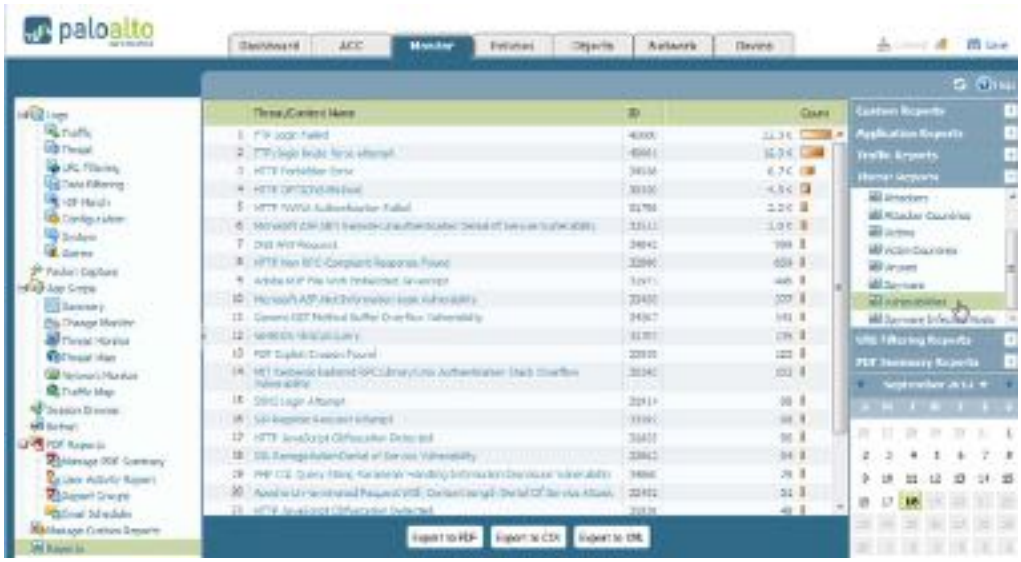
## Monitor the Dashboard

You can also monitor the local log data directly from the **Dashboard** by adding the associated widgets:

 © Palo Alto Networks, Inc.

## View Reports

The firewall also uses the log data to generate reports (**Monitor > Reports**) that display the log data in a tabular or graphical format. See About Reports for more details on the predefined and custom reports available on the firewall.



# Forward Logs to External Services

Depending on the type and severity of the data in the log files, you may want to be alerted to critical events that require your attention, or you may have policies that require you to archive the data for longer than it can be stored on the firewall. In these cases you will want to forward your log data to an external service for archive, notification, and/or analysis.

To forward log data to an external service you must complete the following tasks:

- Configure the firewall to access the remote services that will be receiving the logs. See Define Remote Logging Destinations.
- Configure each log type for forwarding. See Enable Log Forwarding.
- For traffic and threat logs, enabling log forwarding includes setting up a log forwarding profile or a default log forwarding profile. For details, see Log Forwarding Profiles.

 © Palo Alto Networks, Inc.

## Define Remote Logging Destinations

In order to reach an external service—such as a Syslog server or SNMP trap manager—the firewall must know the details of how to access and, if necessary, authenticate to the service. On the firewall, you define this information in a Server Profile. You must create a Server Profile for each external service you want the firewall to interact with. The type of logging destinations you need to set up and which logs you forward will depend on your needs. Some common log forwarding scenarios include the following:

- For immediate notification about critical system events or threats that require your attention, you can generate SNMP traps or send email alerts. See Set Up Email Alerts and/or Set Up SNMP Trap Destinations.
- For long-term storage and archival of data and for centralized device monitoring, you can send the log data to a Syslog server. See Define Syslog Servers. This enables integration with third-party security monitoring tools, such as Splunk! or ArcSight. You can also secure the channel between the firewall and the Syslog server. See Configure the Firewall to Authenticate to the Syslog Server.
- For aggregation and reporting of log data from multiple Palo Alto Networks firewalls, you can forward logs to a Panorama Manager or Panorama Log Collector. See Enable Log Forwarding.

You can define as many Server Profiles as you need. For example, you could use separate Server Profiles to send traffic logs to one Syslog server and system logs to a different one. Or, you could include multiple server entries in a single Server Profile to enable you to log to multiple Syslog servers for redundancy.

By default, all log data is forwarded over the MGT interface. If you plan to use an interface other than MGT, you will need to configure a Service Route for each service to which you plan to forward logs as described in Step 5 in the procedure to Set Up Network Access for External Services.

## Set Up Email Alerts

| Set Up Email Alerts | | |
|---|---|---|
| Step 1 | Create a Server Profile for your email server. | 1. Select **Device > Server Profiles > Email**.<br>2. Click **Add** and then enter a **Name** for the profile.<br>3. (Optional) Select the virtual system to which this profile applies from the **Location** drop-down.<br>4. Click **Add** to add a new email server entry and enter the information required to connect to the Simple Mail Transport Protocol (SMTP) server and send email (you can add up to four email servers to the profile):<br>• **Server**—Name to identify the mail server (1-31 characters). This field is just a label and does not have to be the host name of an existing SMTP server.<br>• **Display Name**—The name to show in the From field of the email.<br>• **From**—The email address where notification emails will be sent from.<br>• **To**—The email address to which notification emails will be sent.<br>• **Additional Recipient**—If you want the notifications sent to a second account, enter the additional address here. You can only add one additional recipient. To add multiple recipients, add the email address of a distribution list.<br>• **Gateway**—The IP address or host name of the SMTP gateway to use to send the emails.<br>5. Click **OK** to save the server profile. |
| Step 2 | (Optional) Customize the format of the email messages the firewall sends. | Select the **Custom Log Format** tab. For details on how to create custom formats for the various log types, refer to the Common Event Format Configuration Guide. |
| Step 3 | Save the server profile and commit your changes. | 1. Click **OK** to save the profile.<br>2. Click **Commit** to save the changes to the running configuration. |

## Set Up SNMP Trap Destinations

Simple Network Management Protocol (SNMP) is a standard facility for monitoring the devices on your network. You can configure the firewall to send SNMP traps to your SNMP management software to alert you to critical system events or threats that require your immediate attention.

You can also use SNMP to monitor the firewall. In this case, your SNMP manager must be configured to get statistics from the firewall rather than (or in addition to) having the firewall send traps to the manager. For more information, see Configure the Firewall to Authenticate to the Syslog Server.

 © Palo Alto Networks, Inc.

**Set Up SNMP Trap Destinations**

Step 1 (SNMP v3 only) Get the engine ID for the firewall.

In many cases, the MIB browser or SNMP manager will automatically discover the engine ID upon successful connection to the SNMP agent on the firewall. You can usually find this information in the agent settings section of the interface. Refer to the documentation for your specific product for instructions on finding the agent information.

In order to find out the firewall's engine ID, you must configure the firewall for SNMP v3 and send a GET message from your SNMP manager or MIB browser as follows:

1. Enable the interface to allow inbound SNMP requests:
   - If you will be receiving SNMP GET messages on the MGT interface, select **Device > Setup > Management** and click to Edit in the Management Interface Settings section of the screen. In the **Services** section, select the **SNMP** check box and then click **OK**.
   - If you will be receiving SNMP GET messages on a different interface, you must associate a management profile with the interface and enable SNMP management.
2. Configure the firewall for SNMP v3 as described in Step 2 in Set Up SNMP Monitoring. If you do not configure the firewall for SNMP v3, your MIB browser will not allow you to GET the engine ID.
3. Connect your MIB browser or SNMP manager to the firewall and run a GET for OID 1.3.6.1.6.3.10.2.1.1.0. The value that is returned is the unique engine ID for the firewall.

Step 2 Create a Server Profile that contains the information for connecting and authenticating to the SNMP manager(s).

1. Select **Device > Server Profiles > SNMP Trap**.
2. Click **Add** and then enter a **Name** for the profile.
3. (Optional) Select the virtual system to which this profile applies from the **Location** drop-down.
4. Specify the version of SNMP you are using (V2c or V3).
5. Click **Add** to add a new **SNMP Trap Receiver** entry (you can add up to four trap receivers per server profile). The required values depend on whether you are using SNMP V2c or V3 as follows:

   SNMP V2c

   - **Server**—Name to identify the SNMP manager (1-31 characters). This field is just a label and does not have to be the host name of an existing SNMP server.
   - **Manager**—The IP address of the SNMP manager to which you want to send traps.
   - **Community**—The community string required to authenticate to the SNMP manager.

   SNMP V3

   - **Server**—Name to identify the SNMP manager (1-31 characters). This field is just a label and does not have to be the host name of an existing SNMP server.
   - **Manager**—The IP address of the SNMP manager to which you want to sent traps.
   - **User**—The username required to authenticate to the SNMP manager.
   - **EngineID**—The engine ID of the firewall, as identified in Step 1. This is a hexadecimal value from 5 to 64 bytes with a 0x prefix. Each firewall has a unique engine ID.
   - **Auth Password**—The password to be used for authNoPriv level messages to the SNMP manager. This password will be hashed using Secure Hash Algorithm (SHA-1), but will not be encrypted.
   - **Priv Password**—The password to be used for authPriv level messages to the SNMP manager. This password be hashed using SHA and will be encrypted using Advanced Encryption Standard (AES 128).
6. Click **OK** to save the server profile.

| Set Up SNMP Trap Destinations (Continued) | | |
|---|---|---|
| Step 3 | (Optional) Set up a service route for SNMP traps. | By default, SNMP traps are sent over the MGT interface. If you want to use a different interface for SNMP traps, you must edit the service route to enable the firewall to reach your SNMP manager. See Set Up Network Access for External Services for instructions. |
| Step 4 | Commit your changes. | Click **Commit**. The device may take up to 90 seconds to save your changes. |
| Step 5 | Enable the SNMP manager to interpret the traps it receives from the firewall. | Load the PAN-OS MIB files into your SNMP management software and compile them. Refer to the documentation for your SNMP manager for specific instructions on how to do this. |

## Define Syslog Servers

Syslog is a standard log transport mechanism that enables the aggregation of log data from different network devices—such as routers, firewalls, printers—from different vendors into a central repository for archive, analysis, and reporting.

The firewall generates six types of logs that can be forwarded to an external syslog server: traffic, threat, WildFire, host information profile (HIP) match, config, and system. If you want to forward all or some of these logs to an external service for long-term storage and analysis, you can use TCP or SSL for reliable and secure transport of logs, or UDP for non-secure transport.

 © Palo Alto Networks, Inc.

| Set Up Syslog Forwarding | |
|---|---|
| Step 1 Create a Server Profile that contains the information for connecting to the Syslog server(s). | 1. Select **Device > Server Profiles > Syslog**.<br>2. Click **Add** and then enter a **Name** for the profile.<br>3. (Optional) Select the virtual system to which this profile applies from the **Location** drop-down.<br>4. Click **Add** to add a new Syslog server entry and enter the information required to connect to the Syslog server (you can add up to four Syslog servers to the same profile):<br>• **Name**—Unique name for the server profile.<br>• **Server**—IP address or fully qualified domain name (FQDN) of the Syslog server.<br>• **Transport**—Select TCP, UDP, or SSL as the method of communication with the syslog server.<br>• **Port**—The port number on which to send Syslog messages (default is UDP on port 514); you must use the same port number on the firewall and the Syslog server.<br>• **Format**—Select the Syslog message format to use, BSD or IETF. Traditionally, BSD format is over UDP and IETF format is over TCP/SSL. For setting up secure syslog forwarding with client authentication, see Configure the Firewall to Authenticate to the Syslog Server.<br>• **Facility**—Select one of the Syslog standard values, which is used to calculate the priority (PRI) field in your Syslog server implementation. You should select the value that maps to how you use the PRI field to manage your Syslog messages.<br>5. (Optional) To customize the format of the Syslog messages the firewall sends, select the **Custom Log Format** tab. For details on how to create custom formats for the various log types, refer to the Common Event Format Configuration Guide.<br>6. Click **OK** to save the server profile. |

| Set Up Syslog Forwarding (Continued) | |
|---|---|
| Step 2 (Optional) Configure the header format used in Syslog messages. Choosing the header format offers more flexibility in filtering and reporting on the log data for some SIEMs.<br>  <br><br>This is a global setting and applies to all syslog server profiles configured on the appliance. | 1. Select **Device > Setup > Management** and click the Edit icon in the Logging and Reporting Settings section.<br>2. Select **Log Export and Reporting**.<br>3. Select one of the following options from the **Send Hostname in Syslog** drop-down:<br>• **FQDN**—(the default) Concatenates the hostname and domain name defined on the sending device.<br>• **hostname**—Uses the hostname defined on the sending device.<br>• **ipv4-address**—Uses the IPv4 address of the interface used to send logs on the device. By default, this is the MGT interface of the device.<br>• **ipv6-address**—Uses the IPv6 address of the interface used to send logs on the device. By default, this is the MGT interface of the device.<br>• **none**—Leaves the hostname field unconfigured on the device. There is no identifier for the device that sent the logs.<br>4. Click **OK** and **Commit**. |
| Step 3 Commit your changes. | Click **Commit**. The device may take up to 90 seconds to save your changes. |
| Step 4 Enable log forwarding. | See Enable Log Forwarding.<br>You must configure each log type for forwarding and specify the severity for which the event is logged.<br>WildFire logs are a type of threat log, but they are not logged and forwarded along with threat logs. While WildFire logs use the same syslog format as threat logs, the threat subtype is preset to WildFire. Therefore, you must enable logging/forwarding for WildFire logs distinctly from threat logs. |
| Step 5 Review the logs on the syslog server. | To parse the logs, see Syslog Field Descriptions. |

## Configure the Firewall to Authenticate to the Syslog Server

To enable client authentication for syslog over SSL, you can use a trusted CA or a self-signed CA for generating certificates that can be used for secure syslog communication. Check for the following when generating a certificate for secure syslog communication:

- The private key must be available on the sending device; the keys cannot be stored on a Hardware Security Module (HSM).
- The subject and the issuer for the certificate must not be identical.

 © Palo Alto Networks, Inc.

- The certificate is neither a trusted CA nor a certificate signing request (CSR). Neither of these types of certificates can be enabled for secure syslog communication.

**Configure the Firewall to Authenticate to the Syslog Server**

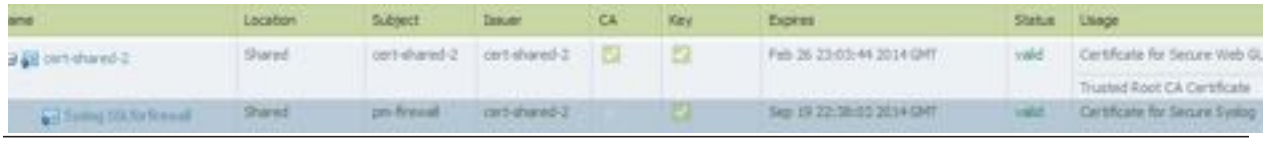
Step 1 If the syslog server requires client authentication, generate the certificate for secure communication. For details on certificates, see Certificate Management.

To verify that the sending device is authorized to communicate with the syslog server, you must enable the following:

- The server and the sending device must have certificates that are signed by the Enterprise CA; or you can generate a self-signed certificate on the firewall, export the CA root certificate from the firewall and import it in to the syslog server.
- Use the Enterprise CA or the self-signed certificate to generate a certificate with the IP address of the sending device (as the Common Name) and enabled for use in secure syslog communication. The syslog server uses this certificate to verify that the firewall is authorized to communicate with the syslog server.

  Use the following steps to generate the certificate on the firewall or Panorama:

1. Select **Device > Certificate Management > Certificates > Device Certificates**.
2. Click **Generate** to create a new certificate that will be signed by a trusted CA or the self-signed CA.
3. Enter a **Name** for the certificate.
4. In **Common Name**, enter the IP address of the device sending logs to the syslog server.
5. Select **Shared** if you want the certificate to be a shared certificate on Panorama or to be shared by all virtual systems in a multiple virtual system firewall.
6. In **Signed by**, select the trusted CA or the self-signed CA that is trusted by both the syslog server and the sending device.
7. Click **Generate**. The certificate and the keypair will be generated.
8. Click the link with name of the certificate and enable the **Certificate for Secure Syslog** option for secure access to the syslog server.
9. **Commit** the changes.
10. Verify the certificate details and that it is marked for **Usage** as **Certificate for Secure Syslog**.



## Enable Log Forwarding

After you create the Server Profiles that define where to send your logs (see Define Remote Logging Destinations), you must enable log forwarding. For each log type, you can specify whether to forward it to Syslog, email, SNMP trap receiver, and/or Panorama.

Before you can forward log files to a Panorama Manager or a Panorama Log Collector, the firewall must be configured as a managed device. You can then enable log forwarding to Panorama for each type of log. For logs forwarded to Panorama, support for centralized log forwarding to an external syslog server is available.

You can use Secure Copy (SCP) commands from the CLI to export the entire log database (logdb) to an SCP server and import it to another firewall: refer to the PAN-OS Command Line Interface (CLI) Reference Guide. Because the log database is too large for an export or import to be practical on the following platforms, they do not support these options: PA-7050 firewall (all PAN-OS releases), Panorama virtual appliance running Panorama 6.0 or later releases, and Panorama M-Series appliances (all Panorama releases).

The way you enable forwarding depends on the log type:

- **Traffic Logs**—You enable forwarding of Traffic logs by creating a Log Forwarding Profile (**Objects > Log Forwarding**) and adding it to the security policies you want to trigger the log forwarding. Only traffic that matches a specific rule within the security policy will be logged and forwarded. For details on setting up a log forwarding profile, see Log Forwarding Profiles.
- **Threat Logs**—You enable forwarding of Threat logs by creating a Log Forwarding Profile (**Objects > Log Forwarding**) that specifies which severity levels you want to forward and then adding it to the security policies for which you want to trigger the log forwarding. A Threat log entry will only be created (and therefore forwarded) if the associated traffic matches a Security Profile (Antivirus, Anti-spyware, Vulnerability, URL Filtering, File Blocking, Data Filtering, or DoS Protection). For details on setting up a log forwarding profile, see Log Forwarding Profiles. The following table summarizes the threat severity levels:

| Severity | Description |
|---|---|
| **Critical** | Serious threats, such as those that affect default installations of widely deployed software, result in root compromise of servers, and the exploit code is widely available to attackers. The attacker usually does not need any special authentication credentials or knowledge about the individual victims and the target does not need to be manipulated into performing any special functions. |
| **High** | Threats that have the ability to become critical but have mitigating factors; for example, they may be difficult to exploit, do not result in elevated privileges, or do not have a large victim pool. |
| **Medium** | Minor threats in which impact is minimized, such as DoS attacks that do not compromise the target or exploits that require an attacker to reside on the same LAN as the victim, affect only non-standard configurations or obscure applications, or provide very limited access. In addition, WildFire Submissions log entries with a malware verdict are logged as Medium. |
| **Low** | Warning-level threats that have very little impact on an organization's infrastructure. They usually require local or physical system access and may often result in victim privacy or DoS issues and information leakage. Data Filtering profile matches are logged as Low. |

 © Palo Alto Networks, Inc.

| Severity | Description |
|---|---|
| **Informational** | Suspicious events that do not pose an immediate threat, but that are reported to call attention to deeper problems that could possibly exist. URL Filtering log entries and WildFire Submissions log entries with a benign verdict are logged as Informational. |

- **Config Logs**—You enable forwarding of Config logs by specifying a Server Profile in the log settings configuration. (**Device > Log Settings > Config Logs**).
- **System Logs**—You enable forwarding of System logs by specifying a Server Profile in the log settings configuration. (**Device > Log Settings > System Logs**). You must select a Server Profile for each severity level you want to forward. For a partial list of system log messages and their corresponding severity levels, refer to the System Log Reference. The following table summarizes the system log severity levels:

| Severity | Description |
|---|---|
| **Critical** | Hardware failures, including HA failover and link failures. |
| **High** | Serious issues, including dropped connections with external devices, such as LDAP and RADIUS servers. |
| **Medium** | Mid-level notifications, such as antivirus package upgrades. |
| **Low** | Minor severity notifications, such as user password changes. |
| **Informational** | Log in/log off, administrator name or password change, any configuration change, and all other events not covered by the other severity levels. |

## Log Forwarding Profiles

Log forwarding profiles allow you to forward traffic and threat logs to Panorama or an external system. A log forwarding profile can be added to a security zone to forward zone protection logs or to a security policy to forward logs for traffic that matches that policy. You can also configure a default log forwarding profile—the settings in the default profile will be used as the default log forwarding settings for new security zones and new security policies. This allows you to consistently include your organization's preferred log forwarding settings in new policies and zones automatically, without administrators having to manually add them each time.

The following sections show how to create a log forwarding profile and how to enable a profile to be used as the default log forwarding settings for new security policies or security zones:

- ▲ Create a Log Forwarding Profile
- ▲ Set Up or Override a Default Log Forwarding Profile

## Create a Log Forwarding Profile

Create a log forwarding profile that can be added to security policies and security zones, in order to forward traffic and threat logs to Panorama or an external system. Forwarded logs can be sent as SNMP traps, syslog messages, or email notifications.

| **Enable a Log Forwarding Profile** | | |
|---|---|---|
| Step 1 | Add a log forwarding profile. | 1. Select **Objects > Log Forwarding Profile** and **Add** a new security profile group.<br>2. Give the profile group a descriptive **Name** to help identify it when adding the profile to security policies or security zones.<br>3. If the firewall is in Multiple Virtual System Mode, enable the profile to be **Shared** by all virtual systems.<br>4. Add settings for the Traffic logs, Threat logs, and WildFire logs:<br>• Select the **Panorama** check box for the severity of the Traffic, Threat, or WildFire logs that you want to be forwarded to Panorama.<br>• Specify logs that you want to forward to additional destinations: **SNMP Trap** destinations, **Email** servers, or **Syslog** servers.<br>5. Click **OK** to save the log forwarding profile. |
| Step 1 | Add the log forwarding profile to a security policy.<br>Traffic that matches the security policy and your log forwarding profile will be forwarded to the destinations defined in your profile.<br>For more details on security policies, see Security Policy. | 1. Select **Policies > Security** and **Add** or modify a security policy.<br>2. Select **Actions** and the log forwarding profile you created in the **Log Forwarding Profile** drop-down.<br>Threat log entries are generated according to the security profiles you have configured, in addition to the settings defined in the log forwarding profile. For more details on security profiles, see Security Profiles.<br>3. Click **OK** to save the security policy. |
| Step 1 | Add the log forwarding profile to a security zone.<br>For more details on setting up security zones, see Configure Interfaces and Zones. | 1. Select **Network > Zones** and **Add** or modify a security zone.<br>2. Select the log forwarding profile from the **Log Setting** drop-down.<br>3. Click **OK** to save the security zone. |
| Step 1 | Save your changes. | **Commit**. |

## Set Up or Override a Default Log Forwarding Profile

Add a new log forwarding profile or modify an existing one to be used as the default log forwarding settings for new security policy rules or new security zones. When an administrator creates a new security policy or a new security zone, the *default* log forwarding profile will be automatically selected as the policy or zone's log forwarding settings (the administrator can choose to manually select different log forwarding settings if desired). Use the following options to set up a default log forwarding profile or to override your default settings.

 © Palo Alto Networks, Inc.

If no default security profile exists, the profile settings for a new security policy are set to **None** by default.

| Set Up or Override a Default Log Forwarding Profile | |
|---|---|
| • Set up a default log forwarding profile. | 1. Select **Objects > Log Forwarding** and **Add** a new log forwarding profile or modify an existing profile.<br>2. **Name** the security profile group *default*:<br>  <br><br>3. Click **OK** and **Commit**.<br>4. Confirm that the *default* log forwarding profile is included in new security policies by default:<br>a. Select **Policies > Security** and **Add** a new security policy.<br>b. Select the **Actions** tab and ensure the **Log Forwarding** field shows the *default* profile selected:<br>  <br><br>5. Confirm the *default* log forwarding profile is included in new security zones by default:<br>a. Select **Network > Zones** and **Add** a new security zone.<br>b. Ensure the **Log Setting** field shows the *default* log forwarding profile selected:<br> <br> |
| • Override a default log forwarding profile. | If you have an existing default log forwarding profile, and you do not want the log forwarding settings defined in that profile to be applied to a new security policy or a new security zone, continue to modify the **Log Setting** field in the policy or zone according to your preference. |

# Monitor the Firewall Using SNMP

All Palo Alto Networks firewalls support standard networking SNMP management information base (MIB) modules as well as proprietary Enterprise MIB modules. You can configure an SNMP manager to get statistics from the firewall. For example, you could configure your SNMP manager to monitor the interfaces, active sessions, concurrent sessions, session utilization percentage, temperature, and/or system uptime on the firewall.

Palo Alto Networks firewalls support SNMP GET requests only; SNMP SET requests are not supported.

| **Set Up SNMP Monitoring** | | |
|---|---|---|
| Step 1 | Enable the interface to allow inbound SNMP requests. | • If you will be receiving SNMP GET messages on the MGT interface, select **Device > Setup > Management** and click to Edit the Management Interface Settings section of the screen. In the **Services** section, select the **SNMP** check box and then click **OK**.<br>• If you will be receiving SNMP GET messages on a different interface, you must associate a management profile with the interface and enable SNMP management. |
| Step 2 | From the web interface on the firewall, configure the settings to allow the SNMP agent on the firewall to respond to incoming GET requests from the SNMP manager. | 1. Select **Device > Setup > Operations > SNMP Setup**.<br>2. Specify the **Physical Location** of the firewall and the name or email address of an administrative **Contact**.<br>3. Select the SNMP **Version** and then enter the configuration details as follows (depending on which SNMP version you are using) and then click **OK**:<br>• **V2c**—Enter the **SNMP Community String** that will allow the SNMP manager access to the SNMP agent on the firewall. The default value is **public**, however because this is a well-known community string, it is a best practice to use a value that is not easily guessed.<br>• **V3**—You must create at least one View and one User in order to use SNMPv3. The view specifies which management information the manager has access to. If you want to allow access to all management information, just enter the top-level **OID** of .1.3.6.1 and specify the **Option** as **include** (you can also create views that exclude certain objects). Use **0xf0** as the **Mask**. Then when you create a user, select the **View** you just created and specify the **Auth Password** and **Priv Password**.<br>The authentication settings (the community string for V2c or the username and passwords for V3) configured on the firewall must match the value configured on the SNMP manager.<br>4. Click **OK** to save the settings.<br>5. Click **Commit** to save the SNMP settings. |
| Step 3 | Enable the SNMP manager to interpret firewall statistics. | Load the PAN-OS MIB files into your SNMP management software and, if necessary, compile them. Refer to the documentation for your SNMP manager for specific instructions on how to do this. |

© Palo Alto Networks, Inc.

| Set Up SNMP Monitoring (Continued) | | |
|---|---|---|
| Step 4 | Identify the statistics you want to monitor. | Using a MIB browser, walk the PAN-OS MIB files to identify the object identifiers (OIDs) that correspond to the statistics you want to monitor. For example, suppose you want to monitor Session Utilization Percentage on the firewall. Using a MIB browser you will see that this statistic corresponds to OID 1.3.6.1.4.1.25461.2.1.2.3.1.0 in the PAN-COMMON-MIB. |
| Step 5 | Configure the SNMP management software to monitor the OIDs you are interested in. | Refer to the documentation for your SNMP manager for specific instructions on how to do this. |
| Step 6 | After you complete the configuration on both the firewall and the SNMP manager, you can begin monitoring the firewall from your SNMP management software. | The following is an example of how an SNMP manager displays real-time session utilization percentage statistics for a monitored PA-500 firewall:   |

# Monitor the Firewall Using NetFlow

NetFlow is an industry-standard protocol that enables the firewall to record statistics on the IP traffic that traverses its interfaces. The firewall exports the statistics as NetFlow fields to a NetFlow collector. The NetFlow collector is a server you use to analyze network traffic for security, administration, accounting and troubleshooting purposes. All firewalls support NetFlow Version 9 except the PA-4000 Series and PA-7050 firewalls. The firewalls support only unidirectional NetFlow, not bidirectional. You can enable NetFlow exports on all interface types except HA, log card, or decrypt mirror. To identify firewall interfaces in a NetFlow collector, see Identify Firewall Interfaces in External Monitoring Systems.

The firewall supports standard and enterprise (PAN-OS specific) NetFlow templates. NetFlow collectors require templates to decipher the exported fields. The firewall selects a template based on the type of data it exports: IPv4 or IPv6 traffic, with or without NAT, and with standard or enterprise-specific fields. For a list of supported templates and field definitions, see NetFlow Templates. The firewall periodically refreshes templates to apply any changes to them. You configure the refresh frequency according to the requirements of the particular NetFlow collector you use.

| **Monitor the Firewall Using NetFlow** | | |
|---|---|---|
| Step 1 | Create a NetFlow server profile. | 1. Select **Device > Server Profiles > NetFlow** and click **Add**.<br>2. Enter a **Name** for the profile.<br>3. Specify the frequency at which the firewall refreshes templates (in **Minutes** or **Packets**) and exports records (**Active Timeout** in minutes).<br>4. Select the **PAN-OS Field Types** check box if you want the firewall to export App-ID and User-ID fields.<br>5. For each NetFlow collector (up to two per profile) that will receive fields, click **Add** and enter an identifying server **Name**, hostname or IP address (**NetFlow Server**), and access **Port** (default 2055).<br>6. Click **OK** to save the profile. |
| Step 2 | Assign the NetFlow server profile to the interfaces that carry the traffic you want to analyze.<br><br>In this example, you assign the profile to an existing Layer 3 interface. | 1. Select **Network > Interfaces > Ethernet** and click an **Interface** name to edit it.<br>2. In the **NetFlow Profile** drop-down, select the NetFlow server profile and click **OK**.<br>3. Click **Commit** and **OK**. |

© Palo Alto Networks, Inc.

# NetFlow Templates

The Palo Alto Networks firewall supports the following NetFlow templates:

| Template | ID |
|---|---|
| IPv4 Standard | 256 |
| IPv4 Enterprise | 257 |
| IPv6 Standard | 258 |
| IPv6 Enterprise | 259 |
| IPv4 with NAT Standard | 260 |
| IPv4 with NAT Enterprise | 261 |

The following table lists the NetFlow fields that the firewall can send, along with the templates that define them:

| Value | Field | Description | Templates |
|---|---|---|---|
| 1 | IN_BYTES | Incoming counter with length N * 8 bits for the number of bytes associated with an IP flow. By default, N is 4. | All templates |
| 2 | IN_PKTS | Incoming counter with length N * 8 bits for the number of packets associated with an IP glow. By default, N is 4 | All templates |
| 4 | PROTOCOL | IP protocol byte. | All templates |
| 5 | TOS | Type of Service byte setting when entering the incoming interface. | All templates |
| 6 | TCP_FLAGS | Total of all the TCP flags in this flow. | All templates |
| 7 | L4_SRC_PORT | TCP/UDP source port number (for example, FTP, Telnet, or equivalent). | All templates |
| 8 | IPV4_SRC_ADDR | IPv4 source address. | IPv4 standard<br>IPv4 enterprise<br>IPv4 with NAT standard<br>IPv4 with NAT enterprise |
| 10 | INPUT_SNMP | Input interface index. The value length is 2 bytes by default, but higher values are possible. For details on how Palo Alto Networks firewalls generate interface indexes, see Identify Firewall Interfaces in External Monitoring Systems. | All templates |
| 11 | L4_DST_PORT | TCP/UDP destination port number (for example, FTP, Telnet, or equivalent). | All templates |

| Value | Field | Description | Templates |
|---|---|---|---|
| 12 | IPV4_DST_ADDR | IPv4 destination address. | IPv4 standard<br>IPv4 enterprise<br>IPv4 with NAT standard<br>IPv4 with NAT enterprise |
| 14 | OUTPUT_SNMP | Output interface index. The value length is 2 bytes by default, but higher values are possible. For details on how Palo Alto Networks firewalls generate interface indexes, see Identify Firewall Interfaces in External Monitoring Systems. | All templates |
| 21 | LAST_SWITCHED | System uptime in milliseconds when the last packet of this flow was switched. | All templates |
| 22 | FIRST_SWITCHED | System uptime in milliseconds when the first packet of this flow was switched. | All templates |
| 27 | IPV6_SRC_ADDR | IPv6 source address. | IPv6 standard<br>IPv6 enterprise |
| 28 | IPV6_DST_ADDR | IPv6 destination address. | IPv6 standard<br>IPv6 enterprise |
| 32 | ICMP_TYPE | Internet Control Message Protocol (ICMP) packet type. This is reported as:<br>ICMP Type * 256 + ICMP code | All templates |
| 61 | DIRECTION | Flow direction:<br>• 0 = ingress<br>• 1 = egress | All templates |
| 148 | flowId | An identifier of a flow that is unique within an *observation domain*. You can use this *information element* to distinguish between different flows if *flow keys* such as IP addresses and port numbers are not reported or are reported in separate records. The flowID corresponds to the session ID field in Traffic and Threat logs. | All templates |
| 233 | firewallEvent | Indicates a firewall event:<br>• 0 = Ignore (invalid)<br>• 1 = Flow created<br>• 2 = Flow deleted<br>• 3 = Flow denied<br>• 4 = Flow alert<br>• 5 = Flow update (the session state changed from active to deny) | All templates |

 © Palo Alto Networks, Inc.

| Value | Field | Description | Templates |
|---|---|---|---|
| 225 | postNATSourceIPv4Address | The definition of this information element is identical to that of sourceIPv4Address, except that it reports a modified value that a NAT middlebox function caused after the packet passed the *observation point*. | IPv4 with NAT standard<br>IPv4 with NAT enterprise |
| 226 | postNATDestinationIPv4Address | The definition of this information element is identical to that of destinationIPv4Address, except that it reports a modified value that a NAT middlebox function caused after the packet passed the observation point. | IPv4 with NAT standard<br>IPv4 with NAT enterprise |
| 227 | postNAPTSourceTransportPort | The definition of this information element is identical to that of sourceTransportPort, except that it reports a modified value that a Network Address Port Translation (NAPT) middlebox function caused after the packet passed the observation point. | IPv4 with NAT standard<br>IPv4 with NAT enterprise |
| 228 | postNAPTDestinationTransportPort | The definition of this information element is identical to that of destinationTransportPort, except that it reports a modified value that a Network Address Port Translation (NAPT) middlebox function caused after the packet passed the observation point. | IPv4 with NAT standard<br>IPv4 with NAT enterprise |
| 346 | privateEnterpriseNumber | This is a unique private enterprise number that identifies Palo Alto Networks: 25461. | IPv4 enterprise<br>IPv4 with NAT enterprise<br>IPv6 enterprise |
| 56701 | App-ID | The name of an application that App-ID identified. The name can be up to 32 bytes. | IPv4 enterprise<br>IPv4 with NAT enterprise<br>IPv6 enterprise |
| 56702 | User-ID | A username that User-ID identified. The name can be up to 64 bytes. | IPv4 enterprise<br>IPv4 with NAT enterprise<br>IPv6 enterprise |

# Identify Firewall Interfaces in External Monitoring Systems

When you use a NetFlow collector (see Monitor the Firewall Using NetFlow) or SNMP manager (see Monitor the Firewall Using SNMP) to monitor traffic flows, an interface index (SNMP ifindex object) identifies the firewall interface that carried a particular flow. The formula that the Palo Alto Networks firewall uses to calculate interface indexes varies by platform and whether the interface is physical or logical.

You cannot use SNMP to monitor logical interfaces, only physical interfaces. You can use NetFlow to monitor logical or physical interfaces.

Most NetFlow collectors use SNMP to determine the name of a physical interface based on the SNMP interface index.

Physical interface indexes have a range of 1-9999, which the firewall calculates as follows:

| Firewall Platform | Calculation | Example Interface Index |
|---|---|---|
| Non-chassis based:<br>VM-Series, PA-200, PA-500, PA-2000 Series, PA-3000 Series, PA-4000 Series, PA-5000 Series<br>The PA-4000 Series platform supports SNMP but not NetFlow. | MGT port + physical port offset<br>• MGT port—This is a constant that depends on the platform:<br>  • 2 for hardware-based firewalls (for example, the PA-5000 Series firewall)<br>  • 1 for the VM-Series firewall<br>• Physical port offset—This is the physical port number. | PA-5000 Series firewall, Eth1/4 =<br>2 (MGT port) + 4 (physical port) = **6** |
| Chassis based:<br>PA-7050 firewalls<br>This platform supports SNMP but not NetFlow. | (Max. ports * slot) + physical port offset + MGT port<br>• Maximum ports—This is a constant of 64.<br>• Slot—This is the chassis slot number of the network interface card.<br>• Physical port offset—This is the physical port number.<br>• MGT port—This is a constant of 5 for PA-7050 firewalls. | PA-7050 firewall, Eth3/9 =<br>[64 (max. ports) * 3 (slot)] + 9 (phyical port) + 5 (MGT port) = **206** |

Logical interface indexes for all platforms are nine-digit numbers that the firewall calculates as follows:

| Interface Type | Range | Digit 9 | Digits 7-8 | Digits 5-6 | Digits 1-4 | Example Interface Index |
|---|---|---|---|---|---|---|
| Layer 3 subinterface | 101010001-199999999 | Type: 1 | Interface slot: 1-9 (01-09) | Interface port: 1-9 (01-09) | Subinterface: suffix 1-9999 (0001-9999) | Eth1/5.22 = 100000000 (type) + 100000 (slot) + 50000 (port) + 22 (suffix) = **101050022** |
| Layer 2 subinterface | 101010001-199999999 | Type: 1 | Interface slot: 1-9 (01-09) | Interface port: 1-9 (01-09) | Subinterface: suffix 1-9999 (0001-9999) | Eth2/3.6 = 100000000 (type) + 200000 (slot) + 30000 (port) + 6 (suffix) = **102030006** |

 © Palo Alto Networks, Inc.

| Interface Type | Range | Digit 9 | Digits 7-8 | Digits 5-6 | Digits 1-4 | Example Interface Index |
|---|---|---|---|---|---|---|
| Vwire subinterface | 101010001-199999999 | Type: 1 | Interface slot: 1-9 (01-09) | Interface port: 1-9 (01-09) | Subinterface: suffix 1-9999 (0001-9999) | Eth4/2.312 = 100000000 (type) + 400000 (slot) + 20000 (port) + 312 (suffix) = **104020312** |
| VLAN | 200000001-200009999 | Type: 2 | 00 | 00 | VLAN suffix: 1-9999 (0001-9999) | VLAN.55 = 200000000 (type) + 55 (suffix) = **200000055** |
| Loopback | 300000001-300009999 | Type: 3 | 00 | 00 | Loopback suffix: 1-9999 (0001-9999) | Loopback.55 = 300000000 (type) + 55 (suffix) = **300000055** |
| Tunnel | 400000001-400009999 | Type: 4 | 00 | 00 | Tunnel suffix: 1-9999 (0001-9999) | Tunnel.55 = 400000000 (type) + 55 (suffix) = **400000055** |
| Aggregate group | 500010001-500089999 | Type: 5 | 00 | AE suffix: 1-8 (01-08) | Subinterface: suffix 1-9999 (0001-9999) | AE5.99 = 500000000 (type) + 50000 (AE Suffix) + 99 (suffix) = **500050099** |

# Manage Reporting

The reporting capabilities on the firewall allow you to keep a pulse on your network, validate your policies, and focus your efforts on maintaining network security for keeping your users safe and productive.

- About Reports
- View Reports
- Disable Predefined Reports
- Generate Custom Reports
- Generate Botnet Reports
- Manage PDF Summary Reports
- Generate User/Group Activity Reports
- Manage Report Groups
- Schedule Reports for Email Delivery

 © Palo Alto Networks, Inc.

## About Reports

The firewall includes predefined reports that you can use as-is, or you can build custom reports that meet your needs for specific data and actionable tasks, or you can combine predefined and custom reports to compile information you need. The firewall provides the following types of reports:

- **Predefined Reports—**Allow you to view a quick summary of the traffic on your network. A suite of predefined reports are available in four categories—Applications, Traffic, Threat, and URL Filtering. See View Reports.
- **User or Group Activity Reports—**Allow you to schedule or create an on-demand report on the application use and URL activity for a specific user or for a user group. The report includes the URL categories and an estimated browse time calculation for individual users. See Generate User/Group Activity Reports.
- **Custom Reports**—Create and schedule custom reports that show exactly the information you want to see by filtering on conditions and columns to include. You can also include query builders for more specific drill down on report data. See Generate Custom Reports.
- **PDF Summary Reports**—Aggregate up to 18 predefined or custom reports/graphs from Threat, Application, Trend, Traffic, and URL Filtering categories into one PDF document. See Manage PDF Summary Reports.
- **Botnet Reports**—Allow you to use behavior-based mechanisms to identify potential botnet-infected hosts in the network. See Interpret Botnet Report Output.
- **Report Groups**—Combine custom and predefined reports into report groups and compile a single PDF that is emailed to one or more recipients. See Manage Report Groups.

Reports can be generated on demand, on a recurring schedule, and can be scheduled for email delivery.

# View Reports

The firewall provides an assortment of over 40 predefined reports that are generated every day; these reports can be viewed directly on the firewall. In addition to these reports, you can view *scheduled* custom reports and summary reports.

About 200 MB of storage is allocated for saving reports on the firewall. This storage space is not user-configurable, and older reports are purged to store recent reports. Therefore, for long-term retention of reports, you can either export the reports or schedule the reports for email delivery. To disable selected reports and conserve system resources on the firewall, see Disable Predefined Reports.

User/group activity reports must be generated on demand or scheduled for email delivery. Unlike the other reports, these reports cannot be saved on the firewall.

**View Reports**

Step 1 Select **Monitor > Reports**.

The reports are chunked into sections on the right-hand side of the window: **Custom Reports**, **Application Reports**, **Traffic Reports**, **Threat Reports**, **URL Filtering Reports**, and **PDF Summary Reports**.

Step 2 Select a report to view. When you select a report, the previous day's report is displayed on screen.

To view reports for any of the previous days, select an available date from the calendar at the bottom of the page and select a report within the same section. If you change sections, the time selection is reset.

Step 3 To view a report offline, you can export the report to PDF, CSV or to XML formats. Click **Export to PDF**, **Export to CSV**, or **Export to XML** at the bottom of the page. Then print or save the file.

 © Palo Alto Networks, Inc.

## Disable Predefined Reports

The firewall includes about 40 predefined reports that are automatically generated each day. If you do not use some or all of these predefined reports, you can disable selected reports and conserve system resources on the firewall.

Before disabling one or more predefined reports, make sure that the report is not included in a Group Report or a PDF Report. If the disabled predefined report is included in a group or PDF report, the Group/PDF report will be rendered without any data.

**Disable Predefined Reports**

1. Select **Device > Setup > Management** on the firewall.
2. Click the Edit icon in the Logging and Reporting Settings section and select the **Log Export and Reporting** tab.
3. To disable reports:
   - Clear the check box corresponding to each report that you want to disable.
   - Select **Deselect All** to disable all predefined reports.

4. Click **OK**, and **Commit** the changes.

## Generate Custom Reports

In order to create purposeful custom reports, you must consider the attributes or key pieces of information that you want to retrieve and analyze. This consideration guides you in making the following selections in a custom report:

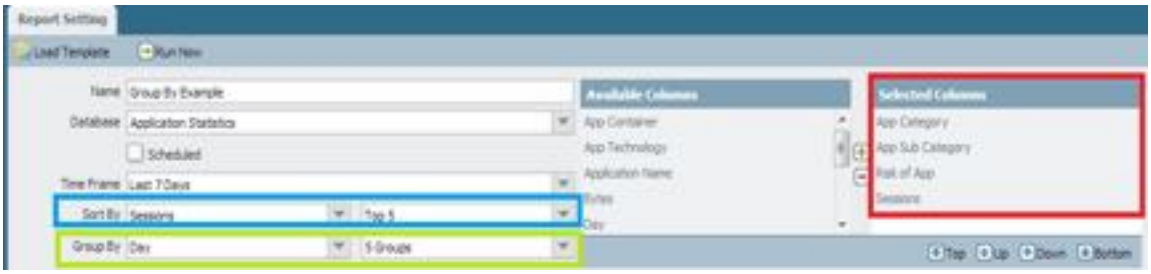
| Selection | Description |
|---|---|
| Data Source | The data file that is used to generate the report. The firewall offers two types of data sources—Summary databases and Detailed logs.<br>• Summary databases are available for traffic, threat, and application statistics. The firewall aggregates the detailed logs on traffic, application, and threat at 15-minute intervals. The data is condensed—duplicate sessions are grouped together and incremented with a repeat counter, and some attributes (or columns) are not included in the summary—to allow faster response time when generating reports.<br>• Detailed logs are itemized and are a complete listing of all the attributes (or columns) that pertain to the log entry. Reports based on detailed logs take much longer to run and are not recommended unless absolutely necessary. |
| Attributes | The columns that you want to use as the match criteria. The attributes are the columns that are available for selection in a report. From the list of **Available Columns**, you can add the selection criteria for matching data and for aggregating the details (the **Selected Columns**). |
| Sort By/ Group By | The **Sort By** and the **Group By** criteria allow you to organize/segment the data in the report; the sorting and grouping attributes available vary based on the selected data source.<br>The Sort By option specifies the attribute that is used for aggregation. If you do not select an attribute to sort by, the report will return the first N number of results without any aggregation.<br>The Group By option allows you to select an attribute and use it as an anchor for grouping data; all the data in the report is then presented in a set of top 5, 10, 25 or 50 groups. For example, when you select Hour as the Group By selection and want the top 25 groups for a 24-hr time period, the results of the report will be generated on an hourly basis over a 24-hr period. The first column in the report will be the hour and the next set of columns will be the rest of your selected report columns. |

 © Palo Alto Networks, Inc.

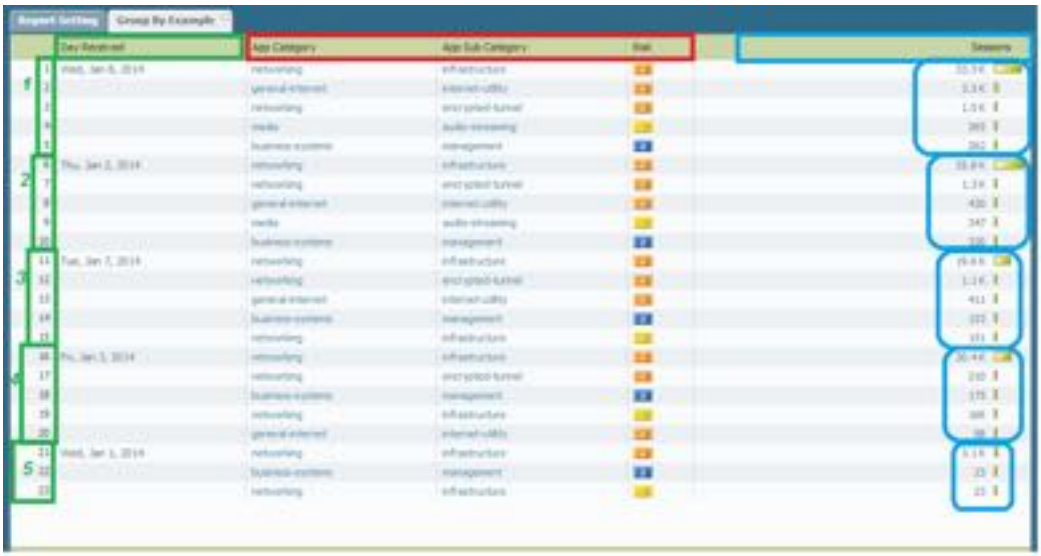
| Selection | Description |
|---|---|
| | The following example illustrates how the **Selected Columns** and **Sort By**/**Group By** criteria work together when generating reports:<br>  <br>The columns circled in red (above) depict the columns selected, which are the attributes that you match against for generating the report. Each log entry from the data source is parsed and these columns are matched on. If multiple sessions have the same values for the selected columns, the sessions are aggregated and the repeat count (or sessions) is incremented.<br>The column circled in blue indicates the chosen sort order. When the sort order (**Sort By**) is specified, the data is sorted (and aggregated) by the selected attribute.<br>The column circled in green indicates the **Group By** selection, which serves as an anchor for the report. The **Group By** column is used as a match criteria to filter for the top N groups. Then, for each of the top N groups, the report enumerates the values for all the other selected columns. |

| Selection | Description |
|---|---|

For example, if a report has the following selections
:



The output will display as follows:



The report is anchored by **Day** and sorted by **Sessions**. It lists the 5 days (**5 Groups**) with maximum traffic in the **Last 7 Days** time frame. The data is enumerated by the **Top 5** sessions for each day for the selected columns—**App Category**, **App Subcategory** and **Risk**.

| | |
|---|---|
| Time Period | The date range for which you want to analyze data. You can define a custom range or select a time period ranging from last 15 minutes to the last 30 days. The reports can be run on demand or scheduled to run at a daily or weekly cadence. |
| Query Builder | The query builder allows you to define specific queries to further refine the selected attributes. It allows you see just what you want in your report using **and** and **or** operators and a match criteria, and then include or exclude data that matches or negates the query in the report. Queries enable you to generate a more focused collation of information in a report. |

 © Palo Alto Networks, Inc.

## Generate Custom Reports

1. Select **Monitor > Manage Custom Reports**.
2. Click **Add** and then enter a **Name** for the report.

   To base a report on an predefined template, click **Load Template** and choose the template. You can then edit the template and save it as a custom report.
3. Select the database to use for the report.

Each time you create a custom report, a **Log View** report is automatically created. This report show the logs that were used to build the custom report. The log view report uses the same name as the custom report, but appends the phrase (Log View) to the report name.

When creating a report group, you can include the log view report with the custom report. For more information, see Manage Report Groups.

4. Select the **Scheduled** check box to run the report each night. The report is then available for viewing in the **Reports** column on the side.
5. Define the filtering criteria. Select the **Time Frame**, the **Sort By** order, **Group By** preference, and select the columns that must display in the report.
6. (Optional) Select the **Query Builder** attributes if you want to further refine the selection criteria. To build a report query, specify the following and click **Add**. Repeat as needed to construct the full query.
   - **Connector**—Choose the connector (and/or) to precede the expression you are adding.
   - **Negate**—Select the check box to interpret the query as a negation. If, for example, you choose to match entries in the last 24 hours and/or are originating from the untrust zone, the negate option causes a match on entries that are not in the past 24 hours and/or are not from the untrust zone.
   - **Attribute**—Choose a data element. The available options depend on the choice of database.
   - **Operator**—Choose the criterion to determine whether the attribute applies (such as =). The available options depend on the choice of database.
   - **Value**—Specify the attribute value to match.

   For example, the following figure (based on the Traffic Log database) shows a query that matches if the traffic log entry was received in the past 24 hours and is from the "untrust" zone.

7. To test the report settings, select **Run Now**. Modify the settings as required to change the information that is displayed in the report.
8. Click **OK** to save the custom report.

**Generate Custom Reports (Continued)**

**Examples of Custom Reports**

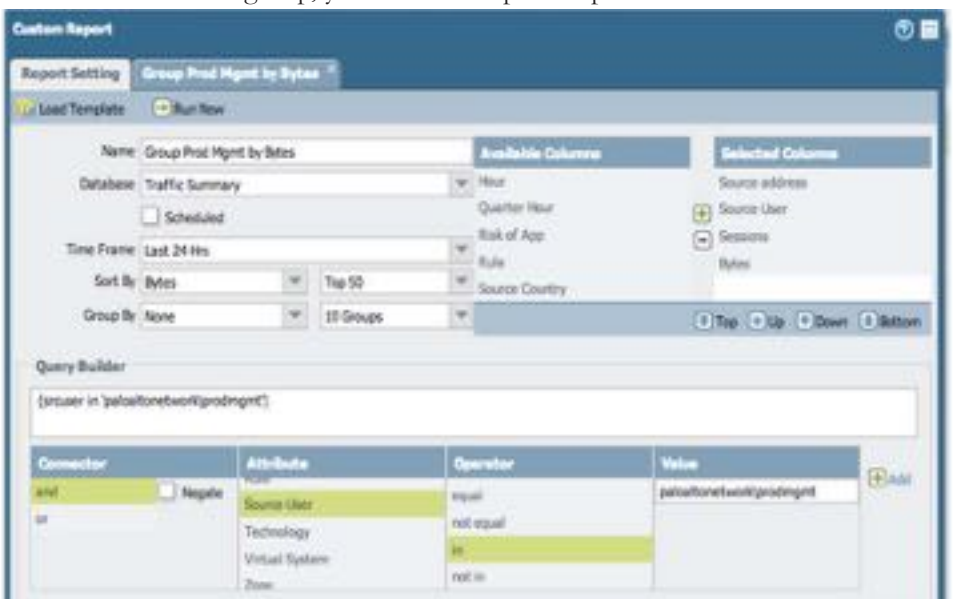
If you want to set up a simple report in which you use the traffic summary database from the last 30 days, and sort the data by the top 10 sessions and these sessions are grouped into 5 groups by day of the week. You would set up the custom report to look like this:

And the PDF output for the report would look as follows:

 © Palo Alto Networks, Inc.

**Generate Custom Reports (Continued)**

Now, if you want to use the query builder to generate a custom report that represents the top consumers of network resources within a user group, you would set up the report to look like this:



The report would display the top users in the product management user group sorted by bytes, as follows:

# Generate Botnet Reports

The botnet report enables you to use heuristic and behavior-based mechanisms to identify potential malware- or botnet-infected hosts in your network. To evaluate botnet activity and infected hosts, the firewall correlates user and network activity data in Threat, URL, and Data Filtering logs with the list of malware URLs in PAN-DB, known dynamic DNS domain providers, and domains registered within the last 30 days. You can configure the report to identify hosts that visited those sites, as well as hosts that communicated with Internet Relay Chat (IRC) servers or that used unknown applications. Malware often use dynamic DNS to avoid IP blacklisting, while IRC servers often use bots for automated functions.

The firewall requires Threat Prevention and URL Filtering licenses to use the botnet report.

▲ Configure a Botnet Report

▲ Interpret Botnet Report Output

## Configure a Botnet Report

You can schedule a botnet report or run it on demand. The firewall generates scheduled botnet reports every 24 hours because behavior-based detection requires correlating traffic across multiple logs over that timeframe.

| **Configure a Botnet Report** | |
|---|---|
| Step 1 Define the types of traffic that indicate possible botnet activity. | 1. Select **Monitor > Botnet** and click **Configuration** on the right side of the page.<br>2. **Enable** and define the **Count** for each type of HTTP Traffic that the report will include.<br>The **Count** values represent the minimum number of events of each traffic type that must occur for the report to list the associated host with a higher confidence score (higher likelihood of botnet infection). If the number of events is less than the **Count**, the report will display a lower confidence score or (for certain traffic types) won't display an entry for the host. For example, if you set the **Count** to three for **Malware URL visit**, then hosts that visit three or more known malware URLs will have higher scores than hosts that visit less than three. For details, see Interpret Botnet Report Output.<br>3. Define the thresholds that determine whether the report will include hosts associated with traffic involving Unknown TCP or Unknown UDP applications.<br>4. Select the **IRC** check box to include traffic involving IRC servers.<br>5. Click **OK** to save the report configuration. |

 © Palo Alto Networks, Inc.

| Configure a Botnet Report (Continued) | |
|---|---|
| Step 2 Schedule the report or run it on demand. | 1. Click **Report Setting** on the right side of the page.<br>2. Select a time interval for the report in the **Test Run Time Frame** drop-down.<br>3. Select the **No. of Rows** to include in the report.<br>4. (Optional) **Add** queries to the Query Builder to filter the report output by attributes such as source/destination IP addresses, users, or zones.<br>For example, if you know in advance that traffic initiated from the IP address 10.3.3.15 contains no potential botnet activity, you can add `not (addr.src in 10.0.1.35)` as a query to exclude that host from the report output. For details, see Interpret Botnet Report Output.<br>5. Select **Scheduled** to run the report daily or click **Run Now** to run the report immediately.<br>6. Click **OK** and **Commit**. |

## Interpret Botnet Report Output

The botnet report displays a line for each host that is associated with traffic you defined as suspicious when configuring the report. For each host, the report displays a confidence score of 1 to 5 to indicate the likelihood of botnet infection, where 5 indicates the highest likelihood. The scores correspond to threat severity levels: 1 is informational, 2 is low, 3 is medium, 4 is high, and 5 is critical. The firewall bases the scores on:

- **Traffic type**—Certain HTTP traffic types are more likely to involve botnet activity. For example, the report assigns a higher confidence to hosts that visit known malware URLs than to hosts that browse to IP domains instead of URLs, assuming you defined both those activities as suspicious.
- **Number of events**—Hosts that are associated with a higher number of suspicious events will have higher confidence scores based on the thresholds (**Count** values) you define when you Configure a Botnet Report.
- **Executable downloads**—The report assigns a higher confidence to hosts that download executable files. Executable files are a part of many infections and, when combined with the other types of suspicious traffic, can help you prioritize your investigations of compromised hosts.

When reviewing the report output, you might find that the sources the firewall uses to evaluate botnet activity (for example, the list of malware URLs in PAN-DB) have gaps. You might also find that these sources identify traffic that you consider safe. To compensate in both cases, you can add query filters when you Configure a Botnet Report.

## Manage PDF Summary Reports

PDF summary reports contain information compiled from existing reports, based on data for the top 5 in each category (instead of top 50). They also contain trend charts that are not available in other reports.

| **Generate PDF Summary Reports** | |
|---|---|
| Step 1 Set up a **PDF Summary Report**. | 1. Select **Monitor > PDF Reports > Manage PDF Summary**.<br>2. Click **Add** and then enter a **Name** for the report.<br>3. Use the drop-down for each report group and select one or more of the elements to design the PDF Summary Report. You can include a maximum of 18 report elements.<br>  <br>• To remove an element from the report, click the **x** icon or clear the selection from the drop-down for the appropriate report group.<br>• To rearrange the reports, drag and drop the icons to another area of the report.<br>4. Click **OK t**o save the report.<br>5. **Commit** the changes. |

© Palo Alto Networks, Inc.

| Generate PDF Summary Reports | |
|---|---|
| Step 2 View the report. | To download and view the PDF Summary Report, see View Reports.   |

## Generate User/Group Activity Reports

User/Group activity reports summarize the web activity of individual users or user groups. Both reports include the same information with a couple exceptions—**Browsing Summary by URL Category** and **Browse time calculations** are included in User Activity Reports, but are not included in Group Activity Reports.

The User Activity Report includes two variables—the **Average Browse Time (sec)** and the **Page Load Threshold (sec) i**n the Logging and Reporting sections of the **Device > Setup > Management tab**—when calculating the browse time. The **Average Browse Time** is the average time that the admin estimates that a user will browse a web page. Any request made after the average browse time has elapsed will be considered a new browsing activity. The calculation uses Container Pages (logged in the URL filtering logs) as the basis and ignores any new web pages that are loaded between the time of the first request (start time) and the average browse time. Example: If the average browse time setting is 2 minutes and a user opens a web page and views that page for 5 minutes, the browse time for that page will still be 2 minutes. This is done because there is no way to determine how long a user views a given page.The Average Browse Time calculation ignores sites categorized as web advertisements and content delivery networks. The **Page Load Threshold** is the estimated time for page elements to load on the page. Any request that occurs between the first page load and the page load threshold is assumed to be elements of the page. Any requests that occur outside of the page load threshold are assumed to be the user clicking a link within the page.

User-ID must be configured on the firewall in order to access the list of user/user groups.

### Generate User/Group Activity Reports

1. Select **Monitor > PDF Reports > User Activity Report**.
2. Click **Add** and then enter a **Name** for the report.
3. Create the report:
   - For a User Activity Report: Select **User** and enter the **Username** or **IP address** (IPv4 or IPv6) of the user who will be the subject of the report.
   - For Group Activity Report: Select **Group** and select the **Group Name** for which to retrieve user group information in the report.
4. Select the time frame for the report from the drop-down.

   The number of logs that are analyzed in a user activity report is determined by the number of rows defined on the **Max Rows in User Activity Report** on the Logging and Reporting Settings section on **Device >Setup > Management**.
5. Select **Include Detailed Browsing** to include detailed URL logs in the report.

   The detailed browsing information can include a large volume of logs (thousands of logs) for the selected user or user group and can make the report very large.
6. To run the report on demand, click **Run Now**.
7. To save the report, click **OK**. User/Group activity reports cannot be saved on the firewall; to schedule the report for email delivery, see Schedule Reports for Email Delivery.

 © Palo Alto Networks, Inc.

# Manage Report Groups

Report groups allow you to create sets of reports that the system can compile and send as a single aggregate PDF report with an optional title page and all the constituent reports included.

| Set up Report Groups | |
|---|---|
| Step 1 Set up report groups.<br><br>You must set up a **Report Group** to email report(s). | 1. Create a Server Profile for your email server.<br>2. Define the **Report Group**. A report group can compile predefined reports, PDF Summary reports, custom reports, and Log View report into a single PDF.<br>a. Select **Monitor > Report Group**.<br>b. Click **Add** and then enter a **Name** for the report group.<br>c. (Optional) Select **Title Page** and add a **Title** for the PDF output.<br>d. Select reports from the left column and click **Add** to move each report to the report group on the right.<br><br>  <br><br>The **Log View** report is a report type that is automatically created each time you create a custom report and uses the same name as the custom report. This report will show the logs that were used to build the contents of the custom report.<br><br>To include the log view data, when creating a report group, add your custom report under the **Custom Reports** list and then add the log view report by selecting the matching report name from the **Log View** list. The report will include the custom report data and the log data that was used to create the custom report.<br>e. Click **OK** to save the settings.<br>f. To use the report group, see Schedule Reports for Email Delivery. |

## Schedule Reports for Email Delivery

Reports can be scheduled for daily delivery or delivered weekly on a specified day. Scheduled reports are executed starting at 2:00 AM, and email delivery starts after all scheduled reports have been generated.

**Schedule Reports for Email Delivery**

1. Select **Monitor > PDF Reports > Email Scheduler**.
2. Select the **Report Group** for email delivery. To set up a report group; see Manage Report Groups.
3. Select the frequency at which to generate and send the report in **Recurrence**.
4. Select the email server profile to use for delivering the reports. To set up an email server profile, see Create a Server Profile for your email server.
5. The **Override Recipient email(s)** allows you to send this report exclusively to the recipients specified in this field. When you add recipients to the **Override Recipient email(s)**, the report is not sent to the recipients configured in the email server profile. Use this option for those occasions when the report is for the attention of someone other than the administrators or recipients defined in the email server profile.

 © Palo Alto Networks, Inc.

# Syslog Field Descriptions

This is a list of the standard fields for each of the five log types that are forwarded to an external server. For ease of parsing, the comma is the delimiter; each field is a comma-separated value (CSV) string. The FUTURE_USE tag applies to fields that the devices do not currently implement.

WildFire logs are a subtype of threat logs and use the same Syslog format.

- Traffic Logs
- Threat Logs
- HIP Match Logs
- Config Logs
- System Logs
- Syslog Severity
- Custom Log/Event Format
- Escape Sequences

## Traffic Logs

**Format:** FUTURE_USE, Receive Time, Serial Number, Type, Subtype, FUTURE_USE, Generated Time, Source IP, Destination IP, NAT Source IP, NAT Destination IP, Rule Name, Source User, Destination User, Application, Virtual System, Source Zone, Destination Zone, Ingress Interface, Egress Interface, Log Forwarding Profile, FUTURE_USE, Session ID, Repeat Count, Source Port, Destination Port, NAT Source Port, NAT Destination Port, Flags, Protocol, Action, Bytes, Bytes Sent, Bytes Received, Packets, Start Time, Elapsed Time, Category, FUTURE_USE, Sequence Number, Action Flags, Source Location, Destination Location, FUTURE_USE, Packets Sent, Packets Received, Session End Reason*

| Field Name | Description |
|---|---|
| Receive Time (receive_time) | Time the log was received at the management plane |
| Serial Number (serial) | Serial number of the device that generated the log |
| Type (type) | Specifies type of log; values are traffic, threat, config, system and hip-match |
| Subtype (subtype) | Subtype of traffic log are as follows:<br>• start—session started<br>• end—session ended<br>• drop—session dropped before the application is identified and there is no rule that allows the session.<br>• deny—session dropped after the application is identified and there is a rule to block or no rule that allows the session. |
| Generated Time (time_generated) | Time the log was generated on the dataplane |

| Field Name | Description |
|---|---|
| Source IP (src) | Original session source IP address |
| Destination IP (dst) | Original session destination IP address |
| NAT Source IP (natsrc) | If Source NAT performed, the post-NAT Source IP address |
| NAT Destination IP (natdst) | If Destination NAT performed, the post-NAT Destination IP address |
| Rule Name (rule) | Name of the rule that the session matched |
| Source User (srcuser) | Username of the user who initiated the session |
| Destination User (dstuser) | Username of the user to which the session was destined |
| Application (app) | Application associated with the session |
| Virtual System (vsys) | Virtual System associated with the session |
| Source Zone (from) | Zone the session was sourced from |
| Destination Zone (to) | Zone the session was destined to |
| Ingress Interface (inbound_if) | Interface that the session was sourced form |
| Egress Interface (outbound_if) | Interface that the session was destined to |
| Log Forwarding Profile (logset) | Log Forwarding Profile that was applied to the session |
| Session ID (sessionid) | An internal numerical identifier applied to each session |
| Repeat Count (repeatcnt) | Number of sessions with same Source IP, Destination IP, Application, and Subtype seen within 5 seconds; used for ICMP only |
| Source Port (sport) | Source port utilized by the session |
| Destination Port (dport) | Destination port utilized by the session |
| NAT Source Port (natsport) | Post-NAT source port |
| NAT Destination Port (natdport) | Post-NAT destination port |

 © Palo Alto Networks, Inc.

| Field Name | Description |
|---|---|
| Flags (flags) | 32-bit field that provides details on session; this field can be decoded by AND-ing the values with the logged value:<br>• 0x80000000—session has a packet capture (PCAP)<br>• 0x02000000—IPv6 session<br>• 0x01000000—SSL session was decrypted (SSL Proxy)<br>• 0x00800000—session was denied via URL filtering<br>• 0x00400000—session has a NAT translation performed (NAT)<br>• 0x00200000—user information for the session was captured via the captive portal (Captive Portal)<br>• 0x00080000—X-Forwarded-For value from a proxy is in the source user field<br>• 0x00040000—log corresponds to a transaction within a http proxy session (Proxy Transaction)<br>• 0x00008000—session is a container page access (Container Page)<br>• 0x00002000—session has a temporary match on a rule for implicit application dependency handling. Available in PAN-OS 5.0.0 and above.<br>• 0x00000800—symmetric return was used to forward traffic for this session |
| Protocol (proto) | IP protocol associated with the session |
| Action (action) | Action taken for the session; values are allow or deny:<br>• Allow—session was allowed by policy<br>• Deny—session was denied by policy |
| Bytes (bytes) | Number of total bytes (transmit and receive) for the session |
| Bytes Sent (bytes_sent) | Number of bytes in the client-to-server direction of the session<br>Available on all models except the PA-4000 Series |
| Bytes Received (bytes_received) | Number of bytes in the server-to-client direction of the session<br>Available on all models except the PA-4000 Series |
| Packets (packets) | Number of total packets (transmit and receive) for the session |
| Start Time (start) | Time of session start |
| Elapsed Time (elapsed) | Elapsed time of the session |
| Category (category) | URL category associated with the session (if applicable) |
| Sequence Number (seqno) | A 64-bit log entry identifier incremented sequentially; each log type has a unique number space. This field is not supported on PA-7050 firewalls. |
| Action Flags (actionflags) | A bit field indicating if the log was forwarded to Panorama |
| Source Location (srcloc) | Source country or Internal region for private addresses; maximum length is 32 bytes |

| Field Name | Description |
|---|---|
| Destination Location (dstloc) | Destination country or Internal region for private addresses. Maximum length is 32 bytes |
| Packets Sent (pkts_sent) | Number of client-to-server packets for the session<br>Available on all models except the PA-4000 Series |
| Packets Received (pkts_received) | Number of server-to-client packets for the session<br>Available on all models except the PA-4000 Series |
| Session End Reason (session_end_reason)<br>New in v6.1! | The reason a session terminated. If the termination had multiple causes, this field displays only the highest priority reason. The possible session end reason values are as follows, in order of priority (where the first is highest):<br>• threat—The firewall detected a threat associated with a reset, drop, or block (IP address) action.<br>• policy-deny—The session matched a security policy with a deny or drop action.<br>• tcp-rst-from-client—The client sent a TCP reset to the server.<br>• tcp-rst-from-server—The server sent a TCP reset to the client.<br>• resources-unavailable—The session dropped because of a system resource limitation. For example, the session could have exceeded the number of out-of-order packets allowed per flow or the global out-of-order packet queue.<br>• tcp-fin—One host or both hosts in the connection sent a TCP FIN message to close the session.<br>• tcp-reuse—A session is reused and the firewall closes the previous session.<br>• decoder—The decoder detects a new connection within the protocol (such as HTTP-Proxy) and ends the previous connection.<br>• aged-out—The session aged out.<br>• unknown—This value applies in the following situations:<br>  • Session terminations that the preceding reasons do not cover (for example, a `clear session all` command).<br>  • For logs generated in a PAN-OS release that does not support the session end reason field (releases older than PAN-OS 6.1), the value will be *unknown* after an upgrade to the current PAN-OS release or after the logs are loaded onto the firewall.<br>  • In Panorama, logs received from firewalls for which the PAN-OS version does not support session end reasons will have a value of *unknown*.<br>• n/a—This value applies when the traffic log type is not *end*. |

## Threat Logs

**Format**: FUTURE_USE, Receive Time, Serial Number, Type, Subtype, FUTURE_USE, Generated Time, Source IP, Destination IP, NAT Source IP, NAT Destination IP, Rule Name, Source User, Destination User, Application, Virtual System, Source Zone, Destination Zone, Ingress Interface, Egress Interface, Log Forwarding Profile, FUTURE_USE, Session ID, Repeat Count, Source Port, Destination Port, NAT Source Port, NAT Destination Port, Flags, Protocol, Action, Miscellaneous, Threat ID, Category, Severity, Direction, Sequence Number, Action Flags, Source Location, Destination Location, FUTURE_USE, Content Type, PCAP_id, Filedigest, Cloud, FUTURE_USE, User Agent*, File Type*, X-Forwarded-For*, Referer*, Sender*, Subject*, Recipient*, Report ID*

| Field Name | Description |
|---|---|
| Receive Time (receive_time) | Time the log was received at the management plane |
| Serial Number (serial) | Serial number of the device that generated the log |
| Type (type) | Specifies type of log; values are traffic, threat, config, system and hip-match |
| Subtype (subtype) | Subtype of threat log. Values include the following:<br>• data—Data pattern matching a Data Filtering profile.<br>• file—File type matching a File Blocking profile.<br>• flood—Flood detected via a Zone Protection profile.<br>• packet—Packet-based attack protection triggered by a Zone Protection profile.<br>• scan—Scan detected via a Zone Protection profile.<br>• spyware—Spyware detected via an Anti-Spyware profile.<br>• url—URL filtering log.<br>• virus—Virus detected via an Antivirus profile.<br>• vulnerability—Vulnerability exploit detected via a Vulnerability Protection profile.<br>• wildfire—A WildFire verdict generated when the firewall submits a file to WildFire per a WildFire Analysis profile and a verdict (malicious, grayware, or benign, depending on what you are logging) is logged in the WildFire Submissions log.<br>• wildfire-virus—Virus detected via an Antivirus profile. |
| Generated Time (time_generated) | Time the log was generated on the dataplane |
| Source IP (src) | Original session source IP address |
| Destination IP (dst) | Original session destination IP address |
| NAT Source IP (natsrc) | If source NAT performed, the post-NAT source IP address |
| NAT Destination IP (natdst) | If destination NAT performed, the post-NAT destination IP address |
| Rule Name (rule) | Name of the rule that the session matched |
| Source User (srcuser) | Username of the user who initiated the session |
| Destination User (dstuser) | Username of the user to which the session was destined |

| Field Name | Description |
|---|---|
| Application (app) | Application associated with the session |
| Virtual System (vsys) | Virtual System associated with the session |
| Source Zone (from) | Zone the session was sourced from |
| Destination Zone (to) | Zone the session was destined to |
| Ingress Interface (inbound_if) | Interface that the session was sourced from |
| Egress Interface (outbound_if) | Interface that the session was destined to |
| Log Forwarding Profile (logset) | Log Forwarding Profile that was applied to the session |
| Session ID (sessionid) | An internal numerical identifier applied to each session |
| Repeat Count (repeatcnt) | Number of sessions with same Source IP, Destination IP, Application, and Subtype seen within 5 seconds; used for ICMP only |
| Source Port (sport) | Source port utilized by the session |
| Destination Port (dport) | Destination port utilized by the session |
| NAT Source Port (natsport) | Post-NAT source port |
| NAT Destination Port (natdport) | Post-NAT destination port |
| Flags (flags) | 32-bit field that provides details on session; this field can be decoded by AND-ing the values with the logged value:<br>• 0x80000000—session has a packet capture (PCAP)<br>• 0x02000000—IPv6 session<br>• 0x01000000—SSL session was decrypted (SSL Proxy)<br>• 0x00800000—session was denied via URL filtering<br>• 0x00400000—session has a NAT translation performed (NAT)<br>• 0x00200000—user information for the session was captured via the captive portal (Captive Portal)<br>• 0x00080000—X-Forwarded-For value from a proxy is in the source user field<br>• 0x00040000—log corresponds to a transaction within a http proxy session (Proxy Transaction)<br>• 0x00008000—session is a container page access (Container Page)<br>• 0x00002000—session has a temporary match on a rule for implicit application dependency handling. Available in PAN-OS 5.0.0 and above<br>• 0x00000800—symmetric return was used to forward traffic for this session |
| Protocol (proto) | IP protocol associated with the session |

 © Palo Alto Networks, Inc.

| Field Name | Description |
|---|---|
| Action (action) | Action taken for the session; values are alert, allow, deny, drop, drop-all-packets, reset-client, reset-server, reset-both, block-url.<br>• Alert—threat or URL detected but not blocked<br>• Allow—flood detection alert<br>• Deny—flood detection mechanism activated and deny traffic based on configuration<br>• Drop—threat detected and associated session was dropped<br>• Drop-all-packets—threat detected and session remains, but drops all packets<br>• Reset-client—threat detected and a TCP RST is sent to the client<br>• Reset-server—threat detected and a TCP RST is sent to the server<br>• Reset-both—threat detected and a TCP RST is sent to both the client and the server<br>• Block-url—URL request was blocked because it matched a URL category that was set to be blocked |
| Miscellaneous (misc) | Field with variable length with a maximum of 1023 characters<br>The actual URI when the subtype is URL<br>File name or file type when the subtype is file<br>File name when the subtype is virus<br>File name when the subtype is WildFire |
| Threat ID (threatid) | Palo Alto Networks identifier for the threat. It is a description string followed by a 64-bit numerical identifier in parentheses for some Subtypes:<br>• 8000 – 8099—scan detection<br>• 8500 – 8599—flood detection<br>• 9999—URL filtering log<br>• 10000 – 19999—sypware phone home detection<br>• 20000 – 29999—spyware download detection<br>• 30000 – 44999—vulnerability exploit detection<br>• 52000 – 52999—filetype detection<br>• 60000 – 69999—data filtering detection<br>• 100000 – 2999999—virus detection<br>• 3000000 – 3999999—WildFire signature feed<br>• 4000000-4999999—DNS Botnet signatures |
| Category (category) | For URL Subtype, it is the URL Category; For WildFire subtype, it is the verdict on the file and is either ‘malicious’ or ‘benign’; For other subtypes, the value is ‘any’. |
| Severity (severity) | Severity associated with the threat; values are informational, low, medium, high, critical |

| Field Name | Description |
|---|---|
| Direction (direction) | Indicates the direction of the attack, *client-to-server* or *server-to-client*<br>• 0—direction of the threat is client to server<br>• 1—direction of the threat is server to client |
| Sequence Number (seqno) | A 64-bit log entry identifier incremented sequentially. Each log type has a unique number space. This field is not supported on PA-7050 firewalls. |
| Action Flags (actionflags) | A bit field indicating if the log was forwarded to Panorama. |
| Source Location (srcloc) | Source country or Internal region for private addresses. Maximum length is 32 bytes. |
| Destination Location (dstloc) | Destination country or Internal region for private addresses. Maximum length is 32 bytes. |
| Content Type (contenttype) | Applicable only when Subtype is URL.<br>Content type of the HTTP response data. Maximum length 32 bytes. |
| PCAP ID (pcap_id) | Pcap-ID is a 64 bit unsigned integral denoting an ID to correlate threat pcap files with extended pcaps taken as a part of that flow. All threat logs will contain either a pcap_id of 0 (no associated pcap), or an ID referencing the extended pcap file. |
| File Digest (filedigest) | Only for WildFire subtype; all other types do not use this field<br>The filedigest string shows the binary hash of the file sent to be analyzed by the WildFire service. |
| Cloud (cloud) | Only for WildFire subtype; all other types do not use this field.<br>The cloud string displays the FQDN of either the WildFire appliance (private) or the WildFire cloud (public) from where the file was uploaded for analysis. |
| New in v6.1! User Agent (user_agent) | Only for the URL Filtering subtype; all other types do not use this field.<br>The User Agent field specifies the web browser that the user used to access the URL, for example Internet Explorer. This information is sent in the HTTP request to the server. |
| New in v6.1! File Type (filetype) | Only for WildFire subtype; all other types do not use this field.<br>Specifies the type of file that the firewall forwarded for WildFire analysis. |
| New in v6.1! X-Forwarded-For (xff) | Only for the URL Filtering subtype; all other types do not use this field.<br>The X-Forwarded-For field in the HTTP header contains the IP address of the user who requested the web page. It allows you to identify the IP address of the user, which is useful particularly if you have a proxy server on your network that replaces the user IP address with its own address in the source IP address field of the packet header. |
| New in v6.1! Referer (referer) | Only for the URL Filtering subtype; all other types do not use this field.<br>The Referer field in the HTTP header contains the URL of the web page that linked the user to another web page; it is the source that redirected (referred) the user to the web page that is being requested. |
| New in v6.1! Sender (sender) | Only for WildFire subtype; all other types do not use this field.<br>Specifies the name of the sender of an email that WildFire determined to be malicious when analyzing an email link forwarded by the firewall. |

 © Palo Alto Networks, Inc.

| Field Name | Description |
|---|---|
| Subject (subject)<br>New in v6.1! | Only for WildFire subtype; all other types do not use this field.<br>Specifies the subject of an email that WildFire determined to be malicious when analyzing an email link forwarded by the firewall. |
| Recipient (recipient)<br>New in v6.1! | Only for WildFire subtype; all other types do not use this field.<br>Specifies the name of the receiver of an email that WildFire determined to be malicious when analyzing an email link forwarded by the firewall. |
| Report ID (reportid)<br>New in v6.1! | Only for WildFire subtype; all other types do not use this field.<br>Identifies the analysis request on the WildFire cloud or the WildFire appliance. |

## HIP Match Logs

**Format:** FUTURE_USE, Receive Time, Serial Number, Type, Subtype, FUTURE_USE, Generated Time, Source User, Virtual System, Machine name, OS, Source Address, HIP, Repeat Count, HIP Type, FUTURE_USE, FUTURE_USE, Sequence Number, Action Flags

| Field Name | Description |
|---|---|
| Receive Time (receive_time) | Time the log was received at the management plane |
| Serial Number (serial) | Serial number of the device that generated the log |
| Type (type) | Type of log; values are traffic, threat, config, system and hip-match |
| Subtype (subtype) | Subtype of HIP match log; unused |
| Generated Time (time_generated) | Time the log was generated on the dataplane |
| Source User (srcuser) | Username of the user who initiated the session |
| Virtual System (vsys) | Virtual System associated with the HIP match log |
| Machine Name (machinename) | Name of the user's machine |
| OS | The operating system installed on the user's machine or device (or on the client system) |
| Source Address (src) | IP address of the source user |
| HIP (matchname) | Name of the HIP object or profile |
| Repeat Count (repeatcnt) | Number of times the HIP profile matched |
| HIP Type (matchtype) | Whether the hip field represents a HIP object or a HIP profile |
| Sequence Number (seqno) | A 64-bit log entry identifier incremented sequentially; each log type has a unique number space. This field is not supported on PA-7050 firewalls. |
| Action Flags (actionflags) | A bit field indicating if the log was forwarded to Panorama |

## Config Logs

**Format:** FUTURE_USE, Receive Time, Serial Number, Type, Subtype, FUTURE_USE, Generated Time, Host, Virtual System, Command, Admin, Client, Result, Configuration Path, Sequence Number, Action Flags, Before Change Detail*, After Change Detail*

| Field Name | Description |
|---|---|
| Receive Time (receive_time) | Time the log was received at the management plane |
| Serial Number (serial) | Serial number of the device that generated the log |
| Type (type) | Type of log; values are traffic, threat, config, system and hip-match |
| Subtype (subtype) | Subtype of configuration log; unused |
| Generated Time (time_generated) | Time the log was generated on the dataplane |
| Host (host) | Host name or IP address of the client machine |
| Virtual System (vsys) | Virtual System associated with the configuration log |
| Command (cmd) | Command performed by the Admin; values are add, clone, commit, delete, edit, move, rename, set. |
| Admin (admin) | Username of the Administrator performing the configuration |
| Client (client) | Client used by the Administrator; values are Web and CLI |
| Result (result) | Result of the configuration action; values are Submitted, Succeeded, Failed, and Unauthorized |
| Configuration Path (path) | The path of the configuration command issued; up to 512 bytes in length |
| Sequance Number (seqno) | A 64bit log entry identifier incremented sequentially; each log type has a unique number space. This field is not supported on PA-7050 firewalls. |
| Action Flags (actionflags) | A bit field indicating if the log was forwarded to Panorama. |
| Before Change Detail (before_change_detail) New in v6.1! | This field is in custom logs only; it is not in the default format.<br>It contains the full xpath before the configuration change. |
| After Change Detail (after_change_detail) New in v6.1! | This field is in custom logs only; it is not in the default format.<br>It contains the full xpath after the configuration change. |

 © Palo Alto Networks, Inc.

## System Logs

**Format:** FUTURE_USE, Receive Time, Serial Number, Type, Subtype, FUTURE_USE, Generated Time, Virtual System, Event ID, Object, FUTURE_USE, FUTURE_USE, Module, Severity, Description, Sequence Number, Action Flags

| Field Name | Description |
|---|---|
| Receive Time (receive_time) | Time the log was received at the management plane |
| Serial Number (serial) | Serial number of the device that generated the log |
| Type (type) | Type of log; values are traffic, threat, config, system and hip-match |
| Subtype (subtype) | Subtype of the system log; refers to the system daemon generating the log; values are crypto, dhcp, dnsproxy, dos, general, global-protect, ha, hw, nat, ntpd, pbf, port, pppoe, ras, routing, satd, sslmgr, sslvpn, userid, url-filtering, vpn |
| Generated Time (time_generated) | Time the log was generated on the dataplane |
| Virtual System (vsys) | Virtual System associated with the configuration log |
| Event ID (eventid) | String showing the name of the event |
| Object (object) | Name of the object associated with the system event |
| Module (module) | This field is valid only when the value of the Subtype field is general. It provides additional information about the sub-system generating the log; values are general, management, auth, ha, upgrade, chassis |
| Severity (severity) | Severity associated with the event; values are informational, low, medium, high, critical |
| Description (opaque) | Detailed description of the event, up to a maximum of 512 bytes |
| Sequence Number (seqno) | A 64-bit log entry identifier incremented sequentially; each log type has a unique number space. This field is not supported on PA-7050 firewalls. |
| Action Flags (actionflags) | A bit field indicating if the log was forwarded to Panorama |

## Syslog Severity

The syslog severity is set based on the log type and contents.

| Log Type/Severity | Syslog Severity |
|---|---|
| Traffic | Info |
| Config | Info |
| Threat/System—Informational | Info |
| Threat/System—Low | Notice |
| Threat/System—Medium | Warning |

| Log Type/Severity | Syslog Severity |
|---|---|
| Threat/System—High | Error |
| Threat/System—Critical | Critical |

## Custom Log/Event Format

To facilitate the integration with external log parsing systems, the firewall allows you to customize the log format; it also allows you to add custom *Key: Value* attribute pairs. Custom message formats can be configured under **Device > Server Profiles > Syslog > Syslog Server Profile > Custom Log Format**.

To achieve ArcSight Common Event Format (CEF) compliant log formatting, refer to the CEF Configuration Guide.

## Escape Sequences

Any field that contains a comma or a double-quote is enclosed in double quotes. Furthermore, if a double-quote appears inside a field it is escaped by preceding it with another double-quote. To maintain backward compatibility, the Misc field in threat log is always enclosed in double-quotes.

 © Palo Alto Networks, Inc.

# User-ID

User Identification (User-ID) is a Palo Alto Networks next-generation firewall feature that allows you to create policies and perform reporting based on users and groups rather than individual IP addresses. The following sections describe the Palo Alto Networks User-ID feature and provide instructions on setting up user- and group-based access:

- User-ID Overview
- User-ID Concepts
- Enable User-ID
- Map Users to Groups
- Map IP Addresses to Users
- Configure a Firewall to Share User Mapping Data with Other Firewalls
- Enable User- and Group-Based Policy
- Verify the User-ID Configuration

© Palo Alto Networks, Inc.

# User-ID Overview

User-ID seamlessly integrates Palo Alto Networks firewalls with a range of enterprise directory and terminal services offerings, enabling you to tie application activity and security policies to users and groups—not just IP addresses. In addition, with User-ID enabled, the Application Command Center (ACC), App-Scope, reports, and logs all include usernames in addition to user IP addresses.

The Palo Alto Networks next-generation firewall supports monitoring of the following enterprise services:

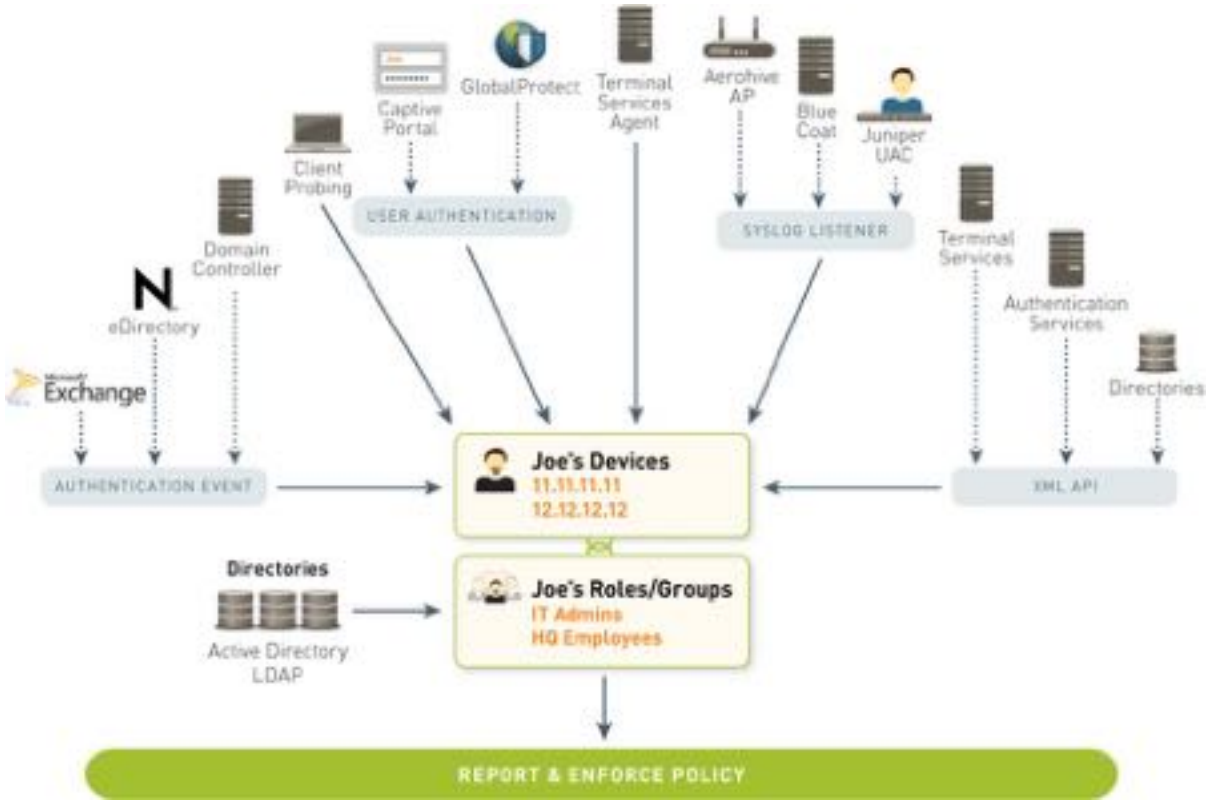
- Microsoft Active Directory
- Lightweight Directory Access Protocol (LDAP)
- Novell eDirectory
- Citrix Metaframe Presentation Server or XenApp
- Microsoft Terminal Services

To be able to create policy based on user and group, the firewall must have a list of all available users and their corresponding group mappings that you can select from when defining your policies. It gets this Group Mapping information by connecting directly to your LDAP directory server.

To be able to enforce the user- and group-based policies, the firewall must be able to map the IP addresses in the packets it receives to usernames. User-ID provides many mechanisms to get these IP address-to-username mappings. For example, it uses agents to monitor server logs for login events and/or probe clients, and/or listen for syslog messages from authenticating services. To identify mappings for IP addresses that were not mapped using one of the agent mechanisms, you can configure the firewall to redirect HTTP requests to a captive portal login. You can tailor the mechanisms you use for User Mapping to suit your environment, and you can even use different mechanisms at different sites.

 © Palo Alto Networks, Inc.

**Figure: User-ID**



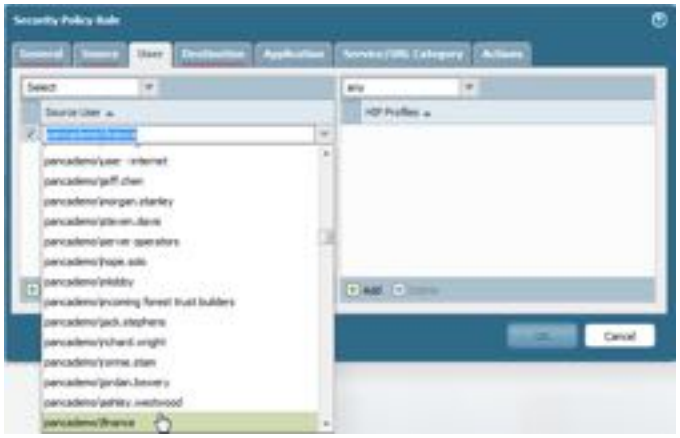
Proceed to User-ID Concepts for information on how User-ID works and Enable User-ID for instructions on setting up User-ID on the firewall.

# User-ID Concepts

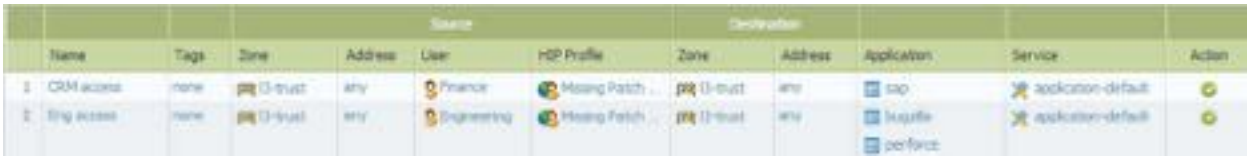
▲ Group Mapping
▲ User Mapping

## Group Mapping

In order to define security policies based on user or group, the firewall must retrieve the list of groups and the corresponding list of members from your directory server. To enable this functionality to Map Users to Groups, you must create an LDAP server profile that instructs the firewall how to connect and authenticate to the server and how to search the directory for the user and group information. After you connect to the LDAP server and configure the group mapping functionality for user identification, you will be able to select users or groups when defining your security policies. The firewall supports a variety of LDAP directory servers, including Microsoft Active Directory (AD), Novell eDirectory, and Sun ONE Directory Server.



You can then define policies based on group membership rather than on individual users for simplified administration. For example, the following security policy allows access to specific internal applications based on group membership:



## User Mapping

Having the names of the users and groups is only one piece of the puzzle. The firewall also needs to know which IP addresses map to which users so that security policies can be enforced appropriately. Figure: User-ID illustrates the different methods that are used to identify users and groups on your network and shows how user mapping and group mapping work together to enable user- and group-based security enforcement and visibility.

The following topics describe the different methods of user mapping:

 © Palo Alto Networks, Inc.

- Server Monitoring
- Client Probing
- Port Mapping
- Syslog
- Captive Portal
- GlobalProtect
- User-ID XML API

## Server Monitoring

With server monitoring a User-ID agent—either a Windows-based agent running on a domain server in your network, or the integrated PAN-OS User-ID agent running on the firewall—monitors the security event logs for specified Microsoft Exchange Servers, domain controllers, or Novell eDirectory servers for login events. For example, in an AD environment, you can configure the User-ID agent to monitor the security logs for Kerberos ticket grants or renewals, Exchange server access (if configured), and file and print service connections. Keep in mind that in order for these events to be recorded in the security log, the AD domain must be configured to log successful account login events. In addition, because users can log in to any of the servers in the domain, you must set up server monitoring for all servers in order to capture all user login events.

Because server monitoring requires very little overhead and because the majority of users can generally be mapped using this method, it is recommended as the base user mapping method for most User-ID deployments. See Configure User Mapping Using the Windows User-ID Agent or Configure User Mapping Using the PAN-OS Integrated User-ID Agent for details.

## Client Probing

In a Microsoft Windows environment, you can configure the User-ID agent to probe client systems using Windows Management Instrumentation (WMI). The Windows-based User-ID agent can also perform NetBIOS probing (not supported on the PAN-OS integrated User-ID agent). Probing is particularly useful in environments with a high IP address turnover because changes will be reflected on the firewall more quickly, enabling more accurate enforcement of user-based policies. However, if the correlation between IP addresses and users is fairly static, you probably do not need to enable client probing. Because probing can generate a large amount of network traffic (based on the total number of mapped IP addresses), the agent that will be initiating the probes should be located as close as possible to the end clients.

If probing is enabled, the agent will probe each learned IP address periodically (every 20 minutes by default, but this is configurable) to verify that the same user is still logged in. In addition, when the firewall encounters an IP address for which it has no user mapping, it will send the address to the agent for an immediate probe.

See Configure User Mapping Using the Windows User-ID Agent or Configure User Mapping Using the PAN-OS Integrated User-ID Agent for details.

## Port Mapping

In environments with multi-user systems—such as Microsoft Terminal Server or Citrix environments—many users share the same IP address. In this case, the user-to-IP address mapping process requires knowledge of the source port of each client. To perform this type of mapping, you must install the Palo Alto Networks Terminal Services Agent on the Windows/Citrix terminal server itself to intermediate the assignment of source ports to the various user processes. For terminal servers that do not support the Terminal Services Agent, such as Linux terminal servers, you can use the XML API to send user mapping information from login and logout events to User-ID. See Configure User Mapping for Terminal Server Users for configuration details.

## Syslog

In environments with existing network services that authenticate users—such as wireless controllers, 802.1x devices, Apple Open Directory servers, proxy servers, or other Network Access Control (NAC) mechanisms—the firewall User-ID agent (either the Windows agent or the PAN-OS integrated agent on the firewall) can listen for authentication syslog messages from those services. Syslog filters, which are provided by a content update (integrated User-ID agent only) or configured manually, allow the User-ID agent to parse and extract usernames and IP addresses from authentication syslog events generated by the external service, and add the information to the User-ID IP address-to-username mappings maintained by the firewall. See Configure User-ID to Receive User Mappings from a Syslog Sender for configuration details.

**Figure: User-ID Integration with Syslog**

 © Palo Alto Networks, Inc.

## Captive Portal

If the firewall or the User-ID agent are unable to map an IP address to a user—for example if the user is not logged in or is using an operating system such as Linux that is not supported by your domain servers—you can configure Captive Portal. When configured, any web traffic (HTTP or HTTS) matching your Captive Portal policy requires user authentication, either transparently via an NT LAN Manager (NTLM) challenge to the browser, or actively by redirecting the user to a web authentication form for authentication against a RADIUS, LDAP, Kerberos, or local authentication database or using client certificate authentication. See Map IP Addresses to User Names Using Captive Portal for details.

## GlobalProtect

For mobile or roaming users, the GlobalProtect client provides the user mapping information to the firewall directly. In this case, every GlobalProtect user has an agent or app running on the client that requires the user to enter login credentials for VPN access to the firewall. This login information is then added to the User-ID user mapping table on the firewall for visibility and user-based security policy enforcement. Because GlobalProtect users must authenticate to gain access to the network, the IP address-to-username mapping is explicitly known. This is the best solution in sensitive environments where you must be certain of who a user is in order to allow access to an application or service. For more information on setting up GlobalProtect, refer to the GlobalProtect Administrator's Guide.

## User-ID XML API

For other types of user access that cannot be mapped using any of the standard user mapping methods or Captive Portal—for example, to add mappings of users connecting from a third-party VPN solution or users connecting to a 802.1x enabled wireless network—you can use the User-ID XML API to capture login events and send them to the User-ID agent or directly to the firewall. See Send User Mappings to User-ID Using the XML API for details.

© Palo Alto Networks, Inc.

# Enable User-ID

You must complete the following tasks to set up the firewall to user users and groups in policy enforcement, logging, and reporting:

- Map Users to Groups
- Map IP Addresses to Users
- Enable User- and Group-Based Policy
- Verify the User-ID Configuration

© Palo Alto Networks, Inc.

# Map Users to Groups

Use the following procedure to connect to your LDAP directory to enable the firewall to retrieve user-to-group mapping information:

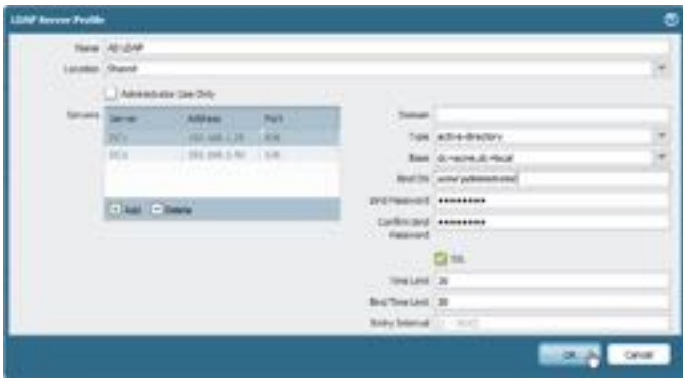
Best practices for group mapping in an Active Directory environment:

- If you have a single domain, you only need one LDAP server profile that connects the firewall to the domain controller with the best connectivity. You can add additional domain controllers for fault tolerance.
- If you have multiple domains and/or multiple forests, you must create a server profile to connect to a domain server in each domain/forest. Take steps to ensure unique usernames in separate forests.
- If you have Universal Groups, create a server profile to connect to the Global Catalogue server.

## Map Users to Groups

Step 1 Create an LDAP Server Profile that specifies how to connect to the directory servers you want the firewall to use to obtain group mapping information.

1. Select **Device > Server Profiles > LDAP**.
2. Click **Add** and then enter a **Name** for the profile.
3. (Optional) Select the virtual system to which this profile applies from the **Location** drop-down.
4. Click **Add** to add a new LDAP server entry and then enter a **Server** name to identify the server (1-31 characters) and the IP **Address** and **Port** number the firewall should use to connect to the LDAP server (default=389 for LDAP; 636 for LDAP over SSL). You can add up to four LDAP servers to the profile, however, all the servers you add to a profile must be of the same type. For redundancy you should add at least two servers.

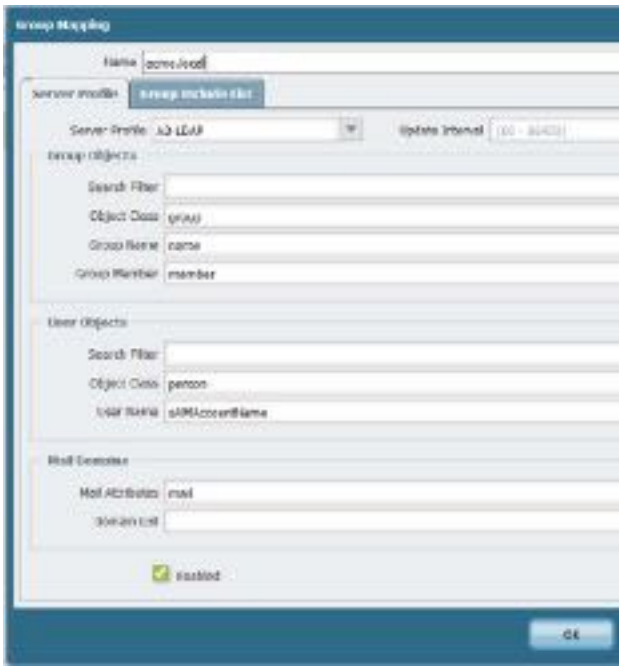


5. Enter the LDAP **Domain** name to prepend to all objects learned from the server. The value you enter here depends on your deployment:
   - If you are using Active Directory, you must enter the NetBIOS domain name; NOT a FQDN (for example, enter `acme`, not `acme.com`). Note that if you need to collect data from multiple domains, you will need to create separate server profiles.
   - If you are using a global catalog server, leave this field blank.
6. Select the **Type** of LDAP server you are connecting to. The correct LDAP attributes in the group mapping settings will automatically be populated based on your selection. However, if you have customized your LDAP schema, you may need to modify the default settings.
7. In the **Base** field, select the DN that corresponds to the point in the LDAP tree where you want the firewall to begin its search for user and group information.
8. Enter the authentication credentials for binding to the LDAP tree in the **Bind DN**, **Bind Password**, and **Confirm Bind Password** fields. The Bind DN can be in either User Principal Name (UPN) format (for example, `administrator@acme.local`) or it can be a fully qualified LDAP name (for example, `cn=administrator,cn=users,dc=acme,dc=local`).
9. If you want the firewall to communicate with the LDAP server(s) over a secure connection, select the SSL check box. If you enable SSL, make sure that you have also specified the appropriate port number.
10. Click **OK** to save the profile.

**Map Users to Groups (Continued)**

Step 2 Add the LDAP server profile to the User-ID Group Mapping configuration.

1. Select **Device > User Identification > Group Mapping Settings** and click **Add**.
2. Enter a unique **Name** to identify the group mapping configuration.
3. Select the **Server Profile** you created in Step 1.
4. (Optional) To filter the groups that User-ID tracks for group mapping, in the Group Objects section enter a **Search Filter** (LDAP query), then specify the **Object Class** (group definition), **Group Name**, and **Group Member**.
5. (Optional) To filter the users that User-ID tracks for group mapping, in the User Objects section enter a **Search Filter** (LDAP query), then specify the **Object Class** (user definition) and **User Name**.
6. (Optional) To match User-ID information with email header information identified in the links and attachments of emails forwarded to WildFire, enter the list of email domains in your organization in the Mail Domains section, **Domain List** field. Use commas to separate multiple domains (up to 256 characters). After you click **OK** (Step 9), PAN-OS automatically populates the **Mail Attributes** field based on your LDAP server type (Sun/RFC, Active Directory, or Novell). When a match occurs, the username in the WildFire log email header section will contain a link that opens the **ACC** tab, filtered by the user or group of users.
7. Make sure the **Enabled** check box is selected.
8. (Optional) To limit which groups appear in security policy, select the **Group Include List** tab and browse the LDAP tree to locate the desired groups. For each group you want to include, select it in the **Available Groups** list and click the add ⊞ icon to move it to the **Included Groups** list.
9. Click **OK** to save the settings.



Step 3 **Commit** the configuration.

 © Palo Alto Networks, Inc.

# Map IP Addresses to Users

The tasks you need to perform to map IP addresses to usernames depends on the type and location of the client systems on your network. Complete as many of the following tasks as necessary to enable mapping of your client systems:

- To map users as they log in to your Exchange servers, domain controllers, or eDirectory servers, or Windows clients that can be directly probed, you must configure a User-ID agent to monitor the server logs and/or probe client systems. You can either install the standalone Windows User-ID agent on one or more member servers in the domain that contains the servers and clients to be monitored (see Configure User Mapping Using the Windows User-ID Agent) or you can configure the on-firewall User-ID agent that is integrated with PAN-OS (Configure User Mapping Using the PAN-OS Integrated User-ID Agent). For guidance as to which agent configuration is appropriate for your network and the number and placements of agents that are required, refer to Architecting User Identification Deployments.
- If you have clients running multi-user systems such as Microsoft Terminal Server or Citrix Metaframe Presentation Server or XenApp, see Configure the Palo Alto Networks Terminal Server Agent for User Mapping for instructions on how to install and configure the agent on a Windows server. If you have a multi-user system that is not running on Windows, you can use the User-ID XML API to send IP address to username mappings directly to the firewall. See Retrieve User Mappings from a Terminal Server Using the User-ID XML API.
- To obtain user mappings from existing network services that authenticate users, such as wireless controllers, 802.1x devices, Apple Open Directory servers, proxy servers, or other Network Access Control (NAC) mechanisms, configure the User-ID agent (either the Windows agent or the agentless user mapping feature on the firewall) to listen for authentication syslog messages from those services. See Configure User-ID to Receive User Mappings from a Syslog Sender.
- If you have users with client systems that are not logged into your domain servers—for example, users running Linux clients that do not log in to the domain—see Map IP Addresses to User Names Using Captive Portal.
- For other clients that you are unable to map using the previous methods, you can use the User-ID XML API to add user mappings directly to the firewall. See Send User Mappings to User-ID Using the XML API.
- Because policy is local to each firewall, each firewall must have a current list of IP address-to-username mappings in order to accurately enforce security policy by group or user. However, you can configure one firewall to collect all the user mappings and distribute them to the other firewalls. For details, see Configure a Firewall to Share User Mapping Data with Other Firewalls.

© Palo Alto Networks, Inc.

# Configure User Mapping Using the Windows User-ID Agent

In most cases, the majority of your network users will have logins to your monitored domain services. For these users, the Palo Alto Networks User-ID agent monitors the servers for login events and performs the IP address-to-user mapping. The way you configure the User-ID agent depends on the size of your environment and the location of your domain servers. As a best practice, you should locate your User-ID agents near your monitored servers (that is, the monitored servers and the Windows User-ID agent should not be across a WAN link from each other). This is because most of the traffic for user mapping occurs between the agent and the monitored server, with only a small amount of traffic—the delta of IP address mappings since the last update—from the agent to the firewall.

The following topics describe how to install and configure the User-ID Agent and how to configure the firewall to retrieve user mapping information from the agent:

- Install the User-ID Agent
- Configure the User-ID Agent for User Mapping

## Install the User-ID Agent

The following procedure shows how to install the User-ID agent on a member server in the domain and set up the service account with the required permissions. If you are upgrading, the installer will automatically remove the older version, however, it is a good idea to back up the config.xml file before running the installer.

For information about the system requirements for installing the Windows-based User-ID agent and for information on the supported server OS versions are supported, refer to "Operating System (OS) Compatibility User-ID Agent" in the User-ID Agent Release Notes, which are available on the Palo Alto Networks Software Updates page.

| Install the Windows User-ID Agent | | |
|---|---|---|
| Step 1 | Decide where to install the User-ID agent(s).<br><br>The User-ID agent queries the Domain Controller and Exchange server logs using Microsoft Remote Procedure Calls (MSRPCs), which require a complete transfer of the entire log at each query. Therefore, you should always install one or more User-ID agents at each site that has servers to be monitored.<br><br> For more detailed information on where to install User-ID agents, refer to Architecting User Identification (User-ID) Deployments. | • You must install the User-ID agent on a system running one of the supported OS versions: see "Operating System (OS) Compatibility User-ID Agent" in the User-ID Agent Release Notes.<br>• Make sure the system you plan to install the User-ID agent on is a member of the domain that the servers it will be monitoring belong to.<br>• As a best practice, install the User-ID agent close to the servers it will be monitoring (there is more traffic between the User-ID agent and the monitored servers than there is between the User-ID agent and the firewall, so locating the agent close to the monitored servers optimizes bandwidth usage).<br>• To ensure the most comprehensive mapping of users, you must monitor all servers that contain user login information. You may need to install multiple User-ID agents to efficiently monitor all of your resources. |

 © Palo Alto Networks, Inc.

| Install the Windows User-ID Agent (Continued) | |
|---|---|
| Step 2 Download the User-ID agent installer.<br><br>As a best practice, install the User-ID agent version that is the same as the PAN-OS version running on the firewalls. | 1. Log in to Palo Alto Networks Support site.<br>2. Select **Software Updates** from the Manage Devices section.<br>3. Scroll to the User Identification Agent section of the screen and **Download** the version of the User-ID agent you want to install.<br>4. Save the `UaInstall-x.x.x-xx.msi` file on the system(s) where you plan to install the agent. |
| Step 3 Run the installer as an administrator.<br> | 1. To launch a command prompt as an administrator, click Start and right-click **Command Prompt** and then select **Run as administrator**.<br>2. From the command line, run the .msi file you downloaded. For example, if you saved the .msi file to the Desktop you would enter the following:<br>`C:\Users\administrator.acme>cd Desktop`<br>`C:\Users\administrator.acme\Desktop>UaInstall-6.0.0-1.msi`<br>3. Follow the setup prompts to install the agent using the default settings. By default, the agent gets installed to the `C:\Program Files (x86)\Palo Alto Networks\User-ID Agent` folder, but you can **Browse** to a different location.<br>4. When the installation completes, **Close** the setup window. |
| Step 4 Launch the User-ID Agent application.<br>  | 1. Click Start and select **User-ID Agent**. |
| Step 5 (Optional) Change the service account that the User-ID agent uses to log in.<br> | By default, the agent uses the administrator account used to install the .msi file. However, you may want to switch this to a restricted account as follows:<br>1. Select **User Identification > Setup** and click **Edit**.<br>2. Select the **Authentication** tab and enter the service account name that you want the User-ID agent to use in the **User name for Active Directory** field.<br>3. Enter the **Password** for the specified account. |

| Install the Windows User-ID Agent (Continued) | |
|---|---|
| Step 6 (Optional) Assign account permissions to the installation folder.<br><br>You only need to perform this step if the service account you configured for the User-ID agent is not a member of the administrators group for the domain or a member of both the Server Operators and the Event Log Readers groups. | 1. Give the service account permissions to the installation folder:<br>a. From the Windows Explorer, navigate to `C:\Program Files\Palo Alto Networks` and right-click the folder and select **Properties**.<br>b. On the **Security** tab, **Add** the User-ID agent service account and assign it permissions to **Modify**, **Read & execute**, **List folder contents**, and **Read** and then click **OK** to save the account settings.<br>2. Give the service account permissions to the User-ID Agent registry sub-tree:<br>a. Run `regedit32` and navigate to the Palo Alto Networks sub-tree in one of the following locations:<br>– **32-bit systems**—`HKEY_LOCAL_MACHINE\Software\Palo Alto Networks`<br>– **64-bit systems**—`HKEY_LOCAL_MACHINE\Software\WOW6432Node\Palo Alto Networks`<br>b. Right-click the Palo Alto Networks node and select **Permissions**.<br>c. Assign the User-ID service account **Full Control** and then click **OK** to save the setting.<br>3. On the domain controller, add the service account to the builtin groups to enable privileges to read the security log events (Event Log Reader group) and open sessions (Server Operator group):<br>a. Run the MMC and Launch the Active Directory Users and Computers snap-in.<br>b. Navigate to the Builtin folder for the domain and then right-click each group you need to edit (Event Log Reader and Server Operator) and select **Add to Group** to open the properties dialog.<br>c. Click **Add** and enter the name of the service account that you configured the User-ID service to use and then click **Check Names** to validate that you have the proper object name.<br>d. Click **OK** twice to save the settings. |

## Configure the User-ID Agent for User Mapping

The Palo Alto Networks User-ID agent is a Windows service that connects to servers on your network—for example, Active Directory servers, Microsoft Exchange servers, and Novell eDirectory servers—and monitors the logs for login events. The agent uses this information to map IP addresses to usernames. Palo Alto Networks firewalls connect to the User-ID agent to retrieve this user mapping information, enabling visibility into user activity by username rather than IP address and enables user- and group-based security enforcement.

 © Palo Alto Networks, Inc.

For information about the server OS versions supported by the User-ID agent, refer to "Operating System (OS) Compatibility User-ID Agent" in the *User-ID Agent Release Notes*, which are available on the Palo Alto Networks Software Updates page.

| **Map IP Addresses to Users Using the User-ID Agent** | | |
|---|---|---|
| Step 1 | Launch the User-ID Agent application. | 1. Select **User-ID Agent** from the Windows Start menu.<br> |
| Step 2 | Define the servers the User-ID agent should monitor to collect IP address to user mapping information.<br>The User-ID agent can monitor a total of up to 100 servers, including syslog senders.<br>Keep in mind that in order to collect all of the required mappings, you must connect to all servers that your users log in to in order to monitor the security log files on all servers that contain login events. | 1. Select **User Identification > Discovery**.<br>2. In the **Servers** section of the screen, click **Add**.<br>3. Enter a **Name** and **Server Address** for the server to be monitored. The network address can be a FQDN or an IP address.<br>4. Select the **Server Type** (**Microsoft Active Directory**, **Microsoft Exchange**, **Novell eDirectory**, or **Syslog Sender**) and then click **OK** to save the server entry. Repeat this step for each server to be monitored.<br>5. (Optional) To enable the firewall to automatically discover domain controllers on your network using DNS lookups, click **Auto Discover**.<br>The auto-discovery locates domain controllers in the local domain only; you must manually add Exchange servers, eDirectory servers, and syslog senders.<br>e. (Optional) To tune the frequency at which the firewall polls configured servers for mapping information, select **User Identification > Setup** and **Edit** the Setup section. On the **Server Monitor** tab, modify the value in the **Server Log Monitor Frequency (seconds)** field. As a best practice, you should increase the value in this field to 5 seconds in environments with older Domain Controllers or high-latency links. Click **OK** to save the changes. |

| Map IP Addresses to Users Using the User-ID Agent (Continued) | | |
|---|---|---|
| Step 3 | (Optional) If you configured the agent to connect to a Novell eDirectory server, you must specify how the agent should search the directory. | 1. Select **User Identification > Setup** and click **Edit** in the Setup section of the window.<br>2. Select the **eDirectory** tab and then complete the following fields:<br>• **Search Base**—The starting point or root context for agent queries, for example: `dc=domain1, dc=example, dc=com`.<br>• **Bind Distinguished Name**—The account to use to bind to the directory, for example: `cn=admin, ou=IT, dc=domain1, dc=example, dc=com`.<br>• **Bind Password**—The bind account password. The agent saves the encrypted password in the configuration file.<br>• **Search Filter**—The search query for user entries (default is `objectClass=Person`).<br>• **Server Domain Prefix**—A prefix to uniquely identify the user. This is only required if there are overlapping name spaces, such as different users with the same name from two different directories.<br>• **Use SSL**—Select the check box to use SSL for eDirectory binding.<br>• **Verify Server Certificate**—Select the check box to verify the eDirectory server certificate when using SSL. |
| Step 4 | (Optional) Enable client probing.<br>Client probing is useful in environments where IP addresses are not tightly bound to users because it ensures that previously mapped addresses are still valid. However, as the total number of learned IP addresses grows, so does the amount of traffic generated. As a best practice, only enable probing on network segments where IP address turnover is high.<br>For more details on the placement of User-ID agents using client probing, refer to Architecting User Identification (User-ID) Deployments. | 1. On the **Client Probing** tab, select the **Enable WMI Probing** check box and/or the **Enable NetBIOS Probing** check box.<br>2. Make sure the Windows firewall will allow client probing by adding a remote administration exception to the Windows firewall for each probed client.<br> For NetBIOS probing to work effectively, each probed client PC must allow port 139 in the Windows firewall and must also have file and printer sharing services enabled. WMI probing is always preferred over NetBIOS whenever possible. |
| Step 5 | Save the configuration. | Click **OK** to save the User-ID agent setup settings and then click **Commit** to restart the User-ID agent and load the new settings. |

 © Palo Alto Networks, Inc.

| Map IP Addresses to Users Using the User-ID Agent (Continued) | | |
|---|---|---|
| Step 6 | (Optional) Define the set of users for which you do not need to provide IP address-to-user name mappings, such as kiosk accounts.<br> You can also use the `ignore-user` list to identify users whom you want to force to authenticate using Captive Portal. | Create an `ignore_user_list.txt` file and save it to the User-ID Agent folder on the domain server where the agent is installed.<br>List the user accounts to ignore; there is no limit to the number of accounts you can add to the list. Each user account name must be on a separate line. For example:<br>`SPAdmin`<br>`SPInstall`<br>`TFSReport` |
| Step 7 | Configure the firewalls to connect to the User-ID agent. | Complete the following steps on each firewall you want to connect to the User-ID agent to receive user mappings:<br>1. Select **Device > User Identification > User-ID Agents** and click **Add**.<br>2. Enter a **Name** for the User-ID agent.<br>3. Enter the IP address of the Windows **Host** on which the User-ID Agent is installed.<br>4. Enter the **Port** number on which the agent will be listening for user mapping requests. This value must match the value configured on the User-ID agent. By default, the port is set to 5007 on the firewall and on newer versions of the User-ID agent. However, some older User-ID agent versions use port 2010 as the default.<br>5. Make sure that the configuration is **Enabled** and then click **OK**.<br>6. **Commit** the changes.<br>7. Verify that the **Connected status** displays as connected (a green light). |
| Step 8 | Verify that the User-ID agent is successfully mapping IP addresses to usernames and that the firewalls can connect to the agent. | 1. Launch the User-ID agent and select **User Identification**.<br>2. Verify that the agent status shows **Agent is running**. If the Agent is not running, click **Start**.<br>3. To verify that the User-ID agent can connect to monitored servers, make sure the Status for each Server is **Connected**.<br>4. To verify that the firewalls can connect to the User-ID agent, make sure the Status for each of the Connected Devices is **Connected**.<br>5. To verify that the User-ID agent is mapping IP addresses to usernames, select **Monitoring** and make sure that the mapping table is populated. You can also **Search** for specific users, or **Delete** user mappings from the list. |

© Palo Alto Networks, Inc.

## Configure User Mapping Using the PAN-OS Integrated User-ID Agent

The following procedure shows how to configure the PAN-OS integrated agent on the firewall for user mapping. The integrated User-ID agent performs the same tasks as the Windows-based agent with the exception of NetBIOS client probing (WMI probing is supported).

| Map IP Addresses to Users Using the Integrated User-ID Agent | | |
|---|---|---|
| Step 1 | Create an Active Directory (AD) account for the firewall agent that has the privilege levels required to log in to each service or host you plan to monitor to collect user mapping data. | • **Windows 2008 or later domain servers**—Add the account to the Event Log Readers group. If you are using the on-device User-ID agent, the account must also be a member of the Distributed COM Users Group.<br>• **Windows 2003 domain servers**—Assign Manage Auditing and Security Logs permissions through group policy.<br>• **WMI probing**—Make sure the account has rights to read the CIMV2 namespace; by default, Domain Administrator and Server Operator accounts have this permission.<br>• **NTLM authentication**—Because the firewall must join the domain if you are using Captive Portal NTLM authentication with an on-device User-ID agent, the Windows account you create for NTLM access must have administrative privileges. Note that due to AD restrictions on virtual systems running on the same host, if you have configured multiple virtual systems, only vsys1 will be able to join the domain. |

 © Palo Alto Networks, Inc.

**Map IP Addresses to Users Using the Integrated User-ID Agent (Continued)**

| | | |
|---|---|---|
| Step 2 | Define the servers the firewall should monitor to collect IP address-to-user mapping information. You can define entries for a total of up to 100 servers of all types, including syslog senders.<br><br>Keep in mind that in order to collect all of the required mappings, you must connect to all servers that your users log in to so that the firewall can monitor the security log files on all servers that contain login events. | 1. Select **Device > User Identification > User Mapping**.<br>2. In the Server Monitoring section of the screen, click **Add**.<br>3. Enter a **Name** and **Network Address** for the server. The network address can be a FQDN or an IP address.<br>4. Select the **Type** of server.<br>5. Make sure the **Enabled** check box is selected and then click **OK**<br>6. (Optional) To enable the firewall to automatically discover domain controllers on your network using DNS lookups, click **Discover**.<br> <br>The auto-discovery feature is for domain controllers only; you must manually add any Exchange servers or eDirectory servers you want to monitor.<br>7. (Optional) Specify the frequency at which the firewall polls Windows servers for mapping information. This is the interval between the end of the last query and the start of the next query.<br>If the query load is high, the observed delay between queries might significantly exceed the specified frequency.<br>a. In the **Palo Alto Networks User ID Agent Setup** section, click the Edit icon.<br>b. Select the **Server Monitor** tab and specify the **Server Log Monitor Frequency** in seconds (default is 2, range is 1-3600).<br>As a best practice, increase the value in this field to 5 seconds in environments with older domain controllers or high-latency links.<br>c. Click **OK** to save the changes. |
| Step 3 | Set the domain credentials for the account the firewall will use to access Windows resources. This is required for monitoring Exchange servers and domain controllers as well as for WMI probing. | 1. Edit the Palo Alto Networks User ID Agent Setup section of the screen.<br>2. On the **WMI Authentication** tab, enter the **User Name** and **Password** for the account that will be used to probe the clients and monitor servers. Enter the user name using the domain\username syntax.<br> |

| Map IP Addresses to Users Using the Integrated User-ID Agent (Continued) | | |
|---|---|---|
| Step 4 | (Optional) Enable WMI probing.<br><br>The on-device agent does not support NetBIOS probing; it is supported on the Windows-based User-ID agent only. | 1. On the **Client Probing** tab, select the **Enable Probing** check box.<br>2. (Optional) If necessary, modify the **Probe Interval** (in minutes) to ensure it is long enough for the User-ID agent to probe all the learned IP addresses (default is 20, range is 1-1440). This is the interval between the end of the last probe request and the start of the next request.<br><br>If the request load is high, the observed delay between requests might significantly exceed the specified interval.<br>3. Make sure the Windows firewall will allow client probing by adding a a remote administration exception to the Windows firewall for each probed client. |
| Step 5 | Save the configuration. | 1. Click **OK** to save the User-ID agent setup settings.<br>2. Click **Commit** to save the configuration. |
| Step 6 | (Optional) Define the set of users for which you do not need to provide IP address-to-user name mappings, such as kiosk accounts.<br><br>You can also use the `ignore-user` list to identify users whom you want to force to authenticate using Captive Portal. | 1. Open a CLI session to the firewall.<br>2. To add the list of user accounts for which you do not want the firewall to perform mapping, run the following command:<br>**set user-id-collector ignore-user <value>**<br>where <value> is a list of the user accounts to ignore; there is no limit to the number of accounts you can add to the list. Separate entries with a space and do not include the domain name with the username. For example:<br>`set user-id-collector ignore-user SPAdmin SPInstall TFSReport`<br>3. **Commit** your changes. |
| Step 7 | Verify the configuration. | 1. From the CLI, enter the following command:<br>`show user server-monitor state all`<br>2. On the **Device > User Identification > User Mapping** tab in the web interface, verify that the **Status** of each server you configured for server monitoring is **Connected**. |

# Configure User-ID to Receive User Mappings from a Syslog Sender

The following topics describe how to configure the User-ID agent (either the Windows agent or the integrated agent on the firewall) as a Syslog listener:

- Configure the Integrated User-ID Agent as a Syslog Listener
- Configure the Windows User-ID Agent as a Syslog Listener

## Configure the Integrated User-ID Agent as a Syslog Listener

The following workflow describes how to configure the PAN-OS integrated User-ID agent to receive syslog messages from authenticating services.

The PAN-OS integrated User-ID agent accepts syslogs over SSL and UDP only. However, you must use caution when using UDP to receive syslog messages because it is an unreliable protocol and as such there is no way to verify that a message was sent from a trusted syslog server. Although you can restrict syslog messages to specific source IP addresses, an attacker can still spoof the IP address, potentially allowing the injection of unauthorized syslog messages into the firewall. As a best practice, always use SSL to listen for syslog messages. However, if you must use UDP, make sure that the syslog server and client are both on a dedicated, secure VLAN to prevent untrusted hosts from sending UDP traffic to the firewall.

| **Collect User Mappings from Syslog Senders** | |
|---|---|
| Step 1 Determine whether there is a pre-defined syslog filter for your particular syslog sender(s).<br><br>Palo Alto Networks provides several pre-defined syslog filters, which are delivered as Application content updates and are therefore updated dynamically as new filters are developed. The pre-defined filters are global to the firewall, whereas manually-defined filters apply to a single virtual system only.<br><br> Any new syslog filters in a given content release will be documented in the corresponding release note along with the specific regex used to define the filter. | 1. Verify that your Application or Application and Threat database is up to date:<br>a. Select **Device > Dynamic Updates**.<br>b. Click **Check Now** (located in the lower left-hand corner of the window) to check for the latest updates.<br>c. If a new update is available, **Download** and **Install** it.<br>2. Check to see what pre-defined filters are available:<br>a. Select **Device > User Identification > User Mapping**.<br>b. In the Server Monitoring section of the screen, click **Add**.<br>c. Select **Syslog Sender** as the server **Type**.<br>d. Select the **Filter** drop-down and check to see if there is a filter for the manufacturer and product you plan to forward syslogs from. If the filter you need is available, skip to Step 5 for instructions on defining the servers. If the filter you need is not available, continue to Step 2. |

**Collect User Mappings from Syslog Senders (Continued)**

Step 2 Manually define syslog filter(s) for extracting the User-ID IP address to username mapping information from syslog messages.

In order to be parsed by the User-ID agent, syslog messages must meet the following criteria:

- Each syslog message must be a single-line text string. Line breaks are delimited by a carriage return and a new line (`\r\n`) or a new line (`\n`).
- The maximum allowed size of an individual syslog message is 2048 bytes.
- Syslog messages sent over UDP must be contained in a single packet; messages sent over SSL can span multiple packets.
- A single packet may contain multiple syslog messages.

1. Review the syslogs generated by the authenticating service to identify the syntax of the login events. This enables you to create the matching patterns that will allow the firewall to identify and extract the authentication events from the syslogs.

   While reviewing the syslogs, also determine whether the domain name is included in the log entries. If the authentication logs do not contain domain information, consider defining a default domain name when adding the syslog sender to the monitored servers list in Step 5.
2. Select **Device > User Identification > User Mapping** and edit the Palo Alto Networks User-ID Agent Setup section.
3. On the **Syslog Filters** tab, **Add** a new syslog parse profile.
4. Enter a name for the **Syslog Parse Profile**.
5. Specify the **Type** of parsing to use to filter out the user mapping information by selecting one of the following options:
   - **Regex Identifier**—With this type of parsing, you specify regular expressions to describe search patterns for identifying and extracting user mapping information from syslog messages. Continue to Step 3 for instructions on creating the regex identifiers.
   - **Field Identifier**—With this type of parsing, you specify a string to match the authentication event, and prefix and suffix strings to identify the user mapping information in the syslogs. Continue to Step 4 for instructions on creating the field identifiers.

 © Palo Alto Networks, Inc.

**Collect User Mappings from Syslog Senders (Continued)**

Step 3 If you selected **Regex Identifier** as the parsing **Type**, create the regex matching patterns for identifying the authentication events and extracting the user mapping information.

The example below shows a regex configuration for matching syslog messages with the following format:

```
[Tue Jul 5 13:15:04 2005 CDT] Administrator
authentication success User:johndoe1
Source:192.168.3.212
```

If the syslog contains a standalone space and/or tab as a delimiter, you must use an \s (for a space) and/or \t (for a tab) in order for the agent to parse the syslog.

1. Specify how to match successful authentication events in the syslogs by entering a matching pattern in the **Event Regex** field. For example, when matched against the example syslog message, the following regex instructs the firewall to extract the first `{1}` instance of the string `authentication success`. The backslash before the space is a standard regex escape character that instructs the regex engine not to treat the space as a special character: `(authentication\ success){1}`.
2. Enter the regex for identifying the beginning of the username in the authentication success messages in the **Username Regex** field. For example, the regex `User:([a-zA-Z0-9\\\._]+)` would match the string `User:johndoe1` in the example message and extract `acme\johndoe1` as the User-ID.

   If the syslogs do not contain domain information and you require domain names in your user mappings, be sure to enter the **Default Domain Name** when defining the monitored server entry in Step 5.
3. Enter the regex for identifying the IP address portion of the authentication success messages in the **Address Regex** field. For example, the following regular expression `Source:([0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3})` would match an IPv4 address (`Source:192.168.0.212` in the example syslog).
4. Click **OK**.

**Collect User Mappings from Syslog Senders (Continued)**

Step 4 If you selected **Field Identifier** as the parsing **Type**, define the string matching patterns for identifying the authentication events and extracting the user mapping information.

The example below shows a field identifier configuration for matching syslog messages with the following format:

```
[Tue Jul 5 13:15:04 2005 CDT] Administrator
authentication success User:johndoe1
Source:192.168.3.212
```

If the syslog contains a standalone space and/or tab as a delimiter, you must use an \s (for a space) and/or \t (for a tab) in order for the agent to parse the syslog.

1. Specify how to match successful authentication events in the syslogs by entering a matching pattern in the **Event String** field. For example, when matched against the sample syslog message, you would enter the string `authentication success` to identify authentication events in the syslog.
2. Enter the matching string for identifying the beginning of the username field within the authentication syslog message in the **Username Prefix** field. For example, the string `User:` identifies the beginning of the username field in the sample syslog.
3. Enter the **Username Delimiter** to mark the end of the username field within an authentication syslog message. For example, if the username is followed by a space, you would enter `\s` to indicate that the username field is delimited by a standalone space in the sample log.
4. Enter the matching string for identifying the beginning of the IP address field within the authentication event log in the **Address Prefix** field. For example, the string `Source:` identifies the beginning of the address field in the example log.
5. Enter the **Address Delimiter** to mark the end of the IP address field within the authentication success message within the field. For example, if the address is followed by a line break, you would enter `\n` to indicate that the address field is delimited by a new line.
6. Click **OK**.

Step 5 Define the servers that will send syslog messages to the firewall for user mapping purposes.

You can define a total of up to 100 monitored servers of all types, including syslog senders. The firewall will discard any syslog messages received from servers that are not on this list.

A Syslog sender using SSL to connect will only show a **Status** of **Connected** when there is an active SSL connection. Syslog senders using UDP will not show a **Status** value.

1. Select **Device > User Identification > User Mapping**.
2. In the Server Monitoring section of the screen, click **Add**.
3. Enter a **Name** and **Network Address** for the server.
4. Select **Syslog Sender** as the server **Type**.
5. Make sure the **Enabled** check box is selected.
6. (Optional) If the syslogs that the authenticating device sends do not include domain information in the login event logs, enter the **Default Domain Name** to append to the user mappings.
7. Click **OK** to save the settings.

 © Palo Alto Networks, Inc.

| Collect User Mappings from Syslog Senders (Continued) | |
|---|---|
| Step 6 Enable syslog listener services in the management profile associated with the interface used for user mapping.<br><br>Use caution when using UDP to receive syslog messages because it is an unreliable protocol and as such there is no way to verify that a message was sent from a trusted syslog server. Although you can restrict syslog messages to specific source IP addresses, an attacker can still spoof the IP address, potentially allowing the injection of unauthorized syslog messages into the firewall. As a best practice, always use SSL to listen for syslog messages when using agentless User Mapping on a firewall. However, if you must use UDP, make sure that the syslog server and client are both on a dedicated, secure VLAN to prevent untrusted hosts from sending UDP traffic to the firewall. | 1. Select **Network > Network Profiles > Interface Mgmt** and then select an interface profile to edit or click **Add** to create a new profile.<br>2. Select **User-ID Syslog Listener-SSL** and/or **User-ID Syslog Listener-UDP**, depending on the protocols you defined when you set up your Syslog Senders in the Server Monitor list.<br><br>On the Windows User-ID agent, the default listening port for syslog over UDP or TCP is 514, but the port value is configurable. For the agentless User Mapping feature on the firewall, only syslog over UDP and SSL are supported and the listening ports (514 for UDP and 6514 for SSL) are not configurable; they are enabled through the management service only.<br><br> <br>3. Click **OK** to save the interface management profile.<br><br>Even after enabling the User-ID Syslog Listener service on the interface, the interface will only accept syslog connections from servers that have a corresponding entry in the User-ID monitored servers configuration. Connections or messages from servers that are not on the list will be discarded. |
| Step 7 Save the configuration. | Click **Commit** to save the configuration. |

**Collect User Mappings from Syslog Senders (Continued)**

Step 8 Verify the configuration by opening an SSH connection to the firewall and then running the following CLI commands:

To see the status of a particular syslog sender:

```
admin@PA-5050> show user server-monitor state Syslog2
        UDP Syslog Listener Service is enabled
        SSL Syslog Listener Service is enabled

Proxy: Syslog2(vsys: vsys1)     Host: Syslog2(10.5.204.41)
        number of log messages                          : 1000
        number of auth. success messages                : 1000
        number of active connections                    : 0
        total connections made                          : 4
```

To see how many log messages came in from syslog senders and how many entries were successfully mapped:

```
admin@PA-5050> show user server-monitor statistics

Directory Servers:
Name                            TYPE     Host            Vsys    Status

------------------------------------------------------------------------------
AD                              AD       10.2.204.43     vsys1   Connected

Syslog Servers:
Name                       Connection Host            Vsys    Status
------------------------------------------------------------------------------
Syslog1                    UDP        10.5.204.40     vsys1   N/A
Syslog2                    SSL        10.5.204.41     vsys1   Not connected
```

To see how many user mappings were discovered through syslog senders:

```
admin@PA-5050> show user ip-user-mapping all type SYSLOG

IP              Vsys   From    User                              IdleTimeout(s) M

## Configure the Windows User-ID Agent as a Syslog Listener

The following workflow describes how to configure a Windows-based User-ID agent to listen for syslogs from authenticating services.

The Windows User-ID agent accepts syslogs over TCP and UDP only. However, you must use caution when using UDP to receive syslog messages because it is an unreliable protocol and as such there is no way to verify that a message was sent from a trusted syslog server. Although you can restrict syslog messages to specific source IP addresses, an attacker can still spoof the IP address, potentially allowing the injection of unauthorized syslog messages into the firewall. As a best practice, use TCP instead of UDP. In either case, make sure that the syslog server and client are both on a dedicated, secure VLAN to prevent untrusted hosts from sending syslogs to the User-ID agent.

 © Palo Alto Networks, Inc.

| Configure the Windows User-ID Agent to Collect User Mappings from Syslog Senders | |
|---|---|
| Step 1 Launch the User-ID Agent application. | 1. Click Start and select **User-ID Agent**.<br> |
| Step 2 Manually define syslog filter(s) for extracting the User-ID IP address to username mapping information from syslog messages.<br><br>In order to be parsed by the User-ID agent, syslog messages must meet the following criteria:<br>• Each syslog message must be a single-line text string. Line breaks are delimited by a carriage return and a new line (\r\n) or a new line (\n).<br>• The maximum allowed size of an individual syslog message is 2048 bytes.<br>• Syslog messages sent over UDP must be contained in a single packet; messages sent over SSL can span multiple packets.<br>• A single packet may contain multiple syslog messages. | 1. Review the syslogs generated by the authenticating service to identify the syntax of the login events. This enables you to create the matching patterns that will allow the firewall to identify and extract the authentication events from the syslogs.<br> While reviewing the syslogs, also determine whether the domain name is included in the log entries. If the authentication logs do not contain domain information, consider defining a default domain name when adding the syslog sender to the monitored servers list in Step 5.<br>2. Select **User Identification > Setup** and click **Edit** in the Setup section of the dialog.<br>3. On the **Syslog** tab, **Add** a new syslog parse profile.<br>4. Enter a **Profile Name** and **Description**.<br>5. Specify the **Type** of parsing to use to filter out the user mapping information by selecting one of the following options:<br>• **Regex**—With this type of parsing, you specify regular expressions to describe search patterns for identifying and extracting user mapping information from syslog messages. Continue to Step 3 for instructions on creating the regex identifiers.<br>• **Field**—With this type of parsing, you specify a sting to match the authentication event, and prefix and suffix strings to identify the user mapping information in the syslogs. Continue to Step 4 for instructions on creating the field identifiers. |

**Configure the Windows User-ID Agent to Collect User Mappings from Syslog Senders (Continued)**

Step 3 If you selected **Regex** as the parsing **Type**, create the regex matching patterns for identifying the authentication events and extracting the user mapping information.

The example below shows a regex configuration for matching syslog messages with the following format:

```
[Tue Jul 5 13:15:04 2005 CDT] Administrator
authentication success User:johndoe1
Source:192.168.3.212
```

If the syslog contains a standalone space and/or tab as a delimiter, you must use an \s (for a space) and/or \t (for a tab) in order for the agent to parse the syslog.

1. Specify how to match successful authentication events in the syslogs by entering a matching pattern in the **Event Regex** field. For example, when matched against the example syslog message, the following regex instructs the firewall to extract the first `{1}` instance of the string `authentication success`. The backslash before the space is a standard regex escape character that instructs the regex engine not to treat the space as a special character: `(authentication\ success){1}`.
2. Enter the regex for identifying the beginning of the username in the authentication success messages in the **Username Regex** field. For example, the regex `User:([a-zA-Z0-9\\\._]+)` would match the string `User:johndoe1` in the example message and extract `acme\johndoe1` as the User-ID.

   If the syslogs do not contain domain information and you require domain names in your user mappings, be sure to enter the **Default Domain Name** when defining the monitored server entry in Step 5.
3. Enter the regex for identifying the IP address portion of the authentication success messages in the **Address Regex** field. For example, the following regular expression `Source:([0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3})` would match an IPv4 address (`Source:192.168.0.212` in the example syslog).
4. Click **OK** to save the profile.

© Palo Alto Networks, Inc.

**Configure the Windows User-ID Agent to Collect User Mappings from Syslog Senders (Continued)**

**Step 4** If you selected **Field Identifier** as the parsing **Type**, define the string matching patterns for identifying the authentication events and extracting the user mapping information.

The example below shows a field identifier configuration for matching syslog messages with the following format:

```
[Tue Jul 5 13:15:04 2005 CDT] Administrator
authentication success User:johndoe1
Source:192.168.3.212
```

If the syslog contains a standalone space and/or tab as a delimiter, you must use an \s (for a space) and/or \t (for a tab) in order for the agent to parse the syslog.

1. Specify how to match successful authentication events in the syslogs by entering a matching pattern in the **Event String** field. For example, when matched against the sample syslog message, you would enter the string `authentication success` to identify authentication events in the syslog.
2. Enter the matching string for identifying the beginning of the username field within the authentication syslog message in the **Username Prefix** field. For example, the string `User:` identifies the beginning of the username field in the sample syslog.
3. Enter the **Username Delimiter** to mark the end of the username field within an authentication syslog message. For example, if the username is followed by a space, you would enter `\s` to indicate that the username field is delimited by a standalone space in the sample log.
4. Enter the matching string for identifying the beginning of the IP address field within the authentication event log in the **Address Prefix** field. For example, the string `Source:` identifies the beginning of the address field in the example log.
5. Enter the **Address Delimiter** to mark the end of the IP address field within the authentication success message within the field. For example, if the address is followed by a line break, you would enter `\n` to indicate that the address field is delimited by a new line.
6. Click **OK** to save the profile.

**Step 5** Enable the syslog listening service on the agent.

As a best practice, make sure that the syslog server and client are both on a dedicated, secure VLAN to prevent untrusted hosts from sending syslogs to the User-ID agent.

1. Select the **Enable Syslog Service** check box.
2. (Optional) Modify the **Syslog Service Port** number to match the port number used by the syslog sender (default=514).
3. To save the agent syslog configuration, click **OK**.

**Step 6** Define the servers that will send syslog messages to the User-ID agent.

You can define up to 100 syslog senders. The User-ID agent will discard any syslog messages received from servers that are not on this list.

1. Select **User Identification > Discovery**.
2. In the **Servers** section of the screen, click **Add**.
3. Enter a **Name** and **Server Address** for the server that will send syslogs to the agent.
4. Select **Syslog Sender** as the **Server Type**.
5. Select a **Filter** you defined in Step 2.
6. (Optional) If the syslogs that the authenticating device sends do not include domain information in the login event logs, enter the **Default Domain Name** to append to the user mappings.
7. Click **OK** to save the settings.

**Step 7** Save the configuration.

Click **Commit** to save the configuration.

**Configure the Windows User-ID Agent to Collect User Mappings from Syslog Senders (Continued)**

Step 8 Verify the configuration by opening an SSH connection to the firewall and then running the following CLI commands:

To see the status of a particular syslog sender:

```
admin@PA-5050> show user server-monitor state Syslog2
        UDP Syslog Listener Service is enabled
        SSL Syslog Listener Service is enabled

Proxy: Syslog2(vsys: vsys1)     Host: Syslog2(10.5.204.41)
        number of log messages                          : 1000
        number of auth. success messages                : 1000
        number of active connections                    : 0
        total connections made                          : 4
```

To see how many log messages came in from syslog senders and how many entries were successfully mapped:

```
admin@PA-5050> show user server-monitor statistics

Directory Servers:
Name                            TYPE     Host            Vsys    Status

------------------------------------------------------------------------------
AD                              AD       10.2.204.43     vsys1   Connected

Syslog Servers:
Name                      Connection Host            Vsys    Status
------------------------------------------------------------------------------
Syslog1                   UDP        10.5.204.40     vsys1   N/A
Syslog2                   SSL        10.5.204.41     vsys1   Not connected
```

To see how many user mappings were discovered through syslog senders:

```
admin@PA-5050> show user ip-user-mapping all type SYSLOG

IP              Vsys   From    User                            IdleTimeout(s) M
axTimeout(s)

# Map IP Addresses to User Names Using Captive Portal

If the firewall receives a request from a zone that has User-ID enabled and the source IP address does not have any user data associated with it yet, it checks its Captive Portal policy for a match to determine whether to perform authentication. This is useful in environments where you have clients that are not logged in to your domain servers, such as Linux clients. This user mapping method is triggered only for web traffic (HTTP or HTTPS) that matches a security rule/policy, but that has not been mapped using a different method.

- Captive Portal Authentication Methods
- Captive Portal Modes
- Configure Captive Portal

## Captive Portal Authentication Methods

Captive Portal uses the following methods to obtain user data from the client when a request matches a Captive Portal policy:

| Authentication Method | Description |
|---|---|
| NT LAN Manager (NTLM) | The firewall uses an encrypted challenge-response mechanism to obtain the user's credentials from the browser. When configured properly, the browser will provide the credentials to the firewall transparently without prompting the user, but will display a prompt for credentials if necessary. If the browser cannot perform NTLM or if NTLM authentication fails, the firewall falls back to web form or client certificate authentication, depending on your Captive Portal configuration.<br>By default, IE supports NTLM. Firefox and Chrome can be configured to use it. You cannot use NTLM to authenticate non-Windows clients. |
| Web Form | Requests are redirected to a web form for authentication. You can configure Captive Portal to use a local user database, RADIUS, LDAP, or Kerberos to authenticate users. Although users will always be prompted for credentials, this authentication method works with all browsers and operating systems. |
| Client Certificate Authentication | Prompts the browser to present a valid client certificate for authenticating the user. To use this method, you must provision client certificates on each user system and install the trusted CA certificate used to issue those certificates on the firewall. This is the only authentication method that enables transparent authentication for Mac OS and Linux clients. |

## Captive Portal Modes

The Captive Portal mode defines how web requests are captured for authentication:

© Palo Alto Networks, Inc.

| Mode | Description |
|---|---|
| Transparent | The firewall intercepts the browser traffic per the Captive Portal rule and impersonates the original destination URL, issuing an HTTP 401 to invoke authentication. However, because the firewall does not have the real certificate for the destination URL, the browser will display a certificate error to users attempting to access a secure site. Therefore you should only use this mode when absolutely necessary, such as in Layer 2 or virtual wire deployments. |
| Redirect | The firewall intercepts unknown HTTP or HTTPS sessions and redirects them to a Layer 3 interface on the firewall using an HTTP 302 redirect in order to perform authentication. This is the preferred mode because it provides a better end-user experience (no certificate errors). However, it does require additional Layer 3 configuration. Another benefit of the Redirect mode is that it provides for the use of session cookies, which enable the user to continue browsing to authenticated sites without requiring re-mapping each time the time outs expire. This is especially useful for users who roam from one IP address to another (for example, from the corporate LAN to the wireless network) because they will not need to re-authenticate upon IP address change as long as the session stays open. In addition, if you plan to use NTLM authentication, you must use Redirect mode because the browser will only provide credentials to trusted sites. |

## Configure Captive Portal

The following procedure shows how to configure Captive Portal using the PAN-OS integrated User-ID agent to redirect requests that match a Captive Portal policy to a Layer 3 interface on the firewall.

If you plan to use Captive Portal without using the other User-ID functions (user mapping and group mapping), you do not need to configure an agent.

| Configure Captive Portal Using the PAN-OS Integrated User-ID Agent | | |
|---|---|---|
| Step 1 | Make sure the firewall has a route to the servers it will monitor to gather user data (for example, your Domain Controllers and your Exchange servers). | The firewall must be able to communicate with the servers over a designated interface (the management [MGT] interface by default), so make sure that the network where your directory servers reside is accessible from that interface. If this configuration doesn't work in your environment, you must configure Captive Portal using the Window-based User-ID agent. |
| Step 2 | Make sure DNS is configured to resolve your Domain Controller addresses. | To verify proper resolution, ping the server FQDN. For example:<br>`admin@PA-200> ping host dc1.acme.com` |

 © Palo Alto Networks, Inc.

| Configure Captive Portal Using the PAN-OS Integrated User-ID Agent (Continued) | | |
|---|---|---|
| Step 3 | (Redirect mode only) Create a Layer 3 interface to which to redirect Captive Portal requests. | 1. Create a management profile to enable the interface to display Captive Portal response pages:<br>a. Select **Network > Interface Mgmt** and click **Add**.<br>b. Enter a **Name** for the profile, select **Response Pages**, and then click **OK**.<br>2. Create the Layer 3 interface. Be sure to attach the management profile you just created (on the **Advanced > Other Info** tab of the Ethernet Interface dialog).<br>3. Create a DNS "A" record that maps the IP address you configured on the Layer 3 interface to an intranet host name (that is, a hostname that does not have a dot in the name, such as `ntlmhost`). |
| Step 4 | (Redirect mode only) To transparently redirect users without displaying certificate errors, install a certificate that matches the IP address of the interface to which you are redirecting requests.You can either generate a self-signed certificate or import a certificate that is signed by an external CA.<br> When setting up Captive Portal for the first time, imported certificates may not work. If you plan to use an imported certificate, complete the initial configuration without specifying a **Server Certificate**. After you get Captive Portal working, you can go back and switch to the imported certificate. | To use a self-signed certificate, you must first create a root CA certificate and then use that CA to sign the certificate you will use for Captive Portal as follows:<br>1. To create a root CA certificate, select **Device > Certificate Management > Certificates > Device Certificates** and then click **Generate**. Enter a **Certificate Name**, such as RootCA. Do not select a value in the **Signed By** field (this is what indicates that it is self-signed). Make sure you select the **Certificate Authority** check box and then click **Generate** the certificate.<br>2. To create the certificate to use for Captive Portal, click **Generate**. Enter a **Certificate Name** and enter the DNS name of the intranet host for the interface as the **Common Name**. In the **Signed By** field, select the CA you created in the previous step. Add an IP address attribute and specify the IP address of the Layer 3 interface to which you will be redirecting requests. **Generate** the certificate.<br>  <br>3. To configure clients to trust the certificate, select the CA certificate on the **Device Certificates** tab and click **Export**. You must then import the certificate as a trusted root CA into all client browsers, either by manually configuring the browser or by adding the certificate to the trusted roots in an Active Directory Group Policy Object (GPO). |

| Configure Captive Portal Using the PAN-OS Integrated User-ID Agent (Continued) | | |
|---|---|---|
| Step 5 | Set up an authentication mechanism to use when the web form is invoked. Note that even if you plan to use NTLM, you must also set up a secondary authentication mechanism that can be used if NTLM authentication fails or if the user agent does not support it.<br><br>**Best Practices:**<br>•If using RADIUS to authenticate users from the web form, be sure to enter a RADIUS domain. This will be used as the default domain if users don't supply one upon login.<br>•If using AD to authenticate users from the web form, make sure to enter **sAMAccountName** as the **LogonAttribute**. | 1. Configure the firewall to connect to the authentication service you plan to use so that it can access the authentication credentials.<br>• If you plan to authenticate using LDAP, Kerberos, or RADIUS, you must create a server profile that instructs the firewall how to connect to the service and access the authentication credentials for your users. Select **Device > Server Profiles** and add a new profile for the specific service you will be accessing.<br>• If you plan to use local database authentication, you must first create the local database. Select **Device > Local User Database** and add the users and groups to be authenticated.<br>2. Create an authentication profile that references the server profile or local user database you just created. Select **Device > Authentication Profile** and add a new profile for use with Captive Portal. For details on creating a specific type of authentication profile, refer to the online help. |
| Step 6 | (Optional) Set up client certificate authentication. Note that you do not need to set up both an authentication profile and a client certificate profile to enable Captive Portal. If you configure both, the user will be required to authenticate using both methods.<br><br>For details on other certificate profile fields, such as whether to use CRL or OCSP, refer to the online help. | 1. Use a root CA certificate to generate a client certificate for each user who will authenticate to Captive Portal. The CA in this case is usually your enterprise CA, not the firewall.<br>2. Export the CA certificate in Base64 format to a system that the firewall can access.<br>3. Import the root CA certificate from the CA that generated the client certificates onto the firewall:<br>a. Select **Device > Certificate Management > Certificates > Device Certificates** and click **Import**.<br>b. Enter a **Certificate Name** that identifies the certificate as your client CA certificate.<br>c. **Browse** to the **Certificate File** you downloaded from the CA.<br>d. Select **Base64 Encoded Certificate (PEM)** as the **File Format** and then click **OK**.<br>e. Select the certificate you just imported on the **Device Certificates** tab to open it.<br>f. Select **Trusted Root CA** and then click **OK**.<br>4. Create the client certificate profile that you will use when you configure Captive Portal.<br>a. Select **Device > Certificates > Certificate Management > Certificate Profile**, click **Add**, and enter a profile **Name**.<br>b. In the **Username Field** drop-down, select the certificate field that contains the user's identity information.<br>c. In the **CA Certificates** field, click **Add**, select the Trusted Root CA certificate you just imported and then click **OK**. |

 © Palo Alto Networks, Inc.

**Configure Captive Portal Using the PAN-OS Integrated User-ID Agent (Continued)**

Step 7 Enable NT LAN Manager (NTLM) authentication.

When using the on-device User-ID agent, the firewall must be able to successfully resolve the DNS name of your Domain Controller in order for the firewall to join the domain. The credentials you supply here will be used to join the firewall to the domain upon successful DNS resolution.

1. Select **Device > User Identification > User Mapping** and edit the Palo Alto Networks User ID Agent Setup section of the screen.
2. On the **NTLM** tab, select the **Enable NTLM authentication processing** check box.
3. Enter the **NTLM Domain** against which the User-ID agent on the firewall should check NTLM credentials.
4. Enter the **Admin User Name** and **Password** for the Active Directory account you created in Step 1 in Map IP Addresses to Users Using the Integrated User-ID Agent for NTLM authentication.

   Do not include the domain in the **Admin User Name** field. Otherwise, the firewall will fail to join the domain.

   Palo Alto Networks recommends that you use a User-ID agent account that is separate from your firewall administrator account.
5. You don't need to configure any other settings for the User-ID agent: click **OK**.

| Configure Captive Portal Using the PAN-OS Integrated User-ID Agent (Continued) | |
|---|---|
| Step 8 Configure the Captive Portal settings. | 1. Select **Device > User Identification > Captive Portal Settings** and Edit the **Captive Portal** section of the screen.<br>2. Make sure the **Enabled** check box is selected.<br>3. Set the **Mode**. This example shows how to set up **Redirect** mode.<br>4. (Redirect mode only) Select the **Server Certificate** the firewall should use to redirect requests over SSL. This is the certificate you created in Step 4.<br>5. (Redirect mode only) Specify the **Redirect Host**, which is the intranet hostname that resolves to the IP address of the Layer 3 interface to which you are redirecting requests, as specified in Step 3.<br>6. Select the authentication method to use if NTLM fails (or if you are not using NTLM):<br>• If you are using LDAP, Kerberos, RADIUS, or local database authentication, select the **Authentication Profile** you created in Step 5.<br>• If you are using client certificate authentication, select the **Certificate Profile** you created in Step 6.<br>  <br>7. Click **OK** to save your settings.<br>8. Click **Commit** to save the Captive Portal configuration. |

# Configure User Mapping for Terminal Server Users

Individual terminal server users appear to have the same IP address and therefore an IP address-to-username mapping is not sufficient to identify a specific user. To enable identification of specific users on Windows-based terminal servers, the Palo Alto Networks Terminal Services agent (TS agent) allocates a port range to each user. It then notifies every connected firewall about the allocated port range, which allows the firewall to create an IP address-port-user mapping table and enable user- and group-based security policy enforcement. For non-Windows terminal servers, you can configure the User-ID XML API to extract user mapping information.

The following sections describe how to configure user mapping for terminal server users:

- Configure the Palo Alto Networks Terminal Server Agent for User Mapping
- Retrieve User Mappings from a Terminal Server Using the User-ID XML API

## Configure the Palo Alto Networks Terminal Server Agent for User Mapping

Use the following procedure to install the TS agent on the terminal server. You must install the TS agent on all terminal servers that your users log in to in order to successfully map all your users.

For information about the supported terminal servers supported by the TS Agent, refer to "Operating System (OS) Compatibility TS Agent" in the Terminal Services Agent Release Notes, which are available on the Palo Alto Networks Software Updates page.

| **Install the Windows Terminal Server Agent** | |
|---|---|
| Step 1 Download the TS Agent installer. | 1. Log in to the Palo Alto Networks Support site.<br>2. Select **Software Updates** from the Manage Devices section.<br>3. Scroll to the **Terminal Services Agent** section and **Download** the version of the agent you want to install.<br>4. Save the `TaInstall64.x64-x.x.x-xx.msi` or `TaInstall-x.x.x-xx.msi` file (be sure to select the appropriate version based on whether the Windows system is running a 32-bit OS or a 64-bit OS) on the system(s) where you plan to install the agent. |

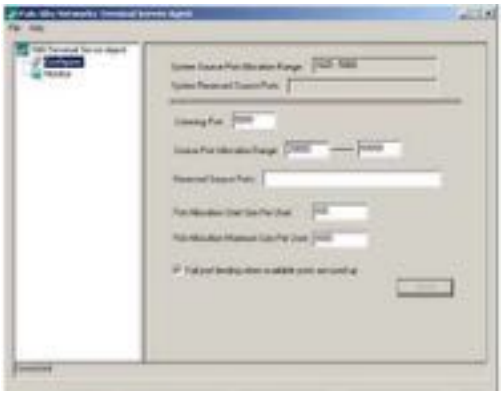
**Install the Windows Terminal Server Agent (Continued)**

| | | |
|---|---|---|
| Step 2 | Run the installer as an administrator.<br> | 1. To launch a command prompt as an administrator, click Start and right-click **Command Prompt** and then select **Run as administrator**.<br>2. From the command line, run the .msi file you downloaded. For example, if you saved the .msi file to the Desktop you would enter the following:<br>`C:\Users\administrator.acme>cd Desktop`<br>`C:\Users\administrator.acme\Desktop>TaInstall-6.0.0-1.msi`<br>3. Follow the setup prompts to install the agent using the default settings. By default, the agent gets installed to the `C:\Program Files (x86)\Palo Alto Networks\Terminal Server Agent` folder, but you can **Browse** to a different location.<br>4. When the installation completes, **Close** the setup window.<br>If you are upgrading to a TS Agent version that has a newer driver than the existing installation, the installation wizard prompts you to reboot the system after upgrading in order to use the new driver. |
| Step 3 | Launch the Terminal Server Agent application. | Click Start and select **Terminal Server Agent**.<br>  |

 © Palo Alto Networks, Inc.

**Install the Windows Terminal Server Agent (Continued)**

Step 4 Define the range of ports for the TS Agent to allocate to end users.



The **System Source Port Allocation Range** and **System Reserved Source Ports** fields specify the range of ports that will be allocated to non-user sessions. Make sure the values specified in these fields do not overlap with the ports you designate for user traffic. These values can only be changed by editing the corresponding Windows registry settings.

1. Select **Configure**.
2. Set the **Source Port Allocation Range** (default 20000-39999). This is the full range of port numbers that the TS Agent will allocate for user mapping. The port range you specify cannot overlap with the **System Source Port Allocation Range**.
3. (Optional) If there are ports/port ranges within the source port allocation that you do not want the TS Agent to allocate to user sessions, specify them as **Reserved Source Ports**. To include multiple ranges, use commas with no spaces, for example: `2000-3000,3500,4000-5000`.
4. Specify the number of ports to allocate to each individual user upon login to the terminal server in the **Port Allocation Start Size Per User** field (default 200).
5. Specify the **Port Allocation Maximum Size Per User**, which is the maximum number of ports the Terminal Server agent can allocate to an individual user.
6. Specify whether to continue processing traffic from the user if the user runs out of allocated ports. By default, the **Fail port binding when available ports are used up** is selected, which indicates that the application will fail to send traffic when all ports are used. To enable users to continue using applications when they run out of ports, clear this check box. Keep in mind that this traffic may not be identified with User-ID.

Step 5 Configure the firewalls to connect to the Terminal Server agent.

Complete the following steps on each firewall you want to connect to the Terminal Server agent to receive user mappings:

1. Select **Device > User Identification > Terminal Server Agents** and click **Add**.
2. Enter a **Name** for the Terminal Server agent.
3. Enter the IP address of the Windows **Host** on which the Terminal Server agent is installed.
4. Enter the **Port** number on which the agent will listen for user mapping requests. This value must match the value configured on the Terminal Server agent. By default, the port is set to 5009 on the firewall and on the agent. If you change it here, you must also change the **Listening Port** field on the Terminal Server agent **Configure** screen.
5. Make sure that the configuration is **Enabled** and then click **OK**.
6. **Commit** the changes.
7. Verify that the **Connected** status displays as connected (a green light).

| Install the Windows Terminal Server Agent (Continued) | |
|---|---|
| Step 6 Verify that the Terminal Server agent is successfully mapping IP addresses to usernames and that the firewalls can connect to the agent.<br>  | 1. Launch the Terminal Server agent and verify that the firewalls can connect by making sure the **Connection Status** for each of Device in the Connection List is **Connected**.<br>2. To verify that the Terminal Server agent is successfully mapping port ranges to usernames, select **Monitoring** and make sure that the mapping table is populated. |

## Retrieve User Mappings from a Terminal Server Using the User-ID XML API

The User-ID XML API is a RESTful API that uses standard HTTP requests to send and receive data. API calls can be made directly from command line utilities such as cURL or using any scripting or application framework that supports RESTful services.

To enable a non-Windows terminal server to send user mapping information directly to the firewall, create scripts that extract the user login and logout events and use them for input to the User-ID XML API request format. Then define the mechanisms for submitting the XML API request(s) to the firewall using cURL or wget and providing the firewall's API key for secure communication. Creating user mappings from multi-user systems such as terminal servers requires use of the following API messages:

- **<multiusersystem>**—Sets up the configuration for an XML API Multi-user System on the firewall. This message allows for definition of the terminal server IP address (this will be the source address for all users on that terminal server). In addition, the <multiusersystem> setup message specifies the range of source port numbers to allocate for user mapping and the number of ports to allocate to each individual user upon login (called the *block size*). If you want to use the default source port allocation range (1025-65534) and block size (200), you do not need to send a <multiusersystem> setup event to the firewall. Instead, the firewall will automatically generate the XML API Multi-user System configuration with the default settings upon receipt of the first user login event message.
- **<blockstart>**—Used with the <login> and <logout> messages to indicate the starting source port number allocated to the user. The firewall then uses the block size to determine the actual range of port numbers to map to the IP address and username in the login message. For example, if the <blockstart> value is 13200 and the block size configured for the multi-user system is 300, the actual source port range allocated to the user is 13200 through 13499. Each connection initiated by the user should use a unique source port number within the allocated range, enabling the firewall to identify the user based on its IP address-port-user mappings for enforcement of user- and group-based security policy rules. When a user exhausts all the ports allocated, the terminal server must send a new <login> message allocating a new port range for the user so that the firewall can update the IP address-port-user mapping. In addition, a single

 © Palo Alto Networks, Inc.

username can have multiple blocks of ports mapped simultaneously. When the firewall receives a <logout> message that includes a <blockstart> parameter, it removes the corresponding IP address-port-user mapping from its mapping table. When the firewall receives a <logout> message with a username and IP address, but no <blockstart>, it removes the user from its table. And, if the firewall receives a <logout> message with an IP address only, it removes the multi-user system and all mappings associated with it.

The XML files that the terminal server sends to the firewall can contain multiple message types and the messages do not need to be in any particular order within the file. However, upon receiving an XML file that contains multiple message types, the firewall will process them in the following order: multiusersystem requests first, followed by logins, then logouts.

The following workflow provides an example of how to use the User-ID XML API to send user mappings from a non-Windows terminal server to the firewall.

**Use the User-ID XML API to Map Non-Windows Terminal Services Users**

Step 1 — Generate the API key that will be used to authenticate the API communication between the firewall and the Terminal server. To generate the key you must provide login credentials for an administrative account; the API is available to all administrators (including role-based administrators with XML API privileges enabled).

Any special characters in the password must be URL/ percent-encoded.

From a browser, log in to the firewall. Then, to generate the API key for the firewall, open a new browser window and enter the following URL:

```
https://<Firewall-IPaddress>/api/?type=keygen&user=<username>&
password=<password>
```

Where <Firewall-IPaddress> is the IP address or FQDN of the firewall and <username> and <password> are the credentials for the administrative user account on the firewall. For example:

```
https://10.1.2.5/api/?type=keygen&user=admin&password=admin
```

The firewall responds with a message containing the key, for example:

```
<response status="success">
   <result>
      <key>k7J335J6hI7nBxIqyfa62sZugWx7ot%2BgzEA9UOnlZRg=</key>
   </result>
</response>
```

**Use the User-ID XML API to Map Non-Windows Terminal Services Users (Continued)**

Step 2 (Optional) Generate a setup message that the terminal server will send to specify the port range and block size of ports per user that your terminal services agent uses.

If the terminal services agent does not send a setup message, the firewall will automatically create a terminal server agent configuration using the following default settings upon receipt of the first login message:

- Default port range: 1025 to 65534
- Per user block size: 200
- Maximum number of multi-user systems: 1000

The following shows a sample setup message:

```
<uid-message>
  <payload>
    <multiusersystem>
      <entry ip="10.1.1.23" startport="20000"
        endport="39999" blocksize="100">
    </multiusersystem>
  </payload>
  <type>update</type>
  <version>1.0</version>
</uid-message>
```

where `entry ip` specifies the IP address assigned to terminal server users, `startport` and `endport` specify the port range to use when assigning ports to individual users, and `blocksize` specifies the number of ports to assign to each user. The maximum blocksize is 4000 and each multi-user system can allocate a maximum of 1000 blocks.

If you define a custom blocksize and or port range, keep in mind that you must configure the values such that every port in the range gets allocated and that there are no gaps or unused ports. For example, if you set the port range to 1000-1499, you could set the block size to 100, but not to 200. This is because if you set it to 200, there would be unused ports at the end of the range.

Step 3 Create a script that will extract the login events and create the XML input file to send to the firewall.

Make sure the script enforces assignment of port number ranges at fixed boundaries with no port overlaps. For example, if the port range is 1000-1999 and the block size is 200, acceptable blockstart values would be 1000, 1200, 1400, 1600, or 1800. Blockstart values of 1001, 1300, or 1850 would be unacceptable because some of the port numbers in the range would be left unused.

The login event payload that the terminal server sends to the firewall can contain multiple login events.

The following shows the input file format for a user-ID XML login event:

```
<uid-message>
<payload>
<login>
<entry name="acme\jjaso" ip="10.1.1.23" blockstart="20000">
<entry name="acme\jparker" ip="10.1.1.23" blockstart="20100">
<entry name="acme\ccrisp" ip="10.1.1.23" blockstart="21000">
</login>
</payload>
<type>update</type>
<version>1.0</version>
</uid-message>
```

The firewall uses this information to populate its user mapping table. Based on the mappings extracted from the example above, if the firewall received a packet with a source address and port of 10.1.1.23:20101, it would map the request to user jparker for policy enforcement.

Each multi-user system can allocate a maximum of 1000 port blocks.

 © Palo Alto Networks, Inc.

**Use the User-ID XML API to Map Non-Windows Terminal Services Users (Continued)**

**Step 4** Create a script that will extract the logout events and create the XML input file to send to the firewall.

Upon receipt of a `logout` event message with a `blockstart` parameter, the firewall removes the corresponding IP address-port-user mapping. If the `logout` message contains a username and IP address, but no `blockstart` parameter, the firewall removes all mappings for the user. If the `logout` message contains an IP address only, the firewall removes the multi-user system and all associated mappings.

The following shows the input file format for a User-ID XML logout event:

```
<uid-message>
  <payload>
     <logout>
        <entry name="acme\jjaso" ip="10.1.1.23"
blockstart="20000">
        <entry name="acme\ccrisp" ip="10.1.1.23">
        <entry ip="10.2.5.4">
     </logout>
  </payload>
  <type>update</type>
  <version>1.0</version>
</uid-message>
```

You can also clear the multiuser system entry from the firewall using the following CLI command: **`clear xml-api multiusersystem`**

**Step 5** Make sure that the scripts you create include a way to dynamically enforce that the port block range allocated using the XML API matches the actual source port assigned to the user on the terminal server and that the mapping is removed when the user logs out or the port allocation changes.

One way to do this would be to use netfilter NAT rules to hide user sessions behind the specific port ranges allocated via the XML API based on the uid. For example, to ensure that a user with the user ID jjaso is mapped to a source network address translation (SNAT) value of 10.1.1.23:20000-20099, the script you create should include the following:

```
[root@ts1 ~]# iptables -t nat -A POSTROUTING -m owner --uid-owner jjaso
-p tcp -j SNAT --to-source 10.1.1.23:20000-20099
```

Similarly, the scripts you create should also ensure that the IP table routing configuration dynamically removes the SNAT mapping when the user logs out or the port allocation changes:

```
[root@ts1 ~]# iptables -t nat -D POSTROUTING 1
```

**Step 6** Define how to package the XML input files containing the setup, login, and logout events into wget or cURL messages for transmission to the firewall.

To apply the files to the firewall using wget:

```
> wget --post file <filename>
"https://<Firewall-IPaddress>/api/?type=user-id&key=<key>&file-name=<inp
ut_filename.xml>&client=wget&vsys=<VSYS_name>"
```

For example, the syntax for sending an input file named login.xml to the firewall at 10.2.5.11 using key `k7J335J6hI7nBxIqyfa62sZugWx7ot%2BgzEA9UOnlZRg` using wget would look as follows:

```
> wget --post file login.xml
"https://10.2.5.11/api/?type=user-id&key=k7J335J6hI7nBxIqyfa62sZugWx
7ot%2BgzEA9UOnlZRg&file-name=login.xml&client=wget&vsys=vsys1"
```

To apply the file to the firewall using cURL:

```
> curl --form file=@<filename>
https://<Firewall-IPaddress>/api/?type=user-id&key=<key>&vsys=<VSYS_name
>
```

For example, the syntax for sending an input file named login.xml to the firewall at 10.2.5.11 using key `k7J335J6hI7nBxIqyfa62sZugWx7ot%2BgzEA9UOnlZRg` using cURL would look as follows:

```
> curl --form file@login.xml
"https://10.2.5.11/api/?type=user-id&key=k7J335J6hI7nBxIqyfa62sZugWx7ot%
2BgzEA9UOnlZRg&vsys=vsys1"
```

| Use the User-ID XML API to Map Non-Windows Terminal Services Users (Continued) | |
|---|---|
| Step 7 Verify that the firewall is successfully receiving login events from the terminal servers. | Verify the configuration by opening an SSH connection to the firewall and then running the following CLI commands:<br>To verify if the terminal server is connecting to the firewall over XML:<br>`admin@PA-5050> show user xml-api multiusersystem`<br>`Host Vsys Users Blocks`<br>`----------`<br>`10.5.204.43 vsys1 5 2`<br>To verify that the firewall is receiving mappings from a terminal server over XML:<br>`admin@PA-5050> show user ip-port-user-mapping all`<br>`Global max host index 1, host hash count 1`<br>`XML API Multi-user System 10.5.204.43`<br>`Vsys 1, Flag 3`<br>`Port range: 20000 - 39999`<br>`Port size: start 200; max 2000`<br>`Block count 100, port count 20000`<br>`20000-20199: acme\administrator`<br>`Total host: 1` |

## Send User Mappings to User-ID Using the XML API

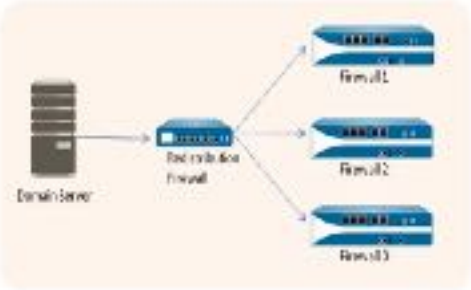
Although the User-ID functionality provides many out-of-the box methods for obtaining user mapping information, you may have some applications or devices that capture user information that cannot be natively integrated with User-ID. In this case you can use the User-ID XML API to create custom scripts that allow you to leverage existing user data and send it to the User-ID agent or directly to the firewall.

The User-ID XML API is a RESTful API that uses standard HTTP requests to send and receive data. API calls can be made directly from command line utilities such as cURL or using any scripting or application framework that supports RESTful services. To leverage user data from an existing system—such as a custom application developed internally or another device that is not supported by one of the existing user mapping mechanisms—you can create custom scripts to extract the data and send it to the firewall or the User-ID agent using the XML API.

To enable an external system to send user mapping information to the User-ID agent or directly to the firewall, you can create scripts that extract the user login and logout events and use them for input to the User-ID XML API request format. Then define the mechanisms for submitting the XML API request(s) to the firewall using cURL or wget using the firewall's API key for secure communication. For more details, refer to the *PAN-OS XML API Usage Guide*.

# Configure a Firewall to Share User Mapping Data with Other Firewalls

Because policy is local to each firewall, each firewall needs current user mapping and group mapping information to accurately enforce security policy by user and group. However, you can configure one firewall to collect all the mapping information and act as a User-ID agent to share that information with other firewalls. The redistribution firewall can share only the information it collects using local methods (for example, the PAN-OS integrated User-ID agent or Captive Portal), not the information collected from the Windows-based User-ID and Terminal Services agents. You configure the receiving firewalls to retrieve the mapping information from the redistribution firewall; they don't need to communicate directly with domain servers.



The following procedure describes how to set up redistribution of User-ID information.

| **Configure a Firewall to Redistribute User Mappings** | | |
|---|---|---|
| Step 1 | Configure the redistribution firewall.<br><br>User-ID configurations apply to a single virtual system only. To redistribute User-ID mappings from multiple virtual systems, you must configure the user mapping settings on each virtual system separately, using a unique pre-shared key in each configuration. | 1. Select **Device > User Identification > User Mapping** and edit the Palo Alto Networks User-ID Agent Setup section.<br>2. Select **Redistribution**.<br>3. Enter a **Collector Name**.<br>4. Enter and confirm the **Pre-Shared Key** that will enable other firewalls to connect to this firewall to retrieve user mapping information.<br>5. Click **OK** to save the redistribution configuration. |
| Step 2 | Create an interface management profile that enables the User-ID service and attach it to the interface that the other firewalls will connect to in order to retrieve user mappings. | 1. Select **Network > Network Profiles > Interface Mgmt** and click **Add**.<br>2. Enter a **Name** for the profile and then select the Permitted Services. At a minimum, select **User-ID Service** and **HTTPS**.<br>3. Click **OK** to save the profile.<br>4. Select **Network > Interfaces > Ethernet** and select the interface you plan to use for redistribution.<br>5. On the **Advanced > Other Info** tab, select the **Management Profile** you just created.<br>6. Click **OK** and **Commit**. |

 © Palo Alto Networks, Inc.

| Configure a Firewall to Redistribute User Mappings (Continued) | | |
|---|---|---|
| Step 3 | Configure the other firewalls to retrieve user mappings from the redistribution firewall.<br><br>If the redistribution firewall has multiple virtual systems configured for redistribution, make sure you are using the pre-shared key that corresponds to the virtual system from which you want this firewall to retrieve User-ID mappings. | Perform the following steps on each firewall that you want to be able to retrieve user mappings:<br>1. Select **Device > User Identification > User-ID Agents**.<br>2. Click **Add** and enter a User-ID agent **Name** for the redistribution firewall.<br>3. Enter the hostname or IP address of the firewall interface that you configured for redistribution in the **Host** field.<br>4. Enter 5007 as the **Port** number on which the redistribution firewall will listen for User-ID requests.<br>5. Enter the **Collector Name** that you specified in the redistribution firewall configuration (Step 1-3).<br>6. Enter and confirm the **Collector Pre-Shared Key**. The key value you enter here must match the value configured on the redistribution firewall (Step 1-4).<br>7. (Optional) If you are using the redistribution firewall to retrieve group mappings in addition to user mappings, select the **Use as LDAP Proxy** check box.<br>8. (Optional) If you are using the redistribution firewall for Captive Portal authentication, select the **Use for NTLM Authentication** check box.<br>9. Make sure that the configuration is **Enabled** and then click **OK**.<br>10. **Commit** the changes. |
| Step 4 | Verify the configuration. | On the **User-ID Agents** tab, verify that the redistribution firewall entry you just added shows a green icon in the **Connected** column.<br><br>If a red icon appears, check traffic logs (**Monitor > Logs > Traffic**) to identify the issue. You can also check to see if any user mapping data has been received by running the following operational commands from the CLI:<br><br>`show user ip-user-mapping` (to view user mapping information on the dataplane)<br><br>`show user ip-user-mapping-mp` (to view mappings on the management plane). |

# Enable User- and Group-Based Policy

In order to enable security policy based on user and/or group, you must enable User-ID for each zone that contains users you want to identify. You can then define policies that allow or deny traffic based on user name or group membership. Additionally, you can create Captive Portal policies to enable identification for IP addresses that do not yet have any user data associated with them.

| Enable User- and Group-Based Policy | |
|---|---|
| Step 1 Enable User-ID on the source zones that contain the users that will send requests that require user-based access controls. | 1. Select **Network > Zones**.<br>2. Click the **Name** of the zone in which you want to enable User-ID to open the Zone dialog.<br>3. Select the **Enable User Identification** check box and then click **OK**.<br>  |

 © Palo Alto Networks, Inc.

| Enable User- and Group-Based Policy (Continued) | |
|---|---|
| Step 2 Create security policies based on user and/or group.<br> As a best practice, create policies based on group rather than user whenever possible. This prevents you from having to continually update your policies (which requires a commit) whenever your user base changes. | 1. After configuring User-ID, you will be able to choose a user name or group name when defining the source or destination of a security rule:<br>a. Select **Policies > Security** and click **Add** to create a new policy or click on an existing policy rule name to open the Security Policy Rule dialog.<br>b. Specify which users and/or groups to match in the policy in one of the following ways:<br>– If you want to specify specific users/groups as matching criteria, select the **User** tab and click the **Add** button in the Source User section to display a list of users and groups discovered by the firewall group mapping function. Select the users and/or groups to add to the policy.<br>– If you want the policy to match any user who has or has not successfully authenticated and you don't need to know the specific user or group name, select **known-user** or **unknown** from the drop-down above the **Source User** list.<br>2. Configure the rest of the policy as appropriate and then click **OK** to save it. For details on other fields in the security policy, see Set Up Basic Security Policies. |

**Enable User- and Group-Based Policy (Continued)**

| | |
|---|---|
| Step 3 Create your Captive Portal policies. | 1. Select **Policies > Captive Portal**.<br>2. Click **Add** and enter a **Name** for the policy.<br>3. Define the matching criteria for the rule by completing the **Source**, **Destination**, and **Service/URL Category** tabs as appropriate to match the traffic you want to authenticate. The matching criteria on these tabs is the same as the criteria you define when creating a security policy. See Set Up Basic Security Policies for details.<br>4. Define the **Action** to take on traffic that matches the rule:<br>• **no-captive-portal**—Allow traffic to pass without presenting a Captive Portal page for authentication.<br>• **web-form**—Present a Captive Portal page for the user to explicitly enter authentication credentials or use client certificate authentication.<br>• **browser-challenge**—Open an NTLM authentication request to the web browser of the user. The web browser will respond using the current login credentials of the user. If the login credentials are not available, the user will be prompted to supply them. If you select this action, you must enable NT LAN Manager (NTLM) authentication when you Configure Captive Portal. If NTLM authentication fails, the firewall falls back to **web-form** authentication.<br>5. Click **OK**.<br>The following example shows a Captive Portal policy that instructs the firewall to present a web form to authenticate unknown users who send HTTP requests from the trust zone to the untrust zone. |
| Step 4 Save your policy settings. | Click **Commit**. |

 © Palo Alto Networks, Inc.

# Verify the User-ID Configuration

After you configure group mapping and user mapping and enable User-ID on your security policies and Captive Portal policies, you should verify that it is working properly.

| Verify the User-ID Configuration | |
|---|---|
| Step 1 Verify that group mapping is working. | From the CLI, enter the following command:<br>**show user group-mapping statistics** |
| Step 2 Verify that user mapping is working. | If you are using the on-device User-ID agent, you can verify this from the CLI using the following command:<br>**show user ip-user-mapping-mp all**<br>`IP Vsys From User Timeout (sec)`<br>`----------`<br>`192.168.201.1 vsys1 UIA acme\george 210`<br>`192.168.201.11 vsys1 UIA acme\duane 210`<br>`192.168.201.50 vsys1 UIA acme\betsy 210`<br>`192.168.201.10 vsys1 UIA acme\administrator 210`<br>`192.168.201.100 vsys1 AD acme\administrator 748`<br>`Total: 5 users`<br>`*: WMI probe succeeded` |
| Step 3 Test your security policy. | • From a machine in the zone where User-ID is enabled, attempt to access sites and applications to test the rules you defined in your policy and ensure that traffic is allowed and denied as expected.<br>• You can also use the `test security-policy-match` command to determine whether the policy is configured correctly. For example, suppose you have a rule that blocks user duane from playing World of Warcraft; you could test the policy as follows:<br>`test security-policy-match application worldofwarcraft source-user acme\duane source any destination any destination-port any protocol 6`<br>`"deny worldofwarcraft" {`<br>`from corporate;`<br>`source any;`<br>`source-region any;`<br>`to internet;`<br>`destination any;`<br>`destination-region any;`<br>`user acme\duane;`<br>`category any;`<br>`application/service worldofwarcraft;`<br>`action deny;`<br>`terminal no;`<br>`}` |

**Verify the User-ID Configuration (Continued)**

Step 4 Test your Captive Portal configuration.

1. From the same zone, go to a machine that is not a member of your directory, such as a Mac OS system, and try to ping to a system external to the zone. The ping should work without requiring authentication.
2. From the same machine, open a browser and navigate to a web site in a destination zone that matches a Captive Portal policy you defined. You should see the Captive Portal web form.

3. Log in using the correct credentials and confirm that you are redirected to the requested page.
4. You can also test your Captive Portal policy using the `test cp-policy-match` command as follows:

```
test cp-policy-match from corporate to internet
source 192.168.201.10 destination 8.8.8.8
Matched rule: 'captive portal' action: web-form
```

Step 5 Verify that user names are displayed in the log files (**Monitor > Logs**).

 © Palo Alto Networks, Inc.

**Verify the User-ID Configuration (Continued)**

Step 6 Verify that user names are displayed in reports (**Monitor > Reports**). For example, when drilling down into the denied applications report, you should see a list of the users who attempted to access the applications as in the following example.

 © Palo Alto Networks, Inc.

# App-ID

To safely enable applications on your network, the Palo Alto Networks next-generation firewalls provide both an application and web perspective—App-ID and URL Filtering—to protect against a full spectrum of legal, regulatory, productivity, and resource utilization risks.

App-ID enables visibility into the applications on the network, so you can learn how they work and understand their behavioral characteristics and their relative risk. This application knowledge allows you to create and enforce security policies to enable, inspect, and shape desired applications and block undesired applications. When you define policies to begin allowing traffic, App-ID begins to classify traffic without any additional configuration.

- App-ID Overview
- Manage Custom or Unknown Applications
- Best Practices for Using App-ID in Policy
- Applications with Implicit Support
- Application Level Gateways
- Disable the SIP Application-level Gateway (ALG)

# App-ID Overview

App-ID, a patented traffic classification system only available in Palo Alto Networks firewalls, determines what the application is irrespective of port, protocol, encryption (SSH or SSL) or any other evasive tactic used by the application. It applies multiple classification mechanisms—application signatures, application protocol decoding, and heuristics—to your network traffic stream to accurately identify applications.

Here's how App-ID identifies applications traversing your network:

- Traffic is matched against policy to check whether it is allowed on the network.
- Signatures are then applied to allowed traffic to identify the application based on unique application properties and related transaction characteristics. The signature also determines if the application is being used on its default port or it is using a non-standard port. If the traffic is allowed by policy, the traffic is then scanned for threats and further analyzed for identifying the application more granularly.
- If App-ID determines that encryption (SSL or SSH) is in use, and a decryption policy is in place, the session is decrypted and application signatures are applied again on the decrypted flow.
- Decoders for known protocols are then used to apply additional context-based signatures to detect other applications that may be tunneling inside of the protocol (e.g., Yahoo! Instant Messenger used across HTTP). Decoders validate that the traffic conforms to the protocol specification and provide support for NAT traversal and opening dynamic pinholes for applications such as SIP and FTP.
- For applications that are particularly evasive and cannot be identified through advanced signature and protocol analysis, heuristics or behavioral analysis may be used to determine the identity of the application.

When the application is identified, the policy check determines how to treat the application, for example—block, or allow and scan for threats, inspect for unauthorized file transfer and data patterns, or shape using QoS.

 © Palo Alto Networks, Inc.

# Manage Custom or Unknown Applications

Palo Alto Networks provides weekly App-ID updates to identify new applications. By default, App-ID is always enabled on the firewall, and you don't need to enable a series of signatures to identify well-known applications. Typically, the only applications that are classified as *unknown* traffic—*tcp, udp or non-syn-tcp*—in the ACC and the traffic logs are commercially available applications that have not yet been added to App-ID, internal or custom applications on your network, or potential threats.

On occasion, the firewall may report an application as unknown for the following reasons:

- Incomplete data—A handshake took place, but no data packets were sent prior to the timeout.
- Insufficient data—A handshake took place followed by one or more data packets; however, not enough data packets were exchanged to identify the application.

The following choices are available to handle unknown applications:

- Create security policies to control unknown applications by unknown TCP, unknown UDP or by a combination of source zone, destination zone, and IP addresses.
- Request an App-ID from Palo Alto Networks—If you would like to inspect and control the applications that traverse your network, for any unknown traffic, you can record a packet capture. If the packet capture reveals that the application is a commercial application, you can submit this packet capture to Palo Alto Networks for App-ID development. If it is an internal application, you can create a custom App-ID and/or define an application override policy.
- Create a custom App-ID with a signature and attach it to a security policy, or create a custom App-ID and define an application override policy—A custom App-ID allows you to customize the definition of the internal application—its characteristics, category and sub-category, risk, port, timeout—and exercise granular policy control in order to minimize the range of unidentified traffic on your network. Creating a custom App-ID also allows you to correctly identify the application in the ACC and traffic logs and is useful in auditing/reporting on the applications on your network. For a custom application you can specify a signature and a pattern that uniquely identifies the application and attach it to a security policy that allows or denies the application.

In order to collect the right data to create a custom application signature, you'll need a good understanding of packet captures and how datagrams are formed. If the signature is created too broadly, you might inadvertently include other similar traffic; if it is defined too narrowly, the traffic will evade detection if it does not strictly match the pattern.

Custom App-IDs are stored in a separate database on the firewall and this database is not impacted by the weekly App-ID updates.

The supported application protocol decoders that enable the firewall to detect applications that may be tunneling inside of the protocol include the following as of content update 424: HTTP, HTTPS, DNS, FTP, IMAP SMTP, Telnet, IRC (Internet Relay Chat), Oracle, RTMP, RTSP, SSH, GNU-Debugger, GIOP (Global Inter-ORB Protocol), Microsoft RPC, Microsoft SMB (also known as CIFS). Additionally, with the 4.0 release of PAN-OS, this custom App-ID capability has been expanded to include unknown TCP and unknown UDP.

Alternatively, if you would like the firewall to process the custom application using fast path (Layer-4 inspection instead of using App-ID for Layer-7 inspection), you can reference the custom App-ID in an application override policy. An application override with a custom application will prevent the session from being processed by the App-ID engine, which is a Layer-7 inspection. Instead it forces the firewall to handle the session as a regular stateful inspection firewall at Layer-4, and thereby saves application processing time.

For example, if you build a custom application that triggers on a host header *www.mywebsite.com*, the packets are first identified as *web-browsing* and then are matched as your custom application (whose parent application is web-browsing). Because the parent application is web-browsing, the custom application is inspected at Layer-7 and scanned for content and vulnerabilities.

If you define an application override, the firewall stops processing at Layer-4. The custom application name is assigned to the session to help identify it in the logs, and the traffic is not scanned for threats.

For more details, refer to the following articles:

- Identifying Unknown Applications
- Video: How to Configure a Custom App-ID
- Custom Application Signatures

 © Palo Alto Networks, Inc.

# Best Practices for Using App-ID in Policy

- Review the ACC for the list of applications on your network, and determine which applications to allow or block. If you are migrating from a firewall where you defined port-based rules, to get a list of applications that run on a given port, search by the port number in the application browser (**Objects > Applications**) on the Palo Alto Networks firewall or in Applipedia.
- Use **application-default** for the **Service**. The firewall compares the port used with the list of default ports for that application. If the port used is not a default port for the application, the firewall drops the session and logs the message **appid policy lookup deny**. If you have an application that is accessed on many ports and you would like to limit the ports on which the application is used, specify it in **Service**/**Service Group** objects in policies.
- Use application filters to dynamically include new applications in existing policy rules. See an example.

# Applications with Implicit Support

When creating a policy to allow specific applications, you must also be sure that you are allowing any other applications on which the application depends. In many cases, you do not have to explicitly allow access to the dependent applications in order for the traffic to flow because the firewall is able to determine the dependencies and allow them implicitly. This implicit support also applies to custom applications that are based on HTTP, SSL, MS-RPC, or RTSP. Applications for which the firewall cannot determine dependent applications on time will require that you explicitly allow the dependent applications when defining your policies. You can determine application dependencies in Applipedia.

The following table lists the applications for which the firewall has implicit support (as of Content Update 484).

**Table: Applications with Implicit Support**

| Application | Implicitly Supports |
|---|---|
| 360-safeguard-update | http |

# Application Level Gateways

The Palo Alto Networks firewall does not classify traffic by port and protocol; instead it identifies the application based on its unique properties and transaction characteristics using the App-ID technology. Some applications, however, require the firewall to dynamically open *pinholes* to establish the connection, determine the parameters for the session and negotiate the ports that will be used for the transfer of data; these applications use the application-layer payload to communicate the dynamic TCP or UDP ports on which the application opens data connections. For such applications, the firewall serves as an Application Level Gateway (ALG), and it opens a pinhole for a limited time and for exclusively transferring data or control traffic. The firewall also performs a NAT rewrite of the payload when necessary.

As of Content Release version 464, the Palo Alto Networks firewall provides NAT ALG support for the following protocols: FTP, H.225, H.248, MGCP, MySQL, Oracle/SQLNet/TNS, RPC, RTSP, SCCP, SIP, and UNIStim.

When the firewall serves as an ALG for the Session Initiation Protocol (SIP), by default it performs NAT on the payload and opens dynamic pinholes for media ports. In some cases, depending on the SIP applications in use in your environment, the SIP endpoints have NAT intelligence embedded in their clients. In such cases, you might need to disable the SIP ALG functionality to prevent the firewall from modifying the signaling sessions. When SIP ALG is disabled, if App-ID determines that a session is SIP, the payload is not translated and dynamic pinholes are not opened. See Disable the SIP Application-level Gateway (ALG).

© Palo Alto Networks, Inc.

# Disable the SIP Application-level Gateway (ALG)

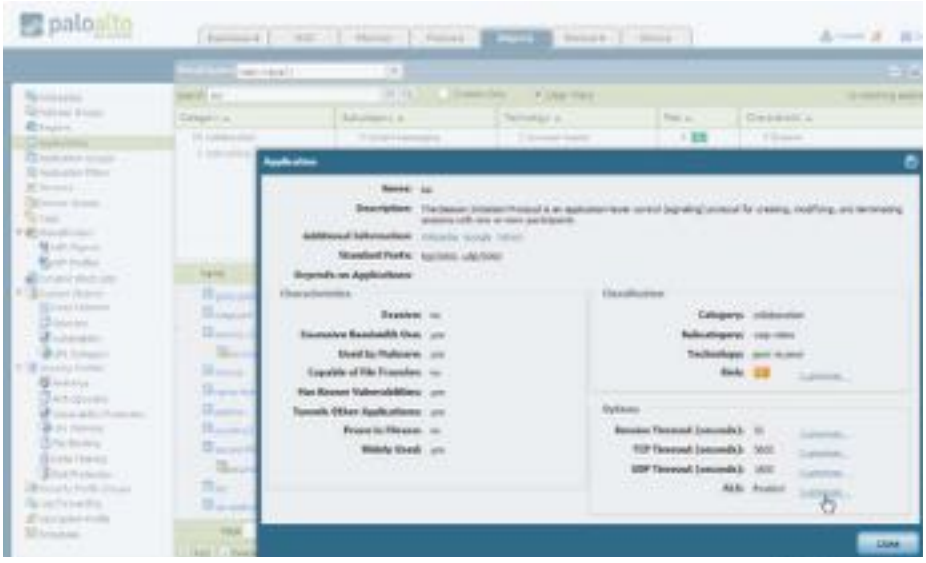
The Palo Alto Networks firewall uses the Session Initiation Protocol (SIP) application-level gateway (ALG) to open dynamic pinholes in the firewall where NAT is enabled. However, some applications—such as VoIP—have NAT intelligence embedded in the client application. In these cases, the SIP ALG on the firewall can interfere with the signaling sessions and cause the client application to stop working.

One solution to this problem is to define an Application Override Policy for SIP, but using this approach disables the App-ID and threat detection functionality. A better approach is to disable the SIP ALG, which does not disable App-ID or threat detection.

The following procedure describes how to disable the SIP ALG.

**Disable the SIP ALG**

1. Select **Objects > Applications**.
2. Select the **sip** application.
   You can type **sip** in the **Search** box to help find the sip application.
3. Select **Customize...** for **ALG** in the Options section of the Application dialog box.



4. Select the **Disable ALG** check box in the Application - sip dialog box and click **OK**.

5. **Close** the Application dialog box and **Commit** the change.

© Palo Alto Networks, Inc.

# Threat Prevention

The Palo Alto Networks next-generation firewall protects and defends your network from commodity threats and advanced persistent threats (APTs). The firewall's multi-pronged detection mechanisms include a signature-based (IPS/Command and Control/Antivirus) approach, heuristics-based (bot detection) approach, sandbox-based (WildFire) approach, and Layer 7 protocol analysis-based (App-ID) approach.

Commodity threats are exploits that are less sophisticated and more easily detected and prevented using a combination of the antivirus, anti-spyware, vulnerability protection and the URL filtering/Application identification capabilities on the firewall.

Advanced threats are perpetuated by organized cyber criminals or malicious groups that use sophisticated attack vectors to target your network, most commonly for intellectual property theft and financial data theft. These threats are more evasive and require intelligent monitoring mechanisms for detailed host and network forensics on malware. The Palo Alto Networks next-generation firewall in conjunction with WildFire and Panorama provides a comprehensive solution that intercepts and break the attack chain and provides visibility to prevent security infringement on your network—including mobile and virtualized—infrastructure.

# Set Up Security Profiles and Policies

The following sections provide basic threat prevention configuration examples:

- Set Up Antivirus, Anti-spyware, and Vulnerability Protection
- Set Up Data Filtering
- Set Up File Blocking

For information on controlling web access as part of your threat prevention strategy, see URL Filtering.

 © Palo Alto Networks, Inc.

## Set Up Antivirus, Anti-spyware, and Vulnerability Protection

The following describes the steps needed to set up the default Antivirus, Anti-spyware, and Vulnerability Protection Security Profiles.

All Anti-spyware and Vulnerability Protection signatures have a default action defined by Palo Alto Networks. You can view the default action by navigating to **Objects > Security Profiles > Anti-Spyware** or **Objects > Security Profiles >Vulnerability Protection** and then selecting a profile. Click the **Exceptions** tab and then click **Show all signatures** and you will see a list of the signatures with the default action in the Action column. To change the default action, you must create a new profile and then create rules with a non-default action, and/or add individual signature exceptions to **Exceptions** in the profile.

| **Set up Antivirus/Anti-spyware/Vulnerability Protection** | | |
|---|---|---|
| Step 1 | Verify that you have a Threat Prevention license. | • The Threat Prevention license bundles the Antivirus, Anti-spyware, and the Vulnerability Protection features in one license.<br>• Select **Device > Licenses** to verify that the **Threat Prevention** license is installed and check the expiration date. |
| Step 2 | Download the latest antivirus threat signatures. | 1. Select **Device > Dynamic Updates** and click **Check Now** at the bottom of the page to retrieve the latest signatures.<br>In the **Actions** column, click **Download** to install the latest Antivirus and Applications and Threats signatures. |
| Step 3 | Schedule signature updates. | 1. From **Device > Dynamic Updates**, click the text to the right of **Schedule** to automatically retrieve signature updates for **Antivirus** and **Applications and Threats**.<br>2. Specify the frequency and timing for the updates and whether the update will be downloaded and installed or only downloaded. If you select **Download Only**, you would need to manually go in and click the **Install** link in the **Action** column to install the signature. When you click **OK**, the update is scheduled. No commit is required.<br>3. (Optional) You can also enter the number of hours in the **Threshold** field to indicate the minimum age of a signature before a download will occur. For example, if you entered **10**, the signature must be at least 10 hours old before it will be downloaded, regardless of the schedule.<br>4. In an HA configuration, you can also click the **Sync To Peer** option to synchronize the content update with the HA peer after download/install. This will not push the schedule settings to the peer device, you need to configure the schedule on each device. |

**Set up Antivirus/Anti-spyware/Vulnerability Protection (Continued)**

### Best Practices for Antivirus Schedules

The general recommendation for antivirus signature update schedules is to perform a **download-and-install** on a daily basis for antivirus and weekly for applications and vulnerabilities.

### Recommendations for HA Configurations:

- **Active/Passive HA**—If the MGT port is used for antivirus signature downloads, you should configure a schedule on both devices and both devices will download/install independently. If you are using a data port for downloads, the passive device will not perform downloads while it is in the passive state. In this case you would set a schedule on both devices and then select the **Sync To Peer** option. This will ensure that whichever device is active, the updates will occur and will then push to the passive device.
- **Active/Active HA**—If the MGT port is used for antivirus signature downloads on both devices, then schedule the download/install on both devices, but do not select the **Sync To Peer** option. If you are using a data port, schedule the signature downloads on both devices and select **Sync To Peer**. This will ensure that if one device in the active/active configuration goes into the active-secondary state, the active device will download/install the signature and will then push it to the active-secondary device.

| | |
|---|---|
| Step 4 Attach the security profiles to a security policy. | 1. Select **Policies > Security**, select the desired policy to modify it and then click the **Actions** tab.<br>2. In **Profile Settings**, click the drop-down next to each security profile you would like to enable. In this example we choose default for **Antivirus, Vulnerability Protection,** and **Anti-spyware**.<br>If no security profiles have been previously defined, select **Profiles** from the **Profile Type** drop-down. You will then see the list of options to select the security profiles.<br>  |
| Step 5 Save the configuration. | Click **Commit**. |

 © Palo Alto Networks, Inc.

## Set Up Data Filtering

The following describes the steps needed to configure a data filtering profile that will detect Social Security Numbers and a custom pattern identified in .doc and .docx documents.

| Data Filtering Configuration Example | | |
|---|---|---|
| Step 1 | Create a Data Filtering security profile. | 1. Select **Objects > Security Profiles > Data Filtering** and click **Add**.<br>2. Enter a **Name** and a **Description** for the profile. In this example the name is *DF_Profile1* with the description *Detect Social Security Numbers*.<br>3. (Optional) If you want to collect data that is blocked by the filter, select the **Data Capture** check box.<br> You must set a password as described in Step 2 if you are using the data capture feature. |
| Step 2 | (Optional) Secure access to the data filtering logs to prevent other administrators from viewing sensitive data.<br><br>When you enable this option, you will be prompted for the password when you view logs in **Monitor > Logs > Data Filtering**. | 1. Select **Device > Setup > Content-ID**.<br>2. Click **Manage Data Protection** in the Content-ID Features section.<br>3. Set the password that will be required to view the data filtering logs. |

**Data Filtering Configuration Example (Continued)**

Step 3 Define the data pattern that will be used in the Data Filtering Profile.

In this example, we will use the keyword **confidential** and will set the option to search for SSN numbers with dashes (Example - 987-654-4320).

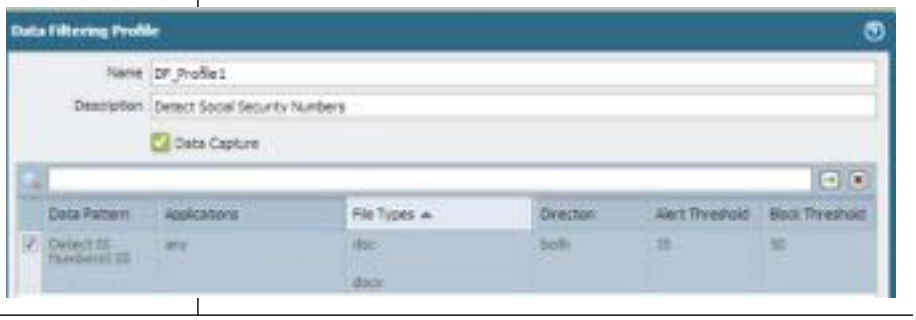
It is helpful to set the appropriate thresholds and define keywords within documents to reduce false positives.

1. From the Data Filtering Profile page click **Add** and select **New** from the **Data Pattern** drop-down. You can also configure data patterns from **Objects > Custom Signatures > Data Patterns**.
2. For this example, name the Data Pattern signature **Detect SS Numbers** and add the description **Data Pattern to detect Social Security numbers**.
3. In the **Weight** section for **SSN#** enter **3**. See Weight and Threshold Values for more details.

4. (Optional) You can also set **Custom Patterns** that will be subject to this profile. In this case, you specify a pattern in the custom patterns **Regex** field and set a weight. You can add multiple match expressions to the same data pattern profile. In this example, we will create a **Custom Pattern** named **SSN_Custom** with a custom pattern of **confidential** (the pattern is case sensitive) and use a weight of **20**. The reason we use the term **confidential** in this example is because we know that our social security Word docs contain this term, so we define that specifically.

 © Palo Alto Networks, Inc.

| Data Filtering Configuration Example (Continued) | | |
|---|---|---|
| Step 4 | Specify which applications to filter and set the file types. | 1. Set **Applications** to **Any.** This will detect any supported application such as: web-browsing, FTP, or SMTP. If you want to narrow down the application, you can select it from the list. For applications such as Microsoft Outlook Web App that uses SSL, you will need to enable decryption. Also make sure you understand the naming for each application. For example, Outlook Web App, which is the Microsoft name for this application is identified as the application **outlook-web** in the PAN-OS list of applications. You can check the logs for a given application to identify the name defined in PAN-OS.<br>2. Set **File Types** to **doc** and **docx** to only scan doc and docx files. |
| Step 5 | Specify the direction of traffic to filter and the threshold values. | 1. Set the **Direction** to **Both**. Files that are uploaded or downloaded will be scanned.<br>2. Set the **Alert Threshold** to **35.** In this case, an alert will be triggered if 5 instances of Social Security Numbers exist and 1 instance of the term **confidential** exists. The formula is 5 SSN instances with a weight of 3 = 15 plus 1 instance of the term confidential with a weight of 20 = 35.<br>3. Set the **Block Threshold** to **50**. The file will be blocked if the threshold of 50 instances of a SSN and/or the term confidential exists in the file. In this case, if the doc contained 1 instance of the word **confidential** with a weight of 20 that equals 20 toward the threshold, and the doc has 15 Social Security Numbers with a weight of 3 that equals 45. Add 20 and 45 and you have 65, which will exceed the block threshold of 50. |



**Data Filtering Configuration Example (Continued)**

| | | |
|---|---|---|
| Step 6 | Attach the Data Filtering profile to the security rule. | 1. Select **Policies > Security** and select the security policy rule to which to apply the profile.<br>2. Click the security policy rule to modify it and then click the **Actions** tab. In the **Data Filtering** drop-down, select the new data filtering profile you created and then click **OK** to save. In this example, the data filtering rule name is **DF_Profile1**.<br>  |
| Step 7 | **Commit** the configuration. | |
| Step 8 | Test the data filtering configuration.<br><br>If you have problems getting Data Filtering to work, you can check the Data Filtering log or the Traffic log to verify the application that you are testing with and make sure your test document has the appropriate number of unique Social Security Number instances. For example, an application such as Microsoft Outlook Web App may seem to be identified as web-browsing, but if you look at the logs, the application is **outlook-web**. Also increase the number of SSNs, or your custom pattern to make sure you are hitting the thresholds. | When testing, you must use real Social Security Numbers and each number must be unique. Also, when defining Custom Patterns as we did in this example with the word **confidential**, the pattern is case sensitive. To keep your test simple, you may want to just test using a data pattern first, then test the SSNs.<br>1. Access a client PC in the trust zone of the firewall and send an HTTP request to upload a .doc or .docx file that contains the exact information you defined for filtering.<br>2. Create a Microsoft Word document with one instance of the term confidential and five Social Security numbers with dashes.<br>3. Upload the file to a website. Use an HTTP site unless you have decryption configured, in which case you can use HTTPS.<br>4. Select **Monitoring > Logs > Data Filtering** logs.<br>5. Locate the log that corresponds to the file you just uploaded. To help filter the logs, use the source of your client PC and the destination of the web server. The action column in the log will show **reset-both**. You can now increase the number of Social Security Numbers in the document to test the block threshold. |

 © Palo Alto Networks, Inc.

## Set Up File Blocking

This example will describe the basic steps needed to set up file blocking and forwarding. In this configuration, we will configure the options needed to prompt users to continue before downloading .exe files from websites. When testing this example, be aware that you may have other systems between you and the source that may be blocking content.

| **Configure File Blocking** | | |
|---|---|---|
| Step 1 | Create the file blocking profile. | 1. Select **Objects > Security Profiles > File Blocking** and click **Add**.<br>2. Enter a **Name** for the file blocking profile, for example *Block_EXE*. Optionally enter a **Description**, such as *Block users from downloading exe files from websites.* |
| Step 2 | Configure the file blocking options. | 1. Click **Add** to define the profile settings.<br>2. Enter a **Name**, such as *BlockEXE*.<br>3. Set the **Applications** for filtering, for example **web-browsing**.<br>4. Set **File Types** to **exe**.<br>5. Set the **Direction** to **download**.<br>6. Set the **Action** to **continue**. By choosing the continue option, users will be prompted with a response page prompting them to click continue before the file will be downloaded.<br> <br>7. Click **OK** to save the profile. |
| Step 3 | Apply the file blocking profile to a security policy. | 1. Select **Policies > Security** and either select an existing policy or create a new policy as described in Set Up Basic Security Policies.<br>2. Click the **Actions** tab within the policy rule.<br>3. In the Profile Settings section, click the drop-down and select the file blocking profile you configured. In this case, the profile name is *Block_EXE*.<br>4. **Commit** the configuration.<br>If no security profiles have been previously defined, select the **Profile Type** drop-down and select **Profiles**. You will then see the list of options to select the security profiles. |

**Configure File Blocking (Continued)**

Step 4 To test your file blocking configuration, access a client PC in the trust zone of the firewall and attempt to download a .exe file from a website in the untrust zone. A response page should display. Click **Continue** to download the file. You can also set other actions, such as alert only, forward (which will forward to WildFire), or block, which will not provide a continue page to the user. The following shows the default response page for File Blocking:

**Example: Default File Blocking Response Page**

Step 5 (Optional) Define custom file blocking response pages (**Device > Response Pages**). This allows you to provide more information to users when they see a response page. You can include information such as company policy information and contact information for a Helpdesk.

When you create a file blocking profile with the action continue or continue-and-forward (used for WildFire forwarding), you can only choose the application web-browsing. If you choose any other application, traffic that matches the security policy will not flow through the firewall due to the fact that the users will not be prompted with a continue page. Also, if the website uses HTTPS, you will need to have a decryption policy in place.

You may want to check your logs to confirm what application is being used when testing this feature. For example, if you are using Microsoft Sharepoint to download files, even though you are using a web-browser to access the site, the application is actually `sharepoint-base`, or `sharepoint-document`. You may want to set the application type to **Any** for testing.

# Prevent Brute Force Attacks

A brute force attack uses a large volume of requests/responses from the same source or destination IP address to break into a system. The attacker employs a trial-and-error method to guess the response to a challenge or a request.

The Vulnerability Protection profile on the firewall includes signatures to protect you from brute force attacks. Each signature has an ID, Threat Name, Severity and is triggered when a pattern is recorded. The pattern specifies the conditions and interval at which the traffic is identified as a brute-force attack; some signatures are associated with another child signature that is of a lower severity and specifies the pattern to match against. When a pattern matches against the signature or child signature, it triggers the default action for the signature.

To enforce protection:

- Attach the vulnerability profile to a security rule. See Set Up Antivirus, Anti-spyware, and Vulnerability Protection.
- Install content updates that include new signatures to protect against emerging threats. See Manage Content Updates.

© Palo Alto Networks, Inc.

# Customize the Action and Trigger Conditions for a Brute Force Signature

The firewall includes two types of predefined brute force signatures—parent signature and child signature. A child signature is a single occurrence of a traffic pattern that matches the signature. A parent signature is associated with a child signature and is triggered when multiple events occur within a time interval and match the traffic pattern defined in the child signature.

Typically, a child signature is of default action *allow* because a single event is not indicative of an attack. In most cases, the action for a child signature is set to allow so that legitimate traffic is not blocked and threat logs are not generated for non-noteworthy events. Therefore, Palo Alto Networks recommends that you only change the default action after careful consideration.

In most cases, the brute force signature is a noteworthy event because of its recurrent pattern. If you would like to customize the action for a brute-force signature, you can do one of the following:

- Create a rule to modify the default action for all signatures in the brute force category. You can define the action to allow, alert, block, reset, or drop the traffic.
- Define an exception for a specific signature. For example, you can search for a CVE and define an exception for it.

  For a parent signature, you can modify both the trigger conditions and the action; for a child signature only the action can be modified.

To effectively mitigate an attack, the **block-ip address** action is recommended over the drop or reset action for most brute force signatures.

| **Customize the Threshold and Action for a Signature** | | |
|---|---|---|
| Step 1 | Create a new Vulnerability Protection Profile. | 1. Select **Objects > Security Profiles > Vulnerability Protection**.<br>2. Click **Add** and enter a **Name** for the Vulnerability Protection Profile. |
| Step 2 | Create a rule that defines the action for all signatures in a category.<br> | 1. Select **Rules**, click **Add** and enter a **Name** for the rule.<br>2. Set the **Action**. In this example, it is set to **Block**.<br>3. Set **Category** to **brute-force**.<br>4. (Optional) If blocking, specify whether to block server or client, the default is any.<br>5. See Step 3 to customize the action for a specific signature.<br>6. See Step 4 to customize the trigger threshold for a parent signature.<br>7. Click **OK** to save the rule and the profile. |

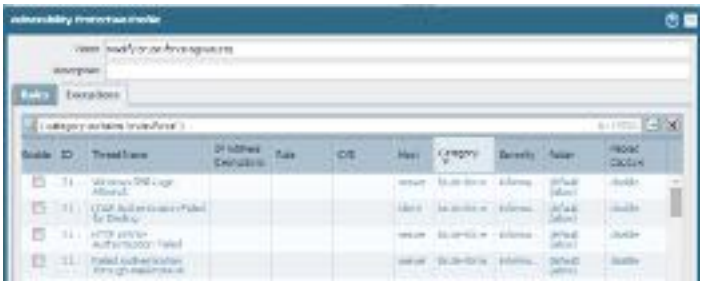
 © Palo Alto Networks, Inc.

**Customize the Threshold and Action for a Signature**

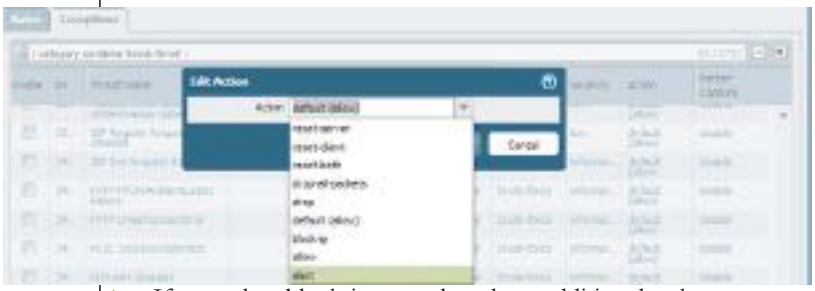
Step 3 (Optional) Customize the action for a specific signature.

1. Select **Exceptions** and click **Show all signatures** to find the signature you want to modify.

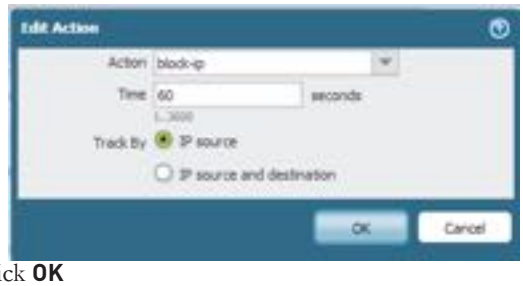
   To view all the signatures in the brute-force category, search for ( category contains 'brute-force' ).
2. To edit a specific signature, click the predefined default action in the **Action** column.



3. Set the action to **allow**, **alert** or **block-ip**.



4. If you select block-ip, complete these additional tasks:
   a. Specify the **Time** period (in seconds) after which to trigger the action.
   b. In the **Track By** field, define whether to block the IP address by **IP source** or by **IP source and destination**.



5. Click **OK**
6. For each modified signature, select the check box in the **Enable** column.
7. Click **OK**.

| Customize the Threshold and Action for a Signature | | |
|---|---|---|
| Step 4 | Customize the trigger conditions for a parent signature.<br><br>A parent signature that can be edited is marked with this icon: .<br><br>In this example, the search criteria was brute force category and CVE-2008-1447. | 1. Click to edit the time attribute and the aggregation criteria for the signature.<br> <br>2. To modify the trigger threshold specify the **Number of Hits** *per x* **seconds**.<br>3. Specify whether to aggregate the number of hits by **source**, **destination** or by **source and destination**.<br>4. Click **OK**. |
| Step 5 | Attach this new profile to a security rule. | |
| Step 6 | Save your changes. | 1. Click **Commit**. |

# Best Practices for Securing Your Network from Layer 4 and Layer 7 Evasions

To monitor and protect your network from most Layer 4 and Layer 7 attacks, here are a few recommendations.

- Upgrade to the most current PAN-OS software version and content release version to ensure that you have the latest security updates. See Manage Content Updates and Install Software Updates.
- For servers, create security policy rules to only allow the application(s) that you sanction on each server. Verify that the standard port for the application matches the listening port on the server. For example, to ensure that only SMTP traffic is allowed to your email server set the Application to smtp and the Service to application-default. If your server uses only a subset of the standard ports (for example, if your SMTP server uses only port 587 while the smtp application has standard ports defined as 25 and 587), you should create a new custom service that only includes port 587 and use that new service in your security policy rule instead of using application-default. Additionally, make sure to restrict access to specific source and destinations zones and sets of IP addresses.
- Attach the following security profiles to your security policies to provide signature-based protection.
  - Create a vulnerability protection profile to block all vulnerabilities with severity low and higher.
  - Create an anti-spyware profile to block all spyware.
  - Create an antivirus profile to block all content that matches an antivirus signature.
- Block all unknown applications/traffic using security policy. Typically, the only applications that are classified as unknown traffic are internal or custom applications on your network, or potential threats. Because unknown traffic can be a non-compliant application or protocol that is anomalous or abnormal, or a known application that is using non-standard ports, unknown traffic should be blocked. See Manage Custom or Unknown Applications.
- Create a file blocking profile that blocks Portable Executable (PE) file types for Internet-based SMB (Server Message Block) traffic from traversing the trust to untrust zones, (ms-ds-smb applications).
- Create a zone protection profile that is configured to protect against packet-based attacks:
  - Remove TCP timestamps on SYN packets before the firewall forwards the packet—When you remove the TCP timestamp option in a SYN packet, the TCP stack on both ends of the TCP connection will not support TCP timestamps. Therefore, by disabling the TCP timestamp for a SYN packet, you can prevent an attack that uses different timestamps on multiple packets for the same sequence number.
  - Drop malformed packets.
  - Drop mismatched and overlapping TCP segments—By deliberately constructing connections with overlapping but different data in them, attackers can attempt to cause misinterpretation of the intent of the connection. This can be used to deliberately induce false positives or false negatives. An attacker can use IP spoofing and sequence number prediction to intercept a user's connection and inject his/her own data into the connection. PAN-OS uses this field to discard such frames with mismatched and overlapping data. The scenarios where the received segment will be discarded are when the segment received is contained within another segment, the segment received overlaps with part of another segment, or the segment completely contains another segment.

© Palo Alto Networks, Inc.

- Verify that support for IPv6 is enabled, if you have configured IPv6 addresses on your network hosts. (**Network > Interfaces > Ethernet> IPv6**)

  This allows access to IPv6 hosts and filters IPv6 packets that are encapsulated in IPv4 packets. Enabling support for IPv6 prevents IPv6 over IPv4 multicast addresses from being leveraged for network reconnaissance.

- Enable support for multicast traffic so that the firewall can enforce policy on multicast traffic. (**Network > Virtual Router > Multicast)**

- Enable the following CLI command to clear the URG bit flag in the TCP header and disallow out-of-band processing of packets.

  The urgent pointer in the TCP header is used to promote a packet for immediate processing by removing it from the processing queue and expediting it through the TCP/IP stack on the host. This process is called out-of-band processing. Because the implementation of the urgent pointer varies by host, to eliminate ambiguity, use the following CLI command to disallow out-of-band processing; the out-of-band byte in the payload becomes part of the payload and the packet is not processed urgently. Making this change allows you to remove ambiguity in how the packet is processed on the firewall and the host, and the firewall sees the exact same stream in the protocol stack as the host for whom the packet is destined.

  ```
  set deviceconfig setting tcp urgent-data clear
  ```

- If you configure the firewall to clear the URG bit flag and the packet has no other flags set in the TCP header, use the following CLI command to configure the firewall to drop packets with no flags:

  ```
  set deviceconfig setting tcp drop-zero-flag yes
  ```

- Enable the following CLI command for disabling the bypass-exceed-queue.

  The bypass exceed queue is required for out of order packets. This scenario is most common in an asymmetric environment where the firewall receives packets out of order. For identification of certain applications (App-ID) the firewall performs heuristic analysis. If the packets are received out of order, the data must be copied to a queue in order to complete the analysis for the application.

  ```
  set deviceconfig setting application bypass-exceed-queue no
  ```

- Enable the following CLI commands for disabling the inspection of packets when the out-of-order packet limit is reached. The Palo Alto Networks firewall can collect up to 64 out-of-order packets per session. This counter identifies that packets have exceeded the 64-packet limit. When the bypass setting is set to **no**, the device drops the out-of-order packets that exceed the 64-packet limit. A commit is required.

  ```
  set deviceconfig setting tcp bypass-exceed-oo-queue no
  set deviceconfig setting ctd tcp-bypass-exceed-queue no
  set deviceconfig setting ctd udp-bypass-exceed-queue no
  ```

- Enable the following CLI commands for checking the TCP timestamp. The TCP timestamp records when the segment was sent and allows the firewall to verify that the timestamp is valid for that session. Packets with invalid timestamps are dropped with this setting is enabled.

  ```
  set deviceconfig setting tcp check-timestamp-option yes
  ```

 © Palo Alto Networks, Inc.

- Disable the HTTP Range option. The HTTP Range option allows a client to fetch part of a file only. When a next-generation firewall in the path of a transfer identifies and drops a malicious file, it terminates the TCP session with a RST packet. If the web browser implements the HTTP Range option, it can start a new session to fetch only the remaining part of the file. This prevents the firewall from triggering the same signature again due to the lack of context into the initial session, while at the same time allowing the web browser to reassemble the file and deliver the malicious content. To prevent this, disable the HTTP Range option as follows:

```
set deviceconfig setting ctd skip-block-http-range no
```

# Enable Passive DNS Collection for Improved Threat Intelligence

Passive DNS is an opt-in feature that enables the firewall to act as a passive DNS sensor and send select DNS information to Palo Alto Networks for analysis in order to improve threat intelligence and threat prevention capabilities. The data collected includes non-recursive (i.e. originating from the local recursive resolver, not individual clients) DNS query and response packet payloads. Data submitted via the Passive DNS Monitoring feature consists solely of mappings of domain names to IP addresses. Palo Alto Networks retains no record of the source of this data and does not have the ability to associate it with the submitter at a future date.

The Palo Alto Networks threat research team uses this information to gain insight into malware propagation and evasion techniques that abuse the DNS system. Information gathered through this data collection is used to improve accuracy and malware detection abilities within PAN-DB URL filtering, DNS-based command-and-control signatures, and WildFire.

DNS responses are only forwarded to the Palo Alto Networks and will only occur when the following requirements are met:

- DNS response bit is set
- DNS truncated bit is not set
- DNS recursive bit is not set
- DNS response code is 0 or 3 (NX)
- DNS question count bigger than 0
- DNS Answer RR count is bigger than 0 or if it is 0, the flags need to be 3 (NX)
- DNS query record type are A, NS, CNAME, AAAA, MX

Passive DNS monitoring is disabled by default, but it is recommended that you enable it to facilitate enhanced threat intelligence. Use the following procedure to enable Passive DNS:

| **Enable Passive DNS** |
|---|
| 1. Select **Objects > Security Profiles > Anti-Spyware**. |
| 2. Select an existing profile to modify it or configure a new profile.<br>The Anti-Spyware profile must be attached to a security policy that governs your DNS server's external DNS traffic. |
| 3. Select the **DNS Signatures** tab and click the **Enable Passive DNS Monitoring** check box. |
| 4. Click **OK** and then **Commit**. |

 © Palo Alto Networks, Inc.

# Use DNS Queries to Identify Infected Hosts on the Network

The DNS sinkhole action in Anti-Spyware profiles enables the firewall to forge a response to a DNS query for a known malicious domain, causing the malicious domain name to resolve to an IP address that you define. This allows you to identify hosts on your network that have been infected with malware. The following topics describe the DNS sinkhole action and provide instructions for enabling it and monitoring logs to identify infected hosts.

- DNS Sinkholing
- Configure DNS Sinkholing
- Identify Infected Hosts

© Palo Alto Networks, Inc.

## DNS Sinkholing

DNS sinkholing helps you to identify infected hosts on the protected network using DNS traffic in situations where the firewall cannot see the infected client's DNS query (that is, the firewall cannot see the originator of the DNS query). In a typical deployment where the firewall is north of the local DNS server, the threat log will identify the local DNS resolver as the source of the traffic rather than the actual infected host. Sinkholing malware DNS queries solves this visibility problem by forging responses to the client host queries directed at malicious domains, so that clients attempting to connect to malicious domains (for command-and-control, for example) will instead attempt to connect to a sinkhole IP address you define as illustrated in Configure DNS Sinkholing. Infected hosts can then be easily identified in the traffic logs because any host that attempts to connect to the sinkhole IP address are most likely infected with malware.

**Figure: DNS Sinkholing Example**

 © Palo Alto Networks, Inc.

## Configure DNS Sinkholing

To enable DNS Sinkholing, you must enable the action in an Anti-spyware profile and attach the profile to a security rule. When a client host attempts to access a malicious domain, the firewall forges the destination IP address in the packet using the IP address you configure as the DNS sinkhole address.

| Configure DNS Sinkholing | | |
|---|---|---|
| Step 1 | Obtain both an IPv4 and IPv6 address to use as the sinkhole IP addresses.<br><br>The DNS sinkhole address must be in a different zone than the client hosts to ensure that when an infected host attempts to start a session with the sinkhole IP address, it will be routed through the firewall. The reason both IPv4 and IPv6 are needed is because malicious software may perform DNS queries using one or both of these protocols.<br><br> This sinkhole addresses must be reserved for this purpose and do not need to be assigned to a physical host. You can optionally use a honey-pot server as a physical host to further analyze the malicious traffic. | This configuration example uses the following DNS sinkhole addresses:<br><br>IPv4 DNS sinkhole address—10.15.0.20<br><br>IPv6 DNS sinkhole address—fd97:3dec:4d27:e37c:5:5:5:5 |
| Step 2 | Configure the sinkhole interface and zone.<br><br>Traffic from the zone where the client hosts reside must route to the zone where the sinkhole IP address is defined, so traffic will be logged.<br><br> Use a dedicated zone for sinkhole traffic, because the infected host will be sending traffic to this zone. | 1. Select **Network > Interfaces** and select an interface to configure as your sinkhole interface.<br>2. In the **Interface Type** drop-down, select **Layer3**.<br>3. To add an IPv4 address, select the **IPv4** tab and select **Static** and then click **Add**. In this example, use the IPv4 address 10.15.0.20 as the sinkhole address.<br>4. Select the **IPv6** tab and click **Static** and then click **Add** and enter an IPv6 address and subnet mask. In this example, use the IPv6 address fd97:3dec:4d27:e37c::/64 as the sinkhole address.<br>5. Click **OK** to save.<br>6. To add a zone for the sinkhole, select **Network > Zones** and click **Add**.<br>7. Enter zone **Name**.<br>8. In the **Type** drop-down select **Layer3**.<br>9. In the **Interfaces** section, click **Add** and add the interface you just configured.<br>10. Click **OK**. |

| Configure DNS Sinkholing (Continued) | | |
|---|---|---|
| Step 3 | Enable DNS sinkholing on the anti-spyware profile. | 1. Select **Objects > Security Profiles > Anti-Spyware**.<br>2. Modify an existing profile, or select one of the existing defaults and clone it.<br>3. **Name** the profile and then select the **DNS Signatures** tab.<br>4. In the **Action on DNS queries** drop-down, select **sinkhole**.<br>5. In the **Sinkhole IPv4** field enter the sinkhole IPv4 sinkhole address you configured in Step 2 (10.15.0.20 in this example).<br>6. In the **Sinkhole IPv6** field enter the sinkhole IPv6 sinkhole address you configured in Step 2 (fd97:3dec:4d27:e37c:5:5:5:5 in this example).<br> The default sinkhole address is the loopback address (127.0.0.1 for IPv4 and ::1 for IPv6).<br>7. (Optional) In the **Packet Capture** drop-down, select **single-packet** or **extended-capture**. The single-packet option will capture the first packet of the session or you can select extended to capture between 1-50 packets. You can then use the packet captures for further analysis.<br>8. Click **OK** to save the profile. |
| Step 4 | Edit the security policy rule that allows traffic from client hosts in the trust zone to the untrust zone to include the sinkhole zone as a destination and attach the anti-spyware profile.<br><br>To ensure that you are identifying traffic from infected hosts, make these changes to the security rule(s) that allow traffic from client hosts in the trust zone to the untrust zone. By adding the sinkhole zone as a destination on the rule, you enable infected clients to send bogus DNS queries to the DNS sinkhole. | 1. Select **Policies > Security**.<br>2. Select an existing rule that allows traffic from the client host zone to the untrust zone.<br>3. On the **Destination** tab, **Add** the Sinkhole zone. This allows client host traffic to flow to the sinkhole zone.<br>4. On the **Actions** tab, select the **Log at Session Start** check box to enable logging. This will ensure that traffic from client hosts in the Trust zone will be logged when accessing the Untrust or Sinkhole zones.<br>5. In the **Profile Setting** section, select the **Anti-Spyware** profile in which you enabled DNS sinkholing.<br>6. Click **OK** to save the security rule and then **Commit**. |

 © Palo Alto Networks, Inc.

| Configure DNS Sinkholing (Continued) | | |
|---|---|---|
| Step 5 | To ensure that you will be able to identify infected hosts, verify that traffic going from the client host in the Trust zone to the new Sinkhole zone is being logged.<br><br>In this example, the infected client host is 192.168.2.10 and the Sinkhole IPv4 address is 10.15.0.20. | 1. From a client host in the trust zone, open a command prompt and run the following command:<br>`C:\>ping <sinkhole address>`<br>The following example output shows the ping request to the DNS sinkhole address at 10.15.0.2 and the result, which is `Request timed out` because in this example the sinkhole IP address is not assigned to a physical host:<br>`C:\>ping 10.15.0.20`<br>`Pinging 10.15.0.20 with 32 bytes of data:`<br>`Request timed out.`<br>`Request timed out.`<br>`Ping statistics for 10.15.0.20:`<br>`Packets: Sent = 4, Received = 0, Lost = 4 (100% loss)`<br>2. On the firewall, select **Monitor > Logs > Traffic** and find the log entry with the Source 192.168.2.10 and Destination 10.15.0.20. This will confirm that the traffic to the sinkhole IP address is traversing the firewall zones.<br> You can search and/or filter the logs and only show logs with the destination 10.15.0.20. To do this, click the IP address (10.15.0.20) in the **Destination** column, which will add the filter (addr.dst in 10.15.0.20) to the search field. Click the Apply Filter icon to the right of the search field to apply the filter. |
| Step 6 | Identify a malicious domain that you can use to verify that the DNS sinkhole functionality is configured properly.<br><br>You must test this feature using a malicious domain that is included in the firewall's current antivirus signature database. The DNS Signatures used to identify malicious domains is only part of the full antivirus signature database, which contains hundreds of thousands of signatures. | To find a malicious domain for testing:<br>1. Select **Device > Dynamic Updates** and in the **Antivirus** section click the **Release Notes** link for the current antivirus DB that is installed. You can also find the antivirus release notes on the support site in Dynamic Updates. In most cases, the signature update is an incremental update, so only new viruses and DNS signatures are listed. There are many antivirus signatures and DNS signatures that will already be installed on the firewall.<br>2. In the second column of the release note, locate a line item with a domain extension (for example, com, edu, or net). The left column will show the domain name. For example, in Antivirus release 1117-1560, there is an item in the left column named "tbsbana" and the right column lists "net".<br>The following shows the content in the release note for this line item:<br>`conficker:tbsbana1 variants: net`<br>Because this domain shows up in the current database, it will work for testing. |

| Configure DNS Sinkholing (Continued) | |
|---|---|
| Step 7 Test the sinkhole action<br><br>This is similar to the action that would be performed if the client host was infected and the malicious application was attempting to reach a hacker server using DNS queries. | 1. From the client host, open a command prompt.<br>2. Perform an NSLOOKUP to a URL that you identified as a known malicious domain in Step 6.<br>For example, using the URL `track.bidtrk.com`:<br>`C:\>nslookup track.bidtrk.com`<br>`Server: my-local-dns.local`<br>`Address: 10.0.0.222`<br>`Non-authoritative answer:`<br>`Name: track.bidtrk.com.org`<br>`Addresses: fd97:3dec:4d27:e37c:5:5:5:5`<br>`10.15.0.20`<br>In the output, note that the NSLOOKUP to the malicious domain has been forged using the sinkhole IP addresses that we configured (10.15.0.20). Because the domain matched a malicious DNS signature, the sinkhole action was performed.<br>3. Select **Monitor > Logs > Threat** and locate the corresponding threat log entry to verify that the correct action was taken on the NSLOOKUP request.<br>4. Perform a ping to `track.bidtrk.com`, which will generate network traffic to the sinkhole address. |

 © Palo Alto Networks, Inc.

## Identify Infected Hosts

After you have configured DNS sinkholing and verified that traffic to a malicious domain goes to the sinkhole address, you should regularly monitor traffic to the sinkhole address, so that you can track down the infected hosts and eliminate the threat.

| DNS Sinkhole Verification and Reporting | | |
|---|---|---|
| Step 1 | Use App Scope to identify infected client hosts. | 1. Select **Monitor > App Scope** and select **Threat Monitor**.<br>2. Click the **Show spyware** button along the top of the display page.<br>3. Select a time range.<br>The following screenshot shows three instances of Suspicious DNS queries, which were generated when the test client host performed an NSLOOKUP on a known malicious domain. Click the graph to see more details about the event.<br> |

**DNS Sinkhole Verification and Reporting (Continued)**

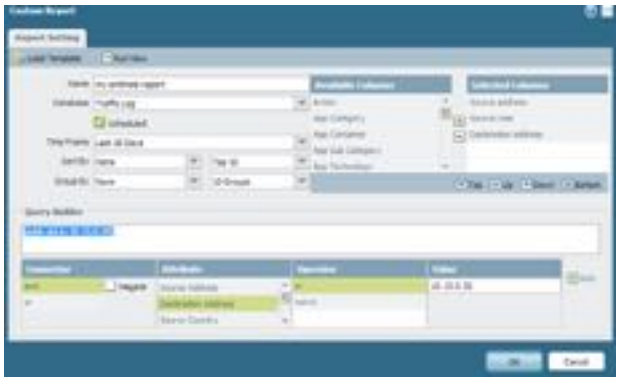
Step 2 Configure a custom report to identify all client hosts that have sent traffic to the sinkhole IP address, which is 10.15.0.20 in this example.

Forward to an SNMP manager, Syslog server and/or Panorama to enable alerts on these events.

In this example, the infected client host performed an NSLOOKUP to a known malicious domain that is listed in the Palo Alto Networks DNS Signature database. When this occurred, the query was sent to the local DNS server, which then forwarded the request through the firewall to an external DNS server. The firewall security policy with the Anti-Spyware profile configured matched the query to the DNS Signature database, which then forged the reply using the sinkhole address of 10.15.0.20 and fd97:3dec:4d27:e37c:5:5:5:5. The client attempts to start a session and the traffic log records the activity with the source host and the destination address, which is now directed to the forged sinkhole address.

Viewing the traffic log on the firewall allows you to identify any client host that is sending traffic to the sinkhole address. In this example, the logs show that the source address 192.168.2.10 sent the malicious DNS query. The host can then be found and cleaned. Without the DNS sinkhole option, the administrator would only see the local DNS server as the system that performed the query and would not see the client host that is infected. If you attempted to run a report on the threat log using the action "Sinkhole", the log would show the local DNS server, not the infected host.

1. Select **Monitor > Manage Custom Reports**.
2. Click **Add** and **Name** the report.
3. Define a custom report that captures traffic to the sinkhole address as follows:
   - **Database**—Select **Traffic Log**.
   - **Scheduled**—Enable **Scheduled** and the report will run every night.
   - **Time Frame**—30 days
   - **Selected Columns**—Select **Source address** or **Source User** (if you have User-ID configured), which will identify the infected client host in the report, and **Destination address**, which will be the sinkhole address.
   - In the section at the bottom of the screen, create a custom query for traffic to the sinkhole address (10.15.0.20 in this example). You can either enter the destination address in the **Query Builder** window (**addr.dst in 10.15.0.20**) or select the following in each column and click **Add**: Connector = and, Attribute = Destination Address, Operator = in, and Value = 10.15.0.20. Click **Add** to add the query.



4. Click **Run Now** to run the report. The report will show all client hosts that have sent traffic to the sinkhole address, which indicates that they are most likely infected. You can now track down the hosts and check them for spyware.

5. To view scheduled reports that have run, select **Monitor > Reports**.

# Content Delivery Network Infrastructure for Dynamic Updates

Palo Alto Networks maintains a Content Delivery Network (CDN) infrastructure for delivering content updates to the Palo Alto Networks devices. The devices access the web resources in the CDN to perform various App-ID and Content-ID functions. For enabling and scheduling the content updates, see Manage Content Updates.

The following table lists the web resources that the firewall accesses for a feature or application:

| Resource | URL | Static Addresses (If a static server is required) |
|---|---|---|
| Application Database | • updates.paloaltonetworks.com:443 | staticupdates.paloaltonetworks.com or the IP address 199.167.52.15 |
| Threat/Antivirus Database | • updates.paloaltonetworks.com:443<br>• downloads.paloaltonetworks.com:443<br>As a best practice, set the update server to updates.paloaltonetworks.com.This allows the Palo Alto Networks device to receive content updates from the server closest to it in the CDN infrastructure. | staticupdates.paloaltonetworks.com or the IP address 199.167.52.15 |
| PAN-DB URL Filtering | *.urlcloud.paloaltonetworks.com<br>Resolves to the primary URL s0000.urlcloud.paloaltonetworks.com and is then redirected to the regional server that is closest:<br>• s0100.urlcloud.paloaltonetworks.com<br>• s0200.urlcloud.paloaltonetworks.com<br>• s0300.urlcloud.paloaltonetworks.com<br>• s0500.urlcloud.paloaltonetworks.com | Static IP addresses are not available. However, you can manually resolve a URL to an IP address and allow access to the regional server IP address. |
| BrightCloud URL Filtering | • database.brightcloud.com:443/80<br>• service.brightcloud.com:80 | Contact BrightCloud Customer Support. |

| Resource | URL | Static Addresses (If a static server is required) |
|---|---|---|
| WildFire | • beta.wildfire.paloaltonetworks.com:443/80<br>• beta-s1.wildfire.paloaltonetworks.com:443/80<br>Beta sites are only accessed by a firewall running a Beta release version.<br>• mail.wildfire.paloaltonetworks.com:25<br>• wildfire.paloaltonetworks.com:443/80 | • mail.wildfire.paloaltonetworks.com:25 or the IP address 54.241.16.83<br>• wildfire.paloaltonetworks.com:443/80 or 54.241.8.199<br>• The regional URL/IP addresses are as follows:<br>• ca-s1.wildfire.paloaltonetworks.com:44 or 54.241.34.71<br>• va-s1.wildfire.paloaltonetworks.com:443or 174.129.24.252<br>• eu-s1.wildfire.paloaltonetworks.com:443 or 54.246.95.247<br>• sg-s1.wildfire.paloaltonetworks.com:443or 54.251.33.241<br>• jp-s1.wildfire.paloaltonetworks.com:443 or 54.238.53.161<br>• portal3.wildfire.paloaltonetworks.com:443/80 or 54.241.8.199<br>• ca-s3.wildfire.paloaltonetworks.com:443 or 54.241.34.71<br>• va-s3.wildfire.paloaltonetworks.com:443 or 23.21.208.35<br>• eu-s3.wildfire.paloaltonetworks.com:443 or 54.246.95.247<br>• sg-s3.wildfire.paloaltonetworks.com:443 or 54.251.33.241<br>• jp-s3.wildfire.paloaltonetworks.com:443 or 54.238.53.161<br>• wildfire.paloaltonetworks.com.jp:443/80 or 180.37.183.53<br>• wf1.wildfire.paloaltonetowrks.jp:443 or 180.37.180.37<br>• wf2.wildfire.paloaltonetworks.jp:443 or 180.37.181.18<br>• portal3.wildfire.paloaltonetworks.jp:443/80 or 180.37.183.53 |

# Decryption

Palo Alto Networks firewalls provide the capability to decrypt and inspect traffic for visibility, control, and granular security. Decryption on a Palo Alto Networks firewall includes the capability to enforce security policies on encrypted traffic, where otherwise the encrypted traffic might not be blocked and shaped according to your configured security settings. Use decryption on a firewall to prevent malicious content from entering your network or sensitive content from leaving your network concealed as encrypted traffic. Enabling decryption on a Palo Alto Networks firewall can include preparing the keys and certificates required for decryption, creating a decryption policy, and configuring decryption port mirroring. See the following topics to learn about and configure decryption:

- Decryption Overview
- Decryption Concepts
- Configure SSL Forward Proxy
- Configure SSL Inbound Inspection
- Configure SSH Proxy
- Configure Decryption Exceptions
- Enable Users to Opt Out of SSL Decryption
- Configure Decryption Port Mirroring
- Temporarily Disable SSL Decryption

© Palo Alto Networks, Inc.

# Decryption Overview

Secure Sockets Layer (SSL) and Secure Shell (SSH) are encryption protocols used to secure traffic between two entities, such as a web server and a client. SSL and SSH encapsulate traffic, encrypting data so that it is meaningless to entities other than the client and server with the keys to decode the data and the certificates to affirm trust between the devices. Traffic that has been encrypted using the protocols SSL and SSH can be decrypted to ensure that these protocols are being used for the intended purposes only, and not to conceal unwanted activity or malicious content.

Palo Alto Networks firewalls decrypt encrypted traffic by using keys to transform strings (passwords and shared secrets) from ciphertext to plaintext (decryption) and from plaintext back to ciphertext (re-encrypting traffic as it exits the device). Certificates are used to establish the firewall as a trusted third party and to create a secure connection. SSL decryption (both forward proxy and inbound inspection) requires certificates to establish trust between two entities in order to secure an SSL/TLS connection. Certificates can also be used when excluding servers from SSL decryption. You can integrate a hardware security module (HSM) with a firewall to enable enhanced security for the private keys used in SSL forward proxy and SSL inbound inspection decryption. To learn more about storing and generating keys using an HSM and integrating an HSM with your firewall, see Secure Keys with a Hardware Security Module. SSH decryption does not require certificates.

Palo Alto Networks firewall decryption is policy-based, and can be used to decrypt, inspect, and control both inbound and outbound SSL and SSH connections. Decryption policies allow you to specify traffic for decryption according to destination, source, or URL category and in order to block or restrict the specified traffic according to your security settings. The firewall uses certificates and keys to decrypt the traffic specified by the policy to plaintext, and then enforces App-ID and security settings on the plaintext traffic, including Decryption, Antivirus, Vulnerability, Anti-Spyware, URL Filtering, and File-Blocking profiles. After traffic is decrypted and inspected on the firewall, the plaintext traffic is re-encrypted as it exits the firewall to ensure privacy and security. Use policy-based decryption on the firewall to achieve outcomes such as the following:

- Prevent malware concealed as encrypted traffic from being introduced into an corporate network.
- Prevent sensitive corporate information from moving outside the corporate network.
- Ensure the appropriate applications are running on a secure network.
- Selectively decrypt traffic; for example, exclude traffic for financial or healthcare sites from decryption by configuring a decryption exception.

The three decryption policies offered on the firewall, SSL Forward Proxy, SSL Inbound Inspection, and SSH Proxy, all provide methods to specifically target and inspect SSL outbound traffic, SSL inbound traffic, and SSH traffic, respectively. The decryption policies provide the settings for you to specify what traffic to decrypt and decryption profiles can be selected when creating a policy, in order to apply more granular security settings to decrypted traffic, such as checks for server certificates, unsupported modes, and failures. This policy-based decryption on the firewall gives you visibility into and control of SSL and SSH encrypted traffic according to configurable parameters.

You can also choose to extend a decryption configuration on the firewall to include Decryption Port Mirroring, which allows for decrypted traffic to be forwarded as plaintext to a third party solution for additional analysis and archiving.

 © Palo Alto Networks, Inc.

# Decryption Concepts

To learn about keys and certificates for decryption, decryption policies, and decryption port mirroring, see the following topics:

- Keys and Certificates for Decryption Policies
- SSL Forward Proxy
- SSL Inbound Inspection
- SSH Proxy
- Decryption Exceptions
- Decryption Port Mirroring

## Keys and Certificates for Decryption Policies

Keys are strings of numbers that are typically generated using a mathematical operation involving random numbers and large primes. Keys are used to transform other strings—such as passwords and shared secrets—from plaintext to ciphertext (called *encryption*) and from ciphertext to plaintext (called *decryption*). Keys can be symmetric (the same key is used to encrypt and decrypt) or asymmetric (one key is used for encryption and a mathematically related key is used for decryption). Any system can generate a key.

X.509 certificates are used to establish trust between a client and a server in order to establish an SSL connection. A client attempting to authenticate a server (or a server authenticating a client) knows the structure of the X.509 certificate and therefore knows how to extract identifying information about the server from fields within the certificate, such as its FQDN or IP address (called a *common name* or *CN* within the certificate) or the name of the organization, department, or user to which the certificate was issued. All certificates must be issued by a certificate authority (CA). After the CA verifies a client or server, the CA issues the certificate and signs it using its private key.

With a decryption policy configured, an SSL/TLS session between the client and the server is established only if the firewall trusts the CA that signed the server's certificate. In order to establish trust, the firewall must have the server's root CA certificate in its certificate trust list (CTL) and use the public key contained in that root CA certificate to verify the signature. The firewall then presents a copy of the server certificate signed by the Forward Trust certificate for the client to authenticate. You can also configure the firewall to use an enterprise CA as a forward trust certificate for SSL Forward Proxy. If the firewall does not have the server's root CA certificate in its CTL, the firewall will present a copy of the server certificate signed by the Forward Untrust certificate to the client. The Forward Untrust certificate ensures that clients are prompted with a certificate warning when attempting to access sites hosted by a server with untrusted certificates.

For detailed information on certificates, see Certificate Management.

To control the trusted CAs that your device trusts, use the **Device > Certificate Management > Certificates > Default Trusted Certificate Authorities** tab on the firewall web interface.

Table: Palo Alto Networks Device Keys and Certificates describes the different keys and certificates used by Palo Alto Networks devices for decryption. As a best practice, use different keys and certificates for each usage.

**Table: Palo Alto Networks Device Keys and Certificates**

| Key/Certificate Usage | Description |
|---|---|
| Forward Trust | The certificate the firewall presents to clients during decryption if the site the client is attempting to connect to has a certificate that is signed by a CA that the firewall trusts. To configure a Forward Trust certificate on the firewall, see Step 2 in the Configure SSL Forward Proxy task. By default, the firewall determines the key size to use for the client certificate based on the key size of the destination server. However, you can also set a specific key size for the firewall to use. See Configure the Key Size for SSL Forward Proxy Server Certificates. For added security, store the forward trust certificate on a Hardware Security Module (HSM), see Store Private Keys on an HSM. |
| Forward Untrust | The certificate the firewall presents to clients during decryption if the site the client is attempting to connect to has a certificate that is signed by a CA that the firewall does not trust. To configure a Forward Untrust certificate on the firewall, see Step 3 in the Configure SSL Forward Proxy task. |

 © Palo Alto Networks, Inc.

| Key/Certificate Usage | Description |
|---|---|
| SSL Exclude Certificate | Certificates for servers that you want to exclude from SSL decryption. For example, if you have SSL decryption enabled, but have certain servers that you do not want included in SSL decryption, such as the web services for your HR systems, you would import the corresponding certificates onto the firewall and configure them as SSL Exclude Certificates. See Exclude a Server From Decryption. |
| SSL Inbound Inspection | The certificate used to decrypt inbound SSL traffic for inspection and policy enforcement. For this application, you would import the server certificate for the servers for which you are performing SSL inbound inspection, or store them on an HSM (see Store Private Keys on an HSM). |

## SSL Forward Proxy

Use an SSL Forward Proxy decryption policy to decrypt and inspect SSL/TLS traffic from internal users to the web. SSL Forward Proxy decryption prevents malware concealed as SSL encrypted traffic from being introduced to your corporate network; for example, if an employee is using her Gmail account from her corporate office and opens an email attachment that contains a virus, SSL Forward Proxy decryption will prevent the virus from infecting the client system and entering the corporate network.

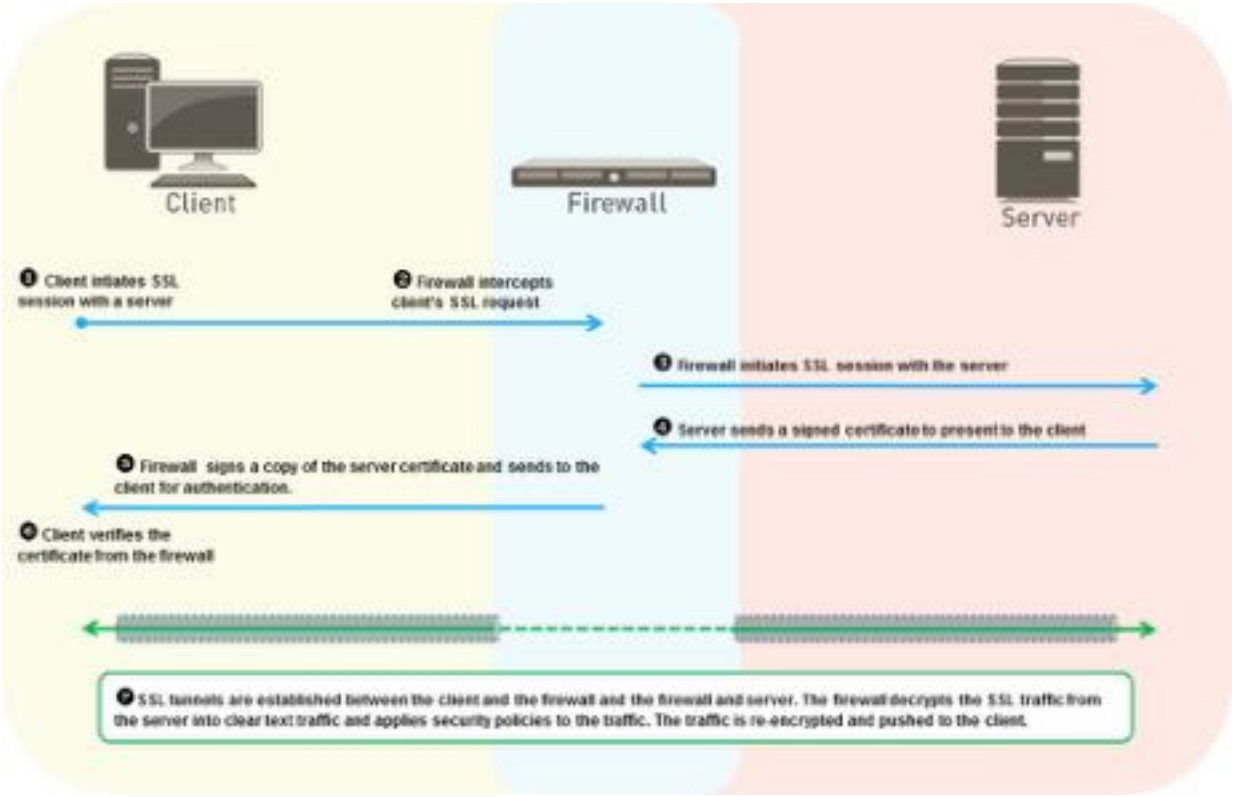
With SSL Forward Proxy decryption, the firewall resides between the internal client and outside server. The firewall uses Forward Trust or Forward Untrust certificates to establish itself as a trusted third party to the session between the client and the server (For details on certificates, see Keys and Certificates for Decryption Policies). When the client initiates an SSL session with the server, the firewall intercepts the client's SSL request and forwards the SSL request to the server. The server sends a certificate intended for the client that is intercepted by the firewall. If the server's certificate is signed by a CA that the firewall trusts, the firewall creates a copy of the server's certificate signed by the Forward Trust certificate and sends the certificate to the client to authenticate. If the server's certificate is signed by a CA that the firewall does not trust, the firewall creates a copy of the server's certificate and signs it with the Forward Untrust certificate and sends it to the client. In this case, the client sees a block page warning that the site they're attempting to connect to is not trusted and the client can choose to proceed or terminate the session. When the client authenticates the certificate, the SSL session is established with the firewall functioning as a trusted forward proxy to the site that the client is accessing.

As the firewall continues to receive SSL traffic from the server that is destined for the client, it decrypts the SSL traffic into clear text traffic and applies security policies to the traffic. The traffic is then re-encrypted on the firewall and the firewall forwards the encrypted traffic to the client.

Figure: SSL Forward Proxy shows this process in detail.

 © Palo Alto Networks, Inc.

**Figure: SSL Forward Proxy**



See Configure SSL Forward Proxy for details on configuring SSL Forward Proxy.

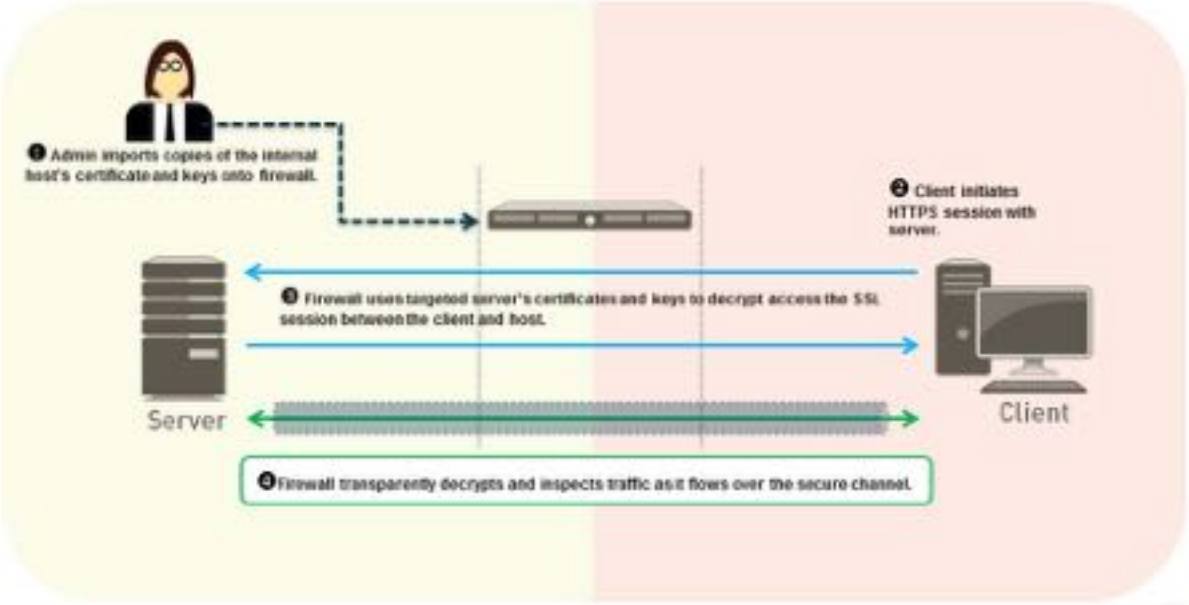
## SSL Inbound Inspection

Use SSL Inbound Inspection to decrypt and inspect inbound SSL traffic from a client to a targeted server (any server you have the certificate for and can import it onto the firewall). For example, if an employee is remotely connected to a web server hosted on the company network and is attempting to add restricted internal documents to his Dropbox folder (which uses SSL for data transmission), SSL Inbound Inspection can be used to ensure that the sensitive data does not move outside the secure company network by blocking or restricting the session.

Configuring SSL Inbound Inspection includes importing the targeted server's certificate and key on to the firewall. Because the targeted server's certificate and key are imported on the firewall, the firewall is able to access the SSL session between the server and the client and decrypt and inspect traffic transparently, rather than functioning as a proxy. The firewall is able to apply security policies to the decrypted traffic, detecting malicious content and controlling applications running over this secure channel.

Figure: SSL Inbound Inspection shows this process in detail.

**Figure: SSL Inbound Inspection**



See Configure SSL Inbound Inspection for details on configuring SSL Inbound Inspection.

 © Palo Alto Networks, Inc.

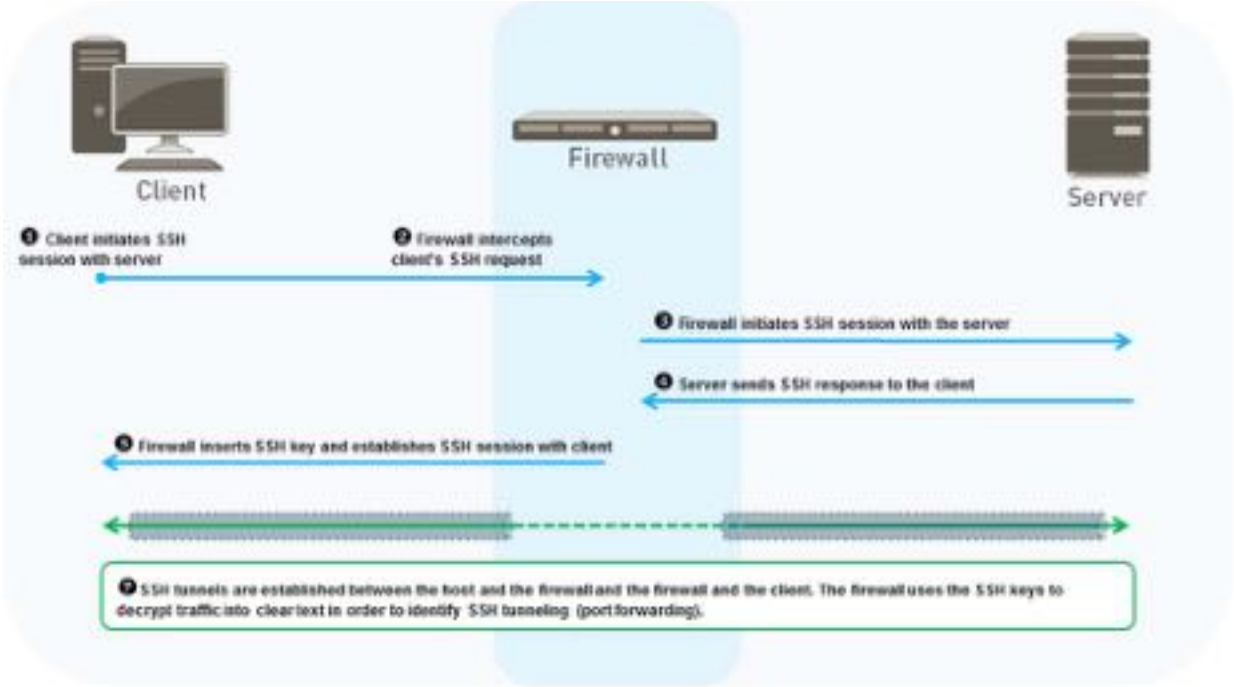
## SSH Proxy

SSH Proxy provides the capability for the firewall to decrypt inbound and outbound SSH connections passing through the firewall, in order to ensure that SSH is not being used to tunnel unwanted applications and content. SSH decryption does not require any certificates and the key used for SSH decryption is automatically generated when the firewall boots up. During the boot up process, the firewall checks to see if there is an existing key. If not, a key is generated. This key is used for decrypting SSH sessions for all virtual systems configured on the device. The same key is also used for decrypting all SSH v2 sessions.

In an SSH Proxy configuration, the firewall resides between a client and a server. When the client sends an SSH request to the server, the firewall intercepts the request and forwards the SSH request to the server. The firewall then intercepts the server's response and forwards the response to the client, establishing an SSH tunnel between the firewall and the client and an SSH tunnel between the firewall and the server, with firewall functioning as a proxy. As traffic flows between the client and the server, the firewall is able to distinguish whether the SSH traffic is being routed normally or if it is using SSH tunneling (port forwarding). Content and threat inspections are not performed on SSH tunnels; however, if SSH tunnels are identified by the firewall, the SSH tunneled traffic is blocked and restricted according to configured security policies.

Figure: SSH Proxy Decryption shows this process in detail.

**Figure: SSH Proxy Decryption**



See Configure SSH Proxy for details on configuring an SSH Proxy policy.

## Decryption Exceptions

Traffic can also be excluded from decryption according to matching criteria (using a decryption policy), a targeted server's traffic can be excluded from decryption (using certificates), and some applications are excluded from decryption by default.

Applications that do not function properly when decrypted by the firewall and are automatically excluded from SSL decryption. The applications that are excluded from SSL decryption by default are excluded because these applications often fail when decrypted due to the application looking for specific details in the certificate that might not be present in the certificate generated for SSL Forward Proxy. Refer to the KB article List of Applications Excluded from SSL Decryption for a current list of applications excluded by default from SSL decryption on the firewall.

You can configure decryption exceptions for certain URL categories or applications that either do not work properly with decryption enabled or for any other reason, including for legal or privacy purposes. You can use a decryption policy to exclude traffic from decryption based on source, destination, service, and URL category. For example, with SSL decryption enabled, you can exclude traffic that is categorized as financial or health-related from decryption, using the URL category selection.

You can also exclude servers from SSL decryption based on the Common Name (CN) in the server's certificate. For example, if you have SSL decryption enabled but have certain servers that you do not want included in SSL decryption, such as the web services for your HR systems, you can exclude those servers from decryption by importing the server certificate onto the firewall and modifying the certificate to be an **SSL Exclude Certificate**.

To exclude traffic from decryption based on source, destination, service, URL category or to exclude a specific server's traffic from decryption, see Configure Decryption Exceptions.

 © Palo Alto Networks, Inc.

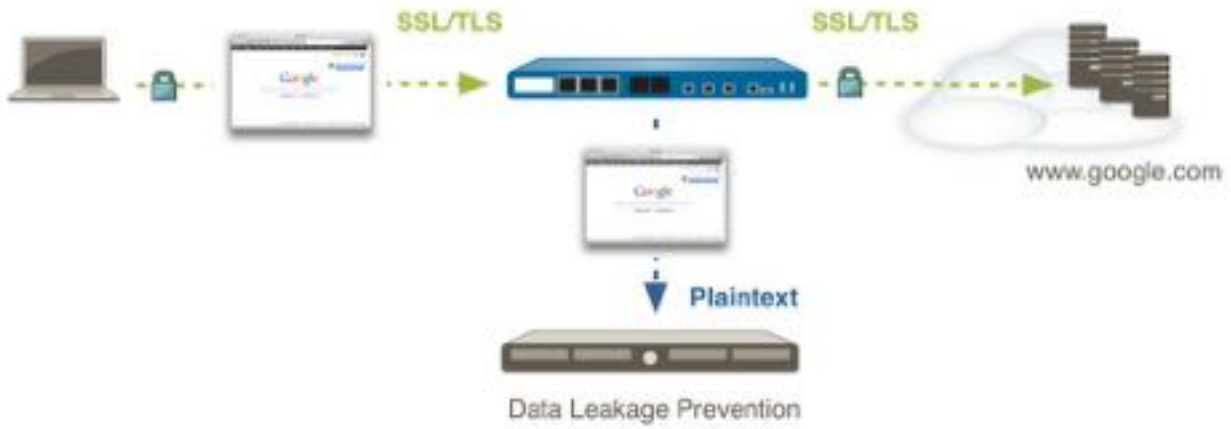
## Decryption Port Mirroring

The Decryption Port mirror feature provides the capability to create a copy of decrypted traffic from a firewall and send it to a traffic collection tool that is capable of receiving raw packet captures–such as NetWitness or Solera–for archiving and analysis. This feature is necessary for organizations that require comprehensive data capture for forensic and historical purposes or data leak prevention (DLP) functionality. Decryption port mirroring is available on PA-7050, PA-5000 Series and PA-3000 Series platforms only and requires that a free license be installed to enable this feature.

Keep in mind that the decryption, storage, inspection, and/or use of SSL traffic is governed in certain countries and user consent might be required in order to use the decryption port mirror feature. Additionally, use of this feature could enable malicious users with administrative access to the firewall to harvest usernames, passwords, social security numbers, credit card numbers, or other sensitive information submitted using an encrypted channel. Palo Alto Networks recommends that you consult with your corporate council before activating and using this feature in a production environment.

Figure: Decryption Port Mirroring shows the process for decryption port mirroring and the section Configure Decryption Port Mirroring describes how to license and use this feature.

**Figure: Decryption Port Mirroring**



# Configure SSL Forward Proxy

Configuring SSL Forward Proxy decryption on the firewall requires setting up the certificates needed for SSL Forward Proxy decryption and creating an SSL Forward Proxy decryption policy. The firewall can use self-signed certificates or certificates signed by an enterprise CA to perform SSL Forward Proxy decryption.

By default, the firewall determines the key size to use for the client certificates it generates based on the key size of the destination server certificate. You can optionally set a static key size to use regardless of the key size of the destination server certificate. See Configure the Key Size for SSL Forward Proxy Server Certificates.

Use the following task to configure SSL Forward Proxy, including how to set up the certificates and create a decryption policy.

| **Configure SSL Forward Proxy** | | |
|---|---|---|
| Step 1 | Ensure that the appropriate interfaces are configured as either virtual wire, Layer 2, or Layer 3 interfaces. | View configured interfaces on the **Network > Interfaces > Ethernet** tab. The **Interface Type** column displays if an interface is configured to be a **Virtual Wire** or **Layer 2**, or **Layer 3** interface. You can select an interface to modify its configuration, including what type of interface it is. |

© Palo Alto Networks, Inc.

**Configure SSL Forward Proxy**

Step 2 Configure the forward trust certificate. Use either a self-signed certificate or a certificate signed by an enterprise CA.

**Using self-signed certificates**

When the certificate of the server that the client is connecting to is signed by a CA that is on the firewall's trusted CA list, the firewall signs a copy of the server's certificate with a self-signed forward trust certificate to present to the client for authentication. In this case, the self-signed certificate must be imported onto each client system so that the client recognizes the firewall as a trusted CA.

Use self-signed certificates for SSL Forward Proxy decryption if you do not use an enterprise CA or if you are only intended to perform decryption for a limited number of client systems (or if you are planning to use a centralized deployment).

**To use a self-signed certificate:**

1. Select **Device > Certificate Management > Certificates**.
2. Click **Generate** at the bottom of the window.
3. Enter a **Certificate Name**, such as *my-fwd-trust*.
4. Enter a **Common Name**, such as **192.168.2.1**. This should be the IP or FQDN that will appear in the certificate. In this case, we are using the IP of the trust interface. Avoid using spaces in this field.
5. Leave the **Signed By** field blank.
6. Click the **Certificate Authority** check box to enable the firewall to issue the certificate. Selecting this check box creates a certificate authority (CA) on the firewall that is imported to the client browsers, so clients trust the firewall as a CA.
7. Click **Generate** to generate the certificate.
8. Click the new certificate *my-fwd-trust* to modify it and enable the **Forward Trust Certificate** option.
9. Export the forward trust certificate for import into client systems by highlighting the certificate and clicking **Export** at the bottom of the window. Choose PEM format, and do not select the **Export private key** option. Because the certificate is self-signed, import it into the browser trusted root CA list on the client systems in order for the clients to trust it. When importing to the client browser, ensure the certificate is added to the Trusted Root Certification Authorities certificate store. On Windows systems, the default import location is the Personal certificate store. You can also simplify this process by using a centralized deployment, such as an Active Directory Group Policy Object (GPO).

   If the forward trust certificate is not imported on the client systems, users will see certificate warnings for each SSL site they visit.
10. Click **OK** to save.

## Configure SSL Forward Proxy

### Using an Enterprise CA

An enterprise CA can issue a signing certificate which the firewall can use to then sign the certificates for sites requiring SSL decryption. Send a Certificate Signing Request (CSR) for the enterprise CA to sign and validate. The firewall can then use the signed enterprise CA certificate for SSL Forward Proxy decryption. Because the enterprise CA is already trusted by the client systems, with this option, you do not need to distribute the certificate to client systems prior to configuring decryption.

**To use an enterprise CA signed certificate, generate a CSR:**

1. Select **Device > Certificate Management > Certificates** and click **Generate**.
2. Enter a **Certificate Name**, such as *my-fwd-proxy*.
3. In the **Signed By** drop-down, select **External Authority (CSR)**.
4. (Optional) If your enterprise CA requires it, add **Certificate Attributes** to further identify the firewall details, such as Country or Department.
5. Click **OK** to save the CSR. The pending certificate is now displayed on the **Device Certificates** tab.
6. Export the CSR:
   a. Select the pending certificate displayed on the **Device Certificates** tab.
   b. Click **Export** to download and save the certificate file.

   Leave **Export private key** unselected in order to ensure that the private key remains securely on the firewall.
   c. Click **OK**.
   d. Provide the certificate file to your enterprise CA. When you receive the signed enterprise CA certificate from your enterprise CA, save the signed enterprise CA certificate for import onto the firewall.
7. Import the signed enterprise CA onto the firewall:
   a. Select **Device > Certificate Management > Certificates** and click **Import**.
   b. Enter the pending **Certificate Name** exactly (in this case, *my-fwd-trust*). The **Certificate Name** that you enter must exactly match the pending certificate's name in order for the pending certificate to be validated.
   c. Select the signed **Certificate File** that you received from your enterprise CA.
   d. Click **OK**. The certificate is displayed as valid with the Key and CA check boxes selected.
   e. Select the validated certificate, in this case, *my-fwd-proxy*, to enable it as a **Forward Trust Certificate** to be used for SSL Forward Proxy decryption.
   f. Click **OK**.

© Palo Alto Networks, Inc.

| Configure SSL Forward Proxy | | |
|---|---|---|
| Step 3 | Configure the forward untrust certificate.<br><br>With SSL Forward Proxy decryption, when the site the client is connecting to uses a certificate signed by a CA that is not in the firewall's trusted CA list, the firewall presents a forward untrust certificate to the client. The forward untrust certificate ensures that clients are prompted with a certificate warning when attempting to access sites with untrusted certificates. | 1. Click **Generate** at the bottom of the certificates page.<br>2. Enter a **Certificate Name**, such as *my-fwd-untrust*.<br>3. Set the **Common Name**, for example **192.168.2.1**. Leave **Signed By** blank.<br>4. Click the **Certificate Authority** check box to enable the firewall to issue the certificate.<br>5. Click **Generate** to generate the certificate.<br>6. Click **OK** to save.<br>7. Click the new *my-ssl-fw-untrust* certificate to modify it and enable the **Forward Untrust Certificate** option.<br> Do not export the forward untrust certificate for import into client systems. If the forward trust certificate is imported on client systems, the users will not see certificate warnings for SSL sites with untrusted certificates.<br>8. Click **OK** to save. |
| Step 4 | (Optional) Set the key size of the SSL Forward Proxy certificates that the firewall presents to clients.<br><br> Changing the key size clears the current certificate cache. | 1. Select **Device > Setup > Session** and, in the Decryption Settings section, click **Forward Proxy Server Certificate Settings**.<br>2. Select a **Key Size**: **Defined by destination host** (default), **1024-bit RSA**, or **2048-bit RSA**. |
| Step 5 | (Optional) Create a Decryption profile.<br><br>Decryption profiles can be associated with a decryption policy, enabling the firewall to block and control various aspects of traffic that is being decrypted. An SSL Forward Proxy decryption profile can be used to perform checks for server certificates, unsupported modes, and failures and block or restrict traffic accordingly. For a complete list of checks that can be performed, navigate to **Objects > Decryption Profiles** on the firewall and click the help icon. | 1. Select **Objects > Decryption Profile** and click **Add**.<br>2. Select the **SSL Forward Proxy** tab to block and control specific aspects of SSL tunneled traffic. For example, you can choose to terminate sessions if system resources are not available to process decryption by selecting **Block sessions if resources not available**.<br>3. Click **OK t**o save the profile. |

| Configure SSL Forward Proxy | |
|---|---|
| Step 6 Configure a decryption policy. | 1. Select **Policies > Decryption** and click **Add**.<br>2. On the **General** tab, give the policy a descriptive **Name**.<br>3. On the **Source** and **Destination** tabs, select **Any** for the **Source Zone** and **Destination Zone** to decrypt all SSL traffic destined for an external server. If you want to specify traffic from or to certain sources or destinations for decryption, click **Add**.<br>4. In the **URL Category** tab, leave **Any** to decrypt all traffic. If you only want to apply this profile to certain website categories, click **Add**.<br> Selecting a URL Category is useful when excluding certain sites from decryption. See Configure Decryption Exceptions.<br>5. On the **Options** tab, select **Decrypt** and select **SSL Forward Proxy** as the **Type** of decryption to perform.<br>6. (Optional) Select a **Decryption Profile** to apply additional settings to decrypted traffic (see Step 5).<br>7. Click **OK** to save. |
| Step 7 **Commit** the configuration. | With an SSL Forward Proxy decryption policy enabled, all traffic identified by the policy is decrypted. Decrypted traffic is blocked and restricted according to the profiles configured on the firewall (including the decryption profiles associated with the policy and Antivirus, Vulnerability, Anti-Spyware, URL Filtering, and File-Blocking profiles). Traffic is re-encrypted as it exits the firewall. |

© Palo Alto Networks, Inc.

# Configure SSL Inbound Inspection

Configuring SSL Inbound Inspection includes installing the targeted server's certificate on the firewall and creating an SSL Inbound Inspection decryption policy.

Use the following task to configure SSL Inbound Inspection.

| Configure SSL Inbound Inspection | | |
|---|---|---|
| Step 1 | Ensure that the appropriate interfaces are configured as either virtual wire, Layer 2, or Layer 3 interfaces. | View configured interfaces on the **Network > Interfaces > Ethernet** tab. The **Interface Type** column displays if an interface is configured to be a **Virtual Wire** or **Layer 2**, or **Layer 3** interface. You can select an interface to modify its configuration, including what type of interface it is. |
| Step 2 | Ensure that the targeted server's certificate is installed on the firewall. | On the web interface, select **Device > Certificate Management > Certificates > Device Certificates** to view certificates installed on the firewall.<br>To import the targeted server's certificate onto the firewall:<br>1. On the **Device Certificates** tab, select **Import**.<br>2. Enter a descriptive **Certificate Name**.<br>3. Browse for and select the targeted server's **Certificate File**.<br>4. Click **OK**. |
| Step 3 | (Optional) Create a Decryption profile.<br>Decryption profiles can be associated with a decryption policy, enabling the firewall to block and control various aspects of traffic that is being decrypted. An SSL Inbound Inspection decryption profile can be used to perform checks for unsupported modes and failures and block or restrict traffic accordingly. For a complete list of checks that can be performed, select **Objects > Decryption Profiles** and then click the help icon. | 1. Select **Objects > Decryption Profile** and click **Add**.<br>2. Select the **SSL Inbound Inspection** tab to block and control specific aspects of SSL traffic. For example, you can choose to terminate sessions if system resources are not available to process decryption by selecting **Block sessions if resources not available**.<br>3. Click **OK t**o save the profile. |

| Configure SSL Inbound Inspection | |
|---|---|
| Step 4 Configure a decryption policy. | 1. Select **Policies > Decryption** and click **Add**.<br>2. On the **General** tab, give the policy a descriptive **Name**.<br>3. On the **Destination** tab, **Add** the **Destination Address** of the targeted server.<br>4. In the **URL Category** tab, leave **Any** to decrypt all traffic. If you only want to apply this profile to certain website categories, click **Add**.<br> Selecting a URL Category is useful when excluding certain sites from decryption. See Configure Decryption Exceptions.<br>5. On the **Options** tab, select **Decrypt** and select **SSL Inbound Inspection** as the **Type** of traffic to decrypt.<br>Select the **Certificate** for the internal server that is the destination of the inbound SSL traffic.<br>6. (Optional) Select a **Decryption Profile** to apply additional settings to decrypted traffic.<br>7. Click **OK** to save. |
| Step 5 **Commit** the configuration. | With an SSL Inbound Inspection decryption policy enabled, all SSL traffic identified by the policy is decrypted and inspected. Decrypted traffic is blocked and restricted according to the profiles configured on the firewall (including the decryption profiles associated with the policy and Antivirus, Vulnerability, Anti-Spyware, URL Filtering, and File-Blocking profiles). Traffic is re-encrypted as it exits the firewall. |

© Palo Alto Networks, Inc.

# Configure SSH Proxy

Configuring SSH Proxy does not require certificates and the key used to decrypt SSH sessions is generated automatically on the firewall during boot up.

Use the following task to configure SSH Proxy decryption.

| Configure SSH Proxy Decryption | | |
|---|---|---|
| Step 1 | Ensure that the appropriate interfaces are configured as either virtual wire, Layer 2, or Layer 3 interfaces. Decryption can only be performed on virtual wire, Layer 2, or Layer 3 interfaces. | View configured interfaces on the **Network > Interfaces > Ethernet** tab. The **Interface Type** column displays if an interface is configured to be a **Virtual Wire** or **Layer 2**, or **Layer 3** interface. You can select an interface to modify its configuration, including what type of interface it is. |
| Step 2 | (Optional) Create a Decryption profile.<br>Decryption profiles can be associated with a decryption policy, enabling the firewall to block and control various aspects of traffic that is being decrypted. The decryption profile can be used to perform checks for server certificates, unsupported modes, and failures and block or restrict traffic accordingly. For a complete list of checks that can be performed, navigate to **Objects > Decryption Profiles** on the firewall and then click the help icon. | 1. Select **Objects > Decryption Profile** and click **Add**.<br>2. Select the **SSH** tab to block and control specific aspects of SSH tunneled traffic. For example, you can choose to terminate sessions if system resources are not available to process decryption by selecting **Block sessions if resources not available**.<br>3. Click **OK** to save the profile. |
| Step 3 | Configure a decryption policy. | 1. Select **Policies > Decryption** and click **Add**.<br>2. On the **General** tab, give the policy a descriptive **Name**.<br>3. On the **Source** and **Destination** tabs, select **Any** to decrypt all SSH traffic.<br>4. On the **URL Category** tab, select **Any** to decrypt all SSH traffic.<br>5. On the **Options** tab, select **Decrypt** and select **SSH Proxy** as the **Type** of traffic to decrypt.<br>6. (Optional) Select a **Decryption Profile** to apply additional settings to decrypted traffic.<br>7. Click **OK** to save. |
| Step 4 | **Commit** the configuration. | With the an SSH Proxy decryption policy enabled, all SSH traffic identified by the policy is decrypted and identified as either regular SSH traffic or as SSH tunneled traffic. SSH tunneled traffic is blocked and restricted according to the profiles configured on the firewall. Traffic is re-encrypted as it exits the firewall. |

# Configure Decryption Exceptions

You can purposefully exclude traffic from decryption based on matching criteria, such the traffic's source, destination, URL category, or service. You can also exclude a specific server's traffic from decryption. See the following topics to configure Decryption Exceptions:

- Exclude Traffic From Decryption
- Exclude a Server From Decryption

## Exclude Traffic From Decryption

To purposefully exclude applications or certain traffic from other existing SSL or SSH decryption policies, you can create a new decryption policy that defines the traffic to exclude from decryption with the **No Decrypt** action selected in the policy. You can define traffic for policy-based exclusion according to matching criteria, such as source, destination, URL categories, or the service (port or protocol). Make sure the decryption policy that excludes traffic from decryption is listed first in your decryption policy list by dragging and dropping the policy above the other decryption policies.

See the following procedure to configure a decryption policy that excludes traffic from SSL or SSH decryption.

| **Exclude Traffic from a Decryption Policy** | | |
|---|---|---|
| Step 1 | Create a decryption policy.<br><br>Use a decryption policy to exclude traffic from decryption according to the traffic's source and destination zones or addresses and URL categories. This example shows how to exclude traffic categorized as financial or health-related from SSL Forward Proxy decryption. | 1. Go to **Policies > Decryption** and click **Add**.<br>2. Give the policy a descriptive **Name**, such as *No-Decrypt-Finance-Health*.<br>3. On the **Source** and **Destination** tabs, select **Any** for the **Source Zone** and **Destination Zone** to apply the *No-Decrypt-Finance-Health* rule to all SSL traffic destined for an external server.<br>4. On the **URL Category** tab, **Add** the URL categories financial-services and health-and-medicine to the policy, specifying that traffic that matches these categories will not be decrypted.<br>5. On the **Options** tab, select **No Decrypt** and select the **Type** of decryption policy you are excluding the traffic from. For example, to exclude traffic categorized as financial or health-related from a separately configured SSL Forward Proxy decryption policy, select **SSL Forward Proxy** as the **Type**.<br>6. Click **OK** to save the *No-Decrypt-Finance-Health* decryption policy. |
| Step 2 | Move the decryption policy to the top of the list of decryption policies. | On the **Decryption > Policies** page, select the policy *No-Decrypt-Finance-Health*, and click **Move Up** until it appears at the top of the list (or you can drag and drop).<br><br>The order in which the decryption policies are listed is the order in which they are applied to network traffic. Moving the policy with the **No Decrypt** action applied to the top of the list ensures that the specified traffic is not decrypted according to another configured policy. |

© Palo Alto Networks, Inc.

| Exclude Traffic from a Decryption Policy | |
|---|---|
| Step 3 **Commit** the configuration. | A decryption policy with **No Decrypt** enabled ensures that the specified traffic is remains encrypted as it flows through the firewall, and that the traffic is not decrypted according to other decryption policies configured and listed on the **Policies > Decryption** page. |

## Exclude a Server From Decryption

You can exclude a targeted server's traffic from SSL decryption based on the Common Name (CN) in the server's certificate. For example, if you have SSL decryption enabled, you could configure a decryption exception for the server on your corporate network that hosts the web services for your HR systems. See the following procedure to configure a server's certificate so that the targeted server's traffic is excluded from decryption:

| Exclude a Server from Decryption | |
|---|---|
| Step 1 | Import the targeted server's certificate onto the firewall:<br>1. On the **Device > Certificate Management > Certificates > Device Certificates** tab, select **Import**.<br>2. Enter a descriptive **Certificate Name**.<br>3. Browse for and select the targeted server's **Certificate File**.<br>4. Click **OK**. |
| Step 2 | Select the targeted server's certificate on the **Device Certificates** tab and enable it as an SSL Exclude Certificate.<br>With the targeted server's certificate imported on the firewall and designated as an SSL Exclude Certificate, the server's traffic is not decrypted as it passes through the firewall. |

# Enable Users to Opt Out of SSL Decryption

In some cases, you might need to alert your users to the fact that the firewall is decrypting certain web traffic and allow them to terminate sessions that they do not want inspected. With SSL Opt Out enabled, the first time a user attempts to browse to an HTTPS site or application that matches your decryption policy, the firewall displays a response page notifying the user that it will decrypt the session. Users can either click **Yes** to allow decryption and continue to the site or click **No** to opt out of decryption and terminate the session. The choice to allow decryption applies to all HTTPS sites that users try to access for the next 24 hours, after which the firewall redisplays the response page. Users who opt out of SSL decryption cannot access the requested web page, or any other HTTPS site, for the next minute. After the minute elapses, the firewall redisplays the response page the next time the users attempt to access an HTTPS site.

The firewall includes a predefined SSL Decryption Opt-out Page that you can enable. You can optionally customize the page with your own text and/or images.

| **Enable Users to Opt Out of SSL Decryption** | |
|---|---|
| Step 1 (Optional) Customize the SSL Decryption Opt-out Page. | 1. Select **Device > Response Pages**.<br>2. Select the **SSL Decryption Opt-out Page** link.<br>3. Select the **Predefined** page and click **Export**.<br>4. Using the HTML text editor of your choice, edit the page.<br>5. If you want to add an image, host the image on a web server that is accessible from your end user systems.<br>6. Add a line to the HTML to point to the image. For example:<br>`<img src="http://cdn.slidesharecdn.com/Acme-logo-96x96.jpg?1382722588"/>`<br>7. Save the edited page with a new filename. Make sure that the page retains its UTF-8 encoding.<br>8. Back on the firewall, select **Device > Response Pages**.<br>9. Select the **SSL Decryption Opt-out Page** link.<br>10. Click **Import** and then enter the path and filename in the **Import File** field or **Browse** to locate the file.<br>11. (Optional) Select the virtual system on which this login page will be used from the **Destination** drop-down or select shared to make it available to all virtual systems.<br>12. Click **OK** to import the file.<br>13. Select the response page you just imported and click **Close**. |
| Step 2 Enable SSL Decryption Opt Out. | 1. On the **Device > Response Pages** page, click the **Disabled** link.<br>2. Select the **Enable SSL Opt-out Page** and click **OK**.<br> <br>3. **Commit** the changes. |

 © Palo Alto Networks, Inc.

| Enable Users to Opt Out of SSL Decryption | |
|---|---|
| Step 3 Verify that the Opt Out page displays when you attempt to browse to a site. | From a browser, go to an encrypted site that matches your decryption policy.<br>Verify that the SSL Decryption Opt-out response page displays.<br> |

# Configure Decryption Port Mirroring

Before you can enable decryption port mirroring, you must obtain and install a Decryption Port Mirror license. The license is free of charge and can be activated through the support portal as described in the following procedure. After you install the Decryption Port Mirror license and reboot the firewall, you can enable decryption port mirroring.

Enabling decryption port mirroring includes enabling the forwarding of decrypted traffic and configuring a decrypt mirror interface. You can then create a decryption profile that specifies the interface and attach it to a decryption policy. To learn more about implementing Decryption Port Mirroring, see Decryption Port Mirroring.

Use the following procedure to obtain and install a Decryption Port Mirror license and configure Decryption Port Mirroring.

| **Configure Decryption Port Mirroring** | |
|---|---|
| Step 1 Request a license for each device on which you want to enable decryption port mirroring. | 1. Log in to the Palo Alto Networks Support site and navigate to the **Assets** tab.<br>2. Select the device entry for the device you want to license and select **Actions**.<br>3. Select **Decryption Port Mirror**. A legal notice displays.<br>4. If you are clear about the potential legal implications and requirements, click **I understand and wish to proceed**.<br>5. Click **Activate**.<br>  |

 © Palo Alto Networks, Inc.

| Configure Decryption Port Mirroring (Continued) | | |
|---|---|---|
| Step 2 | Install the Decryption Port Mirror license on firewall. | 1. From the firewall's web interface, select **Device > Licenses**.<br>2. Click **Retrieve license keys from license server**.<br>3. Verify that the license has been activated on the firewall.<br> <br><br>4. Reboot the firewall (**Device > Setup > Operations**). This feature will not be available for configuration until PAN-OS reloads. |
| Step 3 | Enable the ability to mirror decrypted traffic. Superuser permission is required to perform this step. | **On a firewall with a single virtual system:**<br>1. Select **Device > Setup > Content - ID**.<br>2. Select the **Allow forwarding of decrypted content** check box.<br>3. Click **OK** to save.<br>**On a firewall with multiple virtual systems:**<br>1. Select **Device > Virtual System.**<br>2. Select a Virtual System to edit or create a new Virtual System by selecting **Add**.<br>3. Select the **Allow forwarding of decrypted content** check box.<br>4. Click **OK** to save. |
| Step 4 | Configure a decrypt mirror interface. | 1. Select **Network > Interfaces > Ethernet**.<br>2. Select the Ethernet interface that you want to configure for decryption port mirroring.<br>3. Select **Decrypt Mirror** as the **Interface Type**.<br>This interface type will appear only if the Decryption Port Mirror license is installed.<br>4. Click **OK** to save. |

© Palo Alto Networks, Inc.

| Configure Decryption Port Mirroring (Continued) | | |
|---|---|---|
| Step 5 | Configure a Decryption Profile to enable decryption port mirroring. | 1. Select **Objects > Decryption Profile**.<br>2. Select the **Interface** to use for **Decryption Mirroring**.<br>The **Interface** drop-down contains all Ethernet interfaces that have been defined as the type: **Decrypt Mirror**.<br>3. Specify whether to mirror decrypted traffic before or after policy enforcement.<br>By default, the firewall will mirror all decrypted traffic to the interface before security policies lookup, which allows you to replay events and analyze traffic that generates a threat or triggers a drop action. If you want to only mirror decrypted traffic after security policy enforcement, select the **Forwarded Only** check box. With this option, only traffic that is forwarded through the firewall is mirrored. This option is useful if you are forwarding the decrypted traffic to other threat detection devices, such as a DLP device or another intrusion prevention system (IPS).<br>4. Click **OK** to save the decryption profile. |
| Step 6 | Set a decryption policy for decryption port mirroring. | 1. Select **Policies > Decryption**.<br>2. Click **Add** to configure a decryption policy or select an existing decryption policy to edit.<br>3. In the **Options** tab, select **Decrypt** and the **Decryption Profile** created in Step 4.<br>4. Click **OK** to save the policy. |
| Step 7 | Save the configuration. | Click **Commit**. |

 © Palo Alto Networks, Inc.

# Temporarily Disable SSL Decryption

In some cases you may want to temporarily disable SSL decryption. For example, if your users are having problems accessing an encrypted site or application, you may want to disable SSL decryption in order to troubleshoot the issue. Although you could disable the associated decryption policies, modifying the policies is a configuration change that requires a Commit. Instead, use the following command to temporarily disable SSL decryption and then re-enable it after you finish troubleshooting. This command does not require a commit and it does not persist in your configuration after a reboot.

| **Temporarily Disable SSL Decryption** | |
|---|---|
| • Disable SSL Decryption | `set system setting ssl-decrypt skip-ssl-decrypt yes` |
| • Re-enable SSL Decryption | `set system setting ssl-decrypt skip-ssl-decrypt no` |

# URL Filtering

The Palo Alto Networks URL filtering solution is a powerful PAN-OS feature that is used to monitor and control how users access the web over HTTP and HTTPS. The following topics provide an overview of URL filtering, configuration and troubleshooting information, and best practices for getting the most out of this feature:

- URL Filtering Overview
- URL Filtering Concepts
- PAN-DB Categorization Workflow
- Enable a URL Filtering Vendor
- Determine URL Filtering Policy Requirements
- Monitor Web Activity
- Configure URL Filtering
- Log Client IP Addresses for Proxied HTTP/HTTPS Requests
- Customize the URL Filtering Response Pages
- Configure URL Admin Override
- Enable Safe Search Enforcement
- URL Filtering Use Case Examples
- Troubleshoot URL Filtering

© Palo Alto Networks, Inc.

# URL Filtering Overview

The Palo Alto Networks URL filtering feature compliments the App-ID feature by enabling you to configure your firewall to identify and control access to web (HTTP and HTTPS) traffic. By implementing URL filtering profiles in security policies and by using URL categories as a match criteria in policies (captive portal, decryption, security, and QoS), you will gain complete visibility and control of the traffic that traverses your firewall and will be able to safely enable and control how your users access the web.

The Palo Alto Networks URL filtering solution utilizes a URL filtering database that contains millions of websites and each website is placed in one of approximately 60 different categories. A URL filtering profile that contains the list of categories is then applied to a security policy that allows web traffic (HTTP/HTTPS) from the internal users to the Internet. After the URL filtering profile is applied and the alert or block action is set on a category, you will gain complete visibility into the websites that users access and can then decide which websites or website categories should be allowed, blocked, or logged. You can also define a list of URLs in the URL filtering profile that will always be blocked or allowed and you can create custom URL categories that contain a list of URLs that can be used the same way as the default category list. These same URL categories can also be used as a match criteria in other policies, such as captive portal, decryption, and QoS.

▲ URL Filtering Vendors

▲ Interaction Between App-ID and URL Categories

## URL Filtering Vendors

Palo Alto Networks firewalls support two vendors for URL filtering purposes:

- **PAN-DB**—A Palo Alto Networks developed URL filtering database that is tightly integrated into PAN-OS by utilizing high-performance local caching to perform maximum inline performance for URL lookups while a distributed cloud architecture provides coverage for the latest websites. In addition, PAN-DB is tightly integrated with WildFire such that whenever WildFire deems a site malicious, it updates the corresponding PAN-DB URL category to malware, immediately blocking any future access to the site as long as you have a URL Filtering profile attached to the security policy rule. To view a list of PAN-DB URL filtering categories, refer to https://urlfiltering.paloaltonetworks.com/CategoryList.aspx.
- **BrightCloud**—A third-party URL database that is owned by Webroot, Inc. and is integrated into PAN-OS firewalls. For information on the BrightCloud URL database, visit http://brightcloud.com.

For instructions on configuring the firewall to use one of the supported URL Filtering vendors, see Enable a URL Filtering Vendor.

 © Palo Alto Networks, Inc.

## Interaction Between App-ID and URL Categories

The Palo Alto Networks URL filtering feature in combination with Application Identification (App-ID) provides unprecedented protection against a full spectrum of legal, regulatory, productivity, and resource utilization risks. While App-ID gives you control over what applications users can access, URL filtering provides control over related web activity. When combined with User-ID, you can also apply these controls based on users and groups.

With today's application landscape and the way many applications use HTTP and HTTPS, you will need to determine when to use App-ID and when to use URL filtering in order to define comprehensive web access policies. In most cases, if an App-ID signature exists, you will want to use App-ID to control the content at the application level. For example, although you can control access to Facebook and/or LinkedIn using URL filtering, this would not block the use of all related applications, such as email, chat, as well as any new application that is introduced after you implement your policy.

In some cases, you will want to use both URL filtering and App-ID, but to ensure that conflicts do not occur in your policies, it is important to understand how these features work together. Palo Alto Networks generates signatures for many applications and those signatures can be very granular in regard to various features within the web-based applications—whereas URL filtering would only apply actions based on a specific website or URL category. For example, you may want to block social networking sites in general, but want to allow a few sites in that category to be accessible to specific departments and then control what features of the website are available to the allowed users. For more information, see URL Filtering Use Case Examples.

# URL Filtering Concepts

- URL Categories
- URL Filtering Profile
- URL Filtering Profile Actions
- Block and Allow Lists
- Safe Search Enforcement
- Container Pages
- HTTP Header Logging
- URL Filtering Response Pages
- URL Category as Policy Match Criteria

© Palo Alto Networks, Inc.

## URL Categories

Each website defined in the URL filtering database is assigned one of approximately 60 different URL categories. There are two ways to make use of URL categorization on the firewall:

- **Block or allow traffic based on URL category**—You can create a URL Filtering Profile that specifies an action for each URL category and attach the profile to a policy. Traffic that matches the policy would then be subject to the URL filtering settings in the profile. For example, to block all gaming websites you would set the block action for the URL category *games* in the URL profile and attach it to the security policy rule(s) that allow web access. See Configure URL Filtering for more information.
- **Match traffic based on URL category for policy enforcement**—If you want a specific policy rule to apply only to web traffic to sites in a specific category, you would add the category as match criteria when you create the policy rule. For example, you could use the URL category *streaming-media* in a QoS policy to apply bandwidth controls to all websites that are categorized as streaming media. See URL Category as Policy Match Criteria for more information.

By grouping websites into categories, it makes it easy to define actions based on certain types of websites. In addition to the standard URL categories, there are three additional categories:

| Categories | Description |
|---|---|
| Not-resolved | Indicates that the website was not found in the local URL filtering database and the firewall was unable to connect to the cloud database to check the category. When a URL category lookup is performed, the firewall first checks the dataplane cache for the URL; if no match is found, it will then check the management plane cache, and if no match is found there, it queries the URL database in the cloud.<br>When deciding on what action to take for traffic that is categorized as *not-resolved*, be aware that setting the action to block may be very disruptive to users.<br>For more information on troubleshooting lookup issues, see Troubleshoot URL Filtering. |
| Private-ip-addresses | Indicates that the website is a single domain (no sub-domains), the IP address is in the private IP range, or the URL root domain is unknown to the cloud. |
| Unknown | The website has not yet been categorized, so it does not exist in the URL filtering database on the firewall or in the URL cloud database.<br>When deciding on what action to take for traffic categorized as *unknown*, be aware that setting the action to block may be very disruptive to users because there could be a lot of valid sites that are not in the URL database yet. If you do want a very strict policy, you could block this category, so websites that do not exist in the URL database cannot be accessed.<br>See Configure URL Filtering. |

## URL Filtering Profile

A URL filtering profile is a collection of URL filtering controls that are applied to individual security policy rules to enforce your web access policy. The firewall comes with a default profile that is configured to block threat-prone categories, such as malware, phishing, and adult. You can use the default profile in a security policy, clone it to be used as a starting point for new URL filtering profiles, or add a new URL profile that will have all categories set to allow for visibility into the traffic on your network. You can then customize the newly added URL profiles and add lists of specific websites that should always be blocked or allowed, which provides more granular control over URL categories. For example, you may want to block social-networking sites, but allow some websites that are part of the social-networking category.

The following topics describe the components of the URL Filtering profile:

- URL Filtering Profile Actions
- Block and Allow Lists
- Safe Search Enforcement
- Container Pages
- HTTP Header Logging

 © Palo Alto Networks, Inc.

## URL Filtering Profile Actions

The URL Filtering profile specifies an action for each known URL category. By default, when you create a new URL Filtering profile, the action is set to **allow** for all categories. This means that the users will be able to browse to all sites freely and will not be logged.

The default URL Filtering profile is set to allow access to all URL categories except for the following threat-prone categories, which are blocked: abused-drugs, adult, gambling, hacking, malware, phishing, questionable, and weapons. As a best practice, when you need a custom URL Filtering profile, clone the default profile rather than creating a new one to preserve these settings.

| Action | Description |
|---|---|
| **alert** | The website is allowed and a log entry is generated in the URL filtering log. |
| **allow** | The website is allowed and no log entry is generated. |
| **block** | The website is blocked and the user will see a response page and will not be able to continue to the website. A log entry is generated in the URL filtering log. |
| **continue** | The user will be prompted with a response page indicating that the site has been blocked due to company policy, but the user is prompted with the option to continue to the website. The **continue** action is typically used for categories that are considered benign and is used to improve the user experience by giving them the option to continue if they feel the site is incorrectly categorized. The response page message can be customized to contain details specific to your company. A log entry is generated in the URL filtering log.<br> The Continue page will not be displayed properly on client machines that are configured to use a proxy server. |
| **override** | The user will see a response page indicating that a password is required to allow access to websites in the given category. With this option, the security admin or helpdesk person would provide a password that will grant temporary access to all websites in the given category. A log entry is generated in the URL filtering log. See Configure URL Admin Override.<br> The Override page will not be displayed properly on client machines that are configured to use a proxy server. |
| **none** | The **none** action only applies to custom URL categories. Select **none** to ensure that if multiple URL profiles exist, the custom category will not have any impact on other profiles. For example, if you have two URL profiles and the custom URL category is set to **block** in one of the profiles, the other profile should have the action set to **none** if you do not want it to apply.<br>Also, in order to delete a custom URL category, it must be set to **none** in any profile where it is used. |

## Block and Allow Lists

Block and allow lists allow you to define specific URLs or IP addresses in the URL filtering profile that are always allowed or always blocked, regardless of the action defined for the URL category. When entering URLs in the *Block List* or *Allow List*, enter each URL or IP address in a new row separated by a new line. When using wildcards in the URLs, follow these rules:

- Do not include HTTP and HTTPS when defining URLs. For example, enter `www.paloaltonetworks.com` or `paloaltonetworks.com` instead of https://www.paloaltonetworks.com.
- Entries in the block list must be an exact match and are case-insensitive.

  For example: If you want to prevent a user from accessing any website within the domain paloaltonetworks.com, you would also enter `*.paloaltonetworks.com`, so whatever domain prefix (http://, www, or a sub-domain prefix such as mail.paloaltonetworks.com) is added to the address, the specified action will be taken. The same applies to the sub-domain suffix; if you want to block paloaltonetworks.com/en/US, you would need to add `paloaltonetworks.com/*` as well.

  Further, if you want to specify that the match is for `paloaltonetworks.com` and not `paloaltonetworks.com.au`, you must add a `/` after `.com` to specify the scope for the match to just be `.com` and not for the domain suffix `.com.au`. In this case, you need to add the entry as `*.paloaltonetworks.com/`

  Block and allow lists support wildcard patterns. Use the following characters as separators:

  `.`

  `/`

  `?`

  `&`

  `=`

  `;`

  `+`

  Every substring that is separated by the characters listed above is considered a token. A token can be any number of ASCII characters that does not contain any separator character or *. For example, the following patterns are valid:

  *.yahoo.com (tokens are: "*", "yahoo" and "com")

  www.*.com (tokens are: "www", "*" and "com")

  www.yahoo.com/search=* (tokens are: "www", "yahoo", "com", "search", "*")

  The following patterns are invalid because the character "*" is not the only character in the token.

  ww*.yahoo.com

  www.y*.com

 © Palo Alto Networks, Inc.

## Safe Search Enforcement

Many search engines have a safe search setting that filters out adult images and videos in search query return traffic. On the firewall, you can Enable Safe Search Enforcement so that the firewall will block search results if the end user is not using the strictest safe search settings in the search query. The firewall can enforce safe search for the following search providers: Google, Yahoo, Bing, Yandex, and YouTube. This is a best-effort setting and is not guaranteed by the search providers to work with every website.

To use this feature you must enable the **Safe Search Enforcement** option in a URL filtering profile and attach it to a security policy. The firewall will then block any matching search query return traffic that is not using the strictest safe search settings. There are two methods for blocking the search results:

- Block Search Results that are not Using Strict Safe Search Settings—When an end user attempts to perform a search without first enabling the strictest safe search settings, the firewall blocks the search query results and displays the URL Filtering Safe Search Block Page. By default, this page will provide a URL to the search provider settings for configuring safe search.
- Enable Transparent Safe Search Enforcement—When an end user attempts to perform a search without first enabling the strict safe search settings, the firewall blocks the search results with an HTTP 503 status code and redirects the search query to a URL that includes the safe search parameters. You enable this functionality by importing a new URL Filtering Safe Search Block Page containing the Javascript for rewriting the search URL to include the strict safe search parameters. In this configuration, users will not see the block page, but will instead be automatically redirected to a search query that enforces the strictest safe search options. This safe search enforcement method requires Content Release version 475 or later and is only supported for Google, Yahoo, and Bing searches.

Also, because most search providers now use SSL to return search results, you must also configure a Decryption policy for the search traffic to enable the firewall to inspect the search traffic and enforce safe search.

Safe search enforcement enhancements and support for new search providers is periodically added in content releases. This information is detailed in the Application and Threat Content Release Notes. How sites are judged to be safe or unsafe is performed by each search provider, not by Palo Alto Networks.

Safe search settings differ by search provider as detailed in Table: Search Provider Safe Search Settings.

**Table: Search Provider Safe Search Settings**

| Search Provider | Safe Search Setting Description |
|---|---|
| Google/YouTube | Offers safe search on individual computers or network-wide through Google's safe search virtual IP address:<br><br>**Safe Search Enforcement for Google Searches on Individual Computers**<br><br>In the Google Search Settings, the **Filter explicit results** setting enables safe search functionality. When enabled, the setting is stored in a browser cookie as `FF=` and passed to the server each time the user performs a Google search.<br><br>Appending `safe=active` to a Google search query URL also enables the strictest safe search settings.<br><br>**Safe Search Enforcement for Google and YouTube Searches using a Virtual IP Address**<br><br>Alternatively, Google provides servers that Lock SafeSearch (forcesafesearch.google.com) settings in every Google and YouTube search. By adding a DNS entry for `www.google.com` and `www.youtube.com` (and other relevant Google and YouTube country subdomains) that includes a CNAME record pointing to `forcesafesearch.google.com` to your DNS server configuration, you can ensure that all users on your network are using strict safe search settings every time they perform a Google or YouTube search. Keep in mind, however, that this solution is not compatible with Safe Search Enforcement on the firewall. Therefore, if you are using this option to force safe search on Google, the best practice is to block access to other search engines on the firewall by creating custom URL categories and adding them to the block list in the URL filtering profile.<br><br> If you plan to use the Google Lock SafeSearch solution, consider configuring DNS Proxy (**Network > DNS Proxy**) and setting the inheritance source as the Layer 3 interface on which the firewall receives DNS settings from service provider via DHCP. You would configure the DNS proxy with **Static Entries** for www.google.com and www.youtube.com, using the local IP address for the forcesafesearch.google.com server. |
| Yahoo | Offers safe search on individual computers only. The Yahoo Search Preferences include three SafeSearch settings: **Strict**, **Moderate**, or **Off**. When enabled, the setting is stored in a browser cookie as `vm=` and passed to the server each time the user performs a Yahoo search.<br><br>Appending `vm=r` to a Yahoo search query URL also enables the strictest safe search settings.<br><br> When performing a search on Yahoo Japan (yahoo.co.jp) while logged into a Yahoo account, end users must also enable the **SafeSearch Lock** option. |
| Bing | Offers safe search on individual computers or through their Bing in the Classroom program. The Bing Settings include three SafeSearch settings: **Strict**, **Moderate**, or **Off**. When enabled, the setting is stored in a browser cookie as `adlt=` and passed to the server each time the user performs a Bing search.<br><br>Appending `adlt=strict` to a Bing search query URL also enables the strictest safe search settings.<br><br>The Bing SSL search engine does not enforce the safe search URL parameters and you should therefore should consider blocking Bing over SSL for full safe search enforcement. |

 © Palo Alto Networks, Inc.

## Container Pages

A container page is the main page that a user accesses when visiting a website, but additional websites may be loaded within the main page. If the **Log Container page only** option is enabled in the URL filtering profile, only the main container page will be logged, not subsequent pages that may be loaded within the container page. Because URL filtering can potentially generate a lot of log entries, you may want to turn on this option, so log entries will only contain those URIs where the requested page file name matches the specific mime-types. The default set includes the following mime-types:

- application/pdf
- application/soap+xml
- application/xhtml+xml
- text/html
- text/plain
- text/xml

If you have enabled the **Log container page only** option, there may not always be a correlated URL log entry for threats detected by Antivirus or Vulnerability Protection.

## HTTP Header Logging

URL filtering provides visibility and control over web traffic on your network. For improved visibility into web content, you can configure the URL Filtering profile to log HTTP header attributes included in a web request. When a client requests a web page, the HTTP header includes the user agent, referer, and x-forwarded-for fields as attribute-value pairs and forwards them to the web server. When enabled for logging HTTP headers, the firewall logs the following attribute-value pairs in the URL Filtering logs:

| Attribute | Description |
|---|---|
| User-Agent | The web browser that the user used to access the URL, for example, Internet Explorer. This information is sent in the HTTP request to the server. |
| Referer | The URL of the web page that linked the user to another web page; it is the source that redirected (referred) the user to the web page that is being requested. |
| X-Forwarded-For | The header field option that preserves the IP address of the user who requested the web page. It allows you to identify the IP address of the user particularly if you have a proxy server on your network, where all requests might seem to originate from the proxy server's IP address. |

 © Palo Alto Networks, Inc.

## URL Filtering Response Pages

The firewall provides three predefined response pages that display by default when a user attempts to browse to a site in a category that is configured with one of the block actions in the URL Filtering Profile (block, continue, or override) or when Safe Search Enforcement is enabled:

- **URL Filtering and Category Match Block Page**—Access blocked by a URL filtering profile or because the URL category is blocked by a security policy.

- **URL Filtering Continue and Override Page**—Page with initial block policy that allows users to bypass the block. With the override page, after clicking **Continue**, the user must supply a password to override the policy that blocks the URL.

- **URL Filtering Safe Search Block Page**—Access blocked by a security policy with a URL filtering profile that has the Safe Search Enforcement option enabled. The user will see this page if a search is performed using Google, Bing, Yahoo, or Yandex and their browser or search engine account setting for Safe Search is not set to strict.

You can either use the predefined pages, or you can Customize the URL Filtering Response Pages to communicate your specific acceptable use policies and/or corporate branding. In addition, you can use the URL Filtering Response Page Variables for substitution at the time of the block event or add one of the supported Response Page References to external images, sounds, or style sheets.

**URL Filtering Response Page Variables**

| Variable | Usage |
|---|---|
| <user/> | The firewall replaces the variable with the username (if available via User-ID) or IP address of the user when displaying the response page. |
| <url/> | The firewall replaces the variable with the requested URL when displaying the response page. |
| <category/> | The firewall replaces the variable with the URL filtering category of the blocked request. |
| <pan_form/> | HTML code for displaying the continue button on the URL Filtering Continue and Override page. |

You can also add code that triggers the firewall to display different messages using depending on what URL category the user is attempting to access. For example, the following code snippet from a response page specifies to display Message 1 if the URL category is games, Message 2 if the category as travel, or Message 3 if the category is kids:

```
var cat = "<category/>";
switch(cat)
{
   case 'games':
      document.getElementById("warningText").innerHTML = "Message 1";
      break;
   case 'travel':
      document.getElementById("warningText").innerHTML = "Message 2";
      break;
   case 'kids':
      document.getElementById("warningText").innerHTML = "Message 3";
      break;
}
```

Only a single HTML page can be loaded into each virtual system for each type of block page. However, other resources such as images, sounds, and cascading style sheets (CSS files) can be loaded from other servers at time the response page is displayed in the browser. All references must include a fully qualified URL.

**Response Page References**

| Reference Type | Example HTML Code |
|---|---|
| Image | `<img src="http://virginiadot.org/images/Stop-Sign-gif.gif">` |
| Sound | `<embed src="http://simplythebest.net/sounds/WAV/WAV_files/ movie_WAV_files/ do_not_go.wav" volume="100" hidden="true" autostart="true">` |
| Style Sheet | `<link href="http://example.com/style.css" rel="stylesheet" type="text/css" />` |
| Hyperlink | `<a href="http://en.wikipedia.org/wiki/Acceptable_use_policy">View Corporate Policy</a>` |

 © Palo Alto Networks, Inc.

## URL Category as Policy Match Criteria

URL categories can be used as a match criteria in a policy to provide more granularity in the policy. For example, you may have a decryption policy defined, but you would like specific websites to bypass decryption. To do this, you would configure a decryption policy with the *no-decrypt* action and a URL category would be defined as match criteria for the policy rule, so the policy would only match traffic flows to websites that are part of the specified category.

The following table describes the policy types that can utilize URL categories:

| Policy Type | Description |
|---|---|
| Captive Portal | To ensure that users authenticate before being allowed access to a specific category, you can attach a URL category as a match criterion for the captive portal policy. |
| Decryption | Decryption policies can use URL categories as match criteria to determine if specified websites should be decrypted or not. For example, if you have a decryption policy with the action decrypt for all traffic between two zones, there may be specific website categories, such as *financial-services* and/or *health-and-medicine*, that should not be decrypted. In this case, you would create a new decryption policy with the action of *no-decrypt* that precedes the decrypt policy and then defines a list of URL categories as match criteria for the policy. By doing this, each URL category that is part of the no-decrypt policy will not be decrypted. You could also configure a custom URL category to define your own list of URLs that can then be used in the no-decrypt policy. |
| QoS | A QoS policy can use URL categories to determine throughput levels for specific website categories. For example, you may want to allow the streaming-media category, but limit throughput by adding the URL category as match criteria to the QoS policy. |
| Security | In security policies you can use URL categories both as a match criteria in the **Service/URL Category** tab, and in URL filtering profiles that are attached in the **Actions** tab.<br>If for example, the IT-security group in your company needs access to the hacking category, while all other users are denied access to the category, you must create the following rules:<br>• A security rule that allows the IT-Security group to access content categorized as hacking. The security rule references the *hacking* category in the S**ervices/URL Category** tab and IT-Security group in the **Users** tab.<br>• Another security rule that allows general web access for all users. To this rule you attach a URL filtering profile that blocks the hacking category.<br>The policy that allows access to hacking must be listed before the policy that blocks hacking. This is because security policy rules are evaluated top down, so when a user who is part of the security group attempts to access a hacking site, the policy rule that allows access is evaluated first and will allow the user access to the hacking sites. Users from all other groups are evaluated against the general web access rule which blocks access to the hacking sites. |

# PAN-DB Categorization Workflow

This section describes the PAN-DB components and describes the URL categorization resolution workflow that occurs as users access various URLs through the firewall.

▲ PAN-DB URL Categorization Components
▲ PAN-DB URL Categorization Workflow

## PAN-DB URL Categorization Components

The following table describes the PAN-DB components in detail. The BrightCloud system works similarly, but does not use an initial seed database.

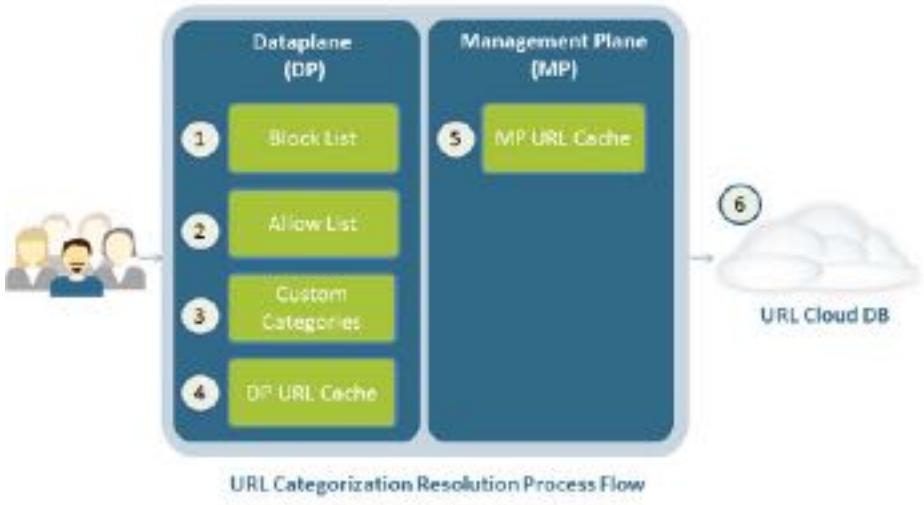
| Component | Description |
|---|---|
| URL Filtering Seed Database | The initial seed database downloaded to the firewall is a small subset of the database that is maintained on the Palo Alto Networks URL cloud servers. The reason this is done is because the full database contains millions of URLs and many of these URLs may never be accessed by your users. When downloading the initial seed database, a region is selected (North America, Europe, APAC, Japan) and each region contains a subset of URLs most accessed for the given region. By doing this, the firewall will store a much smaller URL database, which greatly improves lookup performance. If a user accesses a website that is not in the local URL database, the full cloud database is queried and the firewall will then add the new URL to the local database. In other words, the local database on the firewall will be continually populated/customized based on user activity. Note that the local customized URL database will be cleared if PAN-DB seed database is re-downloaded or if you change the URL database vendor from PAN-DB to BrightCloud. |
| Cloud Service | The PAN-DB cloud service is implemented using Amazon Web Services (AWS). AWS provides a distributed high-performance and stable environment for seed database downloads and URL lookups for Palo Alto Networks firewalls and communication is performed over SSL. The AWS cloud systems hold the entire PAN-DB and is updated as new URLs are identified. The PAN-DB cloud service supports an automated mechanism to update the firewall's local URL database if the version does not match. Each time the firewall queries the cloud servers for URL lookups, it will also check for critical updates. If there have been no queries to the cloud servers for more than 30 minutes, the firewall will check for updates on the cloud systems.<br>The cloud system also provides a mechanism to submit URL category change requests. This is performed through the test-a-site service and is available directly from the device (URL filtering profile setup) and from the Palo Alto Networks Test A Site website. You can also submit a URL categorization change request directly from the URL filtering log on the firewall in the log details section. |

 © Palo Alto Networks, Inc.

| Component | Description |
|---|---|
| Management Plane (MP) URL Cache | When PAN-DB is activated on the firewall, a seed database is downloaded from one of the PAN-DB cloud servers to initially populate the local cache, which is done to improve lookup performance. Each regional seed database contains the top URLs for the region and the size of the seed database (number of URL entries) also depends on the device platform. The URL MP cache is automatically written to the firewall's local drive every eight hours, before the firewall is rebooted, or when the cloud upgrades the URL database version on the firewall. After rebooting the firewall, the file that was saved to the local drive will be loaded to the MP cache. A least recently used (LRU) mechanism is also implemented in the URL MP cache in case the cache is full. If the cache becomes full, the URLs that have been accessed the least will be replaced by the newer URLs. |
| Dataplane (DP) URL Cache | This is a subset of the MP cache and is a customized, dynamic URL database that is stored in the dataplane (DP) and is used to improve URL lookup performance. The URL DP cache is cleared at each firewall reboot. The number of URLs that are stored in the URL DP cache varies by hardware platform and the current URLs stored in the TRIE (data structure). A least recently used (LRU) mechanism is implemented in the DP cache in case the cache is full. If the cache becomes full, the URLs that have been accessed the least will be replaced by the newer URLs. Entries in the URL DP cache expire after a specified period of time and the expiration period cannot be changed by the administrator. |

## PAN-DB URL Categorization Workflow

When a user attempts to access a URL and the URL category needs to be determined, the firewall will compare the URL with the following components (in order) until a match has been found:



URL Categorization Resolution Process Flow

If a URL query matches an expired entry in the URL DP cache, the cache responds with the expired category, but also sends a URL categorization query to the management plane. This is done to avoid unnecessary delays in the DP, assuming that the frequency of changing categories is low. Similarly, in the URL MP cache, if a URL query from the DP matches an expired entry in the MP, the MP responds to the DP with the expired category and will also send a URL categorization request to the cloud service. Upon getting the response from the cloud, the firewall will resend the updated response to the DP.

As new URLs and categories are defined or if critical updates are needed, the cloud database will be updated. Each time the firewall queries the cloud for a URL lookup or if no cloud lookups have occurred for 30 minute, the database versions on the firewall be compared and if they do not match, an incremental update will be performed.

 © Palo Alto Networks, Inc.

# Enable a URL Filtering Vendor

To enable URL filtering on a firewall, you must purchase and activate a URL Filtering license for one of the supported URL Filtering Vendors and then install the database. Use one of the following procedures to enable a URL filtering license on the firewall set up the database. Only one URL filtering license can be active on a firewall.

Starting with PAN-OS 6.0, firewalls managed by Panorama do not need to be running the same URL filtering vendor that is configured on Panorama. For firewalls running PAN-OS 6.0 or later, when a mismatch is detected between the vendor enabled on the firewalls and what is enabled on Panorama, the firewalls can automatically migrate URL categories and/or URL profiles to (one or more) categories that align with that of the vendor enabled on it. For guidance on how to configure URL filtering Panorama if you are managing firewalls running different PAN-OS versions, refer to the Panorama Administrator's Guide.

If you have valid licenses for both PAN-DB and BrightCloud, activating the PAN-DB license automatically deactivates the BrightCloud license (and vice versa).

- Enable PAN-DB URL Filtering
- Enable BrightCloud URL Filtering

# Enable PAN-DB URL Filtering

| Enable PAN-DB URL Filtering | |
|---|---|
| Step 1 Obtain and install a PAN-DB URL filtering license and confirm that it is installed.<br><br>If the license expires, PAN-DB URL filtering continues to work based on the URL category information that exists in the dataplane and management plane caches. However, URL cloud lookups and other cloud-based updates will not function until you install a valid license. | 1. Select **Device > Licenses** and, in the **License Management** section, select the license installation method:<br>• **Activate feature using authorization code**<br>• **Retrieve license keys from license server**<br>• **Manually upload license key**<br>2. After installing the license, confirm that the PAN-DB URL Filtering section, **Date Expires** field, displays a valid date. |
| Step 2 Download the initial seed database and activate PAN-DB URL filtering.<br><br>The firewall must have Internet access; you cannot manually upload the PAN-DB. | 1. In the PAN-DB URL Filtering section, **Download Status** field, click **Download Now**.<br>2. Choose a region (North America, Europe, APAC, Japan) and then click **OK** to start the download.<br>3. After the download completes, click **Activate**.<br><br>If PAN-DB is already the active URL filtering vendor and you click **Re-Download**, this will reactivate PAN-DB by clearing the dataplane and management plane caches and replacing them with the contents of the new seed database. You should avoid doing this unless it is necessary, as you will lose your cache, which is customized based on the web traffic that has previously passed through the firewall based on user activity. |
| Step 3 Schedule the firewall to download dynamic updates for Applications and Threats.<br><br>A Threat Prevention license is required to receive content updates, which covers Antivirus and Applications and Threats. | 1. Select **Device > Dynamic Updates**.<br>2. In the Schedule field in the Applications and Threats section, click the **None** link to schedule periodic updates.<br><br>You can only schedule dynamic updates if the firewall has direct Internet access.If updates are already scheduled in a section, the link text displays the schedule settings.<br><br>The Applications and Threats updates might contain updates for URL filtering related to the **Safe Search Enforcement** option in the URL filtering profile (**Objects > Security Profiles > URL Filtering**). For example, if Palo Alto Networks adds support for a new search provider vendor or if the method used to detect the Safe Search setting for an existing vendor changes, the Application and Threats updates will include that update. |

© Palo Alto Networks, Inc.

# Enable BrightCloud URL Filtering

| Enable BrightCloud URL Filtering | | |
|---|---|---|
| Step 1 | Obtain and install a BrightCloud URL filtering license and confirm that it is installed.<br><br>BrightCloud has an option in the URL filtering profile (**Objects > Security Profiles > URL Filtering**) to either allow all categories or block all categories if the license expires. | 1. Select **Device > Licenses** and, in the **License Management** section, select the license installation method:<br>• **Activate feature using authorization code**<br>• **Retrieve license keys from license server**<br>• **Manually upload license key**<br>2. After installing the license, confirm that the BrightCloud URL Filtering section, **Date Expires** field, displays a valid date. |
| Step 2 | Install the BrightCloud database.<br><br>The way you do this depends on whether or not the firewall has direct Internet access. | **Firewall with Direct Internet Access**<br>In the **Device > Licenses** page, BrightCloud URL Filtering section, Active field, click the **Activate** link to install the BrightCloud database. This operation automatically initiates a system reset.<br>**Firewall without Direct Internet Access**<br>1. Download the BrightCloud database to a host that has Internet access. The firewall must have access to the host:<br>a. On a host with Internet access, go to the Palo Alto Support website (https://support.paloaltonetworks.com) and log in.<br>b. In the Resources section, click **Dynamic Updates**.<br>c. In the BrightCloud Database section, click **Download** and save the file to the host.<br>2. Upload the database to the firewall:<br>a. Log in to the firewall, select **Device > Dynamic Updates** and click **Upload**.<br>b. For the **Type**, select **URL Filtering**.<br>c. Enter the path to the **File** on the host or click **Browse** to find it, then click **OK**. When the Status is *Completed*, click **Close**.<br>3. Install the database:<br>a. In the **Device > Dynamic Updates** page, click **Install From File**.<br>b. For the **Type**, select **URL Filtering**. The firewall automatically selects the file you just uploaded.<br>c. Click **OK** and, when the Result is *Succeeded*, click **Close**. |
| Step 3 | Enable cloud lookups for dynamically categorizing a URL if the category is not available on the local BrightCloud database. | 1. Access the firewall CLI.<br>2. Enter the following commands to enable dynamic URL filtering:<br>`configure`<br>`set deviceconfig setting url dynamic-url yes`<br>`commit` |

| Enable BrightCloud URL Filtering (Continued) | | |
|---|---|---|
| Step 4 | Schedule the firewall to download dynamic updates for Applications and Threats signatures and URL filtering.<br><br>You can only schedule dynamic updates if the firewall has direct Internet access.<br><br>The Applications and Threats updates might contain updates for URL filtering related to the **Safe Search Enforcement** option in the URL filtering profile. For example, if Palo Alto Networks adds support for a new search provider vendor or if the method used to detect the Safe Search setting for an existing vendor changes, the Application and Threats updates will include that update.<br><br>BrightCloud updates include a database of approximately 20 million websites that are stored on the firewall drive. You must schedule the URL filtering updates to receive database updates.<br><br> A Threat Prevention license is required to receive content updates, which covers Antivirus and Applications and Threats. | 1. Select **Device > Dynamic Updates**.<br>2. In the Applications and Threats section, Schedule field, click the **None** link to schedule periodic updates.<br>3. In the URL Filtering section, Schedule field, click the **None** link to schedule periodic updates.<br><br> If updates are already scheduled in a section, the link text displays the schedule settings. |

 © Palo Alto Networks, Inc.

# Determine URL Filtering Policy Requirements

The recommended practice for deploying URL filtering in your organization is to first start with a passive URL filtering profile that will alert on most categories. After setting the alert action, you can then monitor user web activity for a few days to determine patterns in web traffic. After doing so, you can then make decisions on the websites and website categories that should be controlled.

In the procedure that follows, threat-prone sites will be set to block and the other categories will be set to alert, which will cause all websites traffic to be logged. This may potentially create a large amount of log files, so it is best to do this for initial monitoring purposes to determine the types of websites your users are accessing. After determining the categories that your company approves of, those categories should then be set to allow, which will not generate logs. You can also reduce URL filtering logs by enabling the **Log container page only** option in the URL Filtering profile, so only the main page that matches the category will be logged, not subsequent pages/categories that may be loaded within the container page.

| **Configure and Apply a Passive URL Filtering Profile** | | |
|---|---|---|
| Step 1 | Create a new URL Filtering profile. | 1. Select **Objects > Security Profiles > URL Filtering**.<br>2. Select the default profile and then click **Clone**. The new profile will be named **default-1**.<br>3. Select the **default-1** profile and rename it. For example, rename it to URL-Monitoring. |
| Step 2 | Configure the action for all categories to **alert**, except for threat-prone categories, which should remain blocked.<br> To select all items in the category list from a Windows system, click the first category, then hold down the shift key and click the last category—this will select all categories. Hold the control key (ctrl) down and click items that should be deselected. On a Mac, do the same using the shift and command keys. You could also just set all categories to alert and manually change the recommended categories back to block. | 1. In the section that lists all URL categories, select all categories.<br>2. To the right of the *Action* column heading, mouse over and select the down arrow and then select **Set Selected Actions** and choose **alert**.<br>  <br>3. To ensure that you block access to threat-prone sites, select the following categories and then set the action to **block**: abused-drugs, adult, gambling, hacking, malware. phishing, questionable, weapons.<br>4. Click **OK** to save the profile. |
| Step 3 | Apply the URL Filtering profile to the security policy rule(s) that allows web traffic for users. | 1. Select **Policies > Security** and select the appropriate security policy to modify it.<br>2. Select the **Actions** tab and in the **Profile Setting** section, click the drop-down for **URL Filtering** and select the new profile.<br>3. Click **OK** to save. |
| Step 4 | Save the configuration. | Click **Commit**. |

| Configure and Apply a Passive URL Filtering Profile (Continued) | | |
|---|---|---|
| Step 5 | View the URL filtering logs to determine all of the website categories that your users are accessing. In this example, some categories are set to block, so those categories will also appear in the logs.<br><br>For information on viewing the logs and generating reports, see Monitor Web Activity. | Select **Monitor > Logs > URL Filtering**. A log entry will be created for any website that exists in the URL filtering database that is in a category that is set to any action other than **allow**. |

© Palo Alto Networks, Inc.

# Monitor Web Activity

URL filtering logs and reports show all user web activity for URL categories that are set to **alert**, **block**, **continue**, or **override**. By monitoring the logs, you can gain a better understanding of the web activity of your user base to determine a web access policy.

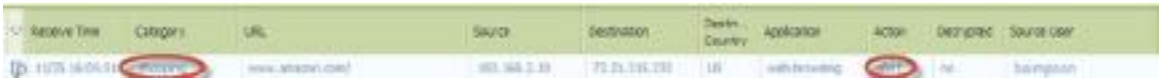
The following topics describe how to monitor web activity:

- Interpret the URL Filtering Logs
- Use the ACC to Monitor Web Activity
- View URL Filtering Reports
- Configure Custom URL Filtering Reports

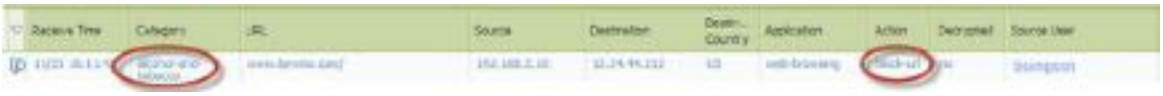
## Interpret the URL Filtering Logs

The following bullet points show examples of the URL filtering logs (**Monitor > Logs > URL filtering**).

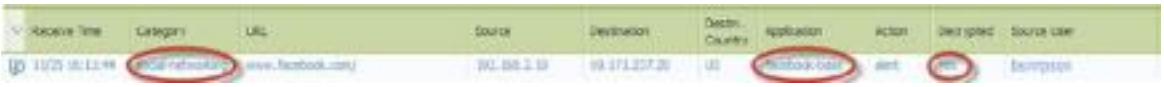
- **Alert log**—In this log, the category is shopping and the action is alert.



- **Block log**—In this log, the category alcohol-and-tobacco was set to block, so the action is block-url and the user will see a response page indicating that the website was blocked.



- **Alert log on encrypted website**—In this example, the category is social-networking and the application is facebook-base, which is required to access the Facebook website and other Facebook applications. Because faceboook.com is always encrypted using SSL, the traffic was decrypted by the firewall, which allows the website to be recognized and controlled if needed.



You can also add several other columns to your URL Filtering log view, such as: to and from zone, content type, and whether or not a packet capture was performed. To modify what columns to display, click the down arrow in any column and select the attribute to display.

 © Palo Alto Networks, Inc.

To view the complete log details and/or request a category change for the given URL that was accessed, click the log details icon in the first column of the log.

## Use the ACC to Monitor Web Activity

For a quick view of the most common categories being accessed in your environment, select the **ACC** tab and scroll down to the **URL Filtering** section. Along the top of this window, you can also set the time range, sort by option, and define how many results will appear. Here you will see the most popular categories that are accessed by your users, sorted by the most popular at the top of the list. In this example, computer-and-internet-info is the most accessed category, followed by private-ip-addresses (internal servers), and search-engines. In the drop-down in the upper right of the statistics, you can also choose to list by URL Categories, Blocked URL Categories, and Blocked URLs.

 © Palo Alto Networks, Inc.

## View URL Filtering Reports

To view the default URL filtering reports, select **Monitor > Reports** and under the **URL Filtering Reports** section, choose one of the reports. You can generate reports on URL Categories, URL users, Web Sites accessed, Blocked Categories, and more. The reports are based on a 24-hour period and the day is selected by choosing a day in the calendar section. You can also export the report to PDF, CSV, or XML.

## View the User Activity Report

This report provides a quick method of viewing user or group activity and also provides an option to view browse time activity.

| Generate a User Activity Report | |
|---|---|
| Step 1 Configure a User Activity Report | 1. Select **Monitor > PDF Reports > User Activity Report**.<br>2. Enter a report **Name** and select the report type. Select **User** to generate a report for one person, or select **Group** for a group of users.<br>You must Enable User-ID in order to be able to select user or group names. If User-ID is not configured, you can select the type **User** and enter the IP address of the user's computer.<br>3. Enter the Username/IP address for a user report or enter the group name for a user group report.<br>4. Select the time period. You can select an existing time period, or select **Custom**.<br>5. Select the **Include Detailed Browsing** check box, so browsing information is included in the report.<br> |
| Step 2 Run the user activity report and then download the report. | 1. Click **Run Now**.<br>2. After the report is generated, click the **Download User Activity Report** link.<br>  <br>3. After the report is downloaded, click **Cancel** and then click **OK** to save the report. |

 © Palo Alto Networks, Inc.

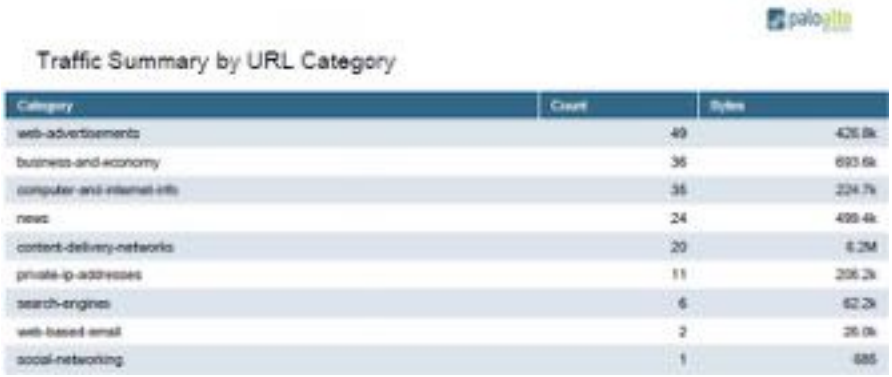
**Generate a User Activity Report (Continued)**

Step 3 View the user activity report by opening the PDF file that was downloaded. The top of the report will contain a table of contents similar to the following:

User Activity Report for 192.168.2.10
Tuesday, December 31, 2013 09:35:47 - 10:35:46

Application Usage 2
Traffic Summary by URL Category 3
Browsing Summary by URL Category 4
Browsing Summary by Website 5
Blocked Browsing Summary by Website 6
Detailed Web Browsing Activity 7

Step 4 Click an item in the table of contents to view details. For example, click *Traffic Summary by URL Category* to view statistics for the selected user or group.



Traffic Summary by URL Category

| Category | Count | Bytes |
|---|---|---|
| web-advertisements | 49 | 426.8k |
| business-and-economy | 36 | 693.6k |
| computer-and-internet-info | 35 | 224.7k |
| news | 24 | 499.4k |
| content-delivery-networks | 20 | 6.2M |
| private-ip-addresses | 11 | 206.2k |
| search-engines | 6 | 62.2k |
| web-based-email | 2 | 26.0k |
| social-networking | 1 | 686 |

## Configure Custom URL Filtering Reports

To generate a detailed report that can also be scheduled, you can configure a custom report and select from a list of all available URL filtering log fields.

| Configure a Custom URL Filtering Report | | |
|---|---|---|
| Step 1 | Add a new custom report. | 1. Select **Monitor > Manage Custom Reports** and click **Add**.<br>2. Enter a report **Name**, for example, My-URL-Custom-Report.<br>3. From the **Database** drop-down, select **URL Log**. |
| Step 2 | Configure report options. | 1. Select the **Time Frame** drop-down and select a range.<br>2. (Optional) To customize how the report is sorted and grouped, select **Sort By** and chose the number of items to display (top 25 for example) and then select **Group By** and select an option such as **Category**, and then select how many groups will be defined.<br>3. In the **Available Columns** list, select the fields to include the report. The following columns are typically used for a URL report:<br>• Action<br>• Category<br>• Destination Country<br>• Source User<br>• URL<br> |
| Step 3 | Run the report to check the results. If the results are satisfactory, set a schedule to run the report automatically. | 1. Click the **Run Now** icon to immediately generate the report that will appear in a new tab.<br>2. (Optional) Click the **Schedule** check box to run the report once per day. This will generate a daily report that details web activity over the last 24 hours. To access the report, select **Monitor > Report** and then expand **Custom Reports** on the right column and select the report. |
| Step 4 | Save the configuration. | Click **Commit**. |

© Palo Alto Networks, Inc.

# Configure URL Filtering

After you Determine URL Filtering Policy Requirements, you should have a basic understanding of what types of websites and website categories your users are accessing. With this information, you are now ready to create custom URL filtering profiles and attach them to the security policy rule(s) that allow web access.

| Configure Website Controls | | |
|---|---|---|
| Step 1 | Create a URL Filtering profile or select an existing one.<br> <br>Because the default URL filtering profile blocks risky and threat-prone content, it is a best practice to clone this profile rather than creating a new profile to preserve these default settings. | 1. Select **Objects > Security Profiles > URL Filtering**.<br>Select the default profile and then click **Clone**. The new profile will be named default-1.<br>2. Select the new profile and rename it. |
| Step 2 | Define how to control access to web content. | In the **Categories** tab, for each category that you want visibility into or control over, select a value from the **Action** column as follows:<br>• If you do not care about traffic to a particular category (that is you neither want to block it nor log it), select **allow**.<br>• For visibility into traffic to sites in a category, select **alert**.<br>• To deny access to traffic that matches the category and to enable logging of the blocked traffic, select **block**.<br>• To require users to click Continue to proceed to a questionable site, select **continue**.<br>• To only allow access if users provide a configured password, select override. For more details on this setting, see Configure URL Admin Override. |
| Step 3 | Define websites that should always be blocked or allowed.<br>For example, to reduce URL filtering logs, you may want add you corporate websites in the allow list, so no logs will be generated for those sites. Or, if there is a website this is being overly used and is not work related in any way, you can add it to the block list.<br>Items in the block list will always be blocked regardless of the action for the associated category, and URLs in the allow list will always be allowed.<br>For more information on the proper format and wildcards usage, see Block and Allow Lists. | 1. In the URL filtering profile, enter URLs or IP addresses in the **Block List** and select an action:<br>• **block**—Block the URL.<br>• **continue**—Prompt users click **Continue** to proceed to the web page.<br>• **override**—The user will be a prompted for a password to continue to the website.<br>• **alert**—Allow the user to access the website and add an alert log entry in the URL log.<br>2. For the **Allow** list, enter IP addresses or URLs that should always be allowed. Each row must be separated by a new line.<br>3. (Optional) Enable Safe Search Enforcement. |

| Configure Website Controls | | |
|---|---|---|
| Step 4 | Modify the setting to log Container Pages only. | The **Log container page only** option is enabled by default so that only the main page that matches the category is logged, not subsequent pages/categories that may be loaded within the container page. To enable logging for all pages/categories, clear the **Log container page only** check box. |
| Step 5 | Enable HTTP Header Logging for one or more of the supported HTTP header fields. | To log an HTTP header field, select one or more of the following fields to log:<br>• **User-Agent**<br>• **Referer**<br>• **X-Forwarded-For** |
| Step 6 | Save the URL filtering profile. | Click **OK**. |
| Step 7 | (Optional) Enable response pages on the ingress interface (the interface that first receives traffic for your users).<br>This option is required if you enable the **continue** or **override** action for any URL category.<br> You can also Customize the URL Filtering Response Pages. | 1. Select **Network > Network Profiles > Interface Mgmt** and either add a new profile or edit an existing profile.<br>2. Click the **Response Pages** check box to enable.<br>3. Click **OK** to save the profile.<br>4. Select **Network > Interfaces** and then edit the Layer 3 interface or VLAN interface that is your ingress interface.<br>5. On the **Advanced** tab, select the Interface Mgmt profile that has the response page option enabled.<br>6. Click **OK** to save the interface configuration. |
| Step 8 | Save the configuration.<br> To test the URL filtering configuration, simply access a website in a category that is set to block or continue to see if the appropriate action is performed. | Click **Commit**. |

 © Palo Alto Networks, Inc.

# Log Client IP Addresses for Proxied HTTP/HTTPS Requests

If you have a proxy server deployed between the users on your network and the firewall, the firewall might identify the proxy server IP address as the source IP address in the traffic that the proxy forwards rather than the IP address of the client that requested the content. In many cases, the proxy server adds an X-Forwarded-For (XFF) header to the traffic packets that includes the IP address of the source client. In such cases, if you want to identify the client that requested the content, you must configure the firewall to log the XFF values. This enables the firewall to get the client IP address, the username if available, the IP address of the last proxy server traversed in a proxy chain, or any string that the field stores. You can then use this information to monitor web access on your network.

You can configure the firewall to log XFF values in the following ways:

- Replace Source IP Addresses with XFF Values in URL Filtering Logs
- Add XFF Values to URL Filtering Logs

## Replace Source IP Addresses with XFF Values in URL Filtering Logs

You can configure the firewall to replace the value in the source IP address field of URL Filtering logs with the XFF values of web request packets. The XFF values can be the IP address of the client that originated the request or, in a proxy chain, the IP address of the last proxy server that processed the request. To ensure that attackers can't read and exploit the XFF values when packets exit the firewall to retrieve content from an external server, you can also configure the firewall to strip the XFF values from outgoing packets. These options are not mutually exclusive: if you configure both, the firewall zeroes out the XFF values only after logging them.

| **Replace Source IP Addresses with XFF Values in URL Filtering Logs** | | |
|---|---|---|
| Step 1 | Enable logging of XFF values. | 1. Select **Device > Setup > Content-ID** and edit the URL Filtering section.<br>2. Select the **x-forwarded-for** check box. |
| Step 2 | Remove XFF values from outgoing web requests. | 1. Select the **Strip x-forwarded-for** check box.<br>2. Click **OK** and **Commit**. |
| Step 3 | Verify the firewall is logging XFF values. | 1. Select **Monitor > Logs > URL Filtering**.<br>2. Verify that the IP addresses in the Source column reflect the XFF values. |

## Add XFF Values to URL Filtering Logs

You can configure the firewall to add the XFF field values of web requests to URL Filtering logs. The XFF value can be a client IP address, a username if available, or any value of up to 128 characters that the field stores.

This method of logging XFF values doesn't replace the source IP address values in URL Filtering logs. When you view the logs, the source field displays the IP address of the proxy server if one is deployed between the user clients and the firewall.

| Add XFF Values to URL Filtering Logs | | |
|---|---|---|
| Step 1 | Configure a URL Filtering profile. | 1. Select **Objects > Security Profiles > URL Filtering**.<br>2. Select an existing profile or **Add** a new profile and enter a descriptive **Name**.<br>You can't enable XFF logging in the default URL Filtering profile.<br>3. In the **Categories** tab, define how to control access to web content. For each category that you want visibility into or control over, select a value in the **Action** column:<br>• If you don't care about traffic to a particular category (that is you neither want to block it nor log it), select **Allow**.<br>• For visibility into traffic to sites in a category, select **Alert**.<br>• To deny access to traffic that matches the category and to enable logging of the blocked traffic, select **Block**.<br>4. Select the **Settings** tab and select the **X-Forwarded-For** check box.<br>5. Click **OK** to save the profile. |
| Step 2 | Attach the URL Filtering profile to a policy rule. | 1. Select **Policies > Security** and click the rule.<br>2. Select the **Actions** tab, set the **Profile Type** to **Profiles**, and select the **URL Filtering** profile you just created.<br>3. Click **OK** and **Commit**. |
| Step 3 | Verify the firewall is logging XFF values. | 1. Select **Monitor > Logs > URL Filtering**.<br>2. Display the XFF values in one of the following ways:<br>• To display the XFF value for a single log—Click the icon for the log to displays its details. The HTTP Headers section displays the X-Forwarded-For value.<br>• To display the XFF values for all logs—Open the drop-down in any column header, select **Columns**, and select the **X-Forwarded-For** check box. The page then displays an X-Forwarded-For column. |

© Palo Alto Networks, Inc.

# Customize the URL Filtering Response Pages

The firewall provides three predefined URL Filtering Response Pages that display by default when a user attempts to browse to a site in a category that is configured with one of the block actions in the URL Filtering Profile (block, continue, or override) or when Safe Search Enforcement blocks a search attempt. However, you can create your own custom response pages with your corporate branding, acceptable use policies, links to your internal resources as follows:

| **Customize the URL Filtering Response Pages** | | |
|---|---|---|
| Step 1 | Export the default response page(s). | 1. Select **Device > Response Pages**.<br>2. Select the link for the URL filtering response page you want to modify.<br>3. Click the response page (predefined or shared) and then click the **Export** link and save the file to your desktop. |
| Step 2 | Edit the exported page. | 1. Using the HTML text editor of your choice, edit the page:<br>• If you want the response page to display custom information about the specific user, URL, or category that was blocked, add one or more of the supported URL Filtering Response Page Variables.<br>• If you want to include custom images (such as your corporate logo), a sound, or style sheet, or link to another URL, for example to a document detailing your acceptable web use policy, include one or more of the supported Response Page References.<br>2. Save the edited page with a new filename. Make sure that the page retains its UTF-8 encoding. For example, in Notepad you would select **UTF-8** from the **Encoding** drop-down in the Save As dialog. |
| Step 3 | Import the customized response page. | 1. Select **Device > Response Pages**.<br>2. Select the link that corresponds to the URL Filtering response page you edited.<br>3. Click **Import** and then enter the path and filename in the **Import File** field or **Browse** to locate the file.<br>4. (Optional) Select the virtual system on which this login page will be used from the **Destination** drop-down or select **shared** to make it available to all virtual systems.<br>5. Click **OK** to import the file. |
| Step 4 | Save the new response page(s). | **Commit** the changes. |
| Step 5 | Verify that the new response page displays. | From a browser, go to the URL that will trigger the response page. For example, to see a modified URL Filtering and Category Match response page, browse to URL that your URL filtering policy is set to block. |

# Configure URL Admin Override

In some cases there may be URL categories that you want to block, but allow certain individuals to browse to on occasion. In this case, you would set the category action to **override** and define a URL admin override password in the firewall Content-ID configuration. When users attempt to browse to the category, they will be required to provide the override password before they are allowed access to the site. Use the following procedure to configure URL admin override:

| **Configure URL Admin Override** | |
|---|---|
| Step 1 Set the URL admin override password. | 1. Select **Device > Setup > Content ID**.<br>2. In the **URL Admin Override** section, click **Add**.<br>3. In the **Location** field, select the virtual system to which this password applies.<br>4. Enter the **Password** and **Confirm Password**.<br>5. Select a **Server Certificate** for the firewall to present to the user if the site with the override is an HTTPS site.<br>6. Select the **Mode** for prompting the user for the password:<br>• **Transparent**—The firewall intercepts the browser traffic destined for site in a URL category you have set to override and impersonates the original destination URL, issuing an HTTP 401 to prompt for the password. Note that the client browser will display certificate errors if it does not trust the certificate.<br>• **Redirect**—The firewall intercepts HTTP or HTTPS traffic to a URL category set to override and redirects the request to a Layer 3 interface on the firewall using an HTTP 302 redirect in order to prompt for the override password. If you select this option, you must provide the **Address** (IP address or DNS hostname) to which to redirect the traffic.<br>7. Click **OK**. |
| Step 2 (Optional) Set a custom override period. | 1. Edit the URL Filtering section.<br>2. To change the amount of time users can browse to a site in a category for which they have successfully entered the override password, enter a new value in the **URL Admin Override Timeout** field. By default, users can access sites within the category for 15 minutes without re-entering the password.<br>3. To change the amount of time users are blocked from accessing a site set to override after three failed attempts to enter the override password, enter a new value in the **URL Admin Lockout Timeout** field. By default, users are blocked for 30 minutes.<br>4. Click **OK**. |

© Palo Alto Networks, Inc.

| Configure URL Admin Override (Continued) | | |
|---|---|---|
| Step 3 | (Redirect mode only) Create a Layer 3 interface to which to redirect web requests to sites in a category configured for override. | 1. Create a management profile to enable the interface to display the URL Filtering Continue and Override Page response page:<br>a. Select **Network > Interface Mgmt** and click **Add**.<br>b. Enter a **Name** for the profile, select **Response Pages**, and then click **OK**.<br>2. Create the Layer 3 interface. Be sure to attach the management profile you just created (on the **Advanced > Other Info** tab of the Ethernet Interface dialog). |
| Step 4 | (Redirect mode only) To transparently redirect users without displaying certificate errors, install a certificate that matches the IP address of the interface to which you are redirecting web requests to a site in a URL category configured for override.You can either generate a self-signed certificate or import a certificate that is signed by an external CA. | To use a self-signed certificate, you must first create a root CA certificate and then use that CA to sign the certificate you will use for URL admin override as follows:<br>1. To create a root CA certificate, select **Device > Certificate Management > Certificates > Device Certificates** and then click **Generate**. Enter a **Certificate Name**, such as RootCA. Do not select a value in the **Signed By** field (this is what indicates that it is self-signed). Make sure you select the **Certificate Authority** check box and then click **Generate** the certificate.<br>2. To create the certificate to use for URL admin override, click **Generate**. Enter a **Certificate Name** and enter the DNS hostname or IP address of the interface as the **Common Name**. In the **Signed By** field, select the CA you created in the previous step. Add an IP address attribute and specify the IP address of the Layer 3 interface to which you will be redirecting web requests to URL categories that have the override action.<br>3. **Generate** the certificate.<br>4. To configure clients to trust the certificate, select the CA certificate on the **Device Certificates** tab and click **Export**. You must then import the certificate as a trusted root CA into all client browsers, either by manually configuring the browser or by adding the certificate to the trusted roots in an Active Directory Group Policy Object (GPO). |
| Step 5 | Specify which URL categories require an override password to enable access. | 1. Select **Objects > URL Filtering** and either select an existing URL filtering profile or **Add** a new one.<br>2. On the **Categories** tab, set the Action to **override** for each category that requires a password.<br>3. Complete any remaining sections on the URL filtering profile and then click **OK** to save the profile. |
| Step 6 | Apply the URL Filtering profile to the security policy rule(s) that allows access to the sites requiring password override for access. | 1. Select **Policies > Security** and select the appropriate security policy to modify it.<br>2. Select the **Actions** tab and in the **Profile Setting** section, click the drop-down for **URL Filtering** and select the profile.<br>3. Click **OK** to save. |
| Step 7 | Save the configuration. | Click **Commit**. |

# Enable Safe Search Enforcement

Many search engines have a safe search setting that filters out adult images and videos for search query return traffic. You can configure Safe Search Enforcement the Palo Alto Networks next-generation firewall to prevent search requests that do not have the strictest safe search settings enabled.

The Safe Search Enforcement for Google and YouTube Searches using a Virtual IP Address is not compatible with Safe Search Enforcement on the firewall.

There are two ways to enforce Safe Search on the firewall:

- Block Search Results that are not Using Strict Safe Search Settings
- Enable Transparent Safe Search Enforcement

## Block Search Results that are not Using Strict Safe Search Settings

By default, when you enable safe search enforcement, when a user attempts to perform a search without using the strictest safe search settings, the firewall will block the search query results and display the URL Filtering Safe Search Block Page. This page provides a link to the search settings page for the corresponding search provider so that the end user can enable the safe search settings. If you plan to use this default method for enforcing safe search, you should communicate the policy to your end users prior to deploying the policy. See Table: Search Provider Safe Search Settings for details on how each search provider implements safe search. The default URL Filtering Safe Search Block Page provides a link to the search settings for the corresponding search provider. You can optionally Customize the URL Filtering Response Pages.

Alternatively, to enable safe search enforcement so that it is transparent to your end users, configure the firewall to Enable Transparent Safe Search Enforcement.

 © Palo Alto Networks, Inc.

| Enable Safe Search Enforcement | | |
|---|---|---|
| Step 1 | Enable Safe Search Enforcement in the URL Filtering profile. | 1. Select **Objects > Security Profiles > URL Filtering**.<br>2. Select an existing profile to modify, or clone the default profile to create a new profile.<br>3. On the **Settings** tab, select the **Safe Search Enforcement** check box to enable it.<br>4. (Optional) Restrict users to specific search engines:<br>a. On the **Categories** tab, set the **search-engines** category to **block**.<br>b. For each search engine that you want end users to be able to access, enter the web address in the **Allow List** text box. For example, to allow users access to Google and Bing searches only, you would enter the following:<br>`www.google.com`<br>`www.bing.com`<br>5. Configure other settings as necessary to:<br>• Define how to control access to web content.<br>• Define websites that should always be blocked or allowed.<br>6. Click **OK** to save the profile. |
| Step 2 | Add the URL Filtering profile to the security policy rule that allows traffic from clients in the trust zone to the Internet. | 1. Select **Policies > Security** and select a rule to which to apply the URL filtering profile that you just enabled for Safe Search Enforcement.<br>2. On the **Actions** tab, select the **URL Filtering** profile.<br>3. Click **OK** to save the security policy rule. |
| Step 3 | Enable SSL Forward Proxy decryption.<br>Because most search engines encrypt their search results, you must enable SSL forward proxy decryption so that the firewall can inspect the search traffic and detect the safe search settings. | 1. Add a custom URL category for the search sites:<br>a. Select **Objects > Custom Objects > URL Category** and **Add** a custom category.<br>b. Enter a **Name** for the category, such as SearchEngineDecryption.<br>c. **Add** the following to the Sites list:<br>`www.bing.*`<br>`www.google.*`<br>`search.yahoo.*`<br>d. Click **OK** to save the custom URL category object.<br>2. Follow the steps to Configure SSL Forward Proxy.<br>3. On the **Service/URL Category** tab in the Decryption policy rule, **Add** the custom URL category you just created and then click **OK**. |

| Enable Safe Search Enforcement (Continued) | | |
|---|---|---|
| Step 4 | (Optional, but recommended) Block Bing search traffic running over SSL.<br><br>Because the Bing SSL search engine does not adhere to the safe search settings, for full safe search enforcement, you must deny all Bing sessions that run over SSL. | 1. Add a custom URL category for Bing:<br>a. Select **Objects > Custom Objects > URL Category** and **Add** a custom category.<br>b. Enter a **Name** for the category, such as EnableBingSafeSearch.<br>c. **Add** the following to the Sites list:<br>`www.bing.com/images/*`<br>`www.bing.com/videos/*`<br>d. Click **OK** to save the custom URL category object.<br>2. Create another URL filtering profile to block the custom category you just created:<br>a. Select **Objects > Security Profiles > URL Filtering**.<br>b. **Add** a new profile and give it a descriptive **Name**.<br>c. Locate the custom category in the Category list and set it to **block**.<br>d. Click **OK** to save the URL filtering profile.<br>3. Add a security policy rule to block Bing SSL traffic:<br>a. Select **Policies > Security** and **Add** a policy rule that allows traffic from your trust zone to the Internet.<br>b. On the **Actions** tab, attach the URL filtering profile you just created to block the custom Bing category.<br>c. On the **Service/URL Category** tab **Add** a **New Service** and give it a descriptive **Name**, such as bingssl.<br>d. Select **TCP** as the **Protocol** and set the **Destination Port** to `443`.<br>e. Click **OK** to save the rule.<br>f. Use the **Move** options to ensure that this rule is below the rule that has the URL filtering profile with safe search enforcement enabled. |
| Step 5 | Save the configuration. | Click **Commit**. |

© Palo Alto Networks, Inc.

**Enable Safe Search Enforcement (Continued)**

| | |
|---|---|
| Step 6 Verify the Safe Search Enforcement configuration.<br><br>This verification step only works if you are using block pages to enforce safe search. If you are using transparent safe search enforcement, the firewall block page will invoke a URL rewrite with the safe search parameters in the query string. | 1. From a computer that is behind the firewall, disable the strict search settings for one of the supported search providers. For example, on bing.com, click the **Preferences** icon on the Bing menu bar.<br><br>  <br><br>2. Set the **SafeSearch** option to **Moderate** or **Off** and click **Save**.<br>3. Perform a Bing search and verify that the URL Filtering Safe Search Block page displays instead of the search results:<br><br> <br><br><br>4. Use the link in the block page to go to the search settings for the search provider and set the safe search setting back to the strictest setting (**Strict** in the case of Bing) and then click **Save**.<br>5. Perform a search again from Bing and verify that the filtered search results display instead of the block page. |

## Enable Transparent Safe Search Enforcement

If you want to enforce filtering of search query results with the strictest safe search filters, but you don't want your end users to have to manually configure the settings, you can enable transparent Safe Search Enforcement as follows. This functionality is supported on Google, Yahoo, and Bing search engines only and requires Content Release version 475 or later.

| **Enable Transparent Safe Search Enforcement** | | |
|---|---|---|
| Step 1 | Make sure the firewall is running Content Release version 475 or later. | 1. Select **Device > Dynamic Updates**.<br>2. Check the **Applications and Threats** section to determine what update is currently running.<br>3. If the firewall is not running the required update or later, click **Check Now** to retrieve a list of available updates.<br>4. Locate the required update and click **Download**.<br>5. After the download completes, click **Install**. |
| Step 1 | Enable Safe Search Enforcement in the URL Filtering profile. | 1. Select **Objects > Security Profiles > URL Filtering**.<br>2. Select an existing profile to modify, or clone the default profile to create a new one.<br>3. On the **Settings** tab, select the **Safe Search Enforcement** check box to enable it.<br>4. (Optional) Allow access to specific search engines only:<br>a. On the **Categories** tab, set the **search-engines** category to **block**.<br>b. For each search engine that you want end users to be able to access, enter the web address in the **Allow List** text box. For example, to allow users access to Google and Bing searches only, you would enter the following:<br>`www.google.com`<br>`www.bing.com`<br>5. Configure other settings as necessary to:<br>• Define how to control access to web content.<br>• Define websites that should always be blocked or allowed.<br>6. Click **OK** to save the profile. |
| Step 2 | Add the URL Filtering profile to the security policy rule that allows traffic from clients in the trust zone to the Internet. | 1. Select **Policies > Security** and select a rule to which to apply the URL filtering profile that you just enabled for Safe Search Enforcement.<br>2. On the **Actions** tab, select the **URL Filtering** profile.<br>3. Click **OK** to save the security policy rule. |

© Palo Alto Networks, Inc.

| Enable Transparent Safe Search Enforcement (Continued) | | |
|---|---|---|
| Step 3 | (Optional, but recommended) Block Bing search traffic running over SSL.<br><br>Because the Bing SSL search engine does not adhere to the safe search settings, for full safe search enforcement, you must deny all Bing sessions that run over SSL. | 1. Add a custom URL category for Bing:<br>a. Select **Objects > Custom Objects > URL Category** and **Add** a custom category.<br>b. Enter a **Name** for the category, such as EnableBingSafeSearch.<br>c. **Add** the following to the Sites list:<br>`www.bing.com/images/*`<br>`www.bing.com/videos/*`<br>d. Click **OK** to save the custom URL category object.<br>2. Create another URL filtering profile to block the custom category you just created:<br>a. Select **Objects > Security Profiles > URL Filtering**.<br>b. **Add** a new profile and give it a descriptive **Name**.<br>c. Locate the custom category you just created in the Category list and set it to **block**.<br>d. Click **OK** to save the URL filtering profile.<br>3. **Add** a security policy rule to block Bing SSL traffic:<br>a. Select **Policies > Security** and **Add** a policy rule that allows traffic from your trust zone to the Internet.<br>b. On the **Actions** tab, attach the URL filtering profile you just created to block the custom Bing category.<br>c. On the **Service/URL Category** tab **Add** a **New Service** and give it a descriptive **Name**, such as bingssl.<br>d. Select **TCP** as the **Protocol**, set the **Destination Port** to `443`.<br>e. Click **OK** to save the rule.<br>f. Use the **Move** options to ensure that this rule is below the rule that has the URL filtering profile with safe search enforcement enabled. |
| Step 4 | Edit the URL Filtering Safe Search Block Page, replacing the existing code with the Javascript for rewriting search query URLs to enforce safe search transparently.<br><br> For a script that you can copy and paste, go here. | 1. Select **Device > Response Pages > URL Filtering Safe Search Block Page**.<br>2. Select **Predefined** and then click **Export** to save the file locally.<br>3. Use an HTML editor and replace all of the existing block page text with the following text and then save the file: |

**Enable Transparent Safe Search Enforcement (Continued)**

```

<script>

    // Grab the URL that's in the browser.
    var s_u = location.href;

    //bing
    // Matches the forward slashes in the beginning, anything, then ".bing." then anything followed by a non
greedy slash. Hopefully the first forward slash.
    var b_a = /^.*\/\/(.+\.bing\..+?)\//.exec(s_u);

    if (b_a) {

        s_u = s_u + "&adlt=strict";
        window.location.replace(s_u);
        document.getElementById("java_off").innerHTML = 'You are being redirected to a safer search!';

    }

    //google
    // Matches the forward slashes in the beginning, anything, then ".google." then anything followed by a non
greedy slash. Hopefully the first forward slash.
    var g_a = /^.*\/\/(.+\.google\..+?)\//.exec(s_u);

    if (g_a) {

     s_u = s_u.replace(/&safe=off/ig,"");
        s_u = s_u + "&safe=active";
        window.location.replace(s_u);
        document.getElementById("java_off").innerHTML = 'You are being redirected to a safer search!';

    }

    //yahoo
    // Matches the forward slashes in the beginning, anything, then ".yahoo."" then anything followed by a non
greedy slash. Hopefully the first forward slash.
    var y_a = /^.*\/\/(.+\.yahoo\..+?)\//.exec(s_u);
    if (y_a) {

        s_u = s_u.replace(/&vm=p/ig,"");
        s_u = s_u + "&vm=r";
        window.location.replace(s_u);
        document.getElementById("java_off").innerHTML = 'You are being redirected to a safer search!';
    }
    document.getElementById("java_off").innerHTML = ' ';

    </script>
</html>
```

 © Palo Alto Networks, Inc.

| Enable Transparent Safe Search Enforcement (Continued) | | |
|---|---|---|
| Step 5 | Import the edited URL Filtering Safe Search Block page onto the firewall. | 1. To import the edited block page, select **Device > Response Pages > URL Filtering Safe Search Block Page**.<br>2. Click **Import** and then enter the path and filename in the **Import File** field or **Browse** to locate the file.<br>3. (Optional) Select the virtual system on which this login page will be used from the **Destination** drop-down or select **shared** to make it available to all virtual systems.<br>4. Click **OK** to import the file. |
| Step 6 | Enable SSL Forward Proxy decryption.<br><br>Because most search engines encrypt their search results, you must enable SSL forward proxy decryption so that the firewall can inspect the search traffic and detect the safe search settings. | 1. Add a custom URL category for the search sites:<br>a. Select **Objects > Custom Objects > URL Category** and **Add** a custom category.<br>b. Enter a **Name** for the category, such as SearchEngineDecryption.<br>c. **Add** the following to the Sites list:<br>`www.bing.*`<br>`www.google.*`<br>`search.yahoo.*`<br>d. Click **OK** to save the custom URL category object.<br>2. Follow the steps to Configure SSL Forward Proxy.<br>3. On the **Service/URL Category** tab in the Decryption policy rule, **Add** the custom URL category you just created and then click **OK**. |
| Step 7 | Save the configuration. | Click **Commit**. |

# URL Filtering Use Case Examples

The following use cases show how to use App-ID to control a specific set of web-based applications and how to use URL categories as match criteria in a policy. When working with App-ID, it is important to understand that each App-ID signature may have dependencies that are required to fully control an application. For example, with Facebook applications, the App-ID facebook-base is required to access the Facebook website and to control other Facebook applications. For example, to configure the firewall to control Facebook email, you would have to allow the App-IDs facebook-base and facebook-mail. As another example, if you search Applipedia (the App-ID database) for LinkedIn, you will see that in order to control LinkedIn mail, you need to apply the same action to both App-IDs: linkedin-base and linkedin-mail. To determine application dependencies for App-ID signatures, visit Applipedia, search for the given application, and then click the application for details.

The User-ID feature is required to implement policies based on users and groups and a Decryption policy is required to identify and control websites that are encrypted using SSL.

This section includes two uses cases:

- Use Case: Control Web Access
- Use Case: Use URL Categories in Policy

 © Palo Alto Networks, Inc.

## Use Case: Control Web Access

When using URL filtering to control user website access, there may be instances where granular control is required for a given website. In this use case, a URL filtering policy is applied to the security policy that allows web access for your users and the *social-networking* URL category is set to block, but the allow list in the URL profile is configured to allow the social networking site Facebook. To further control Facebook, the company policy also states that only marketing has full access to Facebook and all other users within the company can only read Facebook posts and cannot use any other Facebook applications, such as email, posting, chat, and file sharing. To accomplish this requirement, App-ID must be used to provide granular control over Facebook.

The first security rule will allow marketing to access the Facebook website as well as all Facebook applications. Because this allow rule will also allow access to the Internet, threat prevention profiles are applied to the rule, so traffic that matches the policy will be scanned for threats. This is important because the allow rule is terminal and will not continue to check other rules if there is a traffic match.

| **Control Web Access** | | |
|---|---|---|
| Step 1 | Confirm that URL filtering is licensed. | 1. Select **Device > Licenses** and confirm that a valid date appears for the URL filtering database that will used. This will either be PAN-DB or BrightCloud.<br>2. If a valid license is not installed, see Enable PAN-DB URL Filtering. |
| Step 2 | Confirm that User-ID is working. User-ID is required to create policies based on users and groups. | 1. To check group mapping, from the CLI, enter the following command:<br>`show user group-mapping statistics`<br>2. To check user mapping, from the CLI, enter the following command:<br>`show user ip-user-mapping-mp all`<br>3. If statistics do not appear and/or IP to user mapping information is not displayed, see User-ID. |
| Step 3 | Set up a URL filtering profile by cloning the default profile. | 1. Select **Objects > Security Profiles > URL Filtering** and select the **default** profile.<br>2. Click the **Clone** icon. A new profile should appear named **default-1**.<br>3. Select the new profile and rename it. |

| Control Web Access (Continued) | | |
|---|---|---|
| Step 4 | Configure the URL filtering profile to block social-networking and allow Facebook. | 1. Modify the new URL filtering profile and in the **Category** list scroll to **social-networking** and in the **Action** column click on **allow** and change the action to **block**.<br>2. In the **Allow List** box, type `facebook.com`, press enter to start a new line and then type `*.facebook.com`. Both of these formats are required, so all URL variants a user may use will be identified, such as facebook.com, www.facebook.com, and https://facebook.com.<br>  <br>3. Click **OK** to save the profile. |
| Step 5 | Apply the new URL filtering profile to the security policy rule that allows web access from the user network to the Internet. | 1. Select **Policies > Security** and click on the policy rule that allows web access.<br>2. On the **Actions** tab, select the URL profile you just created from the **URL Filtering** drop-down.<br>  <br>3. Click **OK** to save. |

© Palo Alto Networks, Inc.

**Control Web Access (Continued)**

Step 6 Create the security policy that will allow marketing access the Facebook website and all Facebook applications.

This rule must precede other rules because it is more specific than the other policies and because it is an allow rule, which will terminate when a traffic match occurs.

1. Select **Policies > Security** and click **Add**.
2. Enter a **Name** and optionally a **Description** and **Tag**(s).
3. On the **Source** tab add the zone where the users are connected.
4. On the **User** tab in the **Source User** section click **Add**.
5. Select the directory group that contains your *marketing* users.
6. On the **Destination** tab, select the zone that is connected to the Internet.
7. On the **Applications** tab, click **Add** and add the *facebook* App-ID signature.
8. On the **Actions** tab, add the default profiles for **Antivirus**, **Vulnerability Protection**, and **Anti-Spyware**.

9. Click **OK** to save the security profile.

   The *facebook* App-ID signature used in this policy encompasses all Facebook applications, such as facebook-base, facebook-chat, and facebook-mail, so this is the only App-ID signature required in this rule.

   With this policy in place, when a marketing employee attempts to access the Facebook website or any Facebook application, the rule matches based on the user being part of the marketing group. For traffic from any user outside of marketing, the rule will be skipped because there would not be a traffic match and rule processing would continue.

| Control Web Access (Continued) | |
|---|---|
| Step 7 Configure the security policy to block all other users from using any Facebook applications other than simple web browsing. The easiest way to do this is to clone the marketing allow policy and then modify it. | 1. From **Policies > Security** click the marketing Facebook allow policy you created earlier to highlight it and then click the **Clone** icon.<br>2. Enter a **Name** and optionally enter a **Description** and **Tag**('s).<br>3. On the **User** tab highlight the marketing group and delete it and in the drop-down select **any**.<br>4. On the **Applications** tab, click the *facebook* App-ID signature and delete it.<br>5. Click **Add** and add the following App-ID signatures:<br>• facebook-apps<br>• facebook-chat<br>• facebook-file-sharing<br>• facebook-mail<br>• facebook-posting<br>• facebook-social-plugin<br>6. On the **Actions** tab in the **Action Setting** section, select **Deny**. The profile settings should already be correct because this rule was cloned. |
| | <br>7. Click **OK** to save the security profile.<br>8. Ensure that this new deny rule is listed after the marketing allow rule, to ensure that rule processing occurs in the correct order to allow marketing users and then to deny/limit all other users.<br>9. Click **Commit** to save the configuration. |

With these policies in place, any user who is part of the marketing group will have full access to all Facebook applications and any user that is not part of the marketing group will only have read-only access to the Facebook website and will not be able to use Facebook functions such as post, chat, email, and file sharing.

 © Palo Alto Networks, Inc.

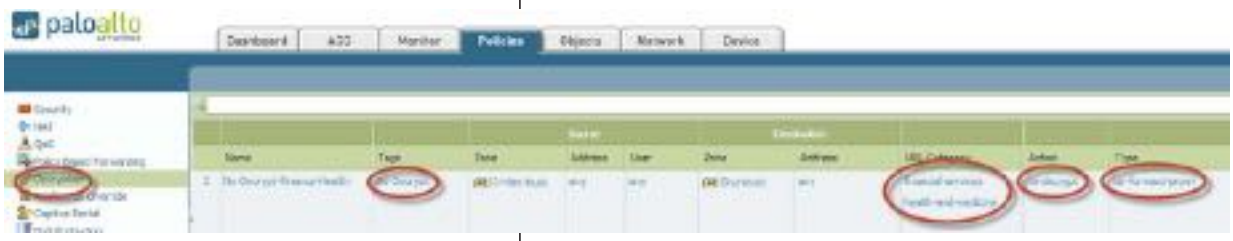
## Use Case: Use URL Categories in Policy

URL categories can also be used as match criteria in the following policy types: captive portal, decryption, security, and QoS. In this use case, URL categories will be used in decryption policies to control which web categories should be decrypted or not decrypted. The first rule is a no-decrypt rule that will not decrypt user traffic if the website category is *financial-services* or *health-and-medicine* and the second rule will decrypt all other traffic. The decryption policy type is *ssl-forward-proxy*, which is used for controlling decryption for all outbound connections performed by users.

**Configure a Decryption Policy Based on URL Category**

Step 1 Create the no-decrypt rule that will be listed first in the decryption policies list. This will prevent any website that is in the *financial-services* or *health-and-medicine* URL categories from being decrypted.

1. Select **Policies > Decryption** and click **Add**.
2. Enter a **Name** and optionally enter a **Description** and **Tag**(s).
3. On the **Source** tab, add the zone where the users are connected.
4. On the **Destination** tab, enter the zone that is connected to the Internet.
5. On the **URL Category** tab, click **Add** and select the *financial-services* and *health-and-medicine* URL categories.
6. On the **Options** tab, set the action to **No Decrypt** and the **Type** to **SSL Forward Proxy**.



7. Click **OK** to save the policy.

| Configure a Decryption Policy Based on URL Category (Continued) | |
|---|---|
| Step 2 Create the decryption policy that will decrypt all other traffic. This policy will be listed after the no-decrypt policy. | 1. Select the no-decrypt policy you created previously and then click **Clone**.<br>2. Enter a **Name** and optionally enter a **Description** and **Tag**(s).<br>3. On the **URL Category** tab, select *financial-services* and *health-and-medicine* and then click the **Delete** icon.<br>4. On the **Options** tab, set the action to **Decrypt** and the **Type** to **SSL Forward Proxy**. |
| |  <br>5. Ensure that this new decryption rule is listed after the no-decrypt rule as shown in the previous screen capture. This will ensure that rule processing occurs in the correct order, so websites in the *financial-services* and *health-and-medicine* are not decrypted<br>6. Click **OK** to save the policy. |
| Step 3 (BrightCloud only) Enable cloud lookups for dynamically categorizing a URL when the category is not available on the local database on the firewall. | 1. Access the CLI on the firewall.<br>2. Enter the following commands to enable Dynamic URL Filtering:<br>a. **configure**<br>b. **set deviceconfig setting url dynamic-url yes**<br>c. commit |
| Step 4 Save the configuration. | Click **Commit**. |

With these two decrypt policies in place, any traffic destined for the *financial-services* or *health-and-medicine* URL categories will not be decrypted. All other traffic will be decrypted.

You can also define more granular control over decryption policies by defining decryption profiles, which are used to perform checks such as server certificate checks or blocking sessions with expired certificates. The profile is then added in the **Options** tab of the decryption policy. For a complete list of checks that can be performed, select **Objects > Decryption Profiles** from the firewall and then click the help icon.

Now that you have a basic understanding of the powerful features of URL filtering, App-ID, and User-ID, you can apply similar policies to your firewall to control any application in the Palo Alto Networks App-ID signature database and control any website contained in the URL filtering database.

For help in troubleshooting URL filtering issues, see Troubleshoot URL Filtering.

 © Palo Alto Networks, Inc.

# Troubleshoot URL Filtering

The following topics provide troubleshooting guidelines for diagnosing and resolving common URL filtering problems.

- Problems Activating PAN-DB
- PAN-DB Cloud Connectivity Issues
- URLs Classified as Not-Resolved
- Incorrect Categorization
- URL Database Out of Date

## Problems Activating PAN-DB

The following table describes procedures that you can use to resolve issues with activating PAN-DB.

| Troubleshoot PAN-DB Activation Issues |
|---|
| 1. Access the CLI on the firewall. |
| 2. Verify whether PAN-DB has been activated by running the following command:<br>`admin@PA-200> show system setting url-database`<br>If the response is `paloaltonetworks`, then PAN-DB is the active vendor. |
| 3. Verify that the firewall has a valid PAN-DB license by running the following command:<br>`admin@PA-200> request license info`<br>You should see the license entry Feature: PAN_DB URL Filtering. If the license is not installed, you will need to obtain and install a license. See Configure URL Filtering. |
| 4. After the license is installed, download a new PAN-DB seed database by running the following command:<br>`admin@PA-200> request url-filtering download paloaltonetworks region <region>` |
| 5. Check the download status by running the following command:<br>`admin@PA-200> request url-filtering download status vendor paloaltonetworks`<br>• If the message is different from `PAN-DB download: Finished successfully`, stop here; there may be a problem connecting to the cloud. Attempt to solve the connectivity issue by performing basic network troubleshooting between the firewall and the Internet. For more information, see PAN-DB Cloud Connectivity Issues.<br>• If the message is `PAN-DB download: Finished successfully`, the firewall successfully downloaded the URL seed database. Try to enable PAN-DB again by running the following command:<br>`admin@PA-200> set system setting url-database paloaltonetworks` |
| 6. If the problems persists, contact Palo Alto Networks support. |

## PAN-DB Cloud Connectivity Issues

To check cloud connectivity, run the following command:

```
admin@pa-200> show url-cloud status
```

If the cloud is accessible, the expected response is similar to the following:

```
admin@PA-200> show url-cloud status
PAN-DB URL Filtering
License :                          valid
Current cloud server :             s0000.urlcloud.paloaltonetworks.com
Cloud connection :                 connected
URL database version - device :    2013.11.18.000
URL database version - cloud :     2013.11.18.000  ( last update time
2013/11/19
 13:20:51 )
URL database status :              good
URL protocol version - device :    pan/0.0.2
URL protocol version - cloud :     pan/0.0.2
Protocol compatibility status :    compatible
```

If the cloud is note accessible, the expected response is similar to the following:

```
admin@PA-200> show url-cloud status
PAN-DB URL Filtering
License :                          valid
Cloud connection :                 not connected
URL database version - device :    2013.11.18.000
URL database version - cloud :     2013.11.18.000  ( last update time
2013/11/19
 13:20:51 )
URL database status :              good
URL protocol version - device :    pan/0.0.2
URL protocol version - cloud :     pan/0.0.2
Protocol compatibility status :    compatible
```

 © Palo Alto Networks, Inc.

The following table describes procedures that you can use to resolve issues based on the output of the show url-cloud status command, how to ping the URL cloud servers, and what to check if the firewall is in a High Availability (HA) configuration.

**Troubleshoot Cloud Connectivity Issues**

- PAN-DB URL Filtering license field shows invalid—Obtain and install a valid PAN-DB license.
- URL database status is out of date—Download a new seed database by running the following command:

  ```
  admin@pa-200> request url-filtering download paloaltonetworks region <region>
  ```
- URL protocol version shows not compatible—Upgrade PAN-OS to the latest version.
- Attempt to ping the PAN-DB cloud server from the firewall by running the following command:

  ```
  admin@pa-200> ping source <ip-address> host s0000.urlcloud.paloaltonetworks.com
  ```
  For example, if your management interface IP address is 10.1.1.5, run the following command:
  ```
  admin@pa-200> ping source 10.1.1.5 host s0000.urlcloud.paloaltonetworks.com
  ```
- If the firewall is in an HA configuration, verify that the HA state of the devices supports connectivity to the cloud systems. You can determine the HA state by running the following command:

  ```
  admin@pa-200> show high-availability state
  ```
  Connection to the cloud will be blocked if the firewall is not in one of the following states:
  - active
  - active-primary
  - active-secondary

If the problem persists, contact Palo Alto Networks support.

## URLs Classified as Not-Resolved

The following table describes procedures you can use to resolve issues where some or all of the URLs being identified by PAN-DB are classified as *Not-resolved*:

**Troubleshoot URLs Classified as Not-Resolved**

1. Check the PAN-DB cloud connection by running the following command:

   ```
   admin@PA-200> show url-cloud status
   ```
   The Cloud connection: field should show *connected*. If you see anything other than *connected*, any URL that do not exist in the management plane cache will be categorized as *not-resolved*. To resolve this issue, see PAN-DB Cloud Connectivity Issues.
2. If the cloud connection status shows *connected*, check the current utilization of the firewall. If the firewall's performance is spiking, URL requests may be dropped (may not reach the management plane), and will be categorized as *not-resolved*.

   To view system resources, run the following command and view the *%CPU* and *%MEM* columns:

   ```
   admin@PA-200> show system resources
   ```
   You can also view system resources from the firewall's web interfaces by clicking the **Dashboard** tab and viewing the **System Resources** section.
3. If the problem persist, contact Palo Alto Networks support.

## Incorrect Categorization

The following steps describe the procedures you can use if you identify a URL that does not have the correct categorization. For example, if the URL *paloaltonetworks.com* was categorized as *alcohol-and-tobacco*, the categorization is not correct; the category should be *computer-and-internet-info*.

**Troubleshoot Incorrect Categorization Issues**

1. Verify the category in the dataplane by running the following command:

   `admin@PA-200>` show running url <*URL*>

   For example, to view the category for the Palo Alto Networks website, run the following command:

   ```
   admin@PA-200> show running url paloaltonetworks.com
   ```

   If the URL stored in the dataplane cache has the correct category (computer-and-internet-info in this example), then the categorization is correct and no further action is required. If the category is not correct, continue to the next step.

2. Verify if the category in the management plane by running the command:

   `admin@PA-200> test url-info-host` <*URL*>

   For example:

   ```
   admin@PA-200> test url-info-host paloaltonetworks.com
   ```

   If the URL stored in the management plane cache has the correct category, remove the URL from the dataplane cache by running the following command:

   `admin@PA-200> clear url-cache url` <*URL*>

   The next time the device requests the category for this URL, the request will be forwarded to the management plane. This will resolve the issue and no further action is required. If this does not solve the issue, go to the next step to check the URL category on the cloud systems.

3. Verify the category in the cloud by running the following command:

   `admin@PA-200> test url-info-cloud <URL>`

4. If the URL stored in the cloud has the correct category, remove the URL from the dataplane and the management plane caches.

   Run the following command to delete a URL from the dataplane cache:

   ```
   admin@PA-200> clear url-cache url <URL>
   ```

   Run the following command to delete a URL from the management plane cache:

   ```
   admin@PA-200> delete url-database url <URL>
   ```

   The next time the device queries for the category of the given URL, the request will be forwarded to the management plane and then to the cloud. This should resolve the category lookup issue. If problems persist, see the next step to submit a categorization change request.

5. To submit a change request from the web interface, go to the URL log and select the log entry for the URL you would like to have changed.

 © Palo Alto Networks, Inc.

**Troubleshoot Incorrect Categorization Issues**

6. Click the **Request Categorization** change link and follow instructions. You can also request a category change from the Palo Alto Networks Test A Site website by searching for the URL and then clicking the **Request Change** icon. To view a list of all available categories with descriptions of each category, refer to https://urlfiltering.paloaltonetworks.com/CategoryList.aspx.

   If your change request is approved, you will receive an email notification. You then have two options to ensure that the URL category is updated on the firewall:

   - Wait until the URL in the cache expires and the next time the URL is accessed by a user, the new categorization update will be put in the cache.
   - Run the following command to force an update in the cache:

     ```
     admin@PA-200> request url-filtering update url <URL>
     ```

## URL Database Out of Date

If you have observed through the syslog or the CLI that PAN-DB is out-of-date, it means that the connection from the firewall to the URL Cloud is blocked. This usually occurs when the URL database on the firewall is too old (version difference is more than three months) and the cloud cannot update the firewall automatically. In order to resolve this issue, you will need to re-download an initial seed database from the cloud (this operation is not blocked). This will result in an automatic re-activation of PAN-DB.

To manually update the database, perform one of the following steps:

- From the web interface, select **Device > Licenses** and in the **PAN-DB URL Filtering** section click the **Re-Download** link.
- From the CLI, run the following command:

  ```
  admin@PA-200> request url-filtering download paloaltonetworks region <region_name>
  ```

When the seed database is re-download, the URL cache in the management plane and dataplane will be purged. The management plane cache will then be re-populated with the contents of the new seed database.

 © Palo Alto Networks, Inc.

# Quality of Service

Quality of Service (QoS) is a set of technologies that work on a network to guarantee its ability to dependably run high-priority applications and traffic under limited network capacity. QoS technologies accomplish this by providing differentiated handling and capacity allocation to specific flows in network traffic. This enables the network administrator to assign the order in which traffic is handled, and the amount of bandwidth afforded to traffic.

Palo Alto Networks Application Quality of Service (QoS) provides basic QoS applied to networks and extends it to provide QoS to applications and users.

Use the following topics to learn about and configure Palo Alto Networks Application QoS:

- QoS Overview
- QoS Concepts
- Configure QoS
- Configure QoS for a Virtual System
- QoS Use Case Examples

- You can use the Palo Alto Networks product comparison tool to view the QoS features supported on your firewall platform. Select two or more product platforms and click **Compare Now** to view QoS feature support for each platform (for example, you can check if your firewall platform supports QoS on subinterfaces and if so, the maximum number of subinterfaces that QoS can be enabled on).
- The PA-7050 firewall supports QoS on Aggregate Ethernet (AE) interfaces as of PAN-OS 6.0.0.

# QoS Overview

Use QoS to prioritize and adjust quality aspects of network traffic. You can assign the order in which packets are handled and allot bandwidth, ensuring preferred treatment and optimal levels of performance are afforded to selected traffic, applications, and users.

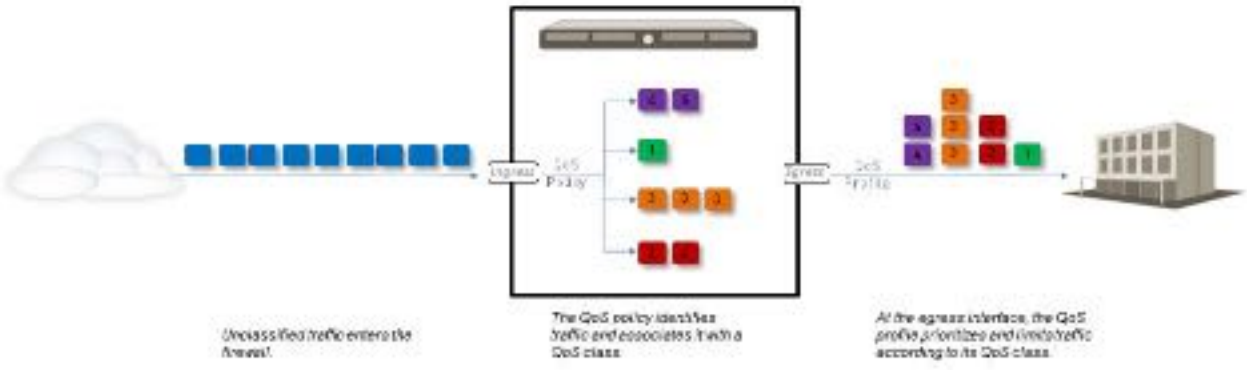
Service quality measurements subject to a QoS implementation are bandwidth (maximum rate of transfer), throughput (actual rate of transfer), latency (delay), and jitter (variance in latency). The capability to shape and control these service quality measurements makes QoS of particular importance to high-bandwidth, real-time traffic such as voice over IP (VoIP), video conferencing, and video-on-demand that has a high sensitivity to latency and jitter. Additionally, use QoS to achieve outcomes such as the following:

- Prioritize network and application traffic, guaranteeing high priority to important traffic or limiting non-essential traffic.
- Achieve equal bandwidth sharing among different subnets, classes, or users in a network.
- Allocate bandwidth externally or internally or both, applying QoS to both upload and download traffic or to only upload or download traffic.
- Ensure low latency for customer and revenue-generating traffic in an enterprise environment.
- Perform traffic profiling of applications to ensure bandwidth usage.

QoS implementation on a Palo Alto Networks firewall begins with three primary configuration components that support a full QoS solution: a QoS Profile, a QoS Policy, and setting up the QoS Egress Interface. Each of these options in the QoS configuration task facilitate a broader process that optimizes and prioritizes the traffic flow and allocates and ensures bandwidth according to configurable parameters.

The figure Figure: QoS Traffic Flow shows traffic as it flows from the source, is shaped by the firewall with QoS enabled, and is ultimately prioritized and delivered to its destination.

**Figure: QoS Traffic Flow**



The QoS configuration options allow you to control the traffic flow and define it at different points in the flow. The Figure: QoS Traffic Flow indicates where the configurable options define the traffic flow. Use the QoS Profile to define QoS classes and use the QoS Policy to associate QoS classes with selected traffic. Enable the QoS Profile on an interface to shape traffic according to the QoS configuration as it flows through the network.

 © Palo Alto Networks, Inc.

You can configure a QoS Profile and QoS Policy individually or in any order, according to your preference. Each of the QoS configuration options has components that influence the definition of the other options and the QoS configuration options can be used to create a full and granular QoS policy or can be used sparingly with minimal administrator action.

Each firewall model supports a maximum number of ports that can be configured with QoS. Refer to the spec sheet for your firewall model or use the product comparison tool to view QoS feature support for two or more firewalls on a single page.

# QoS Concepts

Use the following topics to learn about the different components and mechanisms of a QoS configuration on a Palo Alto Networks firewall:

- QoS for Applications and Users
- QoS Profile
- QoS Classes
- QoS Policy
- QoS Egress Interface
- QoS Cleartext and Tunneled Traffic

## QoS for Applications and Users

A Palo Alto Networks firewall provides basic QoS, controlling traffic leaving the firewall according to network or subnet, and extends the power of QoS to also classify and shape traffic according to application and user. The Palo Alto Networks firewall provides this capability by integrating the features App-ID and User-ID with the QoS configuration. App-ID and User-ID entries that exist to identify specific applications and users in your network are available in the QoS configuration so that you can easily specify applications and users to apply QoS to.

You can use a QoS Policy in the web interface (**Policies** > **QoS**) to apply QoS specifically to an application's traffic:

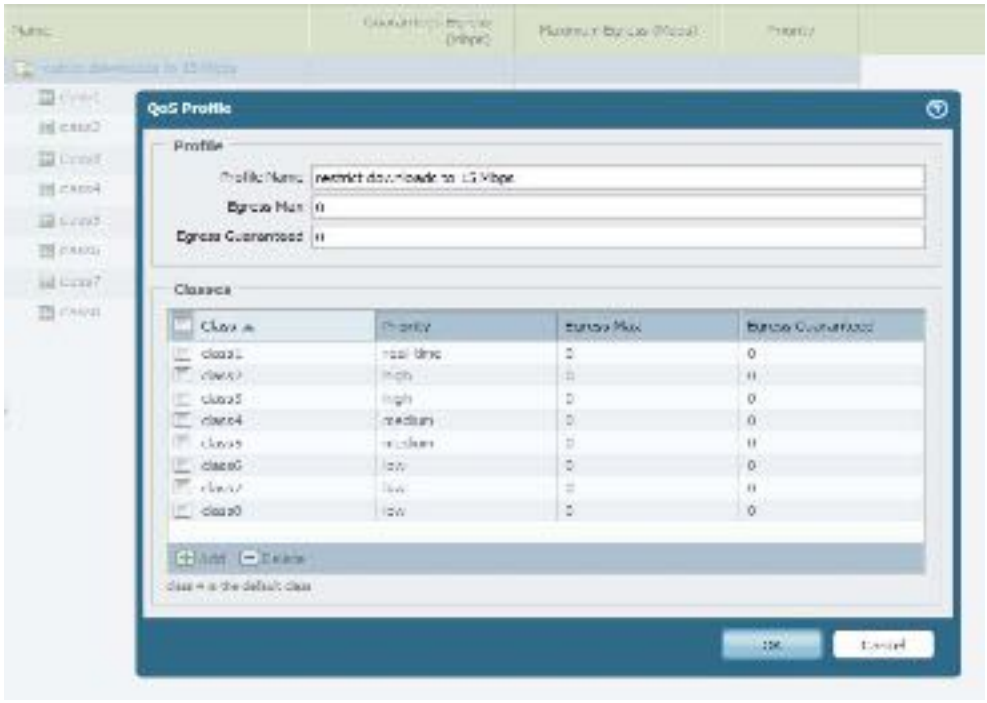
Or to a user's traffic:

See App-ID and User-ID for more information on these features.

© Palo Alto Networks, Inc.

## QoS Profile

Use a QoS profile to define values of up to eight QoS classes contained within that single profile (**Network** > **Network Profiles** > **QoS Profile**):



You enable QoS by applying a QoS profile to the egress interface for network, application or user traffic (or specifically, for cleartext or tunneled traffic). An interface configured with QoS shapes traffic according to the QoS profile class definitions and the traffic associated with those classes in the QoS policy.

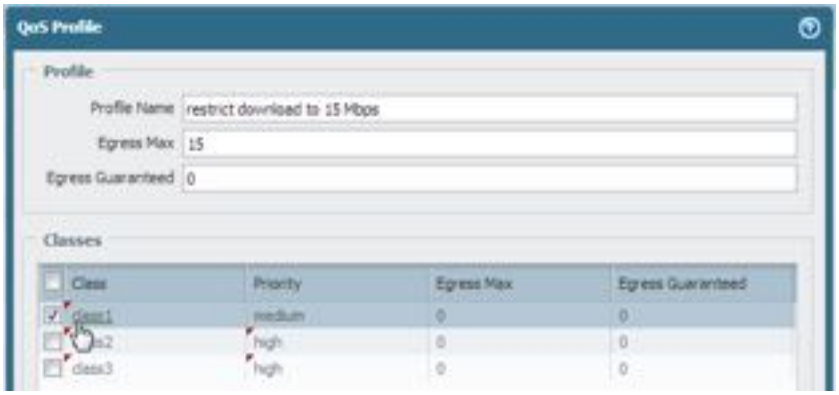
A default QoS Profile is available on the firewall. The default profile and the classes defined in the profile do not have predefined maximum or guaranteed bandwidth limits.

You can set bandwidth limits for a QoS profile and/or set limits for individual QoS classes within the QoS profile. The total guaranteed bandwidth limits of all eight QoS classes in a QoS Profile cannot exceed the total bandwidth allocated to that QoS Profile. Enabling QoS on a physical interface includes setting the maximum bandwidth for traffic leaving the firewall through this interface. A QoS profile's guaranteed bandwidth (the **Egress Guaranteed** field) should not exceed the bandwidth allocated to the physical interface that QoS is enabled on.

For details, see Create a QoS profile.

## QoS Classes

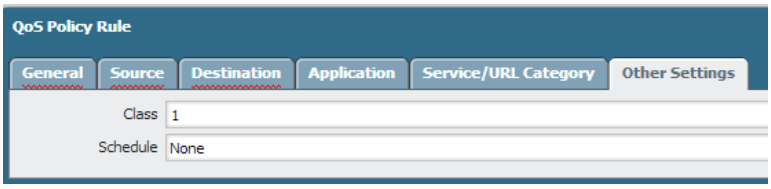
A QoS class determines the priority and bandwidth for traffic it is assigned to. In the web interface, use the QoS profile to define QoS classes (**Network** > **Network Profiles** > **QoS Profile**):



Defining a QoS class includes setting the class's Priority, maximum bandwidth (Egress Max), and guaranteed bandwidth (Egress Guaranteed).

Real-time priority is typically used for applications that are particularly sensitive to latency, such as voice and video applications.

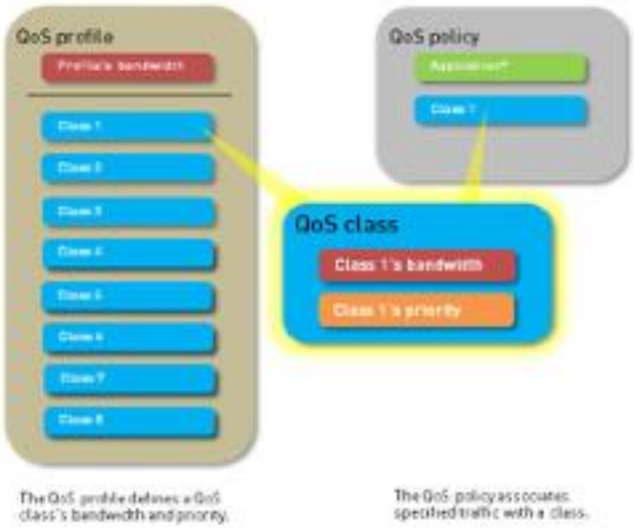
Use the QoS policy to assign a QoS class to specified traffic (**Policies** > **QoS**):



There are up to eight definable QoS classes in a single QoS profile. Unless otherwise configured, traffic that does not match a QoS class is assigned a class of 4.

QoS priority queuing and bandwidth management, the fundamental mechanisms of a QoS configuration, are configured within the QoS class definition (see Step 3). Queuing priority is determined by the priority set for a QoS class. Bandwidth management is determined according to the maximum and guaranteed bandwidths set for a QoS class.

 © Palo Alto Networks, Inc.



The queuing and bandwidth management mechanisms determine the order of traffic and how traffic is handled upon entering or leaving a network:

- **QoS Priority:** One of four QoS priorities can be defined in a QoS class: real-time, high, medium, and low. When a QoS class is associated with specific traffic, the priority defined in that QoS class is assigned to the traffic. Packets in the traffic flow are then queued according to their priority until the network is ready to process them. This method of priority queuing provides the capability to ensure that important traffic, applications, or users takes precedence.
- **QoS Class Bandwidth Management:** QoS class bandwidth management provides the capability to control traffic flows on a network so that traffic does not exceed network capacity, resulting in network congestion, or to allocate specific bandwidth limits to traffic, applications, or users. You can set overall limits on bandwidth using the QoS profile or set limits for individual QoS classes. A QoS profile and QoS classes in the profile have guaranteed and maximum bandwidth limits. The guaranteed bandwidth limit (Egress Guaranteed) ensures that any amount of traffic up to that set bandwidth limit is processed. The maximum bandwidth limit (Egress Max) sets the total limit of bandwidth allocated to either the QoS Profile or QoS Class. Traffic in excess of the Maximum Bandwidth limit is dropped. The total bandwidth limits and guaranteed bandwidth limits of QoS classes in a QoS profile cannot exceed the bandwidth limit of the QoS profile.

## QoS Policy

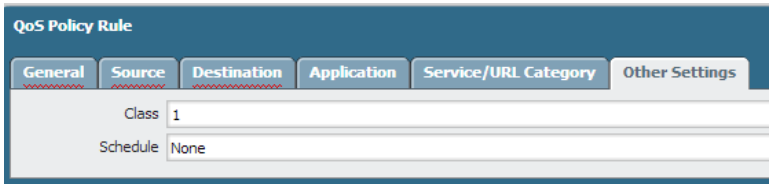
In a QoS configuration, the QoS policy identifies traffic requiring QoS treatment (either preferential treatment or bandwidth-limiting) using a defined parameter or multiple parameters and assigns it a class.

Use the QoS Policy, similar to a security policy, to set the criteria that identifies traffic:

- Applications and application groups.
- Source zones, source addresses, and source users.
- Destination zones and destination addresses.

- Services and service groups limited to specific TCP and/or UDP port numbers.
- URL categories, including custom URL categories.

The QoS Policy in the web interface (**Policies** > **QoS**) allows you to associate the criteria used to specify traffic with a QoS class.



## QoS Egress Interface

Enabling a QoS profile on the egress interface of the traffic identified for QoS treatment completes a QoS configuration. The ingress interface for QoS traffic is the interface on which the traffic enters the firewall. The egress interface for QoS traffic is the interface that traffic leaves the firewall from. QoS is always enabled and enforced on a traffic flow's egress interface. The egress interface in a QoS configuration can either be the external- or internal-facing interface of the firewall, depending on the flow of the traffic receiving QoS treatment.

For example, in an enterprise network, if you are limiting employees' download traffic from a specific website, the egress interface in the QoS configuration is the firewall's internal interface, as the traffic flow is from the Internet, through the firewall, and to your company network. Alternatively, when limiting employees' upload traffic to the same website, the egress interface in the QoS configuration is the firewall's external interface, as the traffic you are limiting flows from your company network, through the firewall, and then to the Internet.

See Step 3 to learn how to Identify the egress interface for applications that you identified as needing QoS treatment.

 © Palo Alto Networks, Inc.

## QoS Cleartext and Tunneled Traffic

Within the QoS physical interface configuration, you can provide more granular QoS settings for cleartext traffic and tunneled traffic leaving through the interface. Individual tunnel interfaces can be assigned different QoS Profiles. Cleartext traffic can be assigned different QoS Profiles according to traffic's source interface and source subnet. In this case, a source interface and source subnet can be associated with a QoS Profile. If you choose not to select cleartext or tunneled traffic for unique QoS treatment, enabling QoS on an interface requires selecting a default QoS Profile to determine how to shape traffic for specific tunnel interfaces or, in the case of cleartext traffic, source interfaces and source subnets.

On Palo Alto Networks firewalls, the term "tunneled traffic" refers to tunnel interface traffic, specifically IPSec traffic in tunnel mode.

# Configure QoS

Use the following task to configure Quality of Service (QoS), including how to create a QoS profile, create a QoS policy, and enable QoS on an interface.

| Configure QoS | | |
|---|---|---|
| Step 1 | Identify the traffic to which to apply QoS.<br><br>This example shows how to use QoS to limit web browsing. | Select **ACC** to view the **Application Command Center** page. Use the settings and charts on the **ACC** page to view trends and traffic related to Applications, URL filtering, Threat Prevention, Data Filtering, and HIP Matches.<br><br>Click any application name to display detailed application information. |
| Step 2 | Identify the egress interface for applications that you identified as needing QoS treatment.<br><br>**Tip:** The egress interface for traffic depends on the traffic flow. If you are shaping incoming traffic, the egress interface is the internal-facing interface. If you are shaping outgoing traffic, the egress interface is the external-facing interface. | Select **Monitor > Logs > Traffic** to view the device's traffic logs.<br><br>To filter and only show logs for a specific application:<br>• If an entry is displayed for the application, click the underlined link in the Application column then click the Submit icon.<br>• If an entry is not displayed for the application, click the Add Log icon and search for the application.<br><br>The **Egress I/F** in the traffic logs displays each application's egress interface. To display the **Egress I/F** column if it is not displayed by default:<br>• Click any column header to add a column to the log:<br>  <br><br>• Click the spyglass icon to the left of any entry to display a detailed log that includes the application's egress interface listed in the Destination section:<br> <br><br>In this example, the egress interface for web-browsing traffic is ethernet 1/1. |

 © Palo Alto Networks, Inc.

**Configure QoS (Continued)**

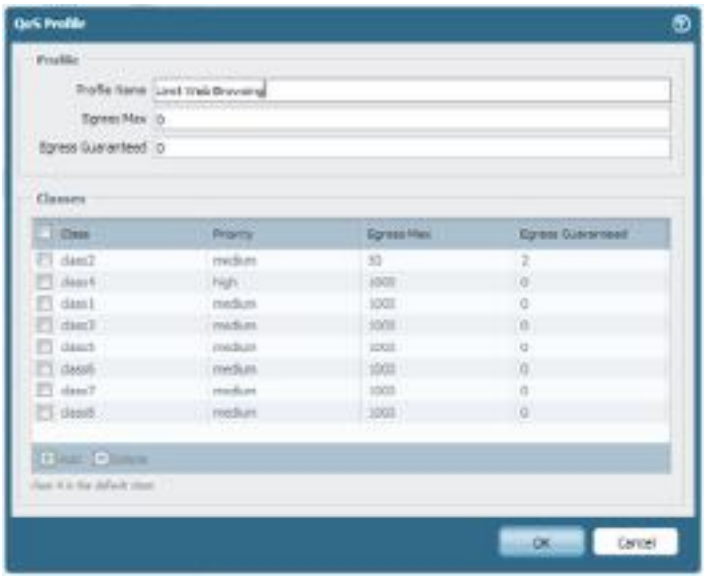
Step 3 Create a QoS profile.

You can edit any existing QoS profile, including the default, by clicking the QoS profile name.

1. Select **Network > Network Profiles > QoS Profile** and click **Add** to open the **QoS Profile** dialog.
2. Enter a descriptive **Profile Name**.
3. Enter an **Egress Max** to set the overall bandwidth allocation for the QoS Profile.
4. Enter an **Egress Guaranteed** to set the guaranteed bandwidth for the QoS Profile.

   Any traffic that exceeds the QoS Profile's egress guaranteed limit is best effort but is not guaranteed.
5. In the Classes section, specify how to treat up to eight individual QoS classes:
   a. Click **Add** to add a class to the QoS Profile.
   b. Select the **Priority** for the class.
   c. Enter an **Egress Max** for a class to set the overall bandwidth limit for that individual class.
   d. Enter an **Egress Guaranteed** for the class to set the guaranteed bandwidth for that individual class.
6. Click **OK** to save the QoS Profile.

In the following example, the QoS Profile named Limit Web Browsing limits traffic identified as Class 2 traffic to maximum bandwidth of 50 Mbps and a guaranteed bandwidth of 2 Mbps. Any traffic that is associated with class 2 in a the QoS policy (Step 4) is subject to these limits.



| Configure QoS (Continued) | |
|---|---|
| Step 4 Create a QoS policy. | 1. Select **Policies > QoS** and click **Add** to open the QoS Policy Rule dialog.<br>2. On the **General** tab, give the QoS Policy Rule a descriptive **Name**.<br>3. Specify the traffic to which the QoS Policy Rule will apply. Use the **Source**, **Destination**, **Application**, and **Service/URL Category** tabs to define matching parameters for identifying traffic.<br>For example, select the **Application** tab, click **Add** and select web-browsing to apply the QoS Policy Rule to that application:<br> <br>(Optional) Define additional parameters. For example, on the **Source** tab, click **Add** to limit a specific user's web-browsing, in this case, user1:<br>  <br>4. On the **Other Settings** tab, select a QoS Class to assign to the QoS Policy Rule. For example, assign Class 2 to the user1's web-browsing traffic:<br> <br>5. Click **OK** to save the QoS Policy Rule. |

© Palo Alto Networks, Inc.

**Configure QoS (Continued)**

Step 5 Enable the QoS Profile on a physical interface.

You can configure settings to select cleartext and tunneled traffic for unique QoS treatment, in addition to the QoS configuration on the physical interface:

To configure specific settings for cleartext traffic using traffic's source interface and source subnet as criteria for QoS identification and treatment, perform Step 5 - 4.

To apply a QoS profile to a specific tunnel interface(s), perform Step 5 - 5

For more information, see QoS Cleartext and Tunneled Traffic.

Check if the platform you're using supports enabling QoS on a sub-interface by reviewing a summary of the Product Specifications.

It is a best practice to always define the **Egress Max** value for a QoS interface.

1. Select **Network > QoS** and click **Add** to open the QoS Interface dialog.
2. Enable QoS on the physical interface:
   a. On the **Physical Interface** tab, select the **Interface Name** of the interface to apply the QoS Profile to.

      In the example, Ethernet 1/1 is the egress interface for web-browsing traffic (see Step 2).

   b. Select **Turn on QoS feature on this interface**.
3. On the **Physical Interface** tab, select a QoS profile to apply by default to all **Clear Text** traffic.

   (Optional) Use the Tunnel Interface field to apply a QoS profile by default to all tunneled traffic.

For example, enable QoS on ethernet 1/1 and apply the QoS Profile named Limit Web Browsing as the default QoS Profile for clear text traffic.

4. (Optional) On the **Clear Text Traffic** tab, configure more granular QoS settings for cleartext traffic:
   - Set the **Egress Guaranteed** and **Egress Max** bandwidths for clear text traffic.
   - Click **Add** to apply a QoS Profile to selected clear text traffic, further selecting the traffic for QoS treatment according to source interface and source subnet (creating a QoS node).
5. (Optional) On the **Tunneled Traffic** tab, configure more granular QoS settings for tunnel interfaces:
   - Set the **Egress Guaranteed** and **Egress Max** bandwidths for tunneled traffic.
   - Click **Add** to associate a selected tunnel interface with a QoS Profile.
6. Click **OK** to save the QoS Profile.
7. **Commit** the changes to enable the QoS Profile on the interface.

| Configure QoS (Continued) | |
|---|---|
| Step 6 Verify QoS configuration. | Select **Network > QoS** to view the **QoS Policies** page and click the **Statistics** link to view QoS bandwidth, active sessions of a selected QoS node or class, and active applications for the selected QoS node or class.<br>For example, see the statistics for ethernet 1/1 with QoS enabled:<br>  <br>Class 2 traffic limited to 2 Mbps of guaranteed bandwidth and a maximum bandwidth of 50 Mbps.<br>Continue to click the tabs to display further information regarding applications, source users, destination users, security rules and QoS rules.<br>Bandwidth limits shown on the **QoS Statistics** window include a hardware adjustment factor. |

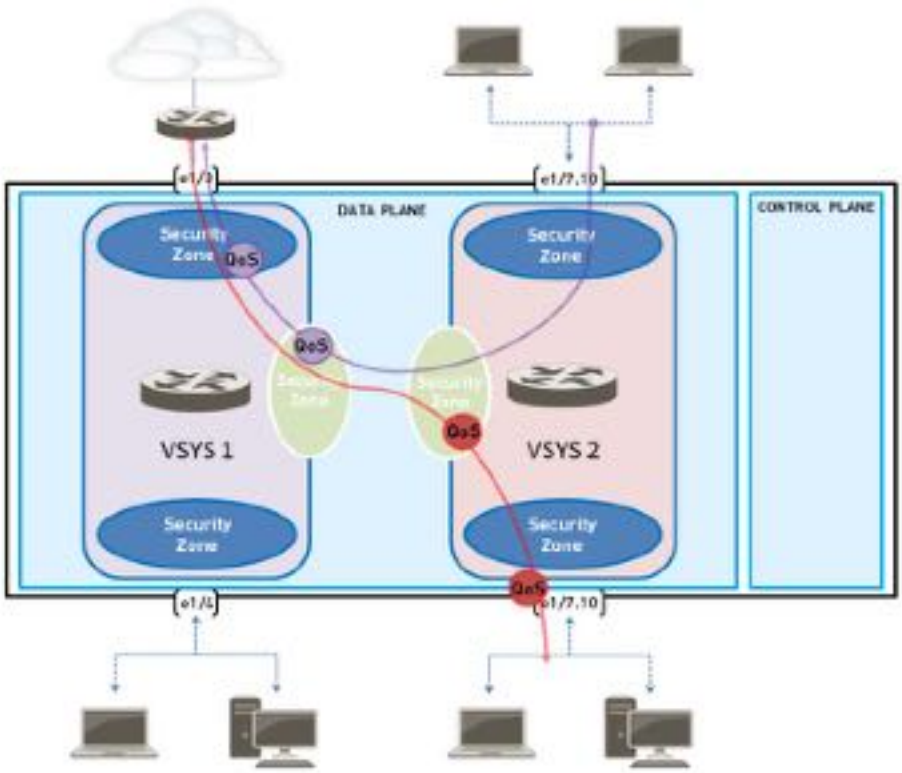
# Configure QoS for a Virtual System

QoS can be configured for a single or several Virtual Systems within a Palo Alto Networks firewall. Because a virtual system is an independent firewall, QoS must be configured independently for a single virtual system to apply a QoS configuration to only that virtual system.

Configuring QoS for a virtual system is similar to configuring QoS on a physical firewall, with the exception that configuring QoS for a virtual system requires specifying the traffic flow's source and destination zones and source and destination interfaces. Because a virtual system exists without set physical boundaries (such as a physical interface) that traffic flows through, specifying source and destination zones and interfaces of a traffic flow allows you to control and shape traffic for that virtual system specifically, as a traffic flow spans more than one virtual system in a virtual environment.

The example below shows two virtual systems configured within a firewall. VSYS 1 (purple) and VSYS 2 (red) each have QoS configured to prioritize or limit two distinct traffic flows, indicated by their corresponding purple (VSYS 1) and red (VSYS 2) lines. The QoS nodes indicate the points at which QoS traffic is identified and then shaped in each virtual system.



| Configure QoS in a Virtual System Environment | | |
|---|---|---|
| Step 1 | Confirm that the appropriate interfaces, virtual routers, and security zones are associated with each virtual system. | • To view configured interfaces, select **Network > Interface**.<br>• To view configured zones, select **Network > Zones**.<br>• To view information on defined virtual routers, select **Network > Virtual Routers**. |
| Step 2 | Identify traffic to apply QoS to. | Select **ACC** to view the **Application Command Center** page. Use the settings and charts on the **ACC** page to view trends and traffic related to Applications, URL filtering, Threat Prevention, Data Filtering, and HIP Matches.<br>To view information for a specific virtual system, select the virtual system from the **Virtual System** drop-down:<br>  <br>Click any application name to display detailed application information. |

© Palo Alto Networks, Inc.

**Configure QoS in a Virtual System Environment**

Step 3 Identify the egress interface for applications that you identified as needing QoS treatment.

In a virtual system environment, QoS is applied to traffic on the traffic's egress point on the virtual system. Depending on a virtual system's configuration and the QoS policy, the egress point of QoS traffic could be associated with a physical interface or could be a configured zone.

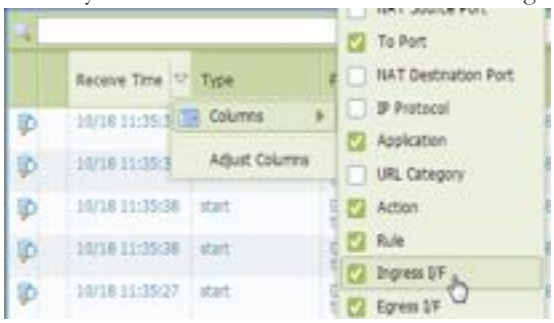
This example shows how to limit web-browsing traffic on vsys 1.

Select **Monitor > Logs > Traffic** to view the device's traffic logs. Each entry has the option to display columns with information necessary to configure QoS in a virtual system environment:

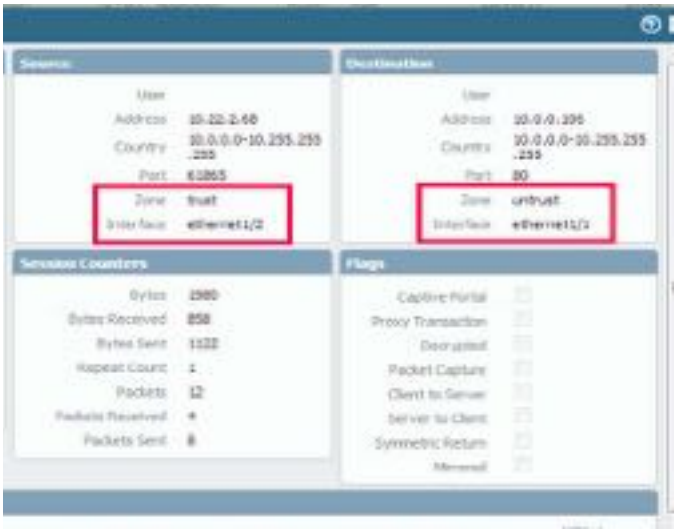
- virtual system
- egress interface
- ingress interface
- source zone
- destination zone

To display a column if it is not displayed by default:

- Click any column header to add a column to the log:



- Click the spyglass icon to the left of any entry to display a detailed log that includes the application's egress interface, as well as source and destination zones, in the **Source** and **Destination** sections:



For example, for web-browsing traffic from VSYS 1, the ingress interface is ethernet 1/2, the egress interface is ethernet 1/1, the source zone is *trust* and the destination zone is *untrust*.

| Configure QoS in a Virtual System Environment | |
|---|---|
| Step 4 Create a QoS Profile.<br><br>You can edit any existing QoS Profile, including the default, by clicking the profile name. | 1. Select **Network > Network Profiles > QoS Profile** and click **Add** to open the QoS Profile dialog.<br>2. Enter a descriptive **Profile Name**.<br>3. Enter an **Egress Max** to set the overall bandwidth allocation for the QoS profile.<br>4. Enter an **Egress Guaranteed** to set the guaranteed bandwidth for the QoS profile.<br><br> Any traffic that exceeds the QoS profile's egress guaranteed limit is best effort but is not guaranteed.<br>5. In the Classes section of the **QoS Profile**, specify how to treat up to eight individual QoS classes:<br>a. Click **Add** to add a class to the QoS Profile.<br>b. Select the **Priority** for the class.<br>c. Enter an **Egress Max** for a class to set the overall bandwidth limit for that individual class.<br>d. Enter an **Egress Guaranteed** for the class to set the guaranteed bandwidth for that individual class.<br>6. Click **OK** to save the QoS profile. |

 © Palo Alto Networks, Inc.

**Configure QoS in a Virtual System Environment**

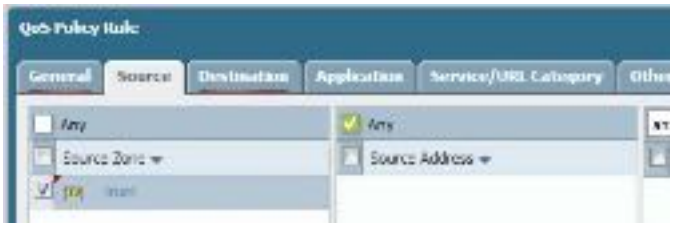
Step 5 Create a QoS policy.

In a multi-VSYS environment, traffic can span more than one virtual system before the ingress point on the virtual system you are configuring QoS for. Specifying source and destination zones for QoS traffic ensures that the traffic is correctly identified as it flows through the specific virtual system (in this example, vsys 1) and QoS is applied to the traffic only for that designated virtual system (and not applied to traffic for other configured virtual systems).

1. Select **Policies > QoS** and click **Add** to open the QoS Policy Rule dialog.
2. On the **General** tab, give the QoS Policy Rule a descriptive **Name**.
3. Specify the traffic to which the QoS policy rule will apply. Use the **Source**, **Destination**, **Application**, and **Service/URL Category** tabs to define matching parameters for identifying traffic.

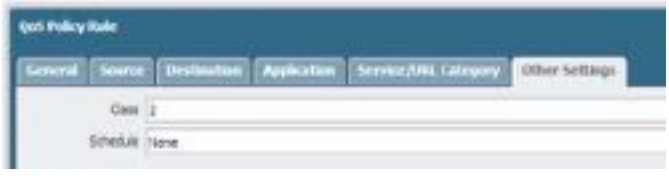
   For example, select the **Application** tab, click **Add** and select web-browsing to apply the QoS Policy Rule to that application:

4. On the **Source** tab, click **Add** to select the source zone of vsys 1's web-browsing traffic.



5. On the **Destination** tab, click **Add** to select the destination zone of vsys 1's web-browsing traffic.

6. On the **Other Settings** tab, and select a **QoS Class** to assign to the QoS policy rule. For example, assign Class 2 to web-browsing traffic on vsys 1:



7. Click **OK** to save the QoS policy rule.

| Configure QoS in a Virtual System Environment | |
|---|---|
| Step 6 Enable the QoS Profile on a physical interface.<br><br>It is a best practice to always define the **Egress Max** value for a QoS interface. | 1. Select **Network > QoS** and click **Add** to open the QoS Interface dialog.<br>2. Enable QoS on the physical interface:<br>a. On the **Physical Interface** tab, select the **Interface Name** of the interface to apply the QoS Profile to.<br>In this example, ethernet 1/1 is the egress interface for web-browsing traffic on vsys 1 (see Step 2).<br> <br>b. Select **Turn on QoS feature on this interface**.<br>3. On the **Physical Interface** tab, select the default QoS profile to apply to all **Clear Text** traffic.<br>(Optional) Use the **Tunnel Interface** field to apply a default QoS profile to all tunneled traffic.<br>4. (Optional) On the **Clear Text Traffic** tab, configure additional QoS settings for clear text traffic:<br>• Set the **Egress Guaranteed** and **Egress Max** bandwidths for clear text traffic.<br>• Click **Add** to apply a QoS Profile to selected clear text traffic, further selecting the traffic for QoS treatment according to source interface and source subnet (creating a QoS node).<br>5. (Optional) On the **Tunneled Traffic** tab, configure additional QoS settings for tunnel interfaces:<br>• Set the **Egress Guaranteed** and **Egress Max** bandwidths for tunneled traffic.<br>• Click **Add** to associate a selected tunnel interface with a QoS Profile.<br>6. Click **OK** to save changes.<br>7. **Commit** the changes. |

© Palo Alto Networks, Inc.

| Configure QoS in a Virtual System Environment | |
|---|---|
| Step 7 Verify QoS configuration. | • Select **Network > QoS** to view the QoS Policies page. The **QoS Policies** page verifies that QoS is enabled and includes a **Statistics** link. Click the Statistics link to view QoS bandwidth, active sessions of a selected QoS node or class, and active applications for the selected QoS node or class.<br>• In a multi-VSYS environment, sessions cannot span multiple systems. Multiple sessions are created for one traffic flow if the traffic passes through more than one virtual system. To browse sessions running on the firewall and view applied QoS Rules and QoS Classes, select **Monitor > Session Browser**. |

# QoS Use Case Examples

The following use cases demonstrate how to use QoS in common scenarios:

- Use Case: QoS for a Single User
- QoS for Voice and Video Applications

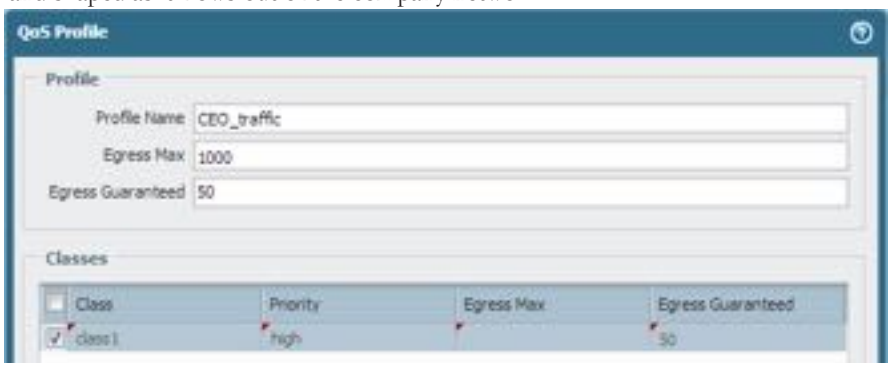
© Palo Alto Networks, Inc.

## Use Case: QoS for a Single User

A CEO finds that during periods of high network usage, she is unable to access enterprise applications to respond effectively to critical business communications. The IT admin wants to ensure that all traffic to and from the CEO receives preferential treatment over other employee traffic so that she is guaranteed not only access to, but high performance of, critical network resources.

### Apply QoS to a Single User

Step 1 The admin creates the QoS profile *CEO_traffic* to define how traffic originating from the CEO will be treated and shaped as it flows out of the company network:



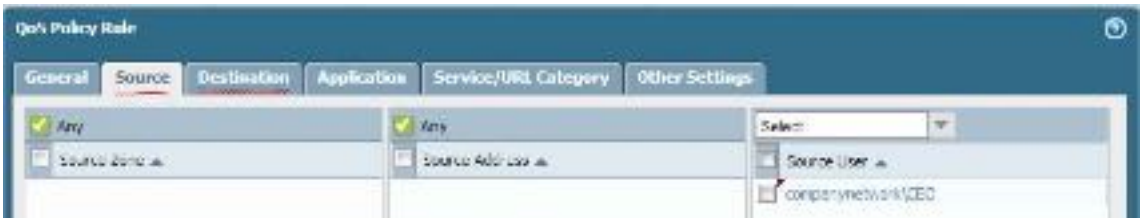
The admin assigns a guaranteed bandwidth (**Egress Guaranteed**) of 50 Mbps to ensure that the CEO will have that amount that bandwidth guaranteed to her at all times (more than she would need to use), regardless of network congestion.

The admin continues by designating Class 1 traffic as high priority and sets the profile's maximum bandwidth usage (**Egress Max**) to 1000 Mbps, the same maximum bandwidth for the interface that the admin will enable QoS on. The admin is choosing to not restrict the CEO's bandwidth usage in any way.

It is a best practice to populate the **Egress Max** field for a QoS profile, even if the max bandwidth of the profile matches the max bandwidth of the interface. The QoS profile's max bandwidth should never exceed the max bandwidth of the interface you are planning to enable QoS on.

**Apply QoS to a Single User (Continued)**

Step 2 The admin creates a QoS policy to identify the CEO's traffic (**Policies** > **QoS**) and assigns it the class that he defined in the QoS profile (see Step 1). Because User-ID is configured, the admin uses the **Source** tab in the QoS policy to singularly identify the CEO's traffic by her company network username. (If User-ID is not configured, the administrator could **Add** the CEO's IP address under **Source Address**. See User-ID.):



The admin associates the CEO's traffic with Class 1 (**Other Settings** tab) and then continues to populate the remaining required policy fields; the admin gives the policy a descriptive **Name** (**General** tab) and selects **Any** for the **Source Zone** (**Source** tab) and **Destination Zone** (**Destination** tab):

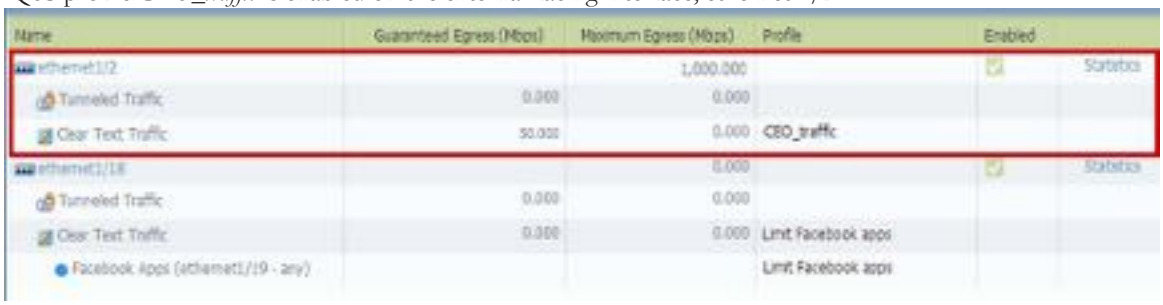
Step 3 Now that Class 1 is associated with the CEO's traffic, the admin enables QoS by checking **Turn on QoS feature on interface** and selecting the traffic flow's egress interface. The egress interface for the CEO's traffic flow is the external-facing interface, in this case, ethernet 1/2:

Because the admin wants to ensure that all traffic originating from the CEO is guaranteed by the QoS profile and associated QoS policy he created, he selects the *CEO_traffic* to apply to **Clear Text** traffic flowing from ethernet 1/2.

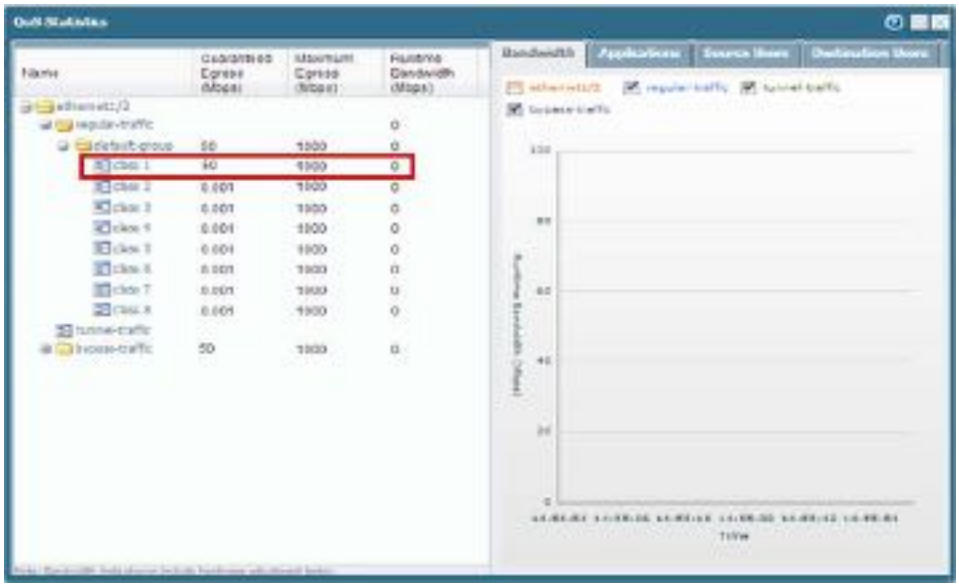
 © Palo Alto Networks, Inc.

**Apply QoS to a Single User (Continued)**

Step 4 After committing the QoS configuration, the admin navigates to the **Network > QoS** page to confirm that the QoS profile *CEO_traffic* is enabled on the external-facing interface, ethernet 1/2:



He clicks **Statistics** to view how traffic originating with the CEO (Class 1) is being shaped as it flows from ethernet 1/2:



This case demonstrates how to apply QoS to traffic originating from a single source user. However, if you also wanted to guarantee or shape traffic to a destination user, you could configure a similar QoS setup. Instead of, or in addition to this work flow, create a QoS policy that specifies the user's IP address as the **Destination Address** on the **Policies > QoS** page (instead of specifying the user's source information, as shown in Step 2) and then enable QoS on the network's internal-facing interface on the **Network > QoS** page (instead of the external-facing interface, as shown in Step 3.)

## QoS for Voice and Video Applications

Voice and video traffic is particularly sensitive to measurements that the QoS feature shapes and controls, especially latency and jitter. For voice and video transmissions to be audible and clear, voice and video packets cannot be dropped, delayed, or delivered inconsistently. A best practice for voice and video applications, in addition to guaranteeing bandwidth, is to guarantee priority to voice and video traffic.

In this example, employees at a company branch office are experiencing difficulties and unreliability in using video conferencing and Voice-over-IP (VoIP) technologies to conduct business communications with other branch offices, with partners, and with customers. An IT admin intends to implement QoS in order to address these issues and ensure effective and reliable business communication for the branch employees. Because the admin wants to guarantee QoS to both incoming and outgoing network traffic, he will enable QoS on both the firewall's internal- and external-facing interfaces.

**Ensure Quality for Voice and Video Applications**

Step 1 The admin creates a QoS profile, defining Class 2 so that any traffic associated with Class 2 receives real-time priority and on an interface with a maximum bandwidth of 1000 Mbps, is guaranteed a bandwidth of 250 Mbps at all times, including peak periods of network usage.

Real-time priority is typically recommended for applications affected by latency, and is particularly useful in guaranteeing performance and quality of voice and video applications.

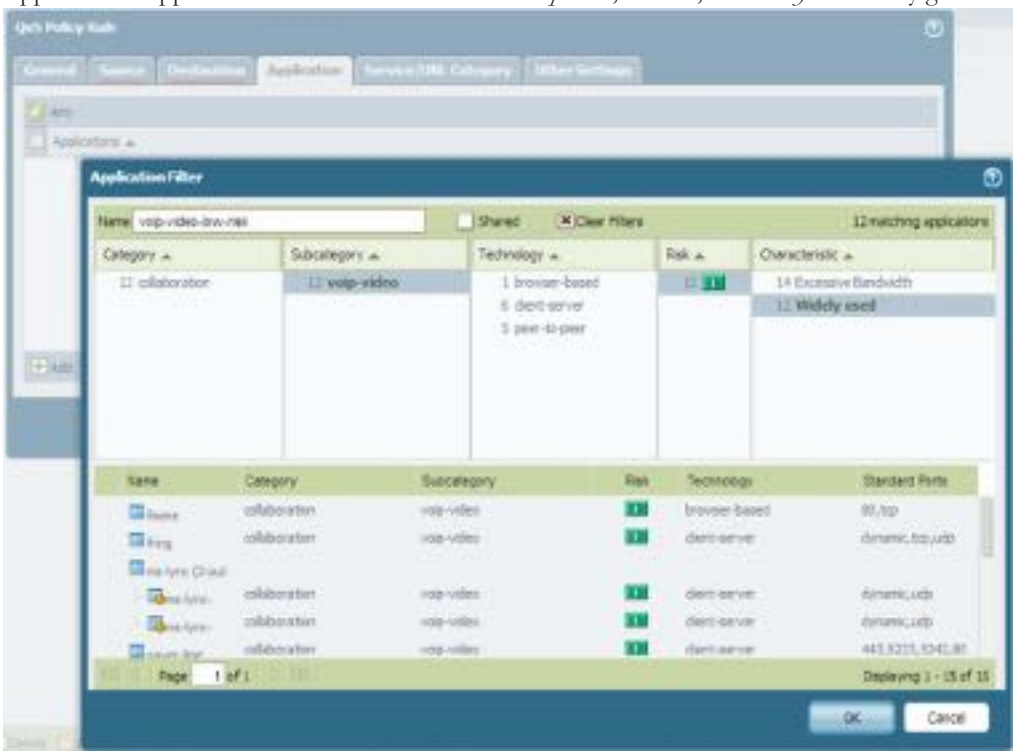
On the **Network > Network Profiles > Qos Profile** page, the admin clicks **Add**, enters the **Profile Name** *ensure voip-video traffic* and defines Class 2 traffic.

 © Palo Alto Networks, Inc.

**Ensure Quality for Voice and Video Applications (Continued)**

Step 2 The admin creates a QoS policy to identify voice and video traffic. Because the company does not have one standard voice and video application, the admin wants to ensure QoS is applied to a few applications that are widely and regularly used by employees to communicate with other offices, with partners, and with customers. On the **Policies > QoS > QoS Policy Rule > Applications** tab, the admin clicks **Add** and opens the **Application Filter** window. The admin continues by selecting criteria to filter the applications he wants to apply QoS to, choosing the Subcategory *voip-video*, and narrowing that down by specifying only voip-video applications that are both low-risk and widely-used.

The application filter is a dynamic tool that, when used to filter applications in the QoS policy, allows QoS to be applied to all applications that meet the criteria of *voip-video*, *low risk*, and *widely used* at any given time.



The admin names the **Application Filter** *voip-video-low-risk* and includes it in the QoS policy:

The admin names the QoS policy *Voice-Video* and associates the *voip-video-low-risk* application filter with Class 2 traffic (as he defined it in Step 1). He is going to use the *Voice-Video* QoS policy for both incoming and outgoing QoS traffic, so he sets **Source** and **Destination** information to **Any**:

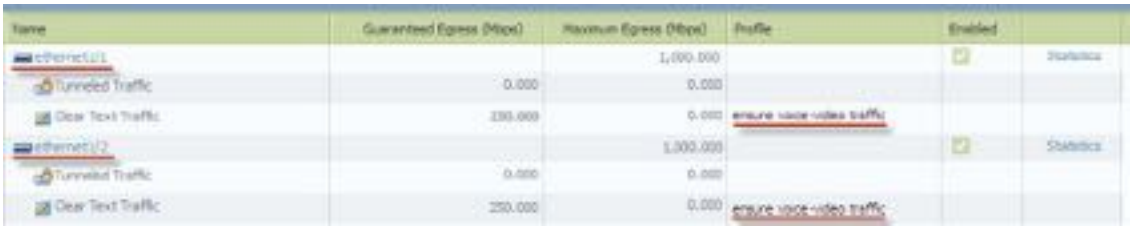
**Ensure Quality for Voice and Video Applications (Continued)**

Step 3 Because the admin wants to ensure QoS for both incoming and outgoing voice and video communications, he enables QoS on the network's external-facing interface (to apply QoS to outgoing communications) and to the internal-facing interface (to apply QoS to incoming communications).

The admin begins by enabling the QoS profile he created in Step 1, *ensure voice-video traffic* (Class 1 in this profile is associated with policy created in Step 2, *Voice-Video*) on the external-facing interface, in this case, ethernet 1/2.

He then enables the same QoS profile *ensure voip-video traffic* on the internal-facing interface, in this case, ethernet 1/1.

Step 4 The admin confirms that QoS is enabled for both incoming and outgoing voice and video traffic:



The admin has successfully enabled QoS on both the network's internal- and external-facing interfaces. Real-time priority is now ensured for voice and video application traffic as it flows both into and out of the network, ensuring that these communications, which are particularly sensitive to latency and jitter, can be used reliably and effectively to perform both internal and external business communications.

# VPNs

Virtual private networks (VPNs) create tunnels that allow users/systems to connect securely over a public network, as if they were connecting over a local area network (LAN). To set up a VPN tunnel, you need a pair of devices that can authenticate each other and encrypt the flow of information between them. The devices can be a pair of Palo Alto Networks firewalls, or a Palo Alto Networks firewall along with a VPN-capable device from another vendor.

- VPN Deployments
- Site-to-Site VPN Overview
- Site-to-Site VPN Concepts
- Set Up Site-to-Site VPN
- Site-to-Site VPN Quick Configs

© Palo Alto Networks, Inc.

# VPN Deployments

The Palo Alto Networks firewall supports the following VPN deployments:

- **Site-to-Site VPN**— A simple VPN that connects a central site and a remote site, or a hub and spoke VPN that connects a central site with multiple remote sites. The firewall uses the IP Security (IPSec) set of protocols to set up a secure tunnel for the traffic between the two sites. See Site-to-Site VPN Overview.
- **Remote User-to-Site VPN**—A solution that uses the GlobalProtect agent to allow a remote user to establish a secure connection through the firewall. This solution uses SSL and IPSec to establish a secure connection between the user and the site. Refer to the GlobalProtect Administrator's Guide.
- **Large Scale VPN**— The Palo Alto Networks GlobalProtect Large Scale VPN (LSVPN) provides a simplified mechanism to roll out a scalable hub and spoke VPN with up to 1024 satellite offices. The solution requires Palo Alto Networks firewalls to be deployed at the hub and at every spoke. It uses certificates for device authentication, SSL for securing communication between all components, and IPSec to secure data. See Large Scale VPN (LSVPN).

**Figure: VPN Deployments**

 © Palo Alto Networks, Inc.

# Site-to-Site VPN Overview

A VPN connection that allows you to connect two Local Area Networks (LANs) is called a site-to-site VPN. You can configure route-based VPNs to connect Palo Alto Networks firewalls located at two sites or to connect a Palo Alto Networks firewall with a third-party security device at another location. The firewall can also interoperate with third-party policy-based VPN devices; the Palo Alto Networks firewall supports route-based VPN.

The Palo Alto Networks firewall sets up a route-based VPN, where the firewall makes a routing decision based on the destination IP address. If traffic is routed to a specific destination through a VPN tunnel, then it is handled as VPN traffic.

The IP Security (IPSec) set of protocols is used to set up a secure tunnel for the VPN traffic, and the information in the TCP/IP packet is secured (and encrypted if the tunnel type is ESP). The IP packet (header and payload) is embedded in another IP payload, and a new header is applied and then sent through the IPSec tunnel. The source IP address in the new header is that of the local VPN peer and the destination IP address is that of the VPN peer on the far end of the tunnel. When the packet reaches the remote VPN peer (the firewall at the far end of the tunnel), the outer header is removed and the original packet is sent to its destination.

In order to set up the VPN tunnel, first the peers need to be authenticated. After successful authentication, the peers negotiate the encryption mechanism and algorithms to secure the communication. The Internet Key Exchange (IKE) process is used to authenticate the VPN peers, and IPSec Security Associations (SAs) are defined at each end of the tunnel to secure the VPN communication. IKE uses digital certificates or preshared keys, and the Diffie Hellman keys to set up the SAs for the IPSec tunnel.The SAs specify all of the parameters that are required for secure transmission— including the security parameter index (SPI), security protocol, cryptographic keys, and the destination IP address—encryption, data authentication, data integrity, and endpoint authentication.

The following figure shows a VPN tunnel between two sites. When a client that is secured by VPN Peer A needs content from a server located at the other site, VPN Peer A initiates a connection request to VPN Peer B. If the security policy permits the connection, VPN Peer A uses the IKE Crypto profile parameters (IKE phase 1) to establish a secure connection and authenticate VPN Peer B. Then, VPN Peer A establishes the VPN tunnel using the IPSec Crypto profile, which defines the IKE phase 2 parameters to allow the secure transfer of data between the two sites.

**Figure: Site-to-Site VPN**

# Site-to-Site VPN Concepts

A VPN connection provides secure access to information between two or more sites. In order to provide secure access to resources and reliable connectivity, a VPN connection needs the following components:

- IKE Gateway
- Tunnel Interface
- Tunnel Monitoring
- Internet Key Exchange (IKE) for VPN

## IKE Gateway

The Palo Alto Networks firewalls or a firewall and another security device that initiate and terminate VPN connections across the two networks are called the IKE Gateways. To set up the VPN tunnel and send traffic between the IKE Gateways, each peer must have an IP address—static or dynamic—or FQDN. The VPN peers use preshared keys or certificates to mutually authenticate each other.

The peers must also negotiate the mode—main or aggressive—for setting up the VPN tunnel and the SA lifetime in IKE Phase 1. Main mode protects the identity of the peers and is more secure because more packets are exchanged when setting up the tunnel. Main mode is the recommended mode for IKE negotiation if both peers support it. Aggressive mode uses fewer packets to set up the VPN tunnel and is hence faster but a less secure option for setting up the VPN tunnel.

See Set up an IKE Gateway for configuration details.

## Tunnel Interface

To set up a VPN tunnel, the Layer 3 interface at each end must have a logical *tunnel* interface for the firewall to connect to and establish a VPN tunnel. A tunnel interface is a logical (virtual) interface that is used to deliver traffic between two endpoints. Each tunnel interface can have a maximum of 10 IPSec tunnels; this means that up to 10 networks can be associated with the same tunnel interface on the firewall.

The tunnel interface must belong to a security zone to apply policy and it must be assigned to a virtual router in order to use the existing routing infrastructure. Ensure that the tunnel interface and the physical interface are assigned to the same virtual router so that the firewall can perform a route lookup and determine the appropriate tunnel to use.

Typically, the Layer 3 interface that the tunnel interface is attached to belongs to an external zone, for example the untrust zone. While the tunnel interface can be in the same security zone as the physical interface, for added security and better visibility, you can create a separate zone for the tunnel interface. If you create a separate zone for the tunnel interface, say a VPN zone, you will need to create security policies to enable traffic to flow between the VPN zone and the trust zone.

 © Palo Alto Networks, Inc.

To route traffic between the sites, a tunnel interface does not require an IP address. An IP address is only required if you want to enable tunnel monitoring or if you are using a dynamic routing protocol to route traffic across the tunnel. With dynamic routing, the tunnel IP address serves as the next hop IP address for routing traffic to the VPN tunnel.

If you are configuring the Palo Alto Networks firewall with a VPN peer that performs policy-based VPN, you must configure a local and remote Proxy ID when setting up the IPSec tunnel. Each peer compares the Proxy-IDs configured on it with what is actually received in the packet in order to allow a successful IKE phase 2 negotiation. If multiple tunnels are required, configure unique Proxy IDs for each tunnel interface; a tunnel interface can have a maximum of 250 ProxyIDs. Each Proxy ID counts towards the IPSec VPN tunnel capacity of the firewall, and the tunnel capacity varies by the firewall model.

See Set up an IPSec Tunnel for configuration details.

## Tunnel Monitoring

For a VPN tunnel, you can check connectivity to a destination IP address across the tunnel. The network monitoring profile on the firewall allows you to verify connectivity (using ICMP) to a destination IP address or a next hop at a specified polling interval, and to specify an action on failure to access the monitored IP address.

If the destination IP is unreachable, you either configure the firewall to wait for the tunnel to recover or configure automatic failover to another tunnel. In either case, the firewall generates a system log that alerts you to a tunnel failure and renegotiates the IPSec keys to accelerate recovery.

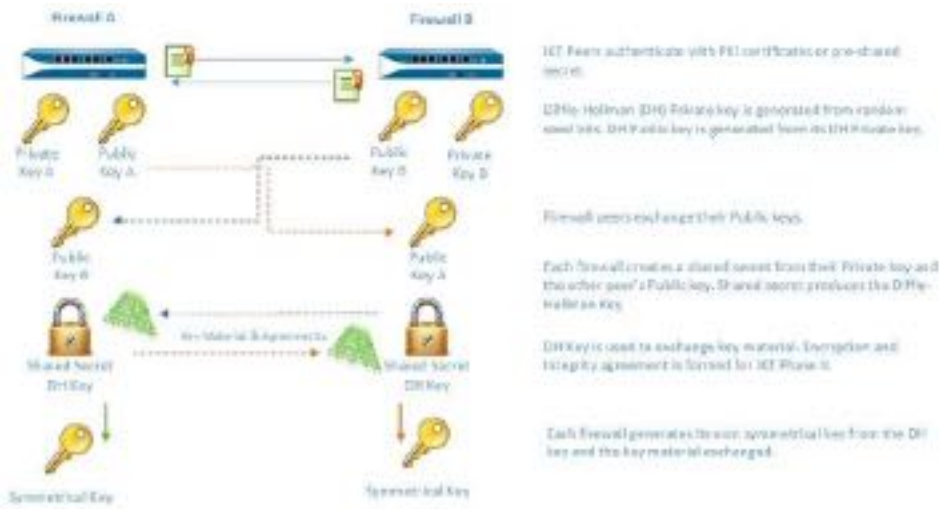
The default monitoring profile is configured to wait for the tunnel to recover; the polling interval is 3 seconds and the failure threshold is 5.

See Set up Tunnel Monitoring for configuration details.

## Internet Key Exchange (IKE) for VPN

The IKE process allows the VPN peers at both ends of the tunnel to encrypt and decrypt packets using mutually agreed-upon keys or certificate and method of encryption. The IKE process occurs in two phases: IKE Phase 1 and IKE Phase 2. Each of these phases use keys and encryption algorithms that are defined using cryptographic profiles— IKE crypto profile and IPSec crypto profile—and the result of the IKE negotiation is a Security Association (SA). An SA is a set of mutually agreed-upon keys and algorithms that are used by both VPN peers to allow the flow of data across the VPN tunnel. The following illustration depicts the key exchange process for setting up the VPN tunnel:

© Palo Alto Networks, Inc.



## IKE Phase 1

In this phase, the firewalls use the parameters defined in the IKE Gateway configuration and the IKE Crypto profile to authenticate each other and set up a secure control channel. IKE Phase supports the use of preshared keys or digital certificates (which use public key infrastructure, PKI) for mutual authentication of the VPN peers. Preshared keys are a simple solution for securing smaller networks because they do not require the support of a PKI infrastructure. Digital certificates can be more convenient for larger networks or implementations that require stronger authentication security.

When using certificates, make sure that the CA issuing the certificate is trusted by both gateway peers and that the maximum length of certificates in the certificate chain is 5 or less. With IKE fragmentation enabled, the firewall can reassemble IKE messages with up to 5 certificates in the certificate chain and successfully establish a VPN tunnel.

The IKE-crypto profile defines the following options that are used in the IKE SA negotiation:

- Diffie-Hellman (DH) Group for generating symmetrical keys for IKE. The Diffie Hellman algorithm uses the private key of one party and the public key of the other to create a shared secret, which is an encrypted key that is shared by both VPN tunnel peers. The DH groups supported on the firewall are: Group 1—768 bits; Group 2—1024 bits (the default); Group 5—1536 bits; Group 14—2048 bits.
- Authentication options—sha1; sha 256; sha 384; sha 512; md5
- Encryption algorithms—3des; aes128; aes192; aes256

## IKE Phase 2

After the tunnel is secured and authenticated, in Phase 2 the channel is further secured for the transfer of data between the networks. IKE Phase 2 uses the keys that were established in Phase 1 of the process and the IPSec Crypto profile, which defines the IPSec protocols and keys used for the SA in IKE Phase 2.

The IPSEC uses the following protocols to enable secure communication:

 © Palo Alto Networks, Inc.

- Encapsulating Security Payload (ESP)—Allows you to encrypt the entire IP packet, and authenticate the source and verify integrity of the data. While ESP requires that you encrypt and authenticate the packet, you can choose to only encrypt or only authenticate by setting the encryption option to Null; using encryption without authentication is discouraged.
- Authentication Header (AH)—Authenticates the source of the packet and verifies data integrity. AH does not encrypt the data payload and is unsuited for deployments where data privacy is important. AH is commonly used when the main concern is to verify the legitimacy of the peer, and data privacy is not required.

**Table: Algorithms Supported for IPSEC Authentication and Encryption**

| ESP | AH |
|---|---|
| Diffie Hellman Exchange options supported | |
| • Group 1—768 bits<br>• Group 2—1024 bits (the default)<br>• Group 5—1536 bits<br>• Group 14—2048 bits.<br>• no-pfs—By default, Perfect Forward Secrecy (pfs) is enabled. With PFS is enabled, a new DH key is generated in IKE phase 2 using one of the groups listed above; this key is independent of the keys exchanged in IKE phase1, and therefore allows for more secure transfer of data.<br>No-pfs implies that the DH key created at phase 1 is not renewed and a single key is used for the IPSEC SA negotiations. Both VPN peers must be enabled or disabled for Perfect Forward Secrecy. | |
| Encryption algorithms supported | |
| • 3des | |

| • none | |

## Methods of Securing IPSec VPN Tunnels (IKE Phase 2)

IPSec VPN tunnels can be secured using manual keys or auto keys. In addition, IPSec configuration options include Diffie-Hellman Group for key agreement, and/or an encryption algorithm and a hash for message authentication.

- **Manual Key**—Manual key is typically used if the Palo Alto Networks firewall is establishing a VPN tunnel with a legacy device, or if you want to reduce the overhead of generating session keys. If using manual keys, the same key must be configured on both peers.

  Manual keys are not recommended for establishing a VPN tunnel because the session keys can be compromised when relaying the key information between the peers; if the keys are compromised, the data transfer is no longer secure.

- **Auto Key**— Auto Key allows you to automatically generate keys for setting up and maintaining the IPSec tunnel based on the algorithms defined in the IPSec Crypto profile.

 © Palo Alto Networks, Inc.

# Set Up Site-to-Site VPN

To set up site-to-site VPN:

- Make sure that your Ethernet interfaces, virtual routers, and zones are configured properly. For more information, see Set Up Interfaces and Zones.
- Create your tunnel interfaces. Ideally, put the tunnel interfaces in a separate zone, so that tunneled traffic can use different policies.
- Set up static routes or assign routing protocols to redirect traffic to the VPN tunnels. To support dynamic routing (OSPF, BGP, RIP are supported), you must assign an IP address to the tunnel interface.
- Define IKE gateways for establishing communication between the peers across each end of the VPN tunnel; also define the cryptographic profile that specifies the protocols and algorithms for identification, authentication, and encryption to be used for setting up VPN tunnels in IKEv1 Phase 1. See Set up an IKE Gateway and Define IKE Crypto Profiles.
- Configure the parameters that are needed to establish the IPSec connection for transfer of data across the VPN tunnel; See Set up an IPSec Tunnel. For IKEv1 Phase-2, see Define IPSec Crypto Profiles.
- (Optional) Specify how the firewall will monitor the IPSec tunnels. See Set up Tunnel Monitoring.
- Define security policies to filter and inspect the traffic.

If there is a deny rule at the end of the security rulebase, intra-zone traffic is blocked unless otherwise allowed. Rules to allow IKE and IPSec applications must be explicitly included above the deny rule.

When these tasks are complete, the tunnel is ready for use. Traffic destined for the zones/addresses defined in policy is automatically routed properly based on the destination route in the routing table, and handled as VPN traffic. For a few examples on site-to-site VPN, see Site-to-Site VPN Quick Configs.

## Set up an IKE Gateway

To set up a VPN tunnel, the VPN peers or gateways must authenticate each other using preshared keys or digital certificates and establish a secure channel in which to negotiate the IPSec security association (SA) that will be used to secure traffic between the hosts on each side.

| **Set up an IKE Gateway** | |
|---|---|
| Step 1 Define the new IKE Gateway. | 1. Select **Network > Network Profiles > IKE Gateway** and enter a **Name f**or the new gateway configuration.<br>2. Select the outgoing **Interface** on the firewall.<br>3. From the **Local IP address** drop-down list, select the IP address that will be used to as the endpoint for the VPN connection. This is the external-facing interface with a publicly routable IP address on the firewall. |

| Set up an IKE Gateway | | |
|---|---|---|
| Step 2 | Define the settings for the peer at the far end of the tunnel. | 1. Select whether the peer uses a **Static** or **Dynamic** IP address in **Peer IP Type**.<br>2. If the **Peer IP Address** is static, enter the IP address of the peer. |
| Step 3 | Select the peer authentication method.<br>This is required for static and dynamic peers. | • For configuring a **Pre-Shared Key**, see Step 4.<br>• For configuring digital **Certificates**, see Step 5. |
| Step 4 | Configure a pre-shared key. | 1. Enter a security key to use for authentication across the tunnel. This key must be the same on both peers.<br>Generate a key that is hard to crack with dictionary attacks; use a pre-shared key generator, if necessary.<br>2. Continue with Step 6. |
| Step 5 | Configure certificate-based authentication.<br> The pre-requisites for certificate-based authentication are as follows:<br>– **Obtain a signed certificate:** See Generate a Certificate on the Firewall or Obtain a Certificate from an External CA.<br>– **Configure the certificate profile**: The certificate profile provides the settings that the IKE gateway uses for negotiating and validating certificate authentication with its peer. See Configure a Certificate Profile. | 1. Select **Certificate** for the **Authentication** method and select the signed certificate from the **Local Certificate** drop-down.<br>If your device is enabled for multi-virtual systems, if the certificate belongs to a virtual system, it must be in the same virtual system as the interface used for the IKE gateway.<br>2. From the **Local Identification** drop-down list, choose one of the following types and enter the value: IP address, FQDN (hostname), User FQDN (email address), Distinguished Name (subject).<br>3. From the **Peer Identification** drop-down, choose one of the following types and enter the value: IP address, FQDN (hostname), User FQDN (email address), Distinguished Name (subject).<br>4. Select a **Certificate Profile** to use.<br>5. Continue with Step 6. |

 © Palo Alto Networks, Inc.

| Set up an IKE Gateway | |
|---|---|
| Step 6 Configure the additional parameters for IKE phase 1 negotiations—Exchange mode, Crypto profile, IKE fragmentation, Dead Peer Detection. | 1. Select **Network > Network Profiles > IKE Gateways** and select the **Advanced Phase 1 Options** tab.<br>2. Choose **auto**, **aggressive**, or **main** for the **Exchange Mode**.<br>When a device is set to use the **auto** exchange mode, it can accept both main mode and aggressive mode negotiation requests; however, whenever possible, it initiates negotiation and allows exchanges in main mode.<br> If the exchange mode is not set to **auto**, you must configure both VPN peers with the same exchange mode to allow each peer to accept negotiation requests.<br>3. Select an existing profile or keep the default profile from **IKE Crypto Profile** drop-down. For details on defining an IKE Crypto profile, see Define IKE Crypto Profiles.<br>4. Select **Passive Mode** if you want the firewall to only respond to IKE connections and never initiate them.<br>5. Select **NAT Traversal Select** to have UDP encapsulation used on IKE and UDP protocols, enabling them to pass through intermediate NAT devices.<br>6. (Only if using certificate-based authentication and the exchange mode is not set as **aggressive** mode) Select **Enable Fragmentation** to enable the firewall to operate with IKE Fragmentation.<br>7. Select the **Dead Peer Detection** check box and enter an **Interval** (2 - 100 seconds); For **Retry,** define the time to delay (2 - 100 seconds) before attempting to re-check availability.<br>Dead peer detection identifies inactive or unavailable IKE peers by sending an IKE phase 1 notification payload to the peer and waiting for an acknowledgment. |
| Step 7 Save the changes. | Click **OK** and **Commit**. |

## Define Cryptographic Profiles

A cryptographic profile specifies the ciphers used for authentication and/or encryption between two IKE peers, and the lifetime of the key. The time period between each renegotiation is known as the lifetime; when the specified time expires, the firewall renegotiates a new set of keys.

For securing communication across the VPN tunnel, the firewall requires IKE and IPSec cryptographic profiles for completing IKE phase 1 and phase 2 negotiations, respectively. The firewall includes a *default* IKE crypto profile and a *default* IPSec crypto profile that is ready for use.

- Define IKE Crypto Profiles
- Define IPSec Crypto Profiles

## Define IKE Crypto Profiles

The IKE crypto profile is used to set up the encryption and authentication algorithms used for the key exchange process in IKE Phase 1, and lifetime of the keys, which specifies how long the keys are valid. To invoke the profile, you must attach it to the IKE Gateway configuration.

All IKE gateways configured on the same interface or local IP address must use the same crypto profile.

| Define an IKE Crypto Profile | | |
|---|---|---|
| Step 1 | Create a new IKE profile. | 1. Select **Network > Network Profiles > IKE Crypto** and select **Add**.<br>2. Enter a **Name f**or the new profile. |
| Step 2 | Select the DH Group to use for setting up the key exchange. | Click **Add** and select the key strength that you want to use for the DH Group.<br>Select more than one DH group if you are not certain of what is supported by the VPN peer. Prioritize the list of ciphers by strength so that the strongest cipher is used for setting up the tunnel. |
| Step 3 | Select the authentication and encryption algorithm. | Click **Add** and select the **Authentication** and **Encryption** algorithms that you want to use for communication between the IKE peers.<br>Selecting multiple algorithms allows the peers to use the strongest cipher/algorithm that is supported on both IKE peers. |
| Step 4 | Specify the duration for which the key is valid. | Select the **Lifetime** for which the key is valid. The time period between each renegotiation is known as the lifetime; when the specified time expires, the firewall will renegotiate a new set of keys. |
| Step 5 | Save your IKE Crypto profile. | Click **OK** and click **Commit**. |
| Step 6 | Attach the IKE Crypto profile to the IKE Gateway configuration. | See Step 6 in Set up an IKE Gateway. |

## Define IPSec Crypto Profiles

The IPSec crypto profile is invoked in IKE Phase 2. It specifies how the data is secured within the tunnel when Auto Key IKE is used to automatically generate keys for the IKE SAs.

 © Palo Alto Networks, Inc.

| Define the IPSec Crypto Profile | | |
|---|---|---|
| Step 1 | Create a new IPSec profile. | 1. Select **Network > Network Profiles > IPSec Crypto** and select **Add**.<br>2. Enter a **Name f**or the new profile.<br>3. Select the **IPSec Protocol**—ESP or AH—that you want to apply to secure the data as it traverses across the tunnel.<br>4. Click **Add** and select the **Authentication** and **Encryption** algorithms for ESP, and **Authentication** algorithms for AH, so that the IKE peers can negotiate the keys for the secure transfer of data across the tunnel.<br>Selecting multiple algorithms allows the peers to use the strongest cipher/algorithm that is supported on both IKE peers. |
| Step 2 | Select the DH Group to use for the IPSec SA negotiations in IKE phase 2. | 1. Select the key strength that you want to use from the **DH Group** drop-down.<br>Select more than one DH group if you are not certain of what key strength is supported by the peer at the other end. The strongest cipher will be used for setting up the tunnel.<br>2. Select **no-pfs**, if you do not want to renew the key that was created at phase 1, the current key is reused for the IPSEC SA negotiations. |
| Step 3 | Specify the duration of the key—time and volume of traffic. | Using a combination of time and traffic volume allows you to ensure safety of data.<br>Select the **Lifetime** or time period for which the key is valid. When the specified time expires, the firewall will renegotiate a new set of keys.<br>Select the **Lifesize** or volume of data after which the keys must be renegotiated. |
| Step 4 | Save your IPSec profile. | Click **OK** and click **Commit**. |
| Step 5 | Attach the IPSec Profile to an IPSec tunnel configuration. | See Step 4 in |

## Set up an IPSec Tunnel

The IPSec tunnel configuration allows you to authenticate and/or encrypt the data (IP packet) as it traverses across the tunnel.

If you are setting up the Palo Alto Networks firewall to work with a peer that supports policy-based VPN, you must define Proxy IDs. Devices that support policy-based VPN use specific security rules/policies or access-lists (source addresses, destination addresses and ports) for permitting interesting traffic through an IPSec tunnel. These rules are referenced during quick mode/IKE phase 2 negotiation, and are exchanged as Proxy-IDs in the first or the second message of the process. So, if you are configuring the Palo Alto Networks firewall to work with a policy-based VPN peer, for a successful phase 2 negotiation you must define the

Proxy-ID so that the setting on both peers is identical. If the Proxy-ID is not configured, because the Palo Alto Networks firewall supports route-based VPN, the default values used as Proxy-ID are source ip: 0.0.0.0/0, destination ip: 0.0.0.0/0 and application: any; and when these values are exchanged with the peer, it results in a failure to set up the VPN connection.

**Set up an IPSec Tunnel**

Step 1 Select **Network > IPSec Tunnels> General** and enter a **Name** for the new tunnel.

Step 2 Select the **Tunnel interface** that will be used to set up the IPSec tunnel.

– To create a new tunnel interface:

1. Select **Network > Interfaces > Tunnel** and click **Add**.
2. In the **Interface Name** field, specify a numeric suffix, such as **.2**.
3. On the **Config** tab, expand the **Security Zone** drop-down to define the zone as follows:

   • To use your trust zone as the termination point for the tunnel, select the zone from the drop-down. Associating the tunnel interface with the same zone (and virtual router) as the external-facing interface on which the packets enter the firewall, mitigates the need to create inter-zone routing.

   • (Recommended) To create a separate zone for VPN tunnel termination, click **New Zone**. In the Zone dialog, define a **Name** for new zone (for example vpn-corp), and click **OK**.
4. In the **Virtual Router** drop-down, select **default**.
5. (Optional) If you want to assign an IPv4 address to the tunnel interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 10.31.32.1/32.
6. If you want to assign an IPv6 address to the tunnel interface, see Step 3.
7. To save the interface configuration, click **OK**.

Step 3 (Optional) Enable IPv6 on the tunnel interface.

1. Select the IPv6 tab on **Network > Interfaces > Tunnel > IPv6**.
2. Select the check box to **Enable IPv6 on the interface**.

   This option allows you to route IPv6 traffic over an IPv4 IPSec tunnel and will provide confidentiality between IPv6 networks. The IPv6 traffic is encapsulated by IPv4 and then ESP. To route IPv6 traffic to the tunnel, you can use a static route to the tunnel, or use OSPFv3, or use a Policy-Based Forwarding (PBF) rule to direct traffic to the tunnel.
3. Enter the 64-bit extended unique **Interface ID** in hexadecimal format, for example, 00:26:08:FF:FE:DE:4E:29. By default, the firewall will use the EUI-64 generated from the physical interface's MAC address.
4. To enter an IPv6 **Address**, click **Add** and enter an IPv6 address and prefix length, for example 2001:400:f00::1/64. If Prefix is not selected, the IPv6 address assigned to the interface will be wholly specified in the address text box.
   a. Select **Use interface ID as host portion** to assign an IPv6 address to the interface that will use the interface ID as the host portion of the address.
   b. Select **Anycast** to include routing through the nearest node.

 © Palo Alto Networks, Inc.

| Set up an IPSec Tunnel | |
|---|---|
| Step 4 Select the type of key that will be used to secure the IPSec tunnel. | Continue to one of the following steps, depending on why type of key exchange you are using:<br>• Set up Auto Key exchange.<br>• Set up Auto Key exchange. |
| • Set up Auto Key exchange. | 1. Select the IKE Gateway. To set up an IKE gateway, see Set up an IKE Gateway.<br>2. (Optional) Select the default IPSec Crypto Profile. To create a new IPSec Profile, see Define IPSec Crypto Profiles. |
| • Set up a Manual Key exchange. | 1. Set up the parameters for the local firewall:<br>a. Specify the **SPI** for the local firewall. SPI is a 32-bit hexadecimal index that is added to the header for IPSec tunneling to assist in differentiating between IPSec traffic flows; it is used to create the SA required for establishing a VPN tunnel.<br>b. Select the **Interface** that will be the tunnel endpoint, and optionally select the IP address for the local interface that is the endpoint of the tunnel.<br>c. Select the protocol to be used—**AH** or **ESP**.<br>d. For AH, select the **Authentication** method from the drop-down and enter a **Key** and then **Confirm Key**.<br>e. For ESP, select the **Authentication** method from the drop-down and enter a **Key** and then **Confirm Key**. Then, select the **Encryption** method and enter a **Key** and then **Confirm Key**, if needed.<br>2. Set up the parameters that pertain to the remote VPN peer.<br>a. Specify the **SPI** for the remote peer.<br>b. Enter the **Remote Address**, the IP address of the remote peer. |
| Step 5 Protect against a replay attack.<br>A replay attack occurs when a packet is maliciously intercepted and retransmitted by the interceptor. | Select the **Show Advanced Options** check box, select **Enable Replay Protection** to detect and neutralize against replay attacks. |
| Step 6 Preserve the Type of Service header for the priority or treatment of IP packets. | In the **Show Advanced Options** section, select **Copy TOS Header**. This copies the Type of Service (TOS) header from the inner IP header to the outer IP header of the encapsulated packets in order to preserve the original TOS information. |
| Step 7 Enable Tunnel Monitoring.<br> You need to assign an IP address to the tunnel interface for monitoring. | To alert the device administrator to tunnel failures and to provide automatic failover to another tunnel interface:<br>1. Specify a **Destination IP** address on the other side of the tunnel to determine if the tunnel is working properly.<br>2. Select a **Profile** to determine the action on tunnel failure. To create a new profile, see Define a Tunnel Monitoring Profile. |

| Set up an IPSec Tunnel | | |
|---|---|---|
| Step 8 | (Required only if the VPN peer uses policy-based VPN). Create a Proxy ID to identify the VPN peers. | 1. Select **Network > IPSec Tunnels > ProxyID**.<br>2. Click **Add** and enter the IP address for the VPN gateway peers.<br>  |
| Step 9 | Save your changes | Click **OK** and **Commit**. |

## Set up Tunnel Monitoring

To provide uninterrupted VPN service, you can use the Dead Peer Detection capability along with the tunnel monitoring capability on the firewall. You can also monitor the status of the tunnel. These monitoring tasks are described in the following sections:

- Define a Tunnel Monitoring Profile
- View the Status of the Tunnels

### Define a Tunnel Monitoring Profile

A tunnel monitoring profile allows you to verify connectivity between the VPN peers; you can configure the tunnel interface to ping a destination IP address at a specified interval and specify the action if the communication across the tunnel is broken.

| Define a Tunnel Monitoring Profile | |
|---|---|
| Step 1 | Select **Network > Network Profiles > Monitor**. A default tunnel monitoring profile is available for use. |
| Step 2 | Click **Add**, and enter a **Name** for the profile. |
| Step 3 | Select the **Action** if the destination IP address is unreachable.<br>• **Wait Recover**—the firewall waits for the tunnel to recover. It continues to use the tunnel interface in routing decisions as if the tunnel were still active.<br>• **Fail Over**—forces traffic to a back-up path if one is available. The firewall disables the tunnel interface, and thereby disables any routes in the routing table that use the interface.<br>In either case, the firewall attempts to accelerate the recovery by negotiating new IPSec keys. |
| Step 4 | Specify the **Interval** and **Threshold** to trigger the specified action.<br>The threshold specifies the number of heartbeats to wait before taking the specified action. The range is 2-100 and the default is 5.<br>The Interval measures the time between heartbeats. The range is 2-10 and the default is 3 seconds. |
| Step 5 | Attach the monitoring profile to the IPsec Tunnel configuration. See Enable Tunnel Monitoring. |

 © Palo Alto Networks, Inc.

## View the Status of the Tunnels

The status of the tunnel informs you about whether or not valid IKE phase-1 and phase-2 SAs have been established, and whether the tunnel interface is up and available for passing traffic.

Because the tunnel interface is a logical interface, it cannot indicate a physical link status. Therefore, you must enable tunnel monitoring so that the tunnel interface can verify connectivity to an IP address and determine if the path is still usable. If the IP address is unreachable, the firewall will either wait for the tunnel to recover or failover. When a failover occurs, the existing tunnel is torn down and routing changes are triggered to set up a new tunnel and redirect traffic.

**View Tunnel Status**

1. Select **Network > IPSec Tunnels**.
2. View the **Tunnel Status**.
   - Green indicates a valid IPSec SA tunnel.
   - Red indicates that IPSec SA is not available or has expired.
3. View the **IKE Gateway Status**.
   - Green indicates a valid IKE phase-1 SA.
   - Red indicates that IKE phase-1 SA is not available or has expired.
4. View the **Tunnel Interface Status**.
   - Green indicates that the tunnel interface is up.
   - Red indicates that the tunnel interface is down, because tunnel monitoring is enabled and the status is down.

To troubleshoot a VPN tunnel that is not yet up, see Interpret VPN Error Messages.

## Test VPN Connectivity

**Test Connectivity**

- Initiate IKE phase 1 by either pinging a host across the tunnel or using the following CLI command:

  **test vpn ike-sa gateway** *gateway_name*
- Then enter the following command to test if IKE phase 1 is set up:

  **show vpn ike-sa gateway** *gateway_name*

  In the output, check if the Security Association displays. If it does not, review the system log messages to interpret the reason for failure.
- Initiate IKE phase 2 by either pinging a host from across the tunnel or using the following CLI command:

  **test vpn ipsec-sa tunnel** *tunnel_name*
- Then enter the following command to test if IKE phase 1 is set up:

  **show vpn ipsec-sa tunnel** *tunnel_name*

  In the output, check if the Security Association displays. If it does not, review the system log messages to interpret the reason for failure.
- To view the VPN traffic flow information, use the following command:

  **show vpn-flow**

```
admin@PA-500> show vpn flow
total tunnels configured:             1
filter - type IPSec, state any

total IPSec tunnel configured:        1
total IPSec tunnel shown:             1

name               id      state    local-ip       peer-ip       tunnel-i/f
------------------------------------------------------------------------------
vpn-to-siteB       5       active    100.1.1.1     200.1.1.1      tunnel.41
```

## Interpret VPN Error Messages

The following table lists some of the common VPN error messages that are logged in the system log.

 © Palo Alto Networks, Inc.

**Table: Syslog Error Messages for VPN Issues**

| If error is this: | Try this: |
|---|---|
| `IKE phase-1 negotiation is failed as initiator, main mode. Failed SA: x.x.x.x[500]-y.y.y.y[500] cookie:84222f276c2fa2e9:0000000000000000 due to timeout.`<br>or<br>`IKE phase 1 negotiation is failed. Couldn't find configuration for IKE phase-1 request for peer IP x.x.x.x[1929]` | • Verify that the public IP address for each VPN peer is accurate in the IKE Gateway configuration.<br>• Verify that the IP addresses can be pinged and that routing issues are not causing the connection failure. |
| `Received unencrypted notify payload (no proposal chosen) from IP x.x.x.x[500] to y.y.y.y[500], ignored...`<br>or<br>`IKE phase-1 negotiation is failed. Unable to process peer's SA payload.` | Check the IKE Crypto profile configuration to verify that the proposals on both sides have a common encryption, authentication, and DH Group proposal. |
| `pfs group mismatched:my: 2peer: 0`<br>or<br>`IKE phase-2 negotiation failed when processing SA payload. No suitable proposal found in peer's SA payload.` | Check the IPSec Crypto profile configuration to verify that:<br>• pfs is either enabled or disabled on both VPN peers<br>• the DH Groups proposed by each peer has at least one DH Group in common |
| `IKE phase-2 negotiation failed when processing Proxy ID. Received local id x.x.x.x/x type IPv4 address protocol 0 port 0, received remote id y.y.y.y/y type IPv4 address protocol 0 port 0.` | The VPN peer on one end is using policy-based VPN. You must configure a Proxy ID on the Palo Alto Networks firewall. See Step 8. |

# Site-to-Site VPN Quick Configs

The following sections provide instructions for configuring some common VPN deployments:

- Site-to-Site VPN with Static Routing
- Site-to-Site VPN with OSPF
- Site-to-Site VPN with Static and Dynamic Routing

## Site-to-Site VPN with Static Routing

The following example shows a VPN connection between two sites that use static routes. Without dynamic routing, the tunnel interfaces on VPN Peer A and VPN Peer B do not require an IP address because the firewall automatically uses the tunnel interface as the next hop for routing traffic across the sites. However, to enable tunnel monitoring, a static IP address has been assigned to each tunnel interface.

 © Palo Alto Networks, Inc.

| Quick Config: Site-to-Site VPN with Static Routing | |
|---|---|
| Step 1 Configure a Layer 3 interface.<br><br>This interface is used for the IKE phase-1 tunnel. | 1. Select **Network > Interfaces > Ethernet** and then select the interface you want to configure for VPN.<br>2. Select **Layer3** from the **Interface Type** drop-down.<br>3. On the **Config** tab, select the **Security Zone** to which the interface belongs:<br>• The interface must be accessible from a zone outside of your trust network. Consider creating a dedicated VPN zone for visibility and control over your VPN traffic.<br>• If you have not yet created the zone, select **New Zone** from the **Security Zone** drop-down, define a **Name** for the new zone and then click **OK**.<br>4. Select the **Virtual Router** to use.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 192.168.210.26/24.<br>6. To save the interface configuration, click **OK**.<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—ethernet1/7<br>• **Security Zone**—untrust<br>• **Virtual Router**—default<br>• **IPv4**—192.168.210.26/24<br>The configuration for VPN Peer B is:<br>• **Interface**—ethernet1/11<br>• **Security Zone**—untrust<br>• **Virtual Router**—default<br>• **IPv4**—192.168.210.120/24 |

| Quick Config: Site-to-Site VPN with Static Routing | |
|---|---|
| Step 2 Create a tunnel interface and attach it to a virtual router and security zone.<br>  | 1. Select **Network > Interfaces > Tunnel** and click **Add**.<br>2. In the **Interface Name** field, specify a numeric suffix, such as **.1**.<br>3. On the **Config** tab, expand the **Security Zone** drop-down to define the zone as follows:<br>• To use your trust zone as the termination point for the tunnel, select the zone from the drop-down.<br>• (Recommended) To create a separate zone for VPN tunnel termination, click **New Zone**. In the Zone dialog, define a **Name** for new zone (for example *vpn-tun*), and then click **OK**.<br>4. Select the **Virtual Router**.<br>5. (Optional) Assign an IP address to the tunnel interface, select the **IPv4** or **IPv6** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface.<br>With static routes, the tunnel interface does not require an IP address. For traffic that is destined to a specified subnet/IP address, the tunnel interface will automatically become the next hop. Consider adding an IP address if you want to enable tunnel monitoring.<br>6. To save the interface configuration, click **OK**.<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—tunnel.11<br>• **Security Zone**—vpn_tun<br>• **Virtual Router**—default<br>• **IPv4**—172.19.9.2/24<br>The configuration for VPN Peer B is:<br>• **Interface**—tunnel.12<br>• **Security Zone**—vpn_tun<br>• **Virtual Router**—default<br>• **IPv4**—192.168.69.2/24 |
| Step 3 Configure a static route, on the virtual router, to the destination subnet.<br> | 1. Select **Network > Virtual Router** and click the router you defined in step 4 above.<br>2. Select **Static Route**, click **Add**, and enter a new route to access the subnet that is at the other end of the tunnel.<br>In this example, the configuration for VPN Peer A is:<br>• **Destination**—192.168.69.0/24<br>• **Interface**—tunnel.11<br>The configuration for VPN Peer B is:<br>• **Destination**—172.19.9.0/24<br>• **Interface**—tunnel.12 |

© Palo Alto Networks, Inc.

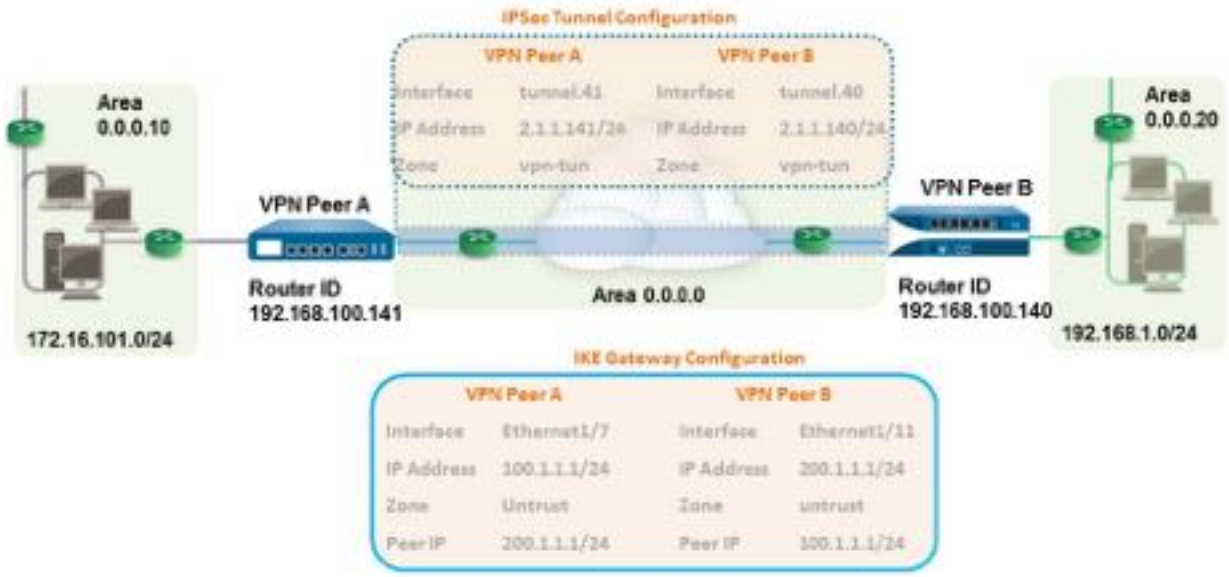
| Quick Config: Site-to-Site VPN with Static Routing | |
|---|---|
| Step 4 Set up the Crypto profiles (IKE Crypto profile for phase 1 and IPSec Crypto profile for phase 2).<br><br>Complete this task on both peers and make sure to set identical values. | 1. Select **Network > Network Profiles > IKE Crypto**. In this example, we use the default profile.<br> <br>2. Select **Network > Network Profiles > IPSec Crypto**. In this example, we use the default profile.<br> |
| Step 5 Set up the IKE Gateway.<br> | 1. Select **Network > Network Profiles > IKE Gateway.**<br>2. Click **Add** and configure the options in the **General** tab**.**<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—ethernet1/7<br>• **Local IP address**—192.168.210.26/24<br>• **Peer IP type/address**—static/192.168.210.120<br>• **Preshared keys**—enter a value<br>• **Local identification**—None; this means that the local IP address will be used as the local identification value.<br>The configuration for VPN Peer B is:<br>• **Interface**—ethernet1/11<br>• **Local IP address**—192.168.210.120/24<br>• **Peer IP type/address**—static/192.168.210.26<br>• **Preshared keys**—enter same value as on Peer A<br>• **Local identification**—None<br>3. Select **Advanced Phase 1 Options** and select the IKE Crypto profile you created earlier to use for IKE phase 1. |

| Quick Config: Site-to-Site VPN with Static Routing | | |
|---|---|---|
| Step 6 | Set up the IPSec Tunnel. | 1. Select **Network > IPSec Tunnels**.<br>2. Click **Add** and configure the options in the **General** tab.<br>In this example, the configuration for VPN Peer A is:<br>• **Tunnel Interface**—tunnel.11<br>• **Type**—Auto Key<br>• **IKE Gateway**—Select the IKE Gateway defined above.<br>• **IPSec Crypto Profile**—Select the IPSec Crypto profile defined in Step 4.<br>The configuration for VPN Peer B is:<br>• **Tunnel Interface**—tunnel.12<br>• **Type**—Auto Key<br>• **IKE Gateway**—Select the IKE Gateway defined above.<br>• **IPSec Crypto Profile**—Select the IPSec Crypto defined in Step 4.<br>3. (Optional) Select **Show Advanced Options**, select **Tunnel Monitor**, and specify a Destination IP address to ping for verifying connectivity. Typically, the tunnel interface IP address for the VPN Peer is used.<br>4. (Optional) To define the action on failure to establish connectivity, see Define a Tunnel Monitoring Profile. |
| Step 7 | Create policies to allow traffic between the sites (subnets). | 1. Select **Policies > Security**.<br>2. Create rules to allow traffic between the untrust and the vpn-tun zone and the vpn-tun and the untrust zone for traffic originating from specified source and destination IP addresses. |
| Step 8 | Save any pending configuration changes. | Click **Commit**. |
| Step 9 | Test VPN connectivity. | See View the Status of the Tunnels. |

## Site-to-Site VPN with OSPF

In this example, each site uses OSPF for dynamic routing of traffic. The tunnel IP address on each VPN peer is statically assigned and serves as the next hop for routing traffic between the two sites.

 © Palo Alto Networks, Inc.



**Quick Config: Site-to-Site VPN with Dynamic Routing using OSPF**

| | |
|---|---|
| Step 1 Configure the Layer 3 interfaces on each firewall. | 1. Select **Network > Interfaces > Ethernet** and then select the interface you want to configure for VPN.<br>2. Select **Layer3** from the **Interface Type** drop-down.<br>3. On the **Config** tab, select the **Security Zone** to which the interface belongs:<br>• The interface must be accessible from a zone outside of your trust network. Consider creating a dedicated VPN zone for visibility and control over your VPN traffic.<br>• If you have not yet created the zone, select **New Zone** from the **Security Zone** drop-down, define a **Name** for the new zone and then click **OK**.<br>4. Select the **Virtual Router** to use.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 192.168.210.26/24.<br>6. To save the interface configuration, click **OK**.<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—ethernet1/7<br>• **Security Zone**—untrust<br>• **Virtual Router**—default<br>• **IPv4**—100.1.1.1/24<br>The configuration for VPN Peer B is:<br>• **Interface**—ethernet1/11<br>• **Security Zone**—untrust<br>• **Virtual Router**—default<br>• **IPv4**—200.1.1.1/24 |

| Quick Config: Site-to-Site VPN with Dynamic Routing using OSPF | |
|---|---|
| Step 2 Create a tunnel interface and attach it to a virtual router and security zone.<br> | 1. Select **Network > Interfaces > Tunnel** and click **Add**.<br>2. In the **Interface Name** field, specify a numeric suffix, say, **.11**.<br>3. On the **Config** tab, expand the **Security Zone** drop-down to define the zone as follows:<br>• To use your trust zone as the termination point for the tunnel, select the zone from the drop-down.<br>• (Recommended) To create a separate zone for VPN tunnel termination, click **New Zone**. In the Zone dialog, define a **Name** for new zone (for example *vpn-tun*), and then click **OK**.<br>4. Select the **Virtual Router**.<br>5. Assign an IP address to the tunnel interface, select the **IPv4** or **IPv6** tab, click **Add** in the IP section, and enter the IP address and network mask/prefix to assign to the interface, for example, 172.19.9.2/24.<br>This IP address will be used as the next hop IP address to route traffic to the tunnel and can also be used to monitor the status of the tunnel.<br>6. To save the interface configuration, click **OK**.<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—tunnel.41<br>• **Security Zone**—vpn_tun<br>• **Virtual Router**—default<br>• **IPv4**—2.1.1.141/24<br>The configuration for VPN Peer B is:<br>• **Interface**—tunnel.40<br>• **Security Zone**—vpn_tun<br>• **Virtual Router**—default<br>• **IPv4**—2.1.1.140/24 |
| Step 3 Set up the Crypto profiles (IKE Crypto profile for phase 1 and IPSec Crypto profile for phase 2).<br>Complete this task on both peers and make sure to set identical values. | 1. Select **Network > Network Profiles > IKE Crypto**. In this example, we use the default profile.<br> <br>2. Select **Network > Network Profiles > IPSec Crypto**. In this example, we use the default profile.<br> |

© Palo Alto Networks, Inc.

| Quick Config: Site-to-Site VPN with Dynamic Routing using OSPF | | |
|---|---|---|
| Step 4 | Set up the OSPF configuration on the virtual router and attach the OSPF areas with the appropriate interfaces on the firewall.<br><br>For more information on the OSPF options that are available on the firewall, see Configure OSPF.<br><br>Use Broadcast as the link type when there are more than two OSPF routers that need to exchange routing information. | 1. Select **Network > Virtual Routers**, and select the default router or add a new router.<br>2. Select **OSPF** (for IPv4) or **OSPFv3** (for IPv6) and select **Enable**.<br>3. In this example, the OSPF configuration for VPN Peer A is:<br>– **Router ID**: 192.168.100.141<br>– **Area ID**: 0.0.0.0 that is assigned to the tunnel.1 interface with Link type: p2p<br>– **Area ID**: 0.0.0.10 that is assigned to the interface Ethernet1/1 and Link Type: Broadcast<br>The OSPF configuration for VPN Peer B is:<br>– **Router ID**: 192.168.100.140<br>– **Area ID**: 0.0.0.0 that is assigned to the tunnel.1 interface with Link type: p2p<br>– **Area ID**: 0.0.0.20 that is assigned to the interface Ethernet1/15 and Link Type: Broadcast |
| Step 5 | Set up the IKE Gateway.<br><br>This examples uses static IP addresses for both VPN peers. Typically, the corporate office uses a statically configured IP address, and the branch side can be a dynamic IP address; dynamic IP addresses are not best suited for configuring stable services such as VPN. | 1. Select **Network > Network Profiles > IKE Gateway.**<br>2. Click **Add** and configure the options in the **General** tab**.**<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—ethernet1/7<br>• **Local IP address**—100.1.1.1/24<br>• **Peer IP address**—200.1.1.1/24<br>• **Preshared keys**—enter a value<br>The configuration for VPN Peer B is:<br>• **Interface**—ethernet1/11<br>• **Local IP address**—200.1.1.1/24<br>• **Peer IP address**—100.1.1.1/24<br>• **Preshared keys**—enter same value as on Peer A<br>3. Select the IKE Crypto profile you created earlier to use for IKE phase 1. |

| Quick Config: Site-to-Site VPN with Dynamic Routing using OSPF | |
|---|---|
| Step 6 Set up the IPSec Tunnel. | 1. Select **Network > IPSec Tunnels**.<br>2. Click **Add** and configure the options in the **General** tab.<br>In this example, the configuration for VPN Peer A is:<br>• **Tunnel Interface**—tunnel.41<br>• **Type**—Auto Key<br>• **IKE Gateway**—Select the IKE Gateway defined above.<br>• **IPSec Crypto Profile**—Select the IKE Gateway defined above.<br>The configuration for VPN Peer B is:<br>• **Tunnel Interface**—tunnel.40<br>• **Type**—Auto Key<br>• **IKE Gateway**—Select the IKE Gateway defined above.<br>• **IPSec Crypto Profile**—Select the IKE Gateway defined above.<br>3. Select **Show Advanced Options**, select **Tunnel Monitor**, and specify a Destination IP address to ping for verifying connectivity.<br>4. To define the action on failure to establish connectivity, see Define a Tunnel Monitoring Profile. |
| Step 7 Create policies to allow traffic between the sites (subnets). | 1. Select **Policies > Security**.<br>2. Create rules to allow traffic between the untrust and the vpn-tun zone and the vpn-tun and the untrust zone for traffic originating from specified source and destination IP addresses. |

 © Palo Alto Networks, Inc.

| Quick Config: Site-to-Site VPN with Dynamic Routing using OSPF | | |
|---|---|---|
| Step 8 | Verify OSPF adjacencies and routes from the CLI. | Verify that both the firewalls can see each other as neighbors with full status. Also confirm that the IP address of the VPN peer's tunnel interface and the OSPF Router ID. Use the following CLI commands on each VPN peer.<br>• **show routing protocol ospf neighbor**<br>  |
| | | • **show routing route type ospf**<br>  |
| Step 9 | Test VPN connectivity. | See Set up Tunnel Monitoring and View the Status of the Tunnels. |

## Site-to-Site VPN with Static and Dynamic Routing

In this example, one site uses static routes and the other site uses OSPF. When the routing protocol is not the same between the locations, the tunnel interface on each firewall must be configured with a static IP address. Then, to allow the exchange of routing information, the firewall that participates in both the static and dynamic routing process must be configured with a *Redistribution profile*. Configuring the redistribution profile enables the virtual router to redistribute and filter routes between protocols—static routes, connected routes, and hosts—

from the static autonomous system to the OSPF autonomous system. Without this redistribution profile, each protocol functions on its own and does not exchange any route information with other protocols running on the same virtual router.

In this example, the satellite office has static routes and all traffic destined to the 192.168.x.x network is routed to tunnel.41. The virtual router on VPN Peer B participates in both the static and the dynamic routing process and is configured with a redistribution profile in order to propagate (*export*) the static routes to the OSPF autonomous system.

 © Palo Alto Networks, Inc.

| Quick Config: Site-to-Site VPN with Static and Dynamic Routing | | |
|---|---|---|
| Step 1 | Configure the Layer 3 interfaces on each firewall. | 1. Select **Network > Interfaces > Ethernet** and then select the interface you want to configure for VPN.<br>2. Select **Layer3** from the **Interface Type** drop-down.<br>3. On the **Config** tab, select the **Security Zone** to which the interface belongs:<br>• The interface must be accessible from a zone outside of your trust network. Consider creating a dedicated VPN zone for visibility and control over your VPN traffic.<br>• If you have not yet created the zone, select **New Zone** from the **Security Zone** drop-down, define a **Name** for the new zone and then click **OK**.<br>4. Select the **Virtual Router** to use.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 192.168.210.26/24.<br>6. To save the interface configuration, click **OK**.<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—ethernet1/7<br>• **Security Zone**—untrust<br>• **Virtual Router**—default<br>• **IPv4**—100.1.1.1/24<br>The configuration for VPN Peer B is:<br>• **Interface**—ethernet1/11<br>• **Security Zone**—untrust<br>• **Virtual Router**—default<br>• **IPv4**—200.1.1.1/24 |
| Step 2 | Set up the Crypto profiles (IKE Crypto profile for phase 1 and IPSec Crypto profile for phase 2).<br>Complete this task on both peers and make sure to set identical values. | 1. Select **Network > Network Profiles > IKE Crypto**. In this example, we use the default profile.<br> <br>2. Select **Network > Network Profiles > IPSec Crypto**. In this example, we use the default profile.<br> |

| Quick Config: Site-to-Site VPN with Static and Dynamic Routing | |
|---|---|
| Step 3 Set up the IKE Gateway.<br><br>With pre-shared keys, to add authentication scrutiny when setting up the IKE phase-1 tunnel, you can set up Local and Peer Identification attributes and a corresponding value that is matched in the IKE negotiation process. | 1. Select **Network > Network Profiles > IKE Gateway.**<br>2. Click **Add** and configure the options in the **General** tab.<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—ethernet1/7<br>• **Local IP address**—100.1.1.1/24<br>• **Peer IP type**—dynamic<br>• **Preshared keys**—enter a value<br>• **Local identification**—select **FQDN(hostname)** and enter the value for VPN Peer A.<br>• **Peer identification**—select **FQDN(hostname)** and enter the value for VPN Peer B<br>The configuration for VPN Peer B is:<br>• **Interface**—ethernet1/11<br>• **Local IP address**—200.1.1.1/24<br>• **Peer IP address**—dynamic<br>• **Preshared keys**—enter same value as on Peer A<br>• **Local identification**—select **FQDN(hostname)** and enter the value for VPN Peer B<br>• **Peer identification**—select **FQDN(hostname)** and enter the value for VPN Peer A<br>3. Select the IKE Crypto profile you created earlier to use for IKE phase 1. |

 © Palo Alto Networks, Inc.

| Quick Config: Site-to-Site VPN with Static and Dynamic Routing | | |
|---|---|---|
| Step 4 | Create a tunnel interface and attach it to a virtual router and security zone.<br> | 1. Select **Network > Interfaces > Tunnel** and click **Add**.<br>2. In the **Interface Name** field, specify a numeric suffix, say, **.41**.<br>3. On the **Config** tab, expand the **Security Zone** drop-down to define the zone as follows:<br>• To use your trust zone as the termination point for the tunnel, select the zone from the drop-down.<br>• (Recommended) To create a separate zone for VPN tunnel termination, click **New Zone**. In the Zone dialog, define a **Name** for new zone (for example *vpn-tun*), and then click **OK**.<br>4. Select the **Virtual Router**.<br>5. Assign an IP address to the tunnel interface, select the **IPv4** or **IPv6** tab, click **Add** in the IP section, and enter the IP address and network mask/prefix to assign to the interface, for example, 172.19.9.2/24.<br>This IP address will be used to route traffic to the tunnel and to monitor the status of the tunnel.<br>6. To save the interface configuration, click **OK**.<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—tunnel.41<br>• **Security Zone**—vpn_tun<br>• **Virtual Router**—default<br>• **IPv4**—2.1.1.141/24<br>The configuration for VPN Peer B is:<br>• **Interface**—tunnel.42<br>• **Security Zone**—vpn_tun<br>• **Virtual Router**—default<br>• **IPv4**—2.1.1.140/24 |
| Step 5 | Specify the interface to route traffic to a destination on the 192.168.x.x network. | 1. On VPN Peer A, select the virtual router.<br>2. Select **Static Routes**, and **Add** tunnel.41 as the **Interface** for routing traffic with a **Destination** in the 192.168.x.x network. |

| Quick Config: Site-to-Site VPN with Static and Dynamic Routing | |
|---|---|
| Step 6 Set up the static route and the OSPF configuration on the virtual router and attach the OSPF areas with the appropriate interfaces on the firewall. | 1. On VPN Peer B, select **Network > Virtual Routers**, and select the default router or add a new router.<br>2. Select **Static Routes** and **Add** the tunnel IP address as the next hop for traffic in the 172.168.x.x. network.<br>Assign the desired route metric; using a lower the value makes the a higher priority for route selection in the forwarding table.<br>3. Select **OSPF** (for IPv4) or **OSPFv3** (for IPv6) and select **Enable**.<br>4. In this example, the OSPF configuration for VPN Peer B is:<br>• Router ID: 192.168.100.140<br>• Area ID: 0.0.0.0 is assigned to the interface Ethernet 1/12 Link type: Broadcast<br>• Area ID: 0.0.0.10 that is assigned to the interface Ethernet1/1 and Link Type: Broadcast<br>• Area ID: 0.0.0.20 is assigned to the interface Ethernet1/15 and Link Type: Broadcast |
| Step 7 Create a redistribution profile to inject the static routes into the OSPF autonomous system.<br> <br> | 1. Create a redistribution profile on VPN Peer B.<br>a. Select **Network > Virtual Routers**, and select the router you used above.<br>b. Select **Redistribution Profiles,** and click **Add**.<br>c. Enter a Name for the profile and select **Redist** and assign a **Priority** value. If you have configured multiple profiles, the profile with the lowest priority value is matched first.<br>d. Set **Source Type** as **static**, and click **OK**. The static route defined in Step 6-2 will be used for the redistribution.<br>2. Inject the static routes in to the OSPF system.<br>a. Select **OSPF> Export Rules** (for IPv4) or **OSPFv3> Export Rules** (for IPv6).<br>b. Click **Add**, and select the redistribution profile that you just created.<br>c. Select how the external routes are brought into the OSPF system. The default option, **Ext2** calculates the total cost of the route using only the external metrics. To use both internal and external OSPF metrics, use **Ext1.**<br>d. Assign a **Metric** (cost value) for the routes injected into the OSPF system. This option allows you to change the metric for the injected route as it comes into the OSPF system.<br>e. Click **OK** to save the changes. |

 © Palo Alto Networks, Inc.

| Quick Config: Site-to-Site VPN with Static and Dynamic Routing | | |
|---|---|---|
| Step 8 | Set up the IPSec Tunnel. | 1. Select **Network > IPSec Tunnels**.<br>2. Click **Add** and configure the options in the **General** tab.<br>In this example, the configuration for VPN Peer A is:<br>• **Tunnel Interface**—tunnel.41<br>• **Type**—Auto Key<br>• **IKE Gateway**—Select the IKE Gateway defined above.<br>• **IPSec Crypto Profile**—Select the IKE Gateway defined above.<br>The configuration for VPN Peer B is:<br>• **Tunnel Interface**—tunnel.40<br>• **Type**—Auto Key<br>• **IKE Gateway**—Select the IKE Gateway defined above.<br>• **IPSec Crypto Profile**—Select the IKE Gateway defined above.<br>3. Select **Show Advanced Options**, select **Tunnel Monitor**, and specify a Destination IP address to ping for verifying connectivity.<br>4. To define the action on failure to establish connectivity, see Define a Tunnel Monitoring Profile. |
| Step 9 | Create policies to allow traffic between the sites (subnets). | 1. Select **Policies > Security**.<br>2. Create rules to allow traffic between the untrust and the vpn-tun zone and the vpn-tun and the untrust zone for traffic originating from specified source and destination IP addresses. |

| Quick Config: Site-to-Site VPN with Static and Dynamic Routing | |
|---|---|
| Step 10 Verify OSPF adjacencies and routes from the CLI. | Verify that both the firewalls can see each other as neighbors with full status. Also confirm that the IP address of the VPN peer's tunnel interface and the OSPF Router ID. Use the following CLI commands on each VPN peer.<br>• **`show routing protocol ospf neighbor`**<br>  |
| | • **show routing route**<br>The following is an example of the output on each VPN peer.<br> |
| Step 11 Test VPN connectivity. | See Set up Tunnel Monitoring and View the Status of the Tunnels. |

# Large Scale VPN (LSVPN)

The GlobalProtect Large Scale VPN (LSVPN) feature on the Palo Alto Networks next-generation firewall simplifies the deployment of traditional hub and spoke VPNs, enabling you to quickly deploy enterprise networks with several branch offices with a minimum amount of configuration required on the remote *satellite* devices. This solution uses certificates for device authentication and IPSec to secure data.

LSVPN enables site-to-site VPNs between Palo Alto Networks firewalls. To set up a site-to-site VPN between a Palo Alto Networks firewall and another device, see VPNs.

The following topics describe the LSVPN components and how to set them up to enable site-to-site VPN services between Palo Alto Networks firewalls:

- LSVPN Overview
- Create Interfaces and Zones for the LSVPN
- Enable SSL Between GlobalProtect LSVPN Components
- Configure the Portal to Authenticate Satellites
- Configure GlobalProtect Gateways for LSVPN
- Configure the GlobalProtect Portal for LSVPN
- Prepare the Satellite Device to Join the LSVPN
- Verify the LSVPN Configuration
- LSVPN Quick Configs

# LSVPN Overview

GlobalProtect provides a complete infrastructure for managing secure access to corporate resources from your remote sites. This infrastructure includes the following components:

- **GlobalProtect Portal**—Provides the management functions for your GlobalProtect LSVPN infrastructure. Every satellite that participates in the GlobalProtect LSVPN receives configuration information from the portal, including configuration information to enable the satellites (the spokes) to connect to the gateways (the hubs). You configure the portal on an interface on any Palo Alto Networks next-generation firewall.
- **GlobalProtect Gateways**—A Palo Alto Networks firewall that provides the tunnel end point for satellite connections. The resources that the satellites access is protected by security policy on the gateway. It is not required to have a separate portal and gateway; a single firewall can function both as portal and gateway.
- **GlobalProtect Satellite**—A Palo Alto Networks firewall at a remote site that establishes IPSec tunnels with the gateway(s) at your corporate office(s) for secure access to centralized resources. Configuration on the satellite firewall is minimal, enabling you to quickly and easily scale your VPN as you add new sites.

The following diagram illustrates how the GlobalProtect LSVPN components work together.

 © Palo Alto Networks, Inc.

# Create Interfaces and Zones for the LSVPN

You must configure the following interfaces and zones for your LSVPN infrastructure:

- **GlobalProtect portal**—Requires a Layer 3 interface for GlobalProtect satellites to connect to. If the portal and gateway are on the same firewall, they can use the same interface. The portal must be in a zone that is accessible from your branch offices.
- **GlobalProtect gateways**—Requires three interfaces: a Layer 3 interface in the zone that is reachable by the remote satellites, an internal interface in the trust zone that connects to the protected resources, and a logical tunnel interface for terminating the VPN tunnels from the satellites. Unlike other site-to-site VPN solutions, the GlobalProtect gateway only requires a single tunnel interface, which it will use for tunnel connections with all of your remote satellites (point-to-multipoint). If you plan to use dynamic routing, you must assign an IP address to the tunnel interface.
- **GlobalProtect satellites**—Requires a single tunnel interface for establishing a VPN with the remote gateways (up to a maximum of 25 gateways). If you plan to use dynamic routing, you must assign an IP address to the tunnel interface.

For more information about portals, gateways, and satellites see LSVPN Overview.

| Set Up Interfaces and Zones for the GlobalProtect LSVPN | |
|---|---|
| Step 1 Configure a Layer 3 interface.<br><br>The portal and each gateway and satellite all require a Layer 3 interface to enable traffic to be routed between sites.<br><br>If the gateway and portal are on the same firewall, you can use a single interface for both components.<br><br>IPv6 addresses are not supported with LSVPN. | 1. Select **Network > Interfaces > Ethernet** and then select the interface you want to configure for GlobalProtect LSVPN.<br>2. Select **Layer3** from the **Interface Type** drop-down.<br>3. On the **Config** tab, select the **Security Zone** to which the interface belongs:<br>• The interface must be accessible from a zone outside of your trust network. Consider creating a dedicated VPN zone for visibility and control over your VPN traffic.<br>• If you have not yet created the zone, select **New Zone** from the **Security Zone** drop-down, define a **Name** for the new zone and then click **OK**.<br>4. Select the **Virtual Router** to use.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 203.0.11.100/24.<br>6. To save the interface configuration, click **OK**. |

| Set Up Interfaces and Zones for the GlobalProtect LSVPN (Continued) | | |
|---|---|---|
| Step 2 | On the firewall(s) hosting GlobalProtect gateway(s), configure the logical tunnel interface that will terminate VPN tunnels established by the GlobalProtect satellites.<br><br>IP addresses are not required on the tunnel interface unless plan to use dynamic routing. However, assigning an IP address to the tunnel interface can be useful for troubleshooting connectivity issues.<br><br>Make sure to enable User-ID in the zone where the VPN tunnels terminate. | 1. Select **Network > Interfaces > Tunnel** and click **Add**.<br>2. In the **Interface Name** field, specify a numeric suffix, such as **.2**.<br>3. On the **Config** tab, expand the **Security Zone** drop-down to define the zone as follows:<br>• To use your trust zone as the termination point for the tunnel, select the zone from the drop-down.<br>• (Recommended) To create a separate zone for VPN tunnel termination, click **New Zone**. In the Zone dialog, define a **Name** for new zone (for example *lsvpn-tun*), select the **Enable User Identification** check box, and then click **OK**.<br>4. Select the **Virtual Router**.<br>5. (Optional) If you want to assign an IP address to the tunnel interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 203.0.11.33/24.<br>6. To save the interface configuration, click **OK**. |
| Step 3 | If you created a separate zone for tunnel termination of VPN connections, create a security policy to enable traffic flow between the VPN zone and your trust zone. For example, the following policy rule enables traffic between the *lsvpn-tun* zone and the *L3-Trust* zone.<br>  <br> | |
| Step 4 | Save the configuration. | Click **Commit**. |

 © Palo Alto Networks, Inc.

# Enable SSL Between GlobalProtect LSVPN Components

All interaction between the GlobalProtect components occurs over an SSL connection. Therefore, you must generate and/or install the required certificates before configuring each component so that you can reference the appropriate certificate(s) and/or certificate profiles in the configurations for each component. The following sections describe the supported methods of certificate deployment, descriptions and best practice guidelines for the various GlobalProtect certificates, and provide instructions for generating and deploying the required certificates:

▲ About Certificate Deployment

▲ Deploy Server Certificates to the GlobalProtect LSVPN Components

## About Certificate Deployment

There are two basic approaches to deploying certificates for GlobalProtect LSVPN:

- **Enterprise Certificate Authority**—If you already have your own enterprise certificate authority, you can use this internal CA to issue an intermediate CA certificate for the GlobalProtect portal to enable it to issue certificates to the GlobalProtect gateways and satellites.
- **Self-Signed Certificates**—You can generate a self-signed root CA certificate on the firewall and use it to issue server certificates for the portal, gateway(s), and satellite(s). As a best practice, create a self-signed root CA certificate on the portal and use it to issue server certificates for the gateways and satellites. This way, the private key used for certificate signing stays on the portal.

## Deploy Server Certificates to the GlobalProtect LSVPN Components

The GlobalProtect LSVPN components use SSL/TLS to mutually authenticate. Before deploying the LSVPN, you must issue server certificates to the portal and gateways. You do not need to create server certificates for the satellite devices because the portal will issue a server certificate for each satellite during the first connection.

In addition, you must import the root CA certificate used to issue the server certificates onto each firewall that you plan to host as a gateway or satellite. Finally, on each gateway and satellite participating in the LSVPN, you must configure a certificate profile that will enable them to establish an SSL/TLS connection using mutual authentication.

The following workflow shows the best practice steps for deploying SSL certificates to the GlobalProtect LSVPN components:

You do not need to issue server certificates for the satellite devices because the portal will issue them as part of the satellite registration process.

| Deploy SSL Server Certificates to the GlobalProtect Components | | |
|---|---|---|
| Step 1 | On the firewall hosting the portal, create the root CA certificate for issuing self-signed certificates for the GlobalProtect components. | To use self-signed certificates, you must first create the root CA certificate that will be used to sign the certificates for the GlobalProtect components as follows:<br>1. To create a root CA certificate, select **Device > Certificate Management > Certificates > Device Certificates** and then click **Generate**.<br>2. Enter a **Certificate Name**, such as *LSVPN_CA*. The certificate name cannot contain any spaces.<br>3. Do not select a value in the **Signed By** field (this is what indicates that it is self-signed).<br>4. Select the **Certificate Authority** check box and then click **OK** to generate the certificate. |
| Step 2 | Generate server certificates for the GlobalProtect portal and gateway(s).<br>You must issue a unique self-signed server certificate for the portal and for each GlobalProtect gateway. The best practice is to issue all of the required certificates on the portal, so that the signing certificate (with the private key) does not have to be exported.<br> If the GlobalProtect portal and gateway are on the same firewall interface, you can use the same server certificate for both components. | Use the root CA on the portal to generate server certificates for each gateway you plan to deploy:<br>1. Select **Device > Certificate Management > Certificates > Device Certificates** and then click **Generate**.<br>2. Enter a **Certificate Name**. The Certificate Name cannot contain any spaces.<br>3. Enter the FQDN (recommended) or IP address of the interface where you plan to configure the gateway in the **Common Name** field.<br>4. In the **Signed By** field, select the *LSVPN_CA* you created previously.<br>5. In the Certificate Attributes section, click **Add** and define the attributes to uniquely identify the gateway. Keep in mind that if you add a **Host Name** attribute (which populates the SAN field of the certificate), it must exactly match the value you defined for the **Common Name**.<br>6. **Generate** the certificate. |

 © Palo Alto Networks, Inc.

| Deploy SSL Server Certificates to the GlobalProtect Components (Continued) | |
|---|---|
| Step 3 Deploy the self-signed server certificates to the gateways.<br><br>**Best Practices:**<br>• Export the self-signed server certificates issued by the root CA from the portal and import them onto the gateways.<br>• Be sure to issue a unique server certificate for each gateway.<br>• The Common Name (CN) and, if applicable, the Subject Alternative Name (SAN) fields of the certificate must match the IP address or fully qualified domain name (FQDN) of the interface where you configure the gateway. | 1. On the portal, select **Device > Certificate Management > Certificates > Device Certificates**, select the gateway certificate you want to deploy, and click **Export**.<br>2. Select **Encrypted Private Key and Certificate (PKCS12)** from the **File Format** drop-down.<br>3. Enter (and re-enter) a **Passphrase** to encrypt the private key associated with the certificate and then click **OK** to download the PKCS12 file to your computer.<br>4. On the gateway, select **Device > Certificate Management > Certificates > Device Certificates** and click **Import**.<br>5. Enter a **Certificate Name**.<br>6. Enter the path and name to the **Certificate File** you just downloaded from the portal, or **Browse** to find the file.<br>7. Select **Encrypted Private Key and Certificate (PKCS12)** as the **File Format**.<br>8. Enter the path and name to the PKCS12 file in the **Key File** field or **Browse** to find it.<br>9. Enter and re-enter the **Passphrase** you used to encrypt the private key when you exported it from the portal and then click **OK** to import the certificate and key. |
| Step 4 Import the root CA certificate used to issue server certificates for the LSVPN components.<br><br>You must import the root CA certificate onto all gateways and satellites. For security reasons, make sure you export the certificate only, and not the associated private key. | 1. Download the root CA certificate from the portal.<br>a. Select **Device > Certificate Management > Certificates > Device Certificates**.<br>b. Select the root CA certificate used to issue certificates for the LSVPN components and click **Export**.<br>c. Select **Base64 Encoded Certificate (PEM)** from the **File Format** drop-down and click **OK** to download the certificate. (Do not export the private key.)<br>2. On the firewalls hosting the gateways and satellites, import the root CA certificate.<br>a. Select **Device > Certificate Management > Certificates > Device Certificates** and click **Import**.<br>b. Enter a **Certificate Name** that identifies the certificate as your client CA certificate.<br>c. **Browse** to the **Certificate File** you downloaded from the CA.<br>d. Select **Base64 Encoded Certificate (PEM)** as the **File Format** and then click **OK**.<br>e. Select the certificate you just imported on the **Device Certificates** tab to open it.<br>f. Select **Trusted Root CA** and then click **OK**.<br>g. **Commit** the changes. |

| Deploy SSL Server Certificates to the GlobalProtect Components (Continued) | | |
|---|---|---|
| Step 5 | Create a certificate profile.<br>The GlobalProtect LSVPN portal and each gateway require a certificate profile that specifies which certificate to use to authenticate the satellites. | 1. Select **Device > Certificate Management > Certificate Profile** and click **Add** and enter a profile **Name**.<br>2. Make sure **Username Field** is set to **None**.<br>3. In the **CA Certificates** field, click **Add**, select the Trusted Root CA certificate you imported in Step 4.<br>4. (Optional, but recommended) Enable use of CRL and/or OCSP to enable certificate status verification.<br>5. Click **OK** to save the profile. |
| Step 6 | Save the configuration. | Click **Commit**. |

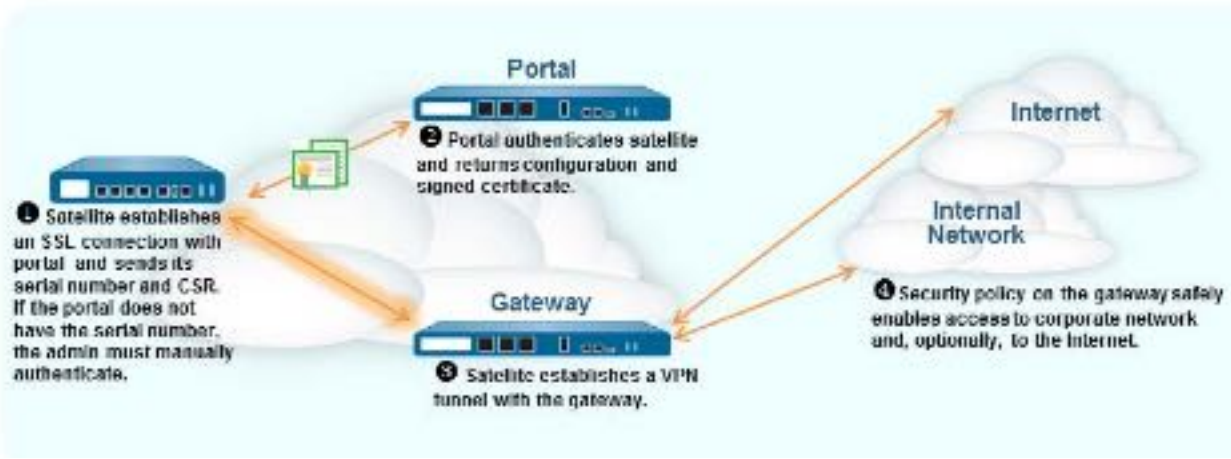
© Palo Alto Networks, Inc.

# Configure the Portal to Authenticate Satellites

In order to register with the LSVPN, each satellite must establish an SSL/TLS connection with the portal. After establishing the connection, the portal authenticates the satellite device to ensure that is authorized to join the LSVPN. After successfully authenticating the satellite, the portal will issue a server certificate for the satellite and push the LSVPN configuration specifying the gateways to which the satellite can connect and the root CA certificate required to establish an SSL connection with the gateways.

There are two ways that the satellite can authenticate to the portal during its initial connection:

- **Serial number**—You can configure the portal with the serial number of the satellite firewalls that are authorized to join the LSVPN. During the initial satellite connection to the portal, the satellite presents its serial number to the portal and if the portal has the serial number in its configuration, the satellite will be successfully authenticated. You add the serial numbers of authorized satellites when you configure the portal. See Configure the Portal.
- **Username and password**—If you would rather provision your satellites without manually entering the serial numbers of the satellite devices into the portal configuration, you can instead require the satellite administrator to authenticate when establishing the initial connection to the portal. Although the portal will always look for the serial number in the initial request from the satellite, if it cannot identify the serial number, the satellite administrator must provide a username and password to authenticate to the portal. Because the portal will always fall back to this form of authentication, you must create an authentication profile in order to commit the portal configuration. This requires that you set up an authentication profile for the portal LSVPN configuration even if you plan to authenticate satellites using the serial number.



The following workflow describes how to set up the portal to authenticate satellites against an existing authentication service. GlobalProtect LSVPN supports external authentication using a local database, LDAP (including Active Directory), Kerberos, or RADIUS.

| Set Up Satellite Authentication | | |
|---|---|---|
| Step 1 | Create a server profile on the portal.<br><br>The server profile instructs the firewall how to connect to an external authentication service to validate the authentication credentials provided by the satellite administrator.<br><br>If you are using local authentication, you can skip this step and instead add a local user configuration for authenticating the satellite administrator.<br><br> If you are using LDAP to connect to Active Directory (AD), you must create a separate LDAP server profile for every AD domain. | 1. Select **Device > Server Profiles** and select type of profile (**LDAP**, **Kerberos**, or **RADIUS**).<br>2. Click **Add** and enter a **Name** for the profile, such as *LSVPN-Auth*.<br>3. (LDAP only) Select the **Type** of LDAP server you are connecting to.<br>4. Click **Add** in the Servers section and then enter information required to connect to the authentication service, including the server **Name**, **IP Address** (or FQDN), and **Port**.<br>5. (RADIUS and LDAP only) Specify settings to enable the firewall to authenticate to the authentication service as follows:<br>• RADIUS—Enter the shared **Secret** when adding the server entry.<br>• LDAP—Enter the **Bind DN** and **Bind Password**.<br>6. (LDAP and Kerberos only) Specify where to search for credentials in the directory service:<br>• LDAP—The **Base** DN specifies where in the LDAP tree to begin searching for users and groups. This field should populate automatically when you enter the server address and port. If it doesn't, check the service route to the LDAP server.<br>• Kerberos—Enter the Kerberos **Realm** name.<br>7. Specify the **Domain** name (without dots, for example `acme` not `acme.com`).<br>8. Click **OK** to save the server profile. |
| Step 2 | Create an authentication profile.<br><br>The authentication profile specifies which server profile to use to authenticate satellites. | 1. Select **Device > Authentication Profile** and click **Add**.<br>2. Enter a **Name** for the profile and then select the **Authentication** type (**Local Database, LDAP**, **Kerberos**, or **RADIUS**).<br>3. Select the **Server Profile** you created in Step 1.<br>4. (LDAP AD) Enter **sAMAccountName** as the **Login Attribute**.<br>5. Click **OK**. |
| Step 3 | Save the configuration. | Click **Commit**. |

 © Palo Alto Networks, Inc.

# Configure GlobalProtect Gateways for LSVPN

Because the GlobalProtect configuration that the portal delivers to the satellites includes the list of gateways the satellite can connect to, it is a good idea to configure the gateways before configuring the portal.

- ▲ Prerequisite Tasks
- ▲ Configure the Gateway

## Prerequisite Tasks

Before you can configure the GlobalProtect gateway, you must have completed the following tasks:

- ❒ Created the interfaces (and zones) for the interface where you plan to configure each gateway. You must configure both the physical interface and the virtual tunnel interface. See Create Interfaces and Zones for the LSVPN.
- ❒ Set up the gateway server certificates and certificate profile required for enable GlobalProtect satellite and gateway to establish a mutual SSL/TLS connection. See Enable SSL Between GlobalProtect LSVPN Components.

## Configure the Gateway

After you have completed the Prerequisite Tasks, configure each GlobalProtect gateway to participate in the LSVPN as follows:

| Configure the Gateway for LSVPN | | |
|---|---|---|
| Step 1 | Add a gateway. | 1. Select **Network > GlobalProtect > Gateways** and click **Add**.<br>2. On the **General** tab, enter a **Name** for the gateway. The gateway name should not contain any spaces and as a best practice it should include the location or other descriptive information that will help identify the gateway.<br>3. (Optional) Select the virtual system to which this gateway belongs from the **Location** field. |
| Step 2 | Specify the network information to enable satellites to connect to the gateway.<br><br>If you have not yet created the network interface for the gateway, see Create Interfaces and Zones for the LSVPN for instructions. If you haven't yet created a server certificate for the gateway, see Deploy Server Certificates to the GlobalProtect LSVPN Components. | 1. Select the **Interface** that satellites will use for ingress access to the gateway.<br>2. Select the **IP Address** for gateway access.<br>3. Select the **Server Certificate** for the gateway from the drop-down. |

| Configure the Gateway for LSVPN (Continued) | | |
|---|---|---|
| Step 3 | Select the certificate profile for the gateway to use to authenticate satellites attempting to establish tunnels.<br><br>If you have not yet set up the certificate profile, see Enable SSL Between GlobalProtect LSVPN Components for instructions. | Select the **Certificate Profile** to you created for SSL communication between the LSVPN components. |
| Step 4 | Configure the tunnel parameters and enable tunneling. | 1. On the GlobalProtect Gateway dialog, select **Satellite Configuration > Tunnel Settings**.<br>2. Select the **Tunnel Configuration** check box to enable tunneling.<br>3. Select the **Tunnel Interface** you defined in Step 2 in Create Interfaces and Zones for the LSVPN.<br>4. (Optional) If you want to preserve the Type of Service (ToS) information in the encapsulated packets, select the **Copy TOS** check box. |
| Step 5 | (Optional) Enable tunnel monitoring.<br><br>Tunnel monitoring enables satellite devices to monitor its gateway tunnel connection, allowing it to failover to a backup gateway if the connection fails. Failover to another gateway is the only type of tunnel monitoring profile supported with LSVPN. | 1. Select the **Tunnel Monitoring** check box.<br>2. Specify the **Destination IP** address the satellite devices should use to determine if the gateway is active. Alternatively, if you configured an IP address for the tunnel interface, you can leave this field blank and the tunnel monitor will instead use the tunnel interface to determine if the connection is active.<br>3. Select **Failover** from the **Tunnel Monitor Profile** drop-down (this is the only supported tunnel monitor profile for LSVPN). |
| Step 6 | Select the Crypto Profile to use when establishing tunnel connections.<br><br>The crypto profile specifies the type IPSec encryption and/or the authentication method for securing the data that will traverse the tunnel. Because both tunnel endpoints in an LSVPN are trusted firewalls within your organization, you can typically use the default profile, which uses ESP-DH group2-AES 128 with SHA-1 encryption.<br><br>However, if you require a different mix of encryption and authentication mechanisms, you can optionally create a custom IPSec crypto profile. | Select **default** from the **IPSec Crypto Profile** drop-down or, optionally, select **New IPSec Crypto Profile** to define a new profile. For details on the authentication and encryption options in the crypto profile, refer to the online help. |

 © Palo Alto Networks, Inc.

| Configure the Gateway for LSVPN (Continued) | | |
|---|---|---|
| Step 7 | Configure the network settings to assign the satellites during establishment of the IPSec tunnel.<br><br> You can also configure the satellite device to push the DNS settings to its local clients by configuring a DHCP server on the firewall hosting the satellite. In this configuration, the satellite will push DNS settings it learns from the gateway to the DHCP clients. | 1. On the GlobalProtect Gateway dialog, select **Satellite Configuration > Network Settings**.<br>2. (Optional) If clients local to the satellite device need to resolve FQDNs on the corporate network, configure the gateway to push DNS settings to the satellites in one of the following ways:<br>• Manually define the **Primary DNS**, **Secondary DNS**, and **DNS Suffix** settings to push to the satellites.<br>• If the gateway has an interface that is configured as a DHCP client, you can set the **Inheritance Source** to that interface and the GlobalProtect satellites will be assigned the same settings received by the DHCP client.<br>3. To specify the **IP Pool** of addresses to assign the tunnel interface on the satellite devices when the VPN is established, click **Add** and then specify the IP address range(s) to use.<br>4. To define what destination subnets to route through the tunnel click **Add** in the **Access Route** area and then enter the routes as follows:<br>• If you want to route all traffic from the satellites through the tunnel, leave this field blank. Note that in this case, all traffic except traffic destined for the local subnet will be tunneled to the gateway.<br>• To route only some traffic through the gateway (called *split tunneling*), specify the destination subnets that must be tunneled. In this case, the satellite will route traffic that is not destined for a specified access route using its own routing table. For example, you may choose to only tunnel traffic destined for your corporate network, and use the local satellite to safely enable Internet access.<br>• If you want to enable routing between satellites, enter the summary route for the network protected by each satellite. |
| Step 8 | (Optional) Define what routes, if any, the gateway will accept from satellites.<br><br>By default, the gateway will not add any routes satellites advertise to its routing table. If you do not want the gateway to accept routes from gateways, you do not need to complete this step. | 1. To enable the gateway to accept routes advertised by satellites, select **Satellite Configuration > Route Filter**.<br>2. Select the **Accept published routes** check box.<br>3. To filter which of the routes advertised by the satellites to add to the gateway routing table, click **Add** and then define the subnets to include. For example, if all the satellites are configured with subnet 192.168.x.0/24 on the LAN side, configuring a permitted route of 192.168.0.0/16 to enable the gateway to only accept routes from the satellite if it is in the 192.168.0.0/16 subnet. |
| Step 9 | Save the gateway configuration. | 1. Click **OK** to save the settings and close the GlobalProtect Gateway dialog.<br>2. **Commit** the configuration. |

# Configure the GlobalProtect Portal for LSVPN

The GlobalProtect portal provides the management functions for your GlobalProtect LSVPN. Every satellite system that participates in the LSVPN receives configuration information from the portal, including information about available gateways as well as the certificate it needs in order to connect to the gateways.

The following sections provide procedures for setting up the portal:

- Prerequisite Tasks
- Configure the Portal
- Define the Satellite Configurations

## Prerequisite Tasks

Before you can configure the GlobalProtect portal, you must have completed the following tasks:

- Created the interfaces (and zones) for the firewall interface where you plan to configure the portal. See Create Interfaces and Zones for the LSVPN.
- Issued the portal server certificate, gateway server certificates, and set up the portal to issue server certificates for the satellites. See Enable SSL Between GlobalProtect LSVPN Components.
- Defined the authentication profile that will be used to authenticate GlobalProtect satellites in the event that the serial number is not available. See Configure the Portal to Authenticate Satellites.
- Configured the global protect gateways. See Configure GlobalProtect Gateways for LSVPN.

 © Palo Alto Networks, Inc.

## Configure the Portal

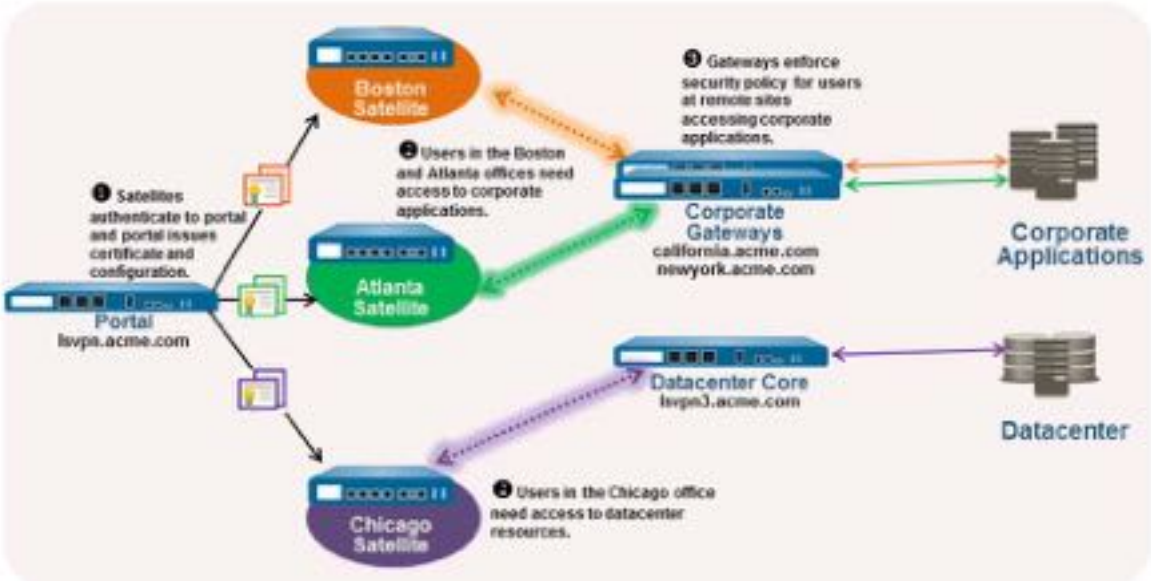
After you have completed the Prerequisite Tasks, configure the GlobalProtect portal as follows:

| Configure the Portal for LSVPN | | |
|---|---|---|
| Step 1 | Add the portal. | 1. Select **Network > GlobalProtect > Portals** and click **Add**.<br>2. On the **Portal Configuration** tab, enter a **Name** for the portal. The portal name should not contain any spaces.<br>3. (Optional) Select the virtual system to which this portal belongs from the **Location** field. |
| Step 2 | Specify the network information to enable satellites to connect to the portal.<br><br>If you have not yet created the network interface for the portal, see Create Interfaces and Zones for the LSVPN for instructions. If you haven't yet created a server certificate for the portal and issued gateway certificates, see Deploy Server Certificates to the GlobalProtect LSVPN Components. | 1. Select the **Interface** that satellites will use for ingress access to the portal.<br>2. Select the **IP Address** for satellite access to the portal.<br>3. Select the **Server Certificate** you generated to enable the satellite to establish SSL connection with the portal. |
| Step 3 | Specify an authentication profile for authenticating satellite devices.<br><br>Even if you plan to manually configure the portal with the serial numbers of the satellites, you must define an authentication profile or you will not be able to save the configuration. | • Select the **Authentication Profile** you defined for authenticating satellites.<br>• If you have not yet set up the authentication profile, select **New Authentication Profile** to create one now. See Configure the Portal to Authenticate Satellites for instructions. If the portal is unable to validate the serial number of a connecting satellite, it will fall back to the authentication profile and therefore you must configure an authentication profile in order to save the portal configuration. |
| Step 4 | Continue with defining the configurations to push to the satellites, or, if you have already created the satellite configurations, save the portal configuration. | Click **OK** to save the portal configuration or continue to Define the Satellite Configurations. |

## Define the Satellite Configurations

When a GlobalProtect satellite connects and successfully authenticates to the GlobalProtect portal, the portal delivers a satellite configuration, which specifies what gateways the satellite can connect to. If all your satellites will use the same gateway and certificate configurations, you can create a single satellite configuration to deliver to all satellites upon successful authentication. However, if you require different satellite configurations—for example if you want one group of satellites to connect to one gateway and another group of satellites to connect to a different gateway—you can create a separate satellite configuration for each. The portal will then use the enrollment username/group name or the serial number of the satellite device to determine which satellite configuration to deploy. As with security rule evaluation, the portal looks for a match starting from the top of the list. When it finds a match, it delivers the corresponding configuration to the satellite.

For example, the following figure shows a network in which some branch offices require VPN access to the corporate applications protected by your perimeter firewalls and another site needs VPN access to the datacenter.



Use the following procedure to create one or more satellite configurations.

 © Palo Alto Networks, Inc.

| Create a GlobalProtect Satellite Configuration | | |
|---|---|---|
| Step 1 | Specify the certificates required to enable satellites to participate in the LSVPN. | 1. Select **Network > GlobalProtect > Portals** and select the portal configuration for which you want to add a satellite configuration and then select the **Satellite Configuration** tab.<br>2. In the **Trusted Root CA** field, click **Add** and then select the CA certificate used to issue the gateway server certificates. The portal will deploy the root CA certificate you add here to all satellites as part of the configuration to enable the satellite to establish an SSL connection with the gateways. As a best practice, all of your gateways should use the same issuer.<br> If the root CA certificate used to issue your gateway server certificates is not on the portal, you can **Import** it now. See Enable SSL Between GlobalProtect LSVPN Components for details on how to import a root CA certificate.<br>3. Select the Root CA certificate that the portal will use to issue certificates to satellites upon successfully authenticating them from the **Issuing Certificate** drop-down. |
| Step 2 | Add a satellite configuration.<br><br>The satellite configuration specifies the GlobalProtect LSVPN configuration settings to deploy to the connecting satellites. You must define at least one satellite configuration. | In the Satellite Configuration section, click **Add** and enter a **Name** for the configuration.<br><br>If you plan to create multiple configurations, make sure the name you define for each is descriptive enough to allow you to distinguish them. |
| Step 3 | Specify which satellites to deploy this configuration to. There are two ways to specify which satellites will get the configuration: by enrollment user/group name and/or using the serial number of the satellite devices.<br><br>The portal uses the **Enrollment User/User Group** settings and/or **Devices** serial numbers to match a satellite to a configuration. Therefore, if you have multiple configurations, be sure to order them properly. As soon as the portal finds a match, it will deliver the configuration. Therefore, more specific configurations must precede more general ones. See Step 6 for instructions on ordering the list of satellite configurations. | Specify the match criteria for the satellite configuration as follows:<br>• To restrict this configuration to satellite devices with specific serial numbers, select the **Devices** tab, click **Add**, and enter serial number (you do not need to enter the satellite hostname; it will be automatically added when the satellite connects). Repeat this step for each satellite you want to receive this configuration.<br>• Select the **Enrollment User/User Group** tab, click **Add**, and then select the user or group you want to receive this configuration. Satellites that do not match on serial number will be required to authenticate as a user specified here (either an individual user or group member).<br><br> Before you can restrict the configuration to specific groups, you must Map Users to Groups. |

| Create a GlobalProtect Satellite Configuration (Continued) | | |
|---|---|---|
| Step 4 | Specify the gateways that satellites with this configuration can establish VPN tunnels with.<br><br> Routes published by the gateway are installed on the satellite as static routes. The metric for the static route is 10x the routing priority. If you have more than one gateway, make sure to also set the routing priority to ensure that routes advertised by backup gateways have higher metrics compared to the same routes advertised by primary gateways. For example, if you set the routing priority for the primary gateway and backup gateway to 1 and 10 respectively, the satellite will use 10 as the metric for the primary gateway and 100 as the metric for the backup gateway. | 1. On the **Gateways** tab, click **Add**.<br>2. Enter a descriptive **Name** for the gateway. The name you enter here should match the name you defined when you configured the gateway and should be descriptive enough identify the location of the gateway.<br>3. Enter the FQDN or IP address of the interface where the gateway is configured in the **Gateways** field. The address you specify must exactly match the Common Name (CN) in the gateway server certificate.<br>4. (Optional) If you are adding two or more gateways to the configuration, the **Routing Priority** helps the satellite pick the preferred gateway. Enter a value in the range of 1-25, with lower numbers having the higher priority (that is, the gateway the satellite will connect to if all gateways are available). The satellite will multiply the routing priority by 10 to determine the routing metric. |
| Step 5 | Save the satellite configuration. | 1. Click **OK** to save the satellite configuration.<br>2. If you want to add another satellite configuration, repeat Step 2 through Step 5. |
| Step 6 | Arrange the satellite configurations so that the proper configuration is deployed to each satellite. | • To move a satellite configuration up on the list of configurations, select the configuration and click **Move Up**.<br>• To move a satellite configuration down on the list of configurations, select the configuration and click **Move Down**. |
| Step 7 | Save the portal configuration. | 1. Click **OK** to save the settings and close the GlobalProtect Portal dialog.<br>2. **Commit** your changes. |

 © Palo Alto Networks, Inc.

# Prepare the Satellite Device to Join the LSVPN

In order to participate in the LSVPN, the satellite devices require a minimal amount of configuration. Because the required configuration is minimal, you can pre-configure the devices before shipping them to your branch offices for installation.

| Prepare the Satellite Device to Join the GlobalProtect LSVPN | | |
|---|---|---|
| Step 1 | Configure a Layer 3 interface. | This is the physical interface the satellite will use to connect to the portal and the gateway. This interface must be in a zone that allows access outside of the local trust network. As a best practice, create a dedicated zone for VPN connections for visibility and control over traffic destined for the corporate gateways. |
| Step 2 | Configure the logical tunnel interface for the tunnel to use to establish VPN tunnels with the GlobalProtect gateways.<br> IP addresses are not required on the tunnel interface unless plan to use dynamic routing. However, assigning an IP address to the tunnel interface can be useful for troubleshooting connectivity issues. | 1. Select **Network > Interfaces > Tunnel** and click **Add**.<br>2. In the **Interface Name** field, specify a numeric suffix, such as **.2**.<br>3. On the **Config** tab, expand the **Security Zone** drop-down and select an existing zone or create a separate zone for VPN tunnel traffic by clicking **New Zone** and defining a **Name** for new zone (for example *lsvpnsat*).<br>4. In the **Virtual Router** drop-down, select **default**.<br>5. (Optional) If you want to assign an IP address to the tunnel interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 2.2.2.11/24.<br>6. To save the interface configuration, click **OK**. |

| Prepare the Satellite Device to Join the GlobalProtect LSVPN (Continued) | | |
|---|---|---|
| Step 3 | If you generated the portal server certificate using a Root CA that is not trusted by the satellites (for example, if you used self-signed certificates), import the root CA certificate used to issue the portal server certificate.<br><br>The root CA certificate is required to enable the satellite device to establish the initial connection with the portal to obtain the LSVPN configuration. | 1. Download the CA certificate that was used to generate the portal server certificates. If you are using self-signed certificates, export the root CA certificate from the portal as follows:<br>a. Select **Device > Certificate Management > Certificates > Device Certificates**.<br>b. Select the CA certificate, and click **Export**.<br>c. Select **Base64 Encoded Certificate (PEM)** from the **File Format** drop-down and click **OK** to download the certificate. (You do not need to export the private key.)<br>2. Import the root CA certificate you just exported onto each satellite as follows.<br>a. Select **Device > Certificate Management > Certificates > Device Certificates** and click **Import**.<br>b. Enter a **Certificate Name** that identifies the certificate as your client CA certificate.<br>c. **Browse** to the **Certificate File** you downloaded from the CA.<br>d. Select **Base64 Encoded Certificate (PEM)** as the **File Format** and then click **OK**.<br>e. Select the certificate you just imported on the **Device Certificates** tab to open it.<br>f. Select **Trusted Root CA** and then click **OK**. |
| Step 4 | Configure the IPSec tunnel configuration. | 1. Select **Network > IPSec Tunnels** and click **Add**.<br>2. On the **General** tab, enter a descriptive **Name** for the IPSec configuration.<br>3. Select the **Tunnel Interface** you created for the satellite.<br>4. Select **GlobalProtect Satellite** as the **Type**.<br>5. Enter the IP address or FQDN of the portal as the **Portal Address**.<br>6. Select the Layer 3 **Interface** you configured for the satellite.<br>7. Select the **Local IP Address** to use on the selected interface. |
| Step 5 | (Optional) Configure the satellite to publish local routes to the gateway.<br><br>Pushing routes to the gateway enables traffic to the subnets local to the satellite via the gateway. However, the gateway must also be configured to accept the routes. | 1. To enable the satellite to push routes to the gateway, on the **Advanced** tab select **Publish all static and connected routes to Gateway**.<br>2. (Optional) If you only want to push routes for specific subnets rather than all routes, click **Add** in the Subnet section and specify which subnet routes to publish. |
| Step 6 | Save the satellite configuration. | 1. Click **OK** to save the IPSec tunnel settings.<br>2. Click **Commit**. |

 © Palo Alto Networks, Inc.

| Prepare the Satellite Device to Join the GlobalProtect LSVPN (Continued) | |
|---|---|
| Step 7 If required, provide the credentials to allow the satellite to authenticate to the portal.<br><br>This step is only required if the portal was unable to find a serial number match in its configuration or if the serial number didn't work. In this case, the satellite will not be able to establish the tunnel with the gateway(s). | 1. Select **Network > IPSec Tunnels** and click the **Gateway Info** link in the Status column of the tunnel configuration you created for the LSVPN.<br>2. Click the **enter credentials** link in the **Portal Status** field and username and password required to authenticate the satellite to the portal.<br><br>After the portal successfully authenticates to the portal, it will receive its signed certificate and configuration, which it will use to connect to the gateway(s). You should see the tunnel establish and the **Status** change to **Active**.<br><br> |

# Verify the LSVPN Configuration

After configuring the portal, gateways, and satellite devices, verify that the satellites are able to connect to the portal and gateway and establish VPN tunnels with the gateway(s).

| Verify the LSVPN Configuration | | |
|---|---|---|
| Step 1 | Verify satellite connectivity with portal. | From the firewall hosting the portal, verify that satellites are successfully connecting by selecting **Network > GlobalProtect > Portal** and clicking **Satellite Info** in the Info column of the portal configuration entry.<br> |
| Step 1 | Verify satellite connectivity with the gateway(s). | On each firewall hosting a gateway, verify that satellites are able to establish VPN tunnels by selecting **Network > GlobalProtect > Gateways** and click **Satellite Info** in the Info column of the gateway configuration entry. Satellites that have successfully established tunnels with the gateway will display on the **Active Satellites** tab.<br> |
| Step 1 | Verify LSVPN tunnel status on the satellite. | On each firewall hosting a satellite, verify the tunnel status by selecting **Network > IPSec Tunnels** and verify active Status as indicated by a green icon.<br> |

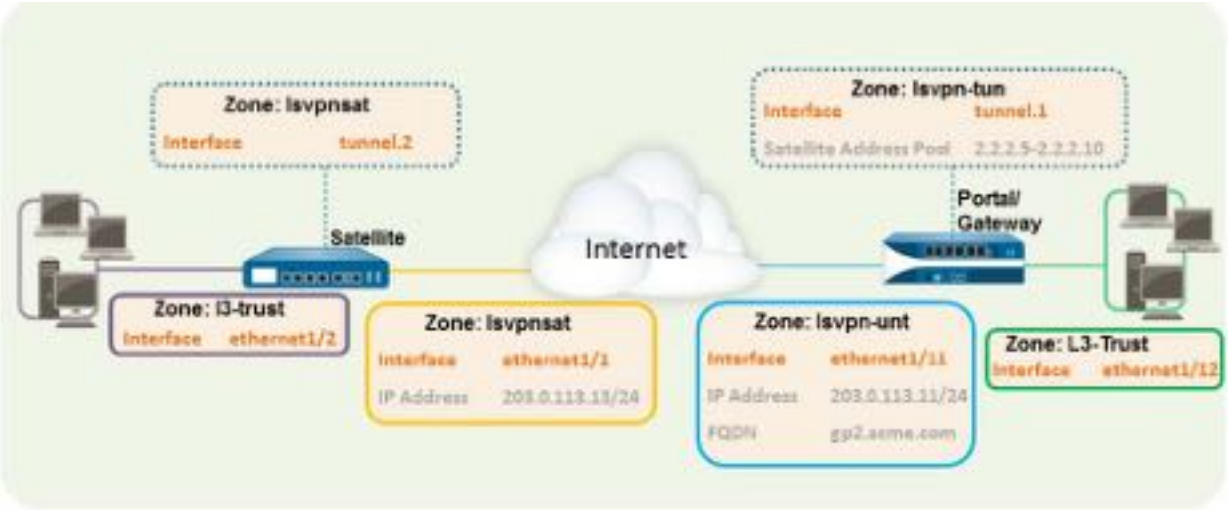
# LSVPN Quick Configs

The following sections provide step-by-step instructions for configuring some common GlobalProtect LSVPN deployments:

- Basic LSVPN Configuration with Static Routing
- Advanced LSVPN Configuration with Dynamic Routing

# Basic LSVPN Configuration with Static Routing

This quick config shows the fastest way to get up and running with LSVPN. In this example, a single firewall at the corporate headquarters site is configured as both a portal and a gateway. Satellite devices can be quickly and easily deployed with minimal configuration for optimized scalability.



The following workflow shows the steps for setting up this basic configuration:

| Quick Config: Basic LSVPN with Static Routing | | |
|---|---|---|
| Step 1 | Configure a Layer 3 interface. | In this example, the Layer 3 interface on the portal/gateway requires the following configuration:<br>• **Interface**—ethernet1/11<br>• **Security Zone**—lsvpn-unt<br>• **IPv4**—203.0.113.11/24 |
| Step 2 | On the firewall(s) hosting GlobalProtect gateway(s), configure the logical tunnel interface that will terminate VPN tunnels established by the GlobalProtect satellites.<br>To enable visibility into users and groups connecting over the VPN, enable User-ID in the zone where the VPN tunnels terminate. | In this example, the Tunnel interface on the portal/gateway requires the following configuration:<br>• **Interface**—tunnel.1<br>• **Security Zone**—lsvpn-tun |
| Step 3 | Create the security policy rule to enable traffic flow between the VPN zone where the tunnel terminates (lsvpn-tun) and the trust zone where the corporate applications reside (L3-Trust).<br>  | |

 © Palo Alto Networks, Inc.

| Quick Config: Basic LSVPN with Static Routing (Continued) | | |
|---|---|---|
| Step 4 | Issue a self-signed server certificate for the portal/gateway.<br><br>The certificate subject name must match the FQDN or IP address of the Layer 3 interface you create for the portal/gateway. | 1. On the firewall hosting the portal, create the root CA certificate for issuing self-signed certificates for the GlobalProtect components. In this example, the root CA certificate, *lsvpn-CA*, will be used to issue the server certificate for the portal/gateway. In addition, the portal will use this root CA certificate to sign the CSRs from the satellite devices.<br>2. Generate server certificates for the GlobalProtect portal and gateway(s).<br><br>Because the portal and gateway will be on the same interface in this example, they can share a server certificate. In this example, the server certificate is named *lsvpnserver*. |
| Step 5 | Create a certificate profile. | In this example, the certificate profile, *lsvpn-profile*, references the root CA certificate *lsvpn-CA*. The gateway will use this certificate profile to authenticate satellites attempting to establish VPN tunnels. |
| Step 6 | Configure an authentication profile for the portal to use if the satellite serial number is not available. | 1. Create a server profile on the portal.<br>2. Create an authentication profile. In this example, the profile *lsvpn-sat* is used to authenticate satellites. |
| Step 7 | Configure the Gateway for LSVPN. | Select **Network > GlobalProtect > Gateways** and **Add** a configuration. This example requires the following gateway configuration:<br>• **Interface**—ethernet1/11<br>• **IP Address**—203.0.113.11/24<br>• **Server Certificate**—lsvpnserver<br>• **Certificate Profile**—lsvpn-profile<br>• **Tunnel Interface**—tunnel.1<br>• **Primary DNS**/**Secondary DNS**—4.2.2.1/4.2.2.2<br>• **IP Pool**—2.2.2.111-2.2.2.120<br>• **Access Route**—10.2.10.0/24 |
| Step 8 | Configure the Portal for LSVPN. | Select **Network > GlobalProtect > Portal** and **Add** a configuration. This example requires the following portal configuration:<br>• **Interface**—ethernet1/11<br>• **IP Address**—203.0.113.11/24<br>• **Server Certificate**—lsvpnserver<br>• **Authentication Profile**—lsvpn-sat |

| Quick Config: Basic LSVPN with Static Routing (Continued) | |
|---|---|
| Step 9 Create a GlobalProtect Satellite Configuration. | On the **Satellite Configuration** tab in the portal configuration, **Add** a Satellite Configuration and a Trusted Root CA and specify the CA the portal will use to issue certificates for the satellites. In this example the required settings are as following:<br>• **Gateway**—203.0.113.11<br>• **Issuing Certificate**—lsvpn-CA<br>• **Trusted Root CA**—lsvpn-CA |
| Step 10 Prepare the Satellite Device to Join the LSVPN. | The satellite configuration in this example requires the following settings:<br>Interface Configuration<br>• Layer 3 interface—ethernet1/1, 203.0.113.13/24<br>• Tunnel interface—tunnel.2<br>• Zone—lsvpnsat<br>Root CA Certificate from Portal<br>• lsvpn-CA<br>IPSec Tunnel Configuration<br>• **Tunnel Interface**—tunnel.2<br>• **Portal Address**—203.0.113.11<br>• **Interface**—ethernet1/1<br>• **Local IP Address**—203.0.113.13/24<br>• **Publish all static and connected routes to Gateway**—enabled |

 © Palo Alto Networks, Inc.

# Advanced LSVPN Configuration with Dynamic Routing

In larger LSVPN deployments with multiple gateways and many satellites, investing a little more time in the initial configuration to set up dynamic routing will simplify the maintenance of gateway configurations because access routes will update dynamically. The following example configuration shows how to extend the basic LSVPN configuration to configure OSPF as the dynamic routing protocol.

Setting up an LSVPN to use OSPF for dynamic routing requires the following additional steps on the gateways and the satellites:

- Manual assignment of IP addresses to tunnel interfaces on all gateways and satellites.
- Configuration of OSPF point-to-multipoint (P2MP) on the virtual router on all gateways and satellites. In addition, as part of the OSPF configuration on each gateway, you must manually define the tunnel IP address of each satellite as an OSPF neighbor. Similarly, on each satellite, you must manually define the tunnel IP address of each gateway as an OSPF neighbor.

Although dynamic routing requires additional setup during the initial configuration of the LSVPN, it reduces the maintenance tasks associated with keeping routes up to date as topology changes occur on your network.

The following figure shows an LSVPN dynamic routing configuration. This example shows how to configure OSPF as the dynamic routing protocol for the VPN.

For a basic setup of a LSVPN, follow the steps in Basic LSVPN Configuration with Static Routing. You can then complete the steps in the following workflow to extend the configuration to use dynamic routing rather than static routing.

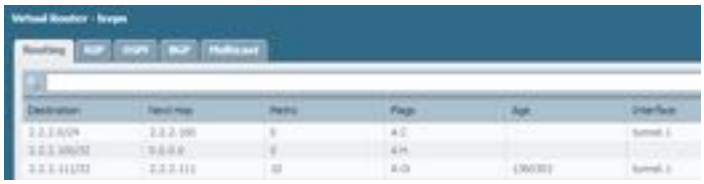
| Quick Config: LSVPN with Dynamic Routing | |
|---|---|
| Step 1 Add an IP address to the tunnel interface configuration on each gateway and each satellite. | Complete the following steps on each gateway and each satellite:<br>1. Select **Network > Interfaces > Tunnel** and select the tunnel configuration you created for the LSVPN to open the Tunnel Interface dialog.<br>If you have not yet created the tunnel interface, see Step 2 in Quick Config: Basic LSVPN with Static Routing.<br>2. On the **IPv4** tab, click **Add** and then enter an IP address and subnet mask. For example, to add an IP address for the gateway tunnel interface you would enter 2.2.2.100/24.<br>3. Click **OK** to save the configuration. |
| Step 2 Configure the dynamic routing protocol on the gateway.<br>  | To configure OSPF on the gateway:<br>1. Select **Network > Virtual Routers** and select the virtual router associated with your VPN interfaces.<br>2. On the **Areas** tab, click **Add** to create the backbone area, or, if it is already configured, click on the area ID to edit it.<br>3. If you are creating a new area, enter an **Area ID** on the **Type** tab.<br>4. On the **Interface** tab, click **Add** and select the tunnel **Interface** you created for the LSVPN.<br>5. Select **p2mp** as the **Link Type**.<br>6. Click **Add** in the Neighbors section and enter the IP address of the tunnel interface of each satellite device, for example 2.2.2.111.<br>7. Click **OK** twice to save the virtual router configuration and then **Commit** the changes on the gateway.<br>8. Repeat this step each time you add a new satellite to the LSVPN. |
| Step 3 Configure the dynamic routing protocol on the satellite.<br>  | To configure OSPF on the satellite:<br>1. Select **Network > Virtual Routers** and select the virtual router associated with your VPN interfaces.<br>2. On the **Areas** tab, click **Add** to create the backbone area, or, if it is already configured, click on the area ID to edit it.<br>3. If you are creating a new area, enter an **Area ID** on the **Type** tab.<br>4. On the **Interface** tab, click **Add** and select the tunnel **Interface** you created for the LSVPN.<br>5. Select **p2mp** as the **Link Type**.<br>6. Click **Add** in the Neighbors section and enter the IP address of the tunnel interface of each GlobalProtect gateway, for example 2.2.2.100.<br>7. Click **OK** twice to save the virtual router configuration and then **Commit** the changes on the gateway.<br>8. Repeat this step each time you add a new gateway. |

 © Palo Alto Networks, Inc.

**Quick Config: LSVPN with Dynamic Routing (Continued)**

Step 4 Verify that the gateways and satellites are able to form router adjacencies.

- On each satellite and each gateway, confirm that peer adjacencies have formed and that routing table entries have been created for the peers (that is, the satellites have routes to the gateways and the gateways have routes to the satellites). Select **Network > Virtual Router** and click the **More Runtime Stats** link for the virtual router you are using for the LSVPN. On the Routing tab, verify that the LSVPN peer has a route.



- On the **OSPF > Interface** tab, verify that the **Type** is **p2mp**.

- On the **OSPF > Neighbor** tab, verify that the firewalls hosting your gateways have established router adjacencies with the firewalls hosting your satellites and vice versa. Also verify that the **Status** is **Full**, indicating that full adjacencies have been established.

# Networking

All Palo Alto Networks next-generation firewalls provide a flexible networking architecture that includes support for dynamic routing, switching, and VPN connectivity, enabling you to deploy the firewall into nearly any networking environment. When configuring the Ethernet ports on your firewall, you can choose from virtual wire, Layer 2, or Layer 3 interface deployments. In addition, to allow you to integrate into a variety of network segments, you can configure different types of interfaces on different ports. The Interface Deployments section provides basic information on each type of deployment. For more detailed deployment information, refer to Designing Networks with Palo Alto Networks Firewalls.

The following topics describe networking concepts and how to integrate Palo Alto Networks next-generation firewalls into your network.

- Interface Deployments
- Virtual Routers
- Static Routes
- RIP
- OSPF
- BGP
- Session Settings and Timeouts
- DHCP
- NAT
- LACP

For information on route distribution, refer to Understanding Route Redistribution and Filtering.

# Interface Deployments

A Palo Alto Networks firewall can operate in multiple deployments at once because the deployments occur at the interface level. The following sections describe the deployments.

- Virtual Wire Deployments
- Layer 2 Deployments
- Layer 3 Deployments
- Tap Mode Deployments

## Virtual Wire Deployments

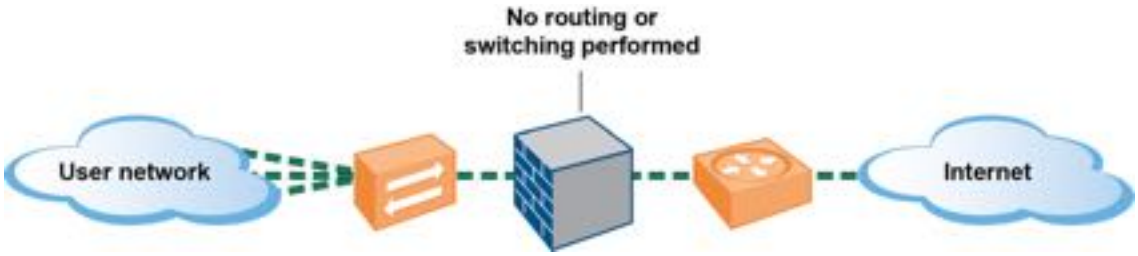
In a virtual wire deployment, the firewall is installed transparently on a network segment by binding two ports together and should be used only when no switching or routing is needed.

A virtual wire deployment allows the following conveniences:

- Simplifies installation and configuration.
- Does not require any configuration changes to surrounding or adjacent network devices.

The "default-vwire" that is shipped as the factory default configuration binds together Ethernet ports 1 and 2 and allows all untagged traffic. You can, however, use a virtual wire to connect any two ports and configure it to block or allow traffic based on the virtual LAN (VLAN) tags; the VLAN tag "0" indicates untagged traffic. You can also create multiple subinterfaces, add them into different zones and then classify traffic according to a VLAN tag, or a combination of a VLAN tag with IP classifiers (address, range, or subnet) to apply granular policy control for specific VLAN tags or for VLAN tags from a specific source IP address, range, or subnet.

**Figure: Virtual Wire Deployment**



### Virtual Wire Subinterfaces

Virtual wire subinterfaces provide flexibility in enforcing distinct policies when you need to manage traffic from multiple customer networks. It allows you to separate and classify traffic into different zones (the zones can belong to separate virtual systems, if required) using the following criteria:

- **VLAN tags** —The example in Figure: Virtual Wire Deployment with Subinterfaces (VLAN Tags only), shows an Internet Service Provider (ISP) using virtual wire subinterfaces with VLAN tags to separate traffic for two different customers.

 © Palo Alto Networks, Inc.

- **VLAN tags in conjunction with IP classifiers (address, range, or subnet)**— The following example shows an ISP with two separate virtual systems on a firewall that manages traffic from two different customers. On each virtual system, the example illustrates how virtual wire subinterfaces with VLAN tags and IP classifiers are used to classify traffic into separate zones and apply relevant policy for customers from each network.

| Virtual Wire Subinterface Workflow |
|---|
| 1. Configure two Ethernet interfaces as type virtual wire, and assign these interfaces to a virtual wire. |
| 2. Create subinterfaces on the parent Virtual Wire to separate CustomerA and CustomerB traffic. Make sure that the VLAN tags defined on each pair of subinterfaces that are configured as virtual wire(s) are identical. This is essential because a virtual wire does not switch VLAN tags. |
| 3. Create new subinterfaces and define IP classifiers. This task is optional and only required if you wish to add additional subinterfaces with IP classifiers for further managing traffic from a customer based on the combination of VLAN tags and a specific source IP address, range or subnet.<br>You can also use IP classifiers for managing untagged traffic. To do so, you must create a sub-interface with the vlan tag "0", and define sub-interface(s) with IP classifiers for managing untagged traffic using IP classifiers |

IP classification may only be used on the subinterfaces associated with one side of the virtual wire. The subinterfaces defined on the corresponding side of the virtual wire must use the same VLAN tag, but must not include an IP classifier.

**Figure: Virtual Wire Deployment with Subinterfaces (VLAN Tags only)**

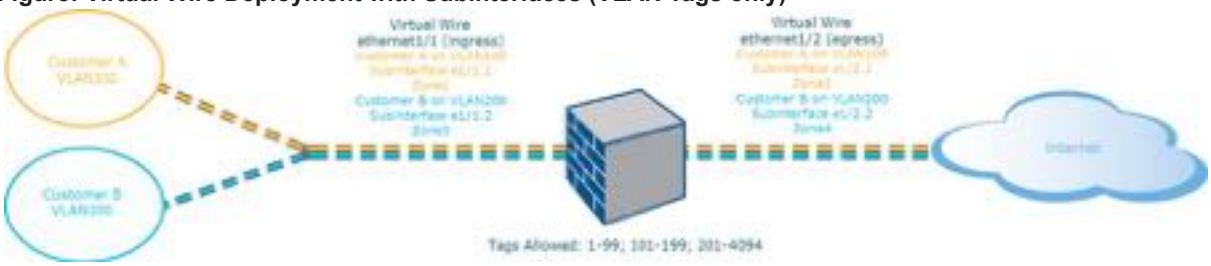


Figure: Virtual Wire Deployment with Subinterfaces (VLAN Tags only) depicts CustomerA and CustomerB connected to the firewall through one physical interface, ethernet1/1, configured as a Virtual Wire; it is the ingress interface. A second physical interface, ethernet1/2, is also part of the Virtual Wire; it is the egress interface that provides access to the Internet. For CustomerA, you also have subinterfaces ethernet1/1.1 (ingress) and ethernet1/2.1 (egress). For CustomerB, you have the subinterface ethernet1/1.2 (ingress) and ethernet1/2.2 (egress). When configuring the subinterfaces, you must assign the appropriate VLAN tag and zone in order to apply policies for each customer. In this example, the policies for CustomerA are created between Zone1 and Zone2, and policies for CustomerB are created between Zone3 and Zone4.

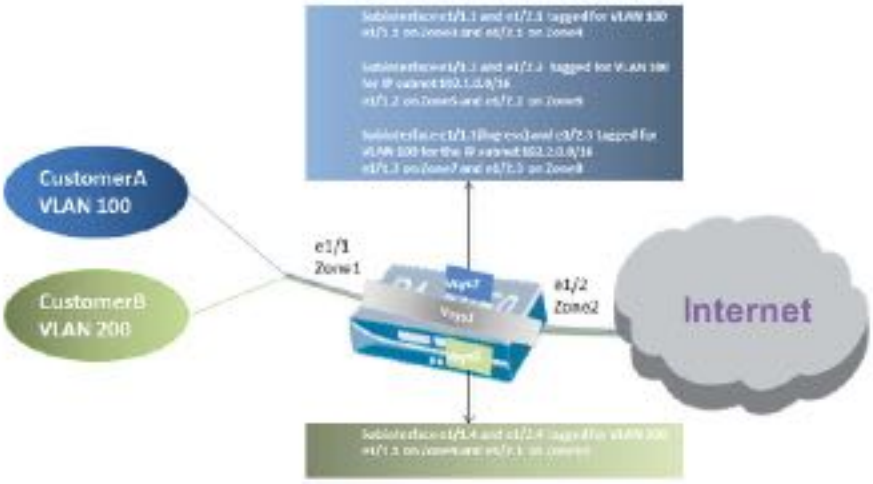
When traffic enters the firewall from CustomerA or CustomerB, the VLAN tag on the incoming packet is first matched against the VLAN tag defined on the ingress subinterfaces. In this example, a single subinterface matches the VLAN tag on the incoming packet, hence that subinterface is selected. The policies defined for the zone are evaluated and applied before the packet exits from the corresponding subinterface.

The same VLAN tag must not be defined on the parent virtual wire interface and the subinterface. Verify that the VLAN tags defined on the Tag Allowed list of the parent virtual wire interface (**Network > Virtual Wires**) are not included on a subinterface.

Figure: Virtual Wire Deployment with Subinterfaces (VLAN Tags and IP Classifiers) depicts CustomerA and CustomerB connected to one physical firewall that has two virtual systems (vsys), in addition to the default virtual system (vsys1). Each virtual system is an independent virtual firewall that is managed separately for each customer. Each vsys has attached interfaces/subinterfaces and security zones that are managed independently.

**Figure: Virtual Wire Deployment with Subinterfaces (VLAN Tags and IP Classifiers)**



Vsys1 is set up to use the physical interfaces ethernet1/1 and ethernet1/2 as a virtual wire; ethernet1/1 is the ingress interface and ethernet1/2 is the egress interface that provides access to the Internet. This virtual wire is configured to accept all tagged and untagged traffic with the exception of VLAN tags 100 and 200 that are assigned to the subinterfaces.

CustomerA is managed on vsys2 and CustomerB is managed on vsys3. On vsys2 and vsys3, the following vwire subinterfaces are created with the appropriate VLAN tags and zones to enforce policy measures.

| Customer | Vsys | Vwire Subinterfaces | Zone | VLAN Tag | IP Classifier |
|---|---|---|---|---|---|
| A | 2 | e1/1.1 (ingress)<br>e1/2.1 (egress) | Zone3<br>Zone4 | 100<br>100 | None |
| | 2 | e1/1.2 (ingress)<br>e1/2.2 (egress) | Zone5<br>Zone6 | 100<br>100 | IP subnet<br>192.1.0.0/16 |
| | 2 | e1/1.3 (ingress)<br>e1/2.3 (egress) | Zone7<br>Zone8 | 100<br>100 | IP subnet<br>192.2.0.0/16 |
| B | 3 | e1/1.4 (ingress)<br>e1/2.4 (egress) | Zone9<br>Zone10 | 200<br>200 | None |

When traffic enters the firewall from CustomerA or CustomerB, the VLAN tag on the incoming packet is first matched against the VLAN tag defined on the ingress subinterfaces. In this case, for CustomerA, there are multiple subinterfaces that use the same VLAN tag. Hence, the firewall first narrows the classification to a subinterface based on the source IP address in the packet. The policies defined for the zone are evaluated and applied before the packet exits from the corresponding subinterface.

 © Palo Alto Networks, Inc.

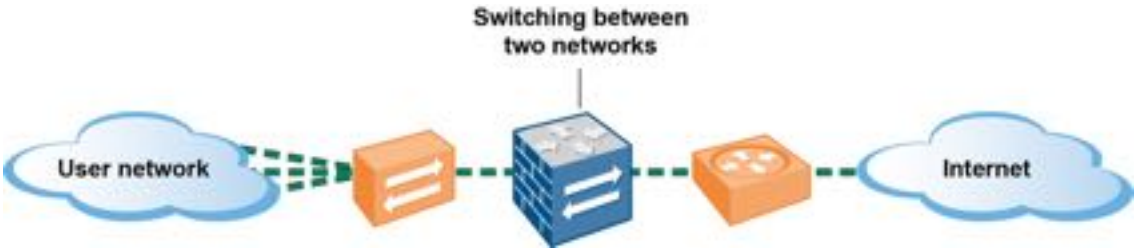
For return-path traffic, the firewall compares the destination IP address as defined in the IP classifier on the customer-facing subinterface and selects the appropriate virtual wire to route traffic through the accurate subinterface.

The same VLAN tag must not be defined on the parent virtual wire interface and the subinterface. Verify that the VLAN tags defined on the Tag Allowed list of the parent virtual wire interface (**Network > Virtual Wires**) are not included on a subinterface.

## Layer 2 Deployments

In a Layer 2 deployment, the firewall provides switching between two or more networks. Each group of interfaces must be assigned to a VLAN object in order for the firewall to switch between them. The firewall will perform VLAN tag switching when layer 2 subinterfaces are attached to a common VLAN object. Choose this option when switching is required.

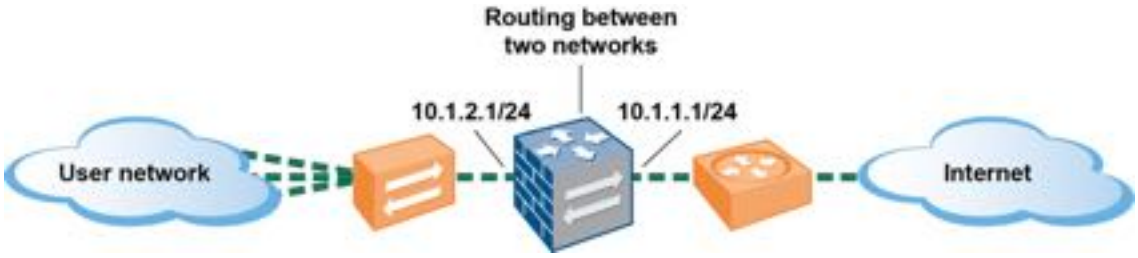
**Figure: Layer 2 Deployment**



## Layer 3 Deployments

In a Layer 3 deployment, the firewall routes traffic between multiple ports. An IP address must be assigned to each interface and a virtual router must be defined to route the traffic. Choose this option when routing is required.

**Figure: Layer 3 Deployment**



In addition, because the firewall must route traffic in a Layer 3 deployment, you must configure a virtual router. See Virtual Routers.

### Point-to-Point Protocol over Ethernet Support

You can configure the firewall to be a Point-to-Point Protocol over Ethernet (PPPoE) termination point to support connectivity in a Digital Subscriber Line (DSL) environment where there is a DSL modem but no other PPPoE device to terminate the connection.

You can choose the PPPoE option and configure the associated settings when an interface is defined as a Layer 3 interface.

PPPoE is not supported in HA active/active mode.

### DHCP Client

You can configure the firewall interface to act as a DHCP client and receive a dynamically assigned IP address. The firewall also provides the capability to propagate settings received by the DHCP client interface into a DHCP server operating on the firewall. This is most commonly used to propagate DNS server settings from an Internet service provider to client machines operating on the network protected by the firewall.

DHCP client is not supported in HA active/active mode.

For more information, see DHCP.

## Tap Mode Deployments

A network tap is a device that provides a way to access data flowing across a computer network. Tap mode deployment allows you to passively monitor traffic flows across a network by way of a switch SPAN or mirror port.

The SPAN or mirror port permits the copying of traffic from other ports on the switch. By dedicating an interface on the firewall as a tap mode interface and connecting it with a switch SPAN port, the switch SPAN port provides the firewall with the mirrored traffic. This provides application visibility within the network without being in the flow of network traffic.

When deployed in tap mode, the firewall is not able to take action, such as block traffic or apply QoS traffic control.

 © Palo Alto Networks, Inc.

# Virtual Routers

The firewall uses virtual routers to obtain routes to other subnets by manually defining a route (static routes) or through participation in Layer 3 routing protocols (dynamic routes). The best routes obtained through these methods are used to populate the firewall's IP route table. When a packet is destined for a different subnet, the Virtual Router obtains the best route from this IP route table and forwards the packet to the next hop router defined in the table.

The Ethernet interfaces and VLAN interfaces defined on the firewall receive and forward the Layer 3 traffic. The destination zone is derived from the outgoing interface based on the forwarding criteria, and policy rules are consulted to identify the security policies to be applied. In addition to routing to other network devices, virtual routers can route to other virtual routers within the same firewall if a next hop is specified to point to another virtual router.

You can configure the virtual router to participate with dynamic routing protocols (BGP, OSPF, or RIP) as well as adding static routes. You can also create multiple virtual routers, each maintaining a separate set of routes that are not shared between virtual routers, enabling you to configure different routing behaviors for different interfaces.

Each Layer 3 interface, loopback interface, and VLAN interface defined on the firewall must be associated with a virtual router. While each interface can belong to only one virtual router, multiple routing protocols and static routes can be configured for a virtual router. Regardless of the static routes and dynamic routing protocols configured for a virtual router, a common general configuration is required. The firewall uses Ethernet switching to reach other devices on the same IP subnet.

The following Layer 3 routing protocols are supported from Virtual Routers:

- RIP
- OSPF
- OSPFv3
- BGP

| **Define a Virtual Router General Configuration** | | |
|---|---|---|
| Step 1 | Gather the required information from your network administrator. | • Interfaces that you want to route<br>• Administrative distances for static, OSFP internal, OSPF external, IBGP, EBGP and RIP |
| Step 2 | Create the virtual router and name it. | 1. Select **Network > Virtual Routers**.<br>2. Click **Add** and enter a name for the virtual router.<br>3. Select interfaces to apply to the virtual router.<br>4. Click **OK**. |
| Step 3 | Select interfaces to apply to the virtual router. | 1. Click **Add** in the Interfaces box.<br>2. Select an already defined interface from the drop-down.<br>3. Repeat Step 2 for all interfaces that you want to add to the virtual router. |

© Palo Alto Networks, Inc.

| Define a Virtual Router General Configuration (Continued) | | |
|---|---|---|
| Step 4 | Set Administrative Distances for static and dynamic routing. | 1. Set Administrative Distances as required.<br>• **Static**—Range: 10-240, Default: 10<br>• **OSPF Internal**—Range: 10-240, Default: 30<br>• **OSPF External**—Range: 10-240, Default: 110<br>• **IBGP**—Range: 10-240, Default: 200<br>• **EBGP**—Range: 10-240, Default: 20<br>• **RIP**—Range: 10-240, Default: 120 |
| Step 5 | Save virtual router general settings. | Click **OK** to save your settings. |
| Step 6 | Commit your changes. | Click **Commit**. The device may take up to 90 seconds to save your changes. |

 © Palo Alto Networks, Inc.

# Static Routes

The following procedure shows how to integrate the firewall into the network using static routing.

| Set Up Interfaces and Zones | | |
|---|---|---|
| Step 1 | Configure a default route to your Internet router. | 1. Select **Network > Virtual Router** and then select the **default** link to open the Virtual Router dialog.<br>2. Select the **Static Routes** tab and click **Add**. Enter a **Name** for the route and enter the route in the **Destination** field (for example, 0.0.0.0/0).<br>3. Select the **IP Address** radio button in the **Next Hop** field and then enter the IP address and netmask for your Internet gateway (for example, 208.80.56.1).<br>4. Click **OK** twice to save the virtual router configuration. |
| Step 2 | Configure the external interface (the interface that connects to the Internet). | 1. Select **Network > Interfaces** and then select the interface you want to configure. In this example, we are configuring Ethernet1/3 as the external interface.<br>2. Select the **Interface Type**. Although your choice here depends on your network topology, this example shows the steps for **Layer3**.<br>3. In the **Virtual Router** drop-down, select **default**.<br>4. On the **Config** tab, select **New Zone** from the **Security Zone** drop-down. In the Zone dialog, define a **Name** for new zone, for example Untrust, and then click **OK**.<br>5. To assign an IP address to the interface, select the **IPv4** tab and **Static** radio button. Click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 208.80.56.100/24.<br>6. To enable you to ping the interface, select **Advanced > Other Info**, expand the **Management Profile** drop-down, and select **New Management Profile**. Enter a **Name** for the profile, select **Ping** and then click **OK**.<br>7. To save the interface configuration, click **OK**. |

| Set Up Interfaces and Zones (Continued) | | |
|---|---|---|
| Step 3 | Configure the interface that connects to your internal network.<br><br>In this example, the interface connects to a network segment that uses private IP addresses. Because private IP addresses cannot be routed externally, you will have to configure NAT. See Configure NAT for details. | 1. Select **Network > Interfaces** and select the interface you want to configure. In this example, we are configuring Ethernet1/4 as the internal interface.<br>2. Select **Layer3** from the **Interface Type** drop-down.<br>3. On the **Config** tab, expand the **Security Zone** drop-down and select **New Zone**. In the Zone dialog, define a **Name** for new zone, for example Trust, and then click **OK**.<br>4. Select the same Virtual Router you used in Step 2, default in this example.<br>5. To assign an IP address to the interface, select the **IPv4** tab and the **Static** radio button, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 192.168.1.4/24.<br>6. To enable you to ping the interface, select the management profile that you created in Step 2-6.<br>7. To save the interface configuration, click **OK**. |
| Step 4 | Configure the interface that connects to the DMZ. | 1. Select the interface you want to configure.<br>2. Select **Layer3** from the **Interface Type** drop-down. In this example, we are configuring Ethernet1/13 as the DMZ interface.<br>3. On the **Config** tab, expand the **Security Zone** drop-down and select **New Zone**. In the Zone dialog, define a **Name** for new zone, for example DMZ, and then click **OK**.<br>4. Select the Virtual Router you used in Step 2, default in this example.<br>5. To assign an IP address to the interface, select the **IPv4** tab and the **Static** radio button, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 10.1.1.1/24.<br>6. To enable you to ping the interface, select the management profile that you created in Step 2-6.<br>7. To save the interface configuration, click **OK**. |
| Step 5 | Save the interface configuration. | Click **Commit**. |
| Step 6 | Cable the firewall. | Attach straight through cables from the interfaces you configured to the corresponding switch or router on each network segment. |
| Step 7 | Verify that the interfaces are active. | From the web interface, select **Network > Interfaces** and verify that icon in the Link State column is green. You can also monitor link state from the **Interfaces** widget on the **Dashboard**.<br><br>  |

# RIP

Routing Information Protocol (RIP) is an interior gateway protocol (IGP) that was designed for small IP networks. RIP relies on hop count to determine routes; the best routes have the fewest number of hops. RIP is based on UDP and uses port 520 for route updates. By limiting routes to a maximum of 15 hops, the protocol helps prevent the development of routing loops, but also limits the supported network size. If more than 15 hops are required, traffic is not routed. RIP also can take longer to converge than OSPF and other routing protocols. The firewall supports RIP v2.

Perform the following procedure to configure RIP.

| **Configure RIP** | | |
|---|---|---|
| Step 1 | Configure general virtual router configuration settings. | See Virtual Routers for details. |
| Step 2 | Configure general RIP configuration settings. | 1. Select the **RIP** tab.<br>2. Select the **Enable** check box to enable the RIP protocol.<br>3. Select the **Reject Default Route** check box if you do not want to learn any default routes through RIP. This is the recommended default setting.<br>4. De-select the **Reject Default Route** check box if you want to permit redistribution of default routes through RIP. |
| Step 3 | Configure interfaces for the RIP protocol. | 1. On **Interfaces** tab, select an interface from the drop-down in the Interface configuration section.<br>2. Select an already defined interface from the drop-down.<br>3. Select the **Enable** check box.<br>4. Select the **Advertise** check box to advertise a default route to RIP peers with the specified metric value.<br>5. You can optionally select a profile from the **Auth Profile** drop-down. See Step 5 for details.<br>6. Select normal, passive or send-only from the **Mode** drop-down.<br>7. Click **OK**. |
| Step 4 | Configure RIP timers. | 1. On the **Timers** tab, enter a value in the **Interval Seconds (sec)** box. This setting defines the length of the timer interval in seconds. This duration is used for the remaining RIP timing fields. Default: 1. Range: 1 - 60.<br>2. Enter an **Update Intervals** to define the number of intervals between route update announcements Default: 30. Range: 1 - 3600.<br>3. Specify the **Delete Intervals** to define the number of intervals between the time that the route expires to its deletion Default: 180. Range: 1 - 3600.<br>4. Specify the **Expire Intervals** to define the number of intervals between the time that the route was last updated to its expiration Default: 120. Range: 1 - 3600. |

| Configure RIP | |
|---|---|
| Step 5 (Optional) Configure Auth Profiles. | By default, the firewall does not use RIP authentication for the exchange between RIP neighbors. Optionally, you can configure RIP authentication between RIP neighbors by either a simple password or using MD5 authentication.<br>**Simple Password RIP authentication**<br>1. Select **Auth Profiles** and click **Add**.<br>2. Enter a name for the authentication profile to authenticate RIP messages.<br>3. Select **Simple Password** as the **Password Type**.<br>4. Enter a simple password and then confirm.<br>**MD5 RIP authentication**<br>1. Select **Auth Profiles** and click **Add**.<br>2. Enter a name for the authentication profile to authenticate RIP messages.<br>3. Select **MD5** as the **Password Type**.<br>4. Click **Add**.<br>5. Enter one or more password entries, including:<br>• Key-ID Range 0-255<br>• Key<br>6. You can optionally select **Preferred** status.<br>7. Click **OK** to specify the key to be used to authenticate outgoing message.<br>8. Click **OK** again in the Virtual Router - RIP Auth Profile dialog box. |

 © Palo Alto Networks, Inc.

# OSPF

Open Shortest Path First (OSPF) is an interior gateway protocol (IGP) that is most often used to dynamically manage network routes in large enterprise network. It determines routes dynamically by obtaining information from other routers and advertising routes to other routers by way of Link State Advertisements (LSAs). The information gathered from the LSAs is used to construct a topology map of the network. This topology map is shared across routers in the network and used to populate the IP routing table with available routes.

Changes in the network topology are detected dynamically and used to generate a new topology map within seconds. A shortest path tree is computed of each route. Metrics associated with each routing interface are used to calculate the best route. These can include distance, network throughput, link availability etc. Additionally, these metrics can be configured statically to direct the outcome of the OSPF topology map.

Palo Alto networks implementation of OSPF fully supports the following RFCs:

- RFC 2328 (for IPv4)
- RFC 5340 (for IPv6)

The following topics provide more information about the OSPF and procedures for configuring OSPF on the firewall:

▲ OSPF Concepts
▲ Configure OSPF
▲ Configure OSPFv3
▲ Configure OSPF Graceful Restart
▲ Confirm OSPF Operation

## OSPF Concepts

The following topics introduce the OSPF concepts you will need to understand in order to configure the firewall to participate in an OSPF network:

▲ OSPFv3
▲ OSPF Neighbors
▲ OSPF Areas
▲ OSPF Router Types

© Palo Alto Networks, Inc.

## OSPFv3

OSPFv3 provides support for the OSPF routing protocol within an IPv6 network. As such, it provides support for IPv6 addresses and prefixes. It retains most of the structure and functions in OSPFv2 (for IPv4) with some minor changes. The following are some of the additions and changes to OSPFv3:

- **Support for multiple instances per link**—With OSPFv3, you can run multiple instances of the OSPF protocol over a single link. This is accomplished by assigning an OSPFv3 instance ID number. An interface that is assigned to an instance ID drops packets that contain a different ID.
- **Protocol Processing Per-link**—OSPFv3 operates per-link instead of per-IP-subnet as on OSPFv2.
- **Changes to Addressing**—IPv6 addresses are not present in OSPFv3 packets, except for LSA payloads within link state update packets. Neighboring routers are identified by the Router ID.
- **Authentication Changes**—OSPFv3 doesn't include any authentication capabilities. Configuring OSPFv3 on a firewall requires an authentication profile that specifies Encapsulating Security Payload (ESP) or IPv6 Authentication Header (AH).The re-keying procedure specified in RFC 4552 is not supported in this release.
- **Support for multiple instances per-link**—Each instance corresponds to an instance ID contained in the OSPFv3 packet header.
- **New LSA Types**—OSPFv3 supports two new LSA types: Link LSA and Intra Area Prefix LSA.

All additional changes are described in detail in RFC 5340.

## OSPF Neighbors

Two OSPF-enabled routers connected by a common network and in the same OSPF area that form a relationship are OSPF neighbors. The connection between these routers can be through a common broadcast domain or by a point-to-point connection. This connection is made through the exchange of hello OSPF protocol packets. These neighbor relationships are used to exchange routing updates between routers.

 © Palo Alto Networks, Inc.

## OSPF Areas

OSPF operates within a single autonomous system (AS). Networks within this single AS, however, can be divided into a number of areas. By default, Area 0 is created. Area 0 can either function alone or act as the OSPF backbone for a larger number of areas. Each OSPF area is named using a 32-bit identifier which in most cases is written in the same dotted-decimal notation as an IP4 address. For example, Area 0 is usually written as 0.0.0.0.

The topology of an area is maintained in its own link state database and is hidden from other areas, which reduces the amount of traffic routing required by OSPF. The topology is then shared in a summarized form between areas by a connecting router.

**Table: OSPF Area Types**

| Area Type | Description |
|---|---|
| Backbone Area | The backbone area (Area 0) is the core of an OSPF network. All other areas are connected to it and all traffic between areas must traverse it. All routing between areas is distributed through the backbone area. While all other OSPF areas must connect to the backbone area, this connection doesn't need to be direct and can be made through a virtual link. |
| Normal OSPF Area | In a normal OSPF area there are no restrictions; the area can carry all types of routes. |
| Stub OSPF Area | A stub area does not receive routes from other autonomous systems. Routing from the stub area is performed through the default route to the backbone area. |
| NSSA Area | The Not So Stubby Area (NSSA) is a type of stub area that can import external routes, with some limited exceptions. |

## OSPF Router Types

Within an OSPF area, routers are divided into the following categories.

- **Internal Router**—A router with that has OSPF neighbor relationships only with devices in the same area.
- **Area Border Router (ABR)**—A router that has OSPF neighbor relationships with devices in multiple areas. ABRs gather topology information from their attached areas and distribute it to the backbone area.
- **Backbone Router**—A backbone router is any OSPF router that is attached to the OSPF backbone. Since ABRs are always connected to the backbone, they are always classified as backbone routers.
- **Autonomous System Boundary Router (ASBR)**—An ASBR is a router that attaches to more than one routing protocol and exchanges routing information between them.

© Palo Alto Networks, Inc.

## Configure OSPF

OSPF determines routes dynamically by obtaining information from other routers and advertising routes to other routers by way of Link State Advertisements (LSAs). The router keeps information about the links between it and the destination and can make highly efficient routing decisions. A cost is assigned to each router interface, and the best routes are determined to be those with the lowest costs, when summed over all the encountered outbound router interfaces and the interface receiving the LSA.

Hierarchical techniques are used to limit the number of routes that must be advertised and the associated LSAs. Because OSPF dynamically processes a considerable amount of route information, it has greater processor and memory requirements than does RIP.

| **Configure OSPF** | | |
|---|---|---|
| Step 1 | Configure general virtual router configuration settings. | See Virtual Routers for details. |
| Step 2 | Configure general OSPF configuration settings. | 1. Select the **OSPF** tab.<br>2. Select the **Enable** check box to enable the OSPF protocol.<br>3. Optionally enter the **Router ID**.<br>4. Select the **Reject Default Route** check box if you do not want to learn any default routes through OSPF. This is the recommended default setting.<br>De-select the **Reject Default Route** check box if you want to permit redistribution of default routes through OSPF. |

© Palo Alto Networks, Inc.

**Configure OSPF (Continued)**

| | |
|---|---|
| Step 3 Configure Areas - Type for the OSFP protocol. | 1. On the **Areas** tab, click **Add**.<br>2. Enter an Area ID for the area in *x.x.x.x* format. This is the identifier that each neighbor must accept to be part of the same area.<br>3. On the **Type** tab, select one of the following from the area **Type** drop-down:<br>• **Normal**—There are no restrictions; the area can carry all types of routes.<br>• **Stub**—There is no outlet from the area. To reach a destination outside of the area, it is necessary to go through the border, which connects to other areas. If you select this option, configure the following:<br>– **Accept Summary**—Link state advertisements (LSA) are accepted from other areas. If this option on a stub area Area Border Router (ABR) interface is disabled, the OSPF area will behave as a Totally Stubby Area (TSA) and the ABR will not propagate any summary LSAs.<br>– **Advertise Default Route**—Default route LSAs will be included in advertisements to the stub area along with a configured metric value in the configured range: 1-255.<br>• **NSSA** (Not-So-Stubby Area)—The firewall can only leave the area by routes other than OSPF routes. If selected, configure **Accept Summary** and **Advertise Default Route** as described for **Stub**. If you select this option, configure the following:<br>– **Type**—Select either **Ext 1** or **Ext 2** route type to advertise the default LSA.<br>– **Ext Ranges**—Click **Add** in the section to enter ranges of external routes that you want to enable or suppress advertising for.<br>4. **Priority**—Enter the OSPF priority for this interface (0-255). This is the priority for the router to be elected as a designated router (DR) or as a backup DR (BDR) according to the OSPF protocol. When the value is zero, the router will not be elected as a DR or BDR.<br>• **Auth Profile**—Select a previously-defined authentication profile.<br>• **Timing**—It is recommended that you keep the default timing settings.<br>• **Neighbors**—For p2pmp interfaces, enter the neighbor IP address for all neighbors that are reachable through this interface.<br>5. Select **normal**, **passive** or **send-only** as the **Mode**.<br>6. Click **OK**. |

| Configure OSPF (Continued) | | |
|---|---|---|
| Step 4 | Configure Areas - Range for the OSFP protocol | 1. On the **Range** tab, click **Add** to aggregate LSA destination addresses in the area into subnets.<br>2. **Advertise** or **Suppress** advertising LSAs that match the subnet, and click **OK**. Repeat to add additional ranges. |
| Step 5 | Configure Areas - Interfaces for the OSFP protocol | 1. On the **Interface** tab, click **Add** and enter the following information for each interface to be included in the area:<br>• **Interface**—Select an interface from the drop-down box.<br>• **Enable**—Selecting this option causes the OSPF interface settings to take effect.<br>• **Passive**—Select the check box to if you do not want the OSPF interface to send or receive OSPF packets. Although OSPF packets are not sent or received if you choose this option, the interface is included in the LSA database.<br>• **Link type**—Choose **Broadcast** if you want all neighbors that are accessible through the interface to be discovered automatically by multicasting OSPF hello messages, such as an Ethernet interface. Choose **p2p** (point-to-point) to automatically discover the neighbor. Choose **p2mp** (point-to-multipoint) when neighbors must be defined manually. Defining neighbors manually is allowed only for **p2mp** mode.<br>• **Metric**—Enter an OSPF metric for this interface. Default: 10. Range: 0-65535.<br>• **Priority**—Enter an OSPF priority for this interface. This is the priority for the router to be elected as a designated router (DR) or as a backup DR (BDR). Default: 1. Range: 0 - 255. If zero is configured, the router will not be elected as a DR or BDR.<br>• **Auth Profile**—Select a previously-defined authentication profile.<br>• **Timing**—The following OSPF timing settings can be set. Palo Alto Networks recommends that you retain the default timing settings.<br>– **Hello Interval (sec)**—Interval at which the OSPF process sends hello packets to its directly connected neighbors. Default: 10 seconds. Range: 0-3600 seconds.<br>– **Dead Counts—**Number of times the hello interval can occur for a neighbor without OSPF receiving a hello packet from the neighbor, before OSPF considers that neighbor down. The **Hello Interval** multiplied by the **Dead Counts** equals the value of the dead timer. Default: 4. Range: 3-20. |

© Palo Alto Networks, Inc.

| Configure OSPF (Continued) | |
|---|---|
| | – **Retransmit Interval (sec)**—Length of time that OSPF waits to receive a link state advertisement (LSA) from a neighbor before OSPF retransmits the LSA. Default: 10 seconds. Range: 0-3600 seconds.<br>– **Transit Delay (sec)**—Length of time that an LSA is delayed before it is sent out of an interface. Default: 1 second. Range: 0-3600 seconds.<br>– **Graceful Restart Hello Delay (sec)**—Applies to an OSPF interface when Active/Passive High Availability is configured. **Graceful Restart Hello Delay** is the length of time during which the firewall sends Grace LSA packets at 1-second intervals. During this time, no hello packets are sent from the restarting firewall. During the restart, the dead timer (which is the **Hello Interval** multiplied by the **Dead Counts**) is also counting down. If the dead timer is too short, the adjacency will go down during the graceful restart because of the hello delay. Therefore, it is recommended that the dead timer be at least four times the value of the **Graceful Restart Hello Delay**. For example, a **Hello Interval** of 10 seconds and a **Dead Counts** of 4 yield a dead timer of 40 seconds. If the **Graceful Restart Hello Delay** is set to 10 seconds, that 10-second delay of hello packets is comfortably within the 40-second dead timer, so the adjacency will not time out during a graceful restart. Default: 10 seconds. Range: 1-10 seconds.<br>• If **p2mp** is selected for **Link Type** interfaces, enter the neighbor IP addresses for all neighbors that are reachable through this interface.<br>2. Click **OK** |
| Step 6 Configure Areas - Virtual Links. | 1. On the **Virtual Link** tab, click **Add** and enter the following information for each virtual link to be included in the backbone area:<br>• **Name**—Enter a name for the virtual link.<br>• **Neighbor ID**—Enter the router ID of the router (neighbor) on the other side of the virtual link.<br>• **Transit Area**—Enter the area ID of the transit area that physically contains the virtual link.<br>• **Enable**—Select to enable the virtual link.<br>• **Timing**—It is recommended that you keep the default timing settings.<br>• **Auth Profile**—Select a previously-defined authentication profile.<br>2. Click **OK**. |

| Configure OSPF (Continued) | |
|---|---|
| Step 7 (Optional) Configure Auth Profiles. | By default, the firewall does not use OSPF authentication for the exchange between OSPF neighbors. Optionally, you can configure OSPF authentication between OSPF neighbors by either a simple password or using MD5 authentication.<br>**Simple Password OSPF authentication**<br>1. On the **Auth Profiles** tab, click **Add**.<br>2. Enter a name for the authentication profile to authenticate OSPF messages.<br>3. Select **Simple Password** as the **Password Type**.<br>4. Enter a simple password and then confirm.<br>**MD5 OSPF authentication**<br>1. On the **Auth Profiles** tab, click **Add**.<br>2. Enter a name for the authentication profile to authenticate OSPF messages.<br>3. Select **MD5** as the **Password Type**.<br>4. Click **Add**.<br>5. Enter one or more password entries, including:<br>• Key-ID Range 0-255<br>• Key<br>• Select the **Preferred** option to specify that the key be used to authenticate outgoing messages.<br>6. Click **OK**.<br>7. Click **OK** again in the Virtual Router - OSPF Auth Profile dialog box. |
| Step 8 Configure Advanced OSPF options. | 1. On the **Advanced** tab, select the **RFC 1583 Compatibility** check box to ensure compatibility with RFC 1583.<br>2. Configure a value for the **SPF Calculation Delay** (sec) timer.<br>This timer allows you to tune the delay time between receiving new topology information and performing an SPF calculation. Lower values enable faster OSPF re-convergence. Routers peering with the firewall should be tuned in a similar manner to optimize convergence times.<br>3. Configure a value for the **LSA Interval (sec)** time. This timer specifies the minimum time between transmissions of two instances of the same LSA (same router, same type, same LSA ID). This is equivalent to MinLSInterval in RFC 2328. Lower values can be used to reduce re-convergence times when topology changes occur. |

 © Palo Alto Networks, Inc.

# Configure OSPFv3

| Configure OSPFv3 | | |
|---|---|---|
| Step 1 | Configure general virtual router configuration settings. | See Virtual Routers for details. |
| Step 2 | Configure general OSPF configuration settings. | 1. Select the **OSPF** tab.<br>2. Select the **Enable** check box to enable the OSPF protocol.<br>3. Select the **Reject Default Route** check box if you do not want to learn any default routes through OSPF. This is the recommended default setting.<br>4. Clear the **Reject Default Route** check box if you want to permit redistribution of default routes through OSPF. |
| Step 3 | Configure general OSPFv3 configuration settings. | 1. Select the **OSPFv3** tab.<br>2. Select the **Enable** check box to enable the OSPF protocol.<br>3. Select the **Reject Default Route** check box if you do not want to learn any default routes through OSPFv3 This is the recommended default setting.<br>De-select the **Reject Default Route** check box if you want to permit redistribution of default routes through OSPFv3. |
| Step 4 | Configure Auth Profile for the OSFPv3 protocol.<br>While OSPFv3 doesn't include any authentication capabilities of its own, it relies entirely on IPsec to secure communications between neighbors. | When configuring an authentication profile, you must use Encapsulating Security Payload (ESP) or IPv6 Authentication Header (AH).<br>**ESP OSPFv3 authentication**<br>1. On the **Auth Profiles** tab, click **Add**.<br>2. Enter a name for the authentication profile to authenticate OSPFv3 messages.<br>3. Specify a Security Policy Index (**SPI**). The SPI must match between both ends of the OSPFv3 adjacency. The SPI number must be a hexadecimal value between 00000000 and FFFFFFFF.<br>4. Select **ESP** for **Protocol**.<br>5. Select a **Crypto Algorithm** from the drop-down.<br>You can enter none or one of the following algorithms: SHA1, SHA256, SHA384, SHA512 or MD5.<br>6. If a **Crypto Algorithm** other than none was selected, enter a value for **Key** and then confirm. |

| Configure OSPFv3 (Continued) | |
|---|---|
| | **AH OSPFv3 authentication**<br>1. On the **Auth Profiles** tab, click **Add**.<br>2. Enter a name for the authentication profile to authenticate OSPFv3 messages.<br>3. Specify a Security Policy Index (**SPI**). The SPI must match between both ends of the OSPFv3 adjacency. The SPI number must be a hexadecimal value between 00000000 and FFFFFFFF.<br>4. Select **AH** for **Protocol**.<br>5. Select a **Crypto Algorithm** from the drop-down.<br>You must enter one of the following algorithms: SHA1, SHA256, SHA384, SHA512 or MD5.<br>6. Enter a value for **Key** and then confirm.<br>7. Click **OK**.<br>8. Click **OK** again in the Virtual Router - OSPF Auth Profile dialog. |
| Step 5 Configure Areas - Type for the OSFP protocol. | 1. On the **Areas** tab, click **Add**.<br>2. Enter an Area ID. This is the identifier that each neighbor must accept to be part of the same area.<br>3. On the **General** tab, select one of the following from the area **Type** drop-down:<br>• **Normal**—There are no restrictions; the area can carry all types of routes.<br>• **Stub**—There is no outlet from the area. To reach a destination outside of the area, it is necessary to go through the border, which connects to other areas. If you select this option, configure the following:<br>– **Accept Summary**—Link state advertisements (LSA) are accepted from other areas. If this option on a stub area Area Border Router (ABR) interface is disabled, the OSPF area will behave as a Totally Stubby Area (TSA) and the ABR will not propagate any summary LSAs.<br>– **Advertise Default Route**—Default route LSAs will be included in advertisements to the stub area along with a configured metric value in the configured range: 1-255. |

 © Palo Alto Networks, Inc.

| Configure OSPFv3 (Continued) | | |
|---|---|---|
| | | • **NSSA** (Not-So-Stubby Area)—The firewall can only leave the area by routes other than OSPF routes. If selected, configure **Accept Summary** and **Advertise Default Route** as described for **Stub**. If you select this option, configure the following:<br>– **Type**—Select either **Ext 1** or **Ext 2** route type to advertise the default LSA.<br>– **Ext Ranges**—Click **Add** in the section to enter ranges of external routes that you want to enable or suppress advertising for. |
| Step 6 | Associate an OSPFv3 authentication profile to an area or an interface. | **To an Area**<br>1. On the **Areas** tab, select an existing area from the table.<br>2. On the **General** tab, select a previously defined **Authentication Profile** from the **Authentication** drop-down.<br>3. Click **OK**.<br>**To an Interface**<br>1. On the **Areas** tab, select an existing area from the table.<br>2. Select the **Interface** tab and click **Add**.<br>3. Select the authentication profile you want to associate with the OSPF interface from the **Auth Profile** drop-down. |
| Step 7 | (Optional) Configure Export Rules | 1. On the **Export** tab, click **Add**.<br>2. Select the **Allow Redistribute Default Route** check box to permit redistribution of default routes through OSPFv3.<br>3. Select the name of a redistribution profile. The value must be an IP subnet or valid redistribution profile name.<br>4. Select a metric to apply for **New Path Type**.<br>5. Specify a **New Tag** for the matched route that has a 32-bit value.<br>6. Assign a metric for the new rule. Range: 1 - 65535.<br>7. Click **OK**. |

| Configure OSPFv3 (Continued) | |
|---|---|
| Step 8 Configure Advanced OSPFv3 options. | 1. On the **Advanced** tab, select the **Disable Transit Routing for SPF Calculation** check box if you want the firewall to participate in OSPF topology distribution without being used to forward transit traffic.<br>2. Configure a value for the **SPF Calculation Delay** (sec) timer.<br>This timer allows you to tune the delay time between receiving new topology information and performing an SPF calculation. Lower values enable faster OSPF re-convergence. Routers peering with the firewall should be tuned in a similar manner to optimize convergence times.<br>3. Configure a value for the **LSA Interval (sec) time**, This timer specifies the minimum time between transmissions of two instances of the same LSA (same router, same type, same LSA ID). This is equivalent to MinLSInterval in RFC 2328. Lower values can be used to reduce re-convergence times when topology changes occur.<br>4. Optionally, Configure OSPF Graceful Restart. |

## Configure OSPF Graceful Restart

OSPF Graceful Restart directs OSPF neighbors to continue using routes through a device during a short transition when it is out of service. This behavior increases network stability by reducing the frequency of routing table reconfiguration and the related route flapping that can occur during short periodic down times.

For a Palo Alto Networks firewall, OSPF Graceful Restart involves the following operations:

- **Firewall as a restarting device**—In a situation where the firewall will be down for a short period of time or is unavailable for short intervals, it sends Grace LSAs to its OSPF neighbors. The neighbors must be configured to run in Graceful Restart Helper mode. In Helper Mode, the neighbors receive the Grace LSAs that inform it that the firewall will perform a graceful restart within a specified period of time defined as the **Grace Period**. During the grace period, the neighbor continues to forward routes through the firewall and to send LSAs that announce routes through the firewall. If the firewall resumes operation before expiration of the grace period, traffic forwarding will continue as before without network disruption. If the firewall does not resume operation after the grace period has expired, the neighbors will exit helper mode and resume normal operation, which will involve reconfiguring the routing table to bypass the firewall.
- **Firewall as a Graceful Restart Helper**—In a situation where neighboring routers may be down for a short periods of time, the firewall can be configured to operate in Graceful Restart Helper mode. If configured in this mode, the firewall will be configured with a **Max Neighbor Restart Time**. When the firewall receives the Grace LSAs from its OSFP neighbor, it will continue to route traffic to the neighbor and advertise routes through the neighbor until either the grace period or max neighbor restart time expires. If neither expires before the neighbor returns to service, traffic forwarding continues as before without network disruption. If either period expires before the neighbor returns to service, the firewall will exit helper mode and resume normal operation, which will involve reconfiguring the routing table to bypass the neighbor.

 © Palo Alto Networks, Inc.

| Configure OSPF Graceful Restart |
|---|
| 1. Select **Network > Virtual Routers** and select the virtual router you want to configure. |
| 2. Select **OSPF > Advanced**. |
| 3. Verify that the following check boxes are selected (they are enabled by default):<br>• **Enable Graceful Restart**<br>• **Enable Helper Mode**<br>• **Enable Strict LSA checking**<br>These check boxes should remain selected unless required by your topology. |
| 4. Configure a **Grace Period** in seconds. |
| 5. Configure a **Max Neighbor Restart Time** in seconds. |

## Confirm OSPF Operation

Once an OSPF configuration has been committed, you can use any of the following operations to confirm that OSPF is operating:

- View the Routing Table
- Confirm OSPF Adjacencies
- Confirm that OSPF Connections are Established

### View the Routing Table

By viewing the routing table, you can see whether OSPF routes have been established. The routing table is accessible from either the web interface or the CLI. If you are using the CLI, use the following commands:

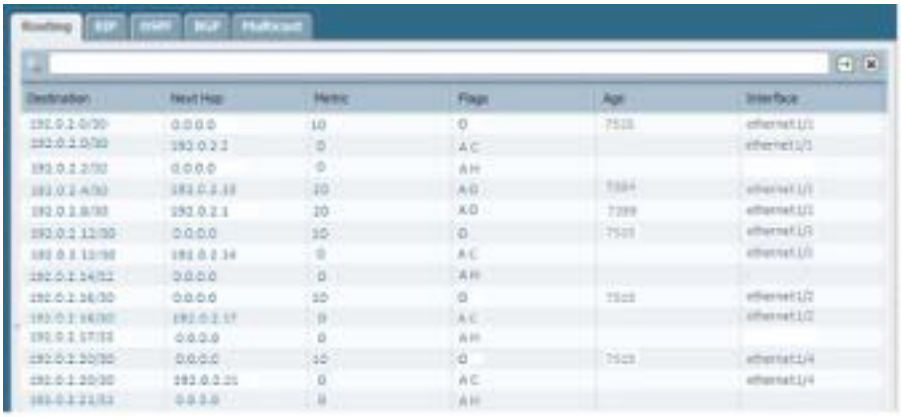
- `show routing route`
- `show routing fib`

The following procedure describes how to use the web interface to view the routing table.

| View the Routing Table |
|---|
| 1. Select **Network > Virtual Routers**. |
|  |

**View the Routing Table**

2. Select the **Routing** tab and examine the **Flags** column of the routing table for routes that were learned by OSPF.

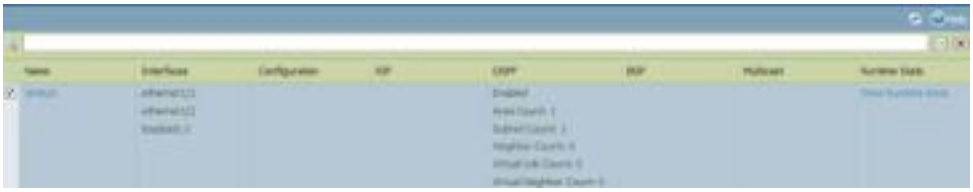


## Confirm OSPF Adjacencies

By viewing the **Neighbor** tab as described in the following procedure, you can confirm that OSPF adjacencies have been established.

**View the Neighbor Tab to Confirm OSPF Adjacencies**

1. Select **Network > Virtual Routers**.



2. Select **OSPF > Neighbor** and examine the **Status** column to determine if OSPF adjacencies have been established.

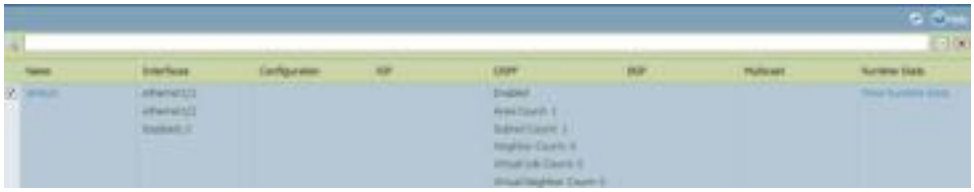
 © Palo Alto Networks, Inc.

## Confirm that OSPF Connections are Established

By viewing the system log, you can confirm that OSPF connections have been established, as described in the following procedure:

**Examine the System Log**

1. Select **Monitor> System** and look for messages to confirm that OSPF adjacencies have been established.



2. Select **OSPF > Neighbor** and examine the **Status** column to determine if OSPF adjacencies have been established.

# BGP

Border Gateway Protocol (BGP) is the primary Internet routing protocol. BGP determines network reachability based on IP prefixes that are available within autonomous systems (AS), where an AS is a set of IP prefixes that a network provider has designated to be part of a single routing policy.

In the routing process, connections are established between BGP peers (or neighbors). If a route is permitted by the policy, it is stored in the routing information base (RIB). Each time the local firewall RIB is updated, the firewall determines the optimal routes and sends an update to the external RIB, if export is enabled.

Conditional advertisement is used to control how BGP routes are advertised. The BGP routes must satisfy conditional advertisement rules before being advertised to peers.

BGP supports the specification of aggregates, which combine multiple routes into a single route. During the aggregation process, the first step is to find the corresponding aggregation rule by performing a longest match that compares the incoming route with the prefix values for other aggregation rules.

The firewall provides a complete BGP implementation, which includes the following features:

- Specification of one BGP routing instance per virtual router.
- Routing policies based on route-map to control import, export and advertisement, prefix-based filtering, and address aggregation.
- Advanced BGP features that include route reflector, AS confederation, route flap dampening, and graceful restart.
- IGP-BGP interaction to inject routes to BGP using redistribution profiles.

BGP configuration consists of the following elements:

- Per-routing-instance settings, which include basic parameters such as local route ID and local AS and advanced options such as path selection, route reflector, AS confederation, route flap, and dampening profiles.
- Authentication profiles, which specify the MD5 authentication key for BGP connections.
- Peer group and neighbor settings, which include neighbor address and remote AS and advanced options such as neighbor attributes and connections.
- Routing policy, which specifies rule sets that peer groups and peers use to implement imports, exports, conditional advertisements, and address aggregation controls.

Perform the following procedure to configure BGP.

| **Configure BGP** | | |
|---|---|---|
| Step 1 | Configure general virtual router configuration settings. | See Virtual Routers for details. |

 © Palo Alto Networks, Inc.

| Configure BGP (Continued) | | |
|---|---|---|
| Step 2 | Configure standard BGP configuration settings. | 1. Select the **BGP** tab.<br>2. Select the **Enable** check box to enable the BGP protocol.<br>3. Assign an IP address to the virtual router in the **Router ID** box.<br>4. Enter the number of the AS to which the virtual router belongs in the **AS Number** box, based on the router ID. Range: 1-4294967295 |
| Step 3 | Configure general BGP configuration settings. | 1. Select **BGP > General**.<br>2. Select the **Reject Default Route** check box to ignore any default routes that are advertised by BGP peers.<br>3. Select the **Install Route** check box to install BGP routes in the global routing table.<br>4. Select the **Aggregate MED** check box to enable route aggregation even when routes have different Multi-Exit Discriminator (MED) values.<br>5. Enter a value for the **Default Local Preference** that specifies a value than can be used to determine preferences among different paths.<br>6. Select one of the following values for the AS format for interoperability purposes:<br>• 2 Byte (default value)<br>• 4 Byte<br>7. Enable or disable each of the following values for **Path Selection**:<br>• **Always Compare MED**—Enable this comparison to choose paths from neighbors in different autonomous systems.<br>• **Deterministic MED Comparison**—Enable this comparison to choose between routes that are advertised by IBGP peers (BGP peers in the same autonomous system).<br>8. Click **Add** to include a new authentication profile and configure the following settings:<br>• **Profile Name**—Enter a name to identify the profile.<br>• **Secret/Confirm Secret**—Enter and confirm a passphrase for BGP peer communications. |

| Configure BGP (Continued) | |
|---|---|
| Step 4 Configure BGP Advanced settings (Optional) | 1. On the **Advanced** tab, select **Graceful Restart** and configure the following timers:<br>• **Stale Route Time (sec)**—Specifies the length of time in seconds that a route can say in the stale state. Range: 1 - 3600 seconds. Default: 120 seconds.<br>• **Local Restart Time (sec)**—Specifies the length of time in seconds that the local device waits to restart. This value is advertised to peers. Range: 1 - 3600 seconds. Default: 120 seconds.<br>• **Max Peer Restart Time (sec)**—Specifies the maximum length of time in seconds that the local device accepts as a grave period restart time for peer devices. Range: 1 - 3600 seconds. Default: 120 seconds.<br>2. Specify an IPv4 identifier to represent the reflector cluster in the **Reflector Cluster ID** box.<br>3. Specify the identifier for the AS confederation to be presented as a single AS to external BGP peers in the **Confederation Member AS** box.<br>4. Click **Add** and enter the following information for each Dampening Profile that you want to configure, select **Enable**, and click **OK**:<br>• **Profile Name**—Enter a name to identify the profile.<br>• **Cutoff**—Specify a route withdrawal threshold above which a route advertisement is suppressed. Range: 0.0-1000.0. Default: 1.25.<br>• **Reuse**—Specify a route withdrawal threshold below which a suppressed route is used again. Range: 0.0-1000.0. Default: 5.<br>• **Max Hold Time (sec)**—Specify the maximum length of time in seconds that a route can be suppressed, regardless of how unstable it has been. Range: 0-3600 seconds. Default: 900 seconds.<br>• **Decay Half Life Reachable (sec)**—Specify the length of time in seconds after which a route's stability metric is halved if the route is considered reachable Range: 0-3600 seconds. Default: 300 seconds.<br>• **Decay Half Life Unreachable (sec)**—Specify the length of time in seconds after which a route's stability metric is halved if the route is considered unreachable. Range: 0 - 3600 seconds. Default: 300 seconds.<br>5. Click **OK**. |

© Palo Alto Networks, Inc.

| Configure BGP (Continued) | | |
|---|---|---|
| Step 5 | Configure the BGP peer group. | 1. Select the **Peer Group** tab and click **Add**.<br>2. Enter a **Name** for the peer group and select **Enable**.<br>3. Select the **Aggregated Confed AS Path** check box to include a path to the configured aggregated confederation AS.<br>4. Select the **Soft Reset with Stored Info** check box to perform a soft reset of the firewall after updating the peer settings.<br>5. Specify the type of peer or group from the **Type** drop-down and configure the associated settings (see below in this table for descriptions of Import Next Hop and Export Next Hop).<br>• **IBGP—Export Next Hop:** Specify **Original** or **Use self**<br>• **EBGP Confed—Export Next Hop:** Specify **Original** or **Use self**<br>• **EBGP Confed—Export Next Hop:** Specify **Original** or **Use self**<br>• **EBGP—Import Next Hop:** Specify **Original** or **Use self**, **Export Next Hop:** Specify **Resolve** or **Use self**. Select **Remove Private AS** if you want to force BGP to remove private AS numbers.<br>6. Click **OK** to save. |
| Step 6 | Configure Import and Export rules.<br>The import/export rules are used to import/export routes from/to other routers. For example, importing the default route from your Internet Service Provider. | 1. Select the **Import** tab and then click **Add** and enter a name in the **Rules** field and select the **Enable** check box.<br>2. Click **Add** and select the **Peer Group** to which the routes will be imported from.<br>3. Click the **Match** tab and define the options used to filter routing information. You can also define the Multi-Exit Discriminator (MED) value and a next hop value to routers or subnets for route filtering. The MED option is an external metric that lets neighbors know about the preferred path into an AS. A lower value is preferred over a higher value.<br>4. Click the **Action** tab and define the action that should occur (allow/deny) based on the filtering options defined in the **Match** tab. If **Deny** is selected, no further options need to be defined. If the **Allow** action is selected, define the other attributes.<br>5. Click the **Export** tab and define export attributes, which are similar to the **Import** settings, but are used to control route information that is exported from the firewall to neighbors.<br>6. Click **OK** to save. |

| Configure BGP (Continued) | | |
|---|---|---|
| Step 7 | Configure conditional advertising, which allows you to control what route to advertise in the event that a different route is not available in the local BGP routing table (LocRIB), indicating a peering or reachability failure. This is useful in cases where you want to try to force routes to one AS over another, for example if you have links to the Internet through multiple ISPs and you want traffic to be routed to one provider instead of the other unless there is a loss of connectivity to the preferred provider. | 1. Select the **Conditional Adv** tab, click **Add** and enter a name in the **Policy** field.<br>2. Select the **Enable** check box.<br>3. Click **Add** and in the **Used By** section enter the peer group(s) that will use the conditional advertisement policy.<br>4. Select the **Non Exist Filter** tab and define the network prefix(es) of the preferred route. This specifies the route that you want to advertise, if it is available in the local BGP routing table. If a prefix is going to be advertised and matches a Non Exist filter, the advertisement will be suppressed.<br>5. Select the **Advertise Filters** tab and define the prefix(es) of the route in the Local-RIB routing table that should be advertised in the event that the route in the non-exist filter is not available in the local routing table. If a prefix is going to be advertised and does not match a Non Exist filter, the advertisement will occur. |
| Step 8 | Configure aggregate options to summaries routes in the BGP configuration.<br><br>BGP route aggregation is used to control how BGP aggregates addresses. Each entry in the table results in one aggregate address being created. This will result in an aggregate entry in the routing table when at least one or more specific route matching the address specified is learned. | 1. Select the **Aggregate** tab, click **Add** and enter a name for the aggregate address.<br>2. In the **Prefix** field, enter the network prefix that will be the primary prefix for the aggregated prefixes.<br>3. Select the **Suppress Filters** tab and define the attributes that will cause the matched routes to be suppressed.<br>4. Select the **Advertise Filters** tab and define the attributes that will cause the matched routes to always be advertised to peers. |
| Step 9 | Configure redistribution rules.<br><br>This rule is used to redistribute host routes and unknown routes that are not on the local RIB to the peers routers. | 1. Select the **Redist Rules** tab and click **Add**.<br>2. In the **Name** field, enter an IP subnet or select a redistribution profile. You can also configure a new redistribution profile from the drop-down if needed.<br>3. Click the **Enable** check box to enable the rule.<br>4. In the **Metric** field, enter the route metric that will be used for the rule.<br>5. In the **Set Origin** drop-down, select **incomplete**, **igp**, or **egp**.<br>6. Optionally set MED, local preference, AS path limit and community values. |

# Session Settings and Timeouts

This section describes the global settings that affect TCP, UDP, and ICMPv6 sessions, in addition to IPv6, NAT64, NAT oversubscription, jumbo frame size, MTU, accelerated aging, and captive portal authentication. There is also a setting (Rematch Sessions) that allows you to apply newly configured security policies to sessions that are already in progress.

The **Device > Setup > Session** tab is where these session settings and timeouts are configured.

The first few topics below provide brief summaries of the Transport Layer of the OSI model, TCP, UDP, and ICMP. For more information about the protocols, refer to their respective RFCs. The remaining topics describe the session timeouts and settings.

- Transport Layer Sessions
- TCP
- UDP
- ICMP
- Configure Session Timeouts
- Configure Session Settings

## Transport Layer Sessions

A network session is a conversation that occurs between two or more communication devices, lasting for some period of time. A session is established and is torn down when the session ends. Different types of sessions occur at three layers of the OSI model: the Transport layer, the Session layer, and the Application layer.

The Transport Layer operates at Layer 4 of the OSI model, providing reliable or unreliable, end-to-end delivery and flow control of data. Internet protocols that implement sessions at the Transport layer include Transmission Control Protocol (TCP) and User Datagram Protocol (UDP).

## TCP

Transmission Control Protocol (TCP) (RFC 793) is one of the main protocols in the Internet Protocol (IP) suite, and is so prevalent that it is frequently referenced together with IP as *TCP/IP*. TCP is considered a reliable transport protocol because it provides error-checking while transmitting and receiving segments, it acknowledges segments received, and it reorders segments that arrive out of order from the device that sent them. TCP also requests and provides retransmission of segments that were dropped. TCP is stateful and connection-oriented, in that a connection between the sender and receiver is established for the duration of the session. TCP provides flow control of packets, so it can handle congestion over networks.

TCP performs a three-way handshake during session setup to initiate and acknowledge a session. After the data is transferred, the session is closed in an orderly manner.

Applications that use TCP as their transport protocol include Hypertext Transfer Protocol (HTTP), Hypertext Transfer Protocol Secure (HTTPS), File Transfer Protocol (FTP), Simple Mail Transfer Protocol (SMTP), Telnet, Post Office Protocol version 3 (POP3), Internet Message Access Protocol (IMAP), and Secure Shell (SSH).

The following topics describe details of the PAN-OS implementation of TCP.

- TCP Half Closed and TCP Time Wait Timers
- Unverified RST Timer

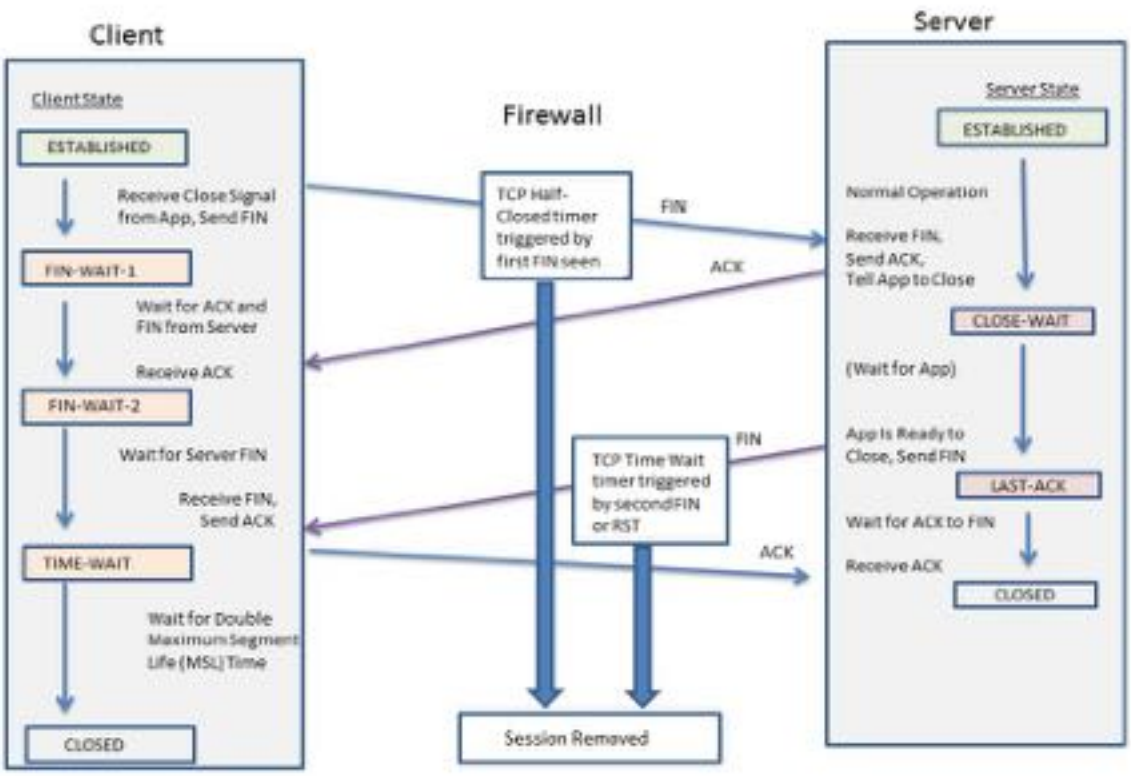
### TCP Half Closed and TCP Time Wait Timers

The TCP connection termination procedure uses a TCP Half Closed timer, which is triggered by the first FIN the firewall sees for a session. The timer is named TCP Half Closed because only one side of the connection has sent a FIN. A second timer, TCP Time Wait, is triggered by the second FIN or a RST.

If the firewall were to have only one timer triggered by the first FIN, a setting that was too short could prematurely close the half-closed sessions. Conversely, a setting that was too long would make the session table grow too much and possibly use up all of the sessions. Two timers allow you to have a relatively long TCP Half Closed timer and a short TCP Time Wait timer, thereby quickly aging fully closed sessions and controlling the size of the session table.

The following figure illustrates when the firewall's two timers are triggered during the TCP connection termination procedure.

 © Palo Alto Networks, Inc.



The TCP Time Wait timer should be set to a value less than the TCP Half Closed timer for the following reasons:

- The longer time allowed after the first FIN is seen gives the opposite side of the connection time to fully close the session.
- The shorter Time Wait time is because there is no need for the session to remain open for a long time after the second FIN or a RST is seen. A shorter Time Wait time frees up resources sooner, yet still allows time for the firewall to see the final ACK and possible retransmission of other datagrams.

If you configure a TCP Time Wait timer to a value greater than the TCP Half Closed timer, the commit will be accepted, but in practice the TCP Time Wait timer will not exceed the TCP Half Closed value.

The timers can be set globally or per application. The global settings are used for all applications by default. If you configure TCP wait timers at the application level, they override the global settings.

## Unverified RST Timer

If the firewall receives a Reset (RST) packet that cannot be verified (because it has an unexpected sequence number within the TCP window or it is from an asymmetric path), the Unverified RST timer controls the aging out of the session. It defaults to 30 seconds; the range is 1-600 seconds. The Unverified RST timer provides an additional security measure, explained in the second bullet below.

A RST packet will have one of three possible outcomes:

- A RST packet that falls outside the TCP window is dropped.

- A RST packet that falls inside the TCP window but does not have the exact expected sequence number is unverified and subject to the Unverified RST timer setting. This behavior helps prevent denial of service (DoS) attacks where the attack tries to disrupt existing sessions by sending random RST packets to the firewall.
- A RST packet that falls within the TCP window and has the exact expected sequence number is subject to the TCP Time Wait timer setting.

## UDP

User Datagram Protocol (UDP) (RFC 768) is another main protocol of the IP suite, and is an alternative to TCP. UDP is stateless and connectionless in that there is no handshake to set up a session, and no connection between the sender and receiver; the packets may take different routes to get to a single destination. UDP is considered an unreliable protocol because it does not provide acknowledgments, error-checking, retransmission, or reordering of datagrams. Without the overhead required to provide those features, UDP has reduced latency and is faster than TCP. UDP is referred to as a best-effort protocol because there is no mechanism or guarantee to ensure that the data will arrive at its destination.

Although UDP uses a checksum for data integrity, it performs no error checking at the network interface level. Error checking is assumed to be unnecessary or is performed by the application rather than UDP itself. UDP has no mechanism to handle flow control of packets.

UDP is often used for applications that require faster speeds and time-sensitive, real-time delivery, such as Voice over IP (VoIP), streaming audio and video, and online games. UDP is transaction-oriented, so it is also used for applications that respond to small queries from many clients, such as Domain Name System (DNS) and Trivial File Transfer Protocol (TFTP).

## ICMP

Internet Control Message Protocol (ICMP) (RFC 792) is another one of the main protocols of the Internet Protocol suite; it operates at the Network layer of the OSI model. ICMP is used for diagnostic and control purposes, to send error messages about IP operations, or messages about requested services or the reachability of a host or router. Network utilities such as traceroute and ping are implemented by using various ICMP messages.

ICMP is a connectionless protocol that does not open or maintain actual sessions. However, the ICMP messages between two devices can be considered a session.

Palo Alto Networks firewalls support ICMPv4 and ICMPv6. ICMPv4 and ICMPv6 error packets can be controlled by configuring a security policy for a zone, and selecting the **icmp** or **ipv6-icmp** application in the policy. Additionally, the ICMPv6 error packet rate can be controlled through the session settings, as described in the section Configure Session Settings.

 © Palo Alto Networks, Inc.

## ICMPv6 Rate Limiting

ICMPv6 rate limiting is a throttling mechanism to prevent flooding and DDoS attempts. The implementation employs an error packet rate and a token bucket, which work together to enable throttling and ensure that ICMP packets do not flood the network segments protected by the firewall.

First the global ICMPv6 error packet rate controls the rate at which ICMP error packets are allowed through the firewall; the default is 100 packets per second; the range is 10 to 65535 packets per second. If the firewall reaches the ICMP error packet rate, then the token bucket comes into play and throttling occurs, as follows.

The concept of a logical token bucket controls the rate at which ICMP messages can be transmitted. The number of tokens in the bucket is configurable, and each token represents an ICMP message that can be sent. The token count is decremented each time an ICMP message is sent; when the bucket reaches zero tokens, no more ICMP messages can be sent until another token is added to the bucket. The default size of the token bucket is 100 tokens (packets); the range is 10 to 65535 tokens.

To change the default token bucket size or error packet rate, see the section Configure Session Settings.

# Configure Session Timeouts

A session timeout defines the duration of time for which PAN-OS maintains a session on the firewall after inactivity in the session. By default, when the session timeout for the protocol expires, PAN-OS closes the session.

On the firewall, you can define a number of timeouts for TCP, UDP, and ICMP sessions in particular. The Default timeout applies to any other type of session. All of these timeouts are global, meaning they apply to all of the sessions of that type on the firewall.

In addition to the global settings, you have the flexibility to define timeouts for an individual application in the **Objects > Applications** tab. The firewall applies application timeouts to an application that is in established state. When configured, timeouts for an application override the global TCP or UDP session timeouts.

Returning to the global settings, perform the optional tasks below if you need to change default values of the global session timeout settings for TCP, UDP, ICMP, Captive Portal authentication, or other types of sessions. All values are in seconds.

The defaults are optimal values. However, you can modify these according to your network needs. Setting a value too low could cause sensitivity to minor network delays and could result in a failure to establish connections with the firewall. Setting a value too high could delay failure detection.

| **Change Session Timeouts** | | |
|---|---|---|
| Step 1 | Access the Session Settings. | 1. Select **Device > Setup > Session**.<br>2. In the Session Timeouts section, click the Edit icon. |

| Change Session Timeouts (Continued) | | |
|---|---|---|
| Step 2 | (Optional) Change miscellaneous timeouts. | • **Default**—Maximum length of time that a non-TCP/UDP or non-ICMP session can be open without a response. Default: 30. Range: 1-1599999.<br>• **Discard Default**—Maximum length of time that a non-TCP/UDP session remains open after PAN-OS denies a session based on security policies configured on the firewall. Default: 60. Range: 1-1599999.<br>• **Scan**—Maximum length of time that any session remains open after it is considered inactive; an application is regarded as inactive when it exceeds the application trickling threshold defined for the application. Default: 10. Range: 5-30.<br>• **Captive Portal**—Authentication session timeout for the Captive Portal web form. To access the requested content, the user must enter the authentication credentials in this form and be successfully authenticated. Default: 30. Range: 1-1599999.<br>To define other Captive Portal timeouts, such as the idle timer and the expiration time before the user must be re-authenticated, select **Device > User Identification > Captive Portal Settings**. See Configure Captive Portal. |
| Step 3 | (Optional) Change TCP timeouts. | • **Discard TCP**—Maximum length of time that a TCP session remains open after it is denied based on a security policy configured on the firewall. Default: 90. Range: 1-1599999.<br>• **TCP**—Maximum length of time that a TCP session remains open without a response, after a TCP session is in the Established state (after the handshake is complete and/or data is being transmitted). Default: 3600. Range: 1-1599999.<br>• **TCP Handshake**—Maximum length of time permitted between receiving the SYN-ACK and the subsequent ACK to fully establish the session. Default: 10. Range: 1-60.<br>• **TCP init**—Maximum length of time permitted between receiving the SYN and SYN-ACK prior to starting the TCP handshake timer. Default: 5. Range: 1-60.<br>• **TCP Half Closed**—Maximum length of time between receiving the first FIN and receiving the second FIN or a RST. Default: 120. Range: 1-604800.<br>• **TCP Time Wait**—Maximum length of time after receiving the second FIN or a RST. Default: 15. Range: 1-600.<br>• **Unverified RST**—Maximum length of time after receiving a RST that cannot be verified (the RST is within the TCP window but has an unexpected sequence number, or the RST is from an asymmetric path). Default: 30. Range: 1-600.<br>• See also the **Scan** timeout in the section (Optional) Change miscellaneous timeouts. |

 © Palo Alto Networks, Inc.

| Change Session Timeouts (Continued) | | |
|---|---|---|
| Step 4 | (Optional) Change UDP timeouts. | • **Discard UDP**—Maximum length of time that a UDP session remains open after it is denied based on a security policy configured on the firewall. Default: 60. Range: 1-1599999.<br>• **UDP**—Maximum length of time that a UDP session remains open without a UDP response. Default: 30. Range: 1-1599999.<br>• See also the **Scan** timeout in the section (Optional) Change miscellaneous timeouts. |
| Step 5 | (Optional) Change ICMP timeouts. | • **ICMP**—Maximum length of time that an ICMP session can be open without an ICMP response. Default: 6. Range: 1-1599999.<br>• See also the **Discard Default** and **Scan** timeout in the section (Optional) Change miscellaneous timeouts. |
| Step 6 | Commit the changes. | Click **OK** and **Commit** the changes. |

## Configure Session Settings

This topic describes various settings for sessions other than timeouts values. Perform these optional tasks if you need to change the default settings.

| Change Session Settings | | |
|---|---|---|
| Step 1 | Access the Session Settings. | 1. Select **Device > Setup > Session.**<br>2. In the **Session Settings** section, click the **Edit** icon. |

| Change Session Settings (Continued) | |
|---|---|
| Step 2 (Optional) Change session settings. | • **Rematch Sessions**—Causes the firewall to apply newly configured security policies to sessions that are already in progress. This capability is enabled by default. If this setting is disabled, any policy change applies only to sessions initiated after the policy change was committed.<br>For example, if a Telnet session started while an associated policy was configured that allowed Telnet, and you subsequently committed a policy change to deny Telnet, the firewall applies the revised policy to the current session and blocks it.<br>• **ICMPv6 Token Bucket Size**—Default: 100 tokens. See the section ICMPv6 Rate Limiting.<br>• **ICMPv6 Error Packet Rate (per sec)**—Default: 100. See the section ICMPv6 Rate Limiting.<br>• **Enable IPv6 Firewalling**—Enables firewall capabilities for IPv6. All IPv6-based configurations are ignored if IPv6 is not enabled. Even if IPv6 is enabled for an interface, the **IPv6 Firewalling** setting must also be enabled for IPv6 to function.<br>• **Enable Jumbo Frame**—Enables jumbo frame support on Ethernet interfaces. Jumbo frames have a maximum transmission unit (MTU) of 9216 bytes and are available on certain platforms.<br>**Global MTU**—Establishes the maximum transmission unit (MTU) available globally; this field is tied to the **Enable Jumbo Frame** field.<br>• If you do not check **Enable Jumbo Frame**, the **Global MTU** defaults to 1500 bytes; the range is 576 to 1500 bytes.<br>• If you check **Enable Jumbo Frame**, the **Global MTU** defaults to 9192 bytes; the range is 9192 to 9216 bytes.<br> If you enable jumbo frames and you have interfaces where the MTU is not specifically configured, those interfaces will automatically inherit the jumbo frame size. Therefore, before you enable jumbo frames, if you have any interface that you do not want to have jumbo frames, you must set the MTU for that interface to 1500 bytes or another value.<br>• **NAT64 IPv6 Minimum Network MTU**—Sets the global MTU for IPv6 translated traffic. The default of 1280 bytes is based on the standard minimum MTU for IPv6 traffic. |

 © Palo Alto Networks, Inc.

| Change Session Settings (Continued) | |
|---|---|
| | • **NAT Oversubscription Rate**—If NAT is configured to be Dynamic IP and Port (DIPP) translation, an oversubscription rate can be configured to multiply the number of times that the same translated IP address and port pair can be used concurrently. The rate is 1, 2, 4, or 8. The default setting is based on the firewall platform.<br>  • A rate of 1 means no oversubscription; each translated IP address and port pair can be used only once at a time.<br>  • If the setting is **Platform Default**, user configuration of the rate is disabled and the default oversubscription rate for the platform applies.<br>Reducing the oversubscription rate decreases the number of source device translations, but provides higher NAT rule capacities.<br>• **Accelerated Aging**—Enables faster aging-out of idle sessions. Select the check box to enable accelerated aging, and, if necessary, change the threshold (%) and scaling factor.<br>  • **Accelerated Aging Threshold**—Percentage of the session table that is full when accelerated aging begins. The default is 80%. When the session table reaches this threshold (% full), PAN-OS applies the **Accelerated Aging Scaling Factor** to the aging calculations for all sessions.<br>  • **Accelerated Aging Scaling Factor**—Scaling factor used in the accelerated aging calculations. The default scaling factor is 2, meaning that the accelerated aging occurs at a rate twice as fast as the configured idle time. The configured idle time divided by 2 results in a faster timeout of one-half the time. To calculate the session's accelerated aging, PAN-OS divides the configured idle time (for that type of session) by the scaling factor to determine a shorter timeout.<br>For example, if the scaling factor is 10, a session that would normally time out after 3600 seconds would time out 10 times faster (in 1/10 of the time), which is 360 seconds. |
| Step 3 Commit the changes. | Click **OK** and **Commit** the changes. |

# DHCP

This section describes Dynamic Host Configuration Protocol (DHCP) and the tasks required to configure an interface on a Palo Alto Networks firewall to act as a DHCP server, client, or relay agent. By assigning these roles to different interfaces, the firewall can perform multiple roles.

- DHCP Overview
- DHCP Messages
- DHCP Addressing
- DHCP Options
- Restrictions to Palo Alto Networks Implementation of DHCP
- Configure an Interface as a DHCP Server
- Configure an Interface as a DHCP Client
- Configure an Interface as a DHCP Relay Agent
- Monitor and Troubleshoot DHCP

## DHCP Overview

DHCP is a standardized protocol defined in RFC 2131, Dynamic Host Configuration Protocol. DHCP has two main purposes: to provide TCP/IP and link-layer configuration parameters and to provide network addresses to dynamically configured hosts on a TCP/IP network.

DHCP uses a client-server model of communication. This model consists of three roles that the device can fulfill: DHCP client, DHCP server, and DHCP relay agent.

- A device acting as a DHCP client (host) can request an IP address and other configuration settings from a DHCP server. Users on client devices save configuration time and effort, and need not know the network's addressing plan or other resources and options they are inheriting from the DHCP server.
- A device acting as a DHCP server can service clients. By using any of three DHCP Addressing mechanisms, the network administrator saves configuration time and has the benefit of reusing a limited number of IP addresses when a client no longer needs network connectivity. The server can deliver IP addressing and many DHCP options to many clients.
- A device acting as a DHCP relay agent transmits DHCP messages between DHCP clients and servers.

DHCP uses *User Datagram Protocol* (UDP), RFC 768, as its transport protocol. DHCP messages that a client sends to a server are sent to well-known port 67 (UDP—Bootstrap Protocol and DHCP). DHCP Messages that a server sends to a client are sent to port 68.

An interface on a Palo Alto Networks firewall can perform the role of a DHCP server, client, or relay agent. The interface of a DHCP server or relay agent must be a Layer 3 Ethernet, Aggregated Ethernet, or Layer 3 VLAN interface. The network administrator configures the firewall's interfaces with the appropriate settings for any combination of roles. The configuration tasks for each role are provided in this document.

 © Palo Alto Networks, Inc.

## DHCP Messages

DHCP uses eight standard message types, which are identified by an option type number in the DHCP message. For example, when a client wants to find a DHCP server, it broadcasts a DHCPDISCOVER message on its local physical subnetwork. If there is no DHCP server on its subnet and if DHCP Helper or DHCP Relay is configured properly, the message is forwarded to DHCP servers on a different physical subnet. Otherwise, the message will go no further than the subnet on which it originated. One or more DHCP servers will respond with a DHCPOFFER message that contains an available network address and other configuration parameters.

When the client needs an IP address, it sends a DHCPREQUEST to one or more servers. Of course if the client is requesting an IP address, it doesn't have one yet, so RFC 2131 requires that the broadcast message the client sends out have a source address of 0 in its IP header.

When a client requests configuration parameters from a server, it might receive responses from more than one server. Once a client has received its IP address, it is said that the client has at least an IP address and possibly other configuration parameters *bound* to it. DHCP servers manage such binding of configuration parameters to clients.

The following table lists the DHCP messages.

| DHCP Message | Description |
|---|---|
| DHCPDISCOVER | Client broadcast to find available DHCP servers. |
| DHCPOFFER | Server response to client's DHCPDISCOVER, offering configuration parameters. |
| DHCPREQUEST | Client message to one or more servers to do any of the following:<br>• Request parameters from one server and implicitly decline offers from other servers.<br>• Confirm that a previously allocated address is correct after, for example, a system reboot.<br>• Extend the lease of a network address. |
| DHCPACK | Server to client acknowledgment message containing configuration parameters, including a confirmed network address. |
| DHCPNAK | Server to client negative acknowledgment indicating the client's understanding of the network address is incorrect (for example, if the client has moved to a new subnet), or a client's lease has expired. |
| DHCPDECLINE | Client to server message indicating the network address is already being used. |
| DHCPRELEASE | Client to server message giving up the user of the network address and canceling the remaining time on the lease. |
| DHCPINFORM | Client to server message requesting only local configuration parameters; client has an externally configured network address. |

## DHCP Addressing

There are three ways that a DHCP server either assigns or sends an IP address to a client:

- **Automatic allocation**—The DHCP server assigns a permanent IP address to a client from its **IP Pools**. On the firewall, a **Lease** specified as **Unlimited** means the allocation is permanent.
- **Dynamic allocation**—The DHCP server assigns a reusable IP address from **IP Pools** of addresses to a client for a maximum period of time, known as a *lease*. This method of address allocation is useful when the customer has a limited number of IP addresses; they can be assigned to clients who need only temporary access to the network. See the DHCP Leases section.
- **Static allocation**—The network administrator chooses the IP address to assign to the client and the DHCP server sends it to the client. A static DHCP allocation is permanent; it is done by configuring a DHCP server and choosing a **Reserved Address** to correspond to the **MAC Address** of the client device. The DHCP assignment remains in place even if the client logs off, reboots, has a power outage, etc.

  Static allocation of an IP address is useful, for example, if you have a printer on a LAN and you do not want its IP address to keep changing, because it is associated with a printer name through DNS. Another example is if a client device is used for something crucial and must keep the same IP address, even if the device is turned off, unplugged, rebooted, or a power outage occurs, etc.

  Keep these points in mind when configuring a **Reserved Address**:

  - It is an address from the **IP Pools**. You may configure multiple reserved addresses.
  - If you configure no **Reserved Address**, the clients of the server will receive new DHCP assignments from the pool when their leases expire or if they reboot, etc. (unless you specified that a **Lease** is **Unlimited**).
  - If you allocate all of the addresses in the **IP Pools** as a **Reserved Address,** there are no dynamic addresses free to assign to the next DHCP client requesting an address.
  - You may configure a **Reserved Address** without configuring a **MAC Address**. In this case, the DHCP server will not assign the **Reserved Address** to any device. You might reserve a few addresses from the pool and statically assign them to a fax and printer, for example, without using DHCP.

## DHCP Leases

A lease is defined as the time period for which a DHCP server allocates a network address to a client. The lease might be extended (renewed) upon subsequent requests. If the client no longer needs the address, it can release the address back to the server before the lease is up. The server is then free to assign that address to a different client if it has run out of unassigned addresses.

The lease period configured for a DHCP server applies to all of the addresses that a single DHCP server (interface) dynamically assigns to its clients. That is, all of that interface's addresses assigned dynamically are of **Unlimited** duration or have the same **Timeout** value. A different DHCP server configured on the firewall may have a different lease term for its clients. A **Reserved Address** is a static address allocation and is not subject to the lease terms.

Per the DHCP standard, RFC 2131, a DHCP client does not wait for its lease to expire, because it risks getting a new address assigned to it. Instead, when a DHCP client reaches the halfway point of its lease period, it attempts to extend its lease so that it retains the same IP address. Thus, the lease duration is like a sliding window.

Typically if an IP address was assigned to a device, the device was subsequently taken off the network and its lease was not extended, the DHCP server will let that lease run out. Because the client is gone from the network and no longer needs the address, the lease duration in the server is reached and the lease is in "Expired" state.

 © Palo Alto Networks, Inc.

The firewall has a hold timer that prevents the expired IP address from being reassigned immediately. This behavior temporarily reserves the address for the device in case it comes back onto the network. But if the address pool runs out of addresses, the server re-allocates this expired address before the hold timer expires. Expired addresses are cleared automatically as the systems needs more addresses or when the hold timer releases them.

In the CLI, use the `show dhcp server lease` operational command to view lease information about the allocated IP addresses. If you do not want to wait for expired leases to be released automatically, you can use the `clear dhcp lease interface value expired-only` command to clear expired leases, making those addresses available in the pool again. You can use the `clear dhcp lease interface value ip ip` command to release a particular IP address. Use the `clear dhcp lease interface value mac mac_address` command to release a particular MAC address.

## DHCP Options

The history of DHCP and DHCP options traces back to the Bootstrap Protocol (BOOTP). BOOTP was used by a host to configure itself dynamically during its booting procedure. A host could receive an IP address and a file from which to download a boot program from a server, along with the server's address and the address of an Internet gateway.

Included in the BOOTP packet was a vendor information field, which could contain a number of tagged fields containing various types of information, such as the subnet mask, the BOOTP file size, and many other values. RFC 1497 describes the *BOOTP Vendor Information Extensions*.

These extensions eventually expanded with the use of DHCP and DHCP host configuration parameters, also known as options. Similar to vendor extensions, DHCP options are tagged data items that provide information to a DHCP client. The options are sent in a variable-length field at the end of a DHCP message. For example, the DHCP Message Type is option 53, and a value of 1 indicates the DHCPDISCOVER message. DHCP options are defined in RFC 2132, DHCP Options and BOOTP Vendor Extensions.

A DHCP client can negotiate with the server, limiting the server to send only those options that the client requests.

The Palo Alto Networks firewall supports a subset of the standard DHCP options for its implementation of DHCP server. Such options are configured on the DHCP server and sent to the clients that sent a DHCPREQUEST to the server. The clients are said to *inherit* and implement the options that they are programmed to accept. The firewall supports the following predefined options on its DHCP servers, shown in the order in which they appear on the **DHCP Server** configuration screen:

| DHCP Option | DHCP Option Name |
|---|---|
| 51 | Lease duration |
| 3 | Gateway |
| 1 | IP Pool Subnet (mask) |
| 6 | Domain Name System (DNS) server address (primary and secondary) |
| 44 | Windows Internet Name Service (WINS) server address (primary and secondary) |

| DHCP Option | DHCP Option Name |
|---|---|
| 41 | Network Information Service (NIS) server address (primary and secondary) |
| 42 | Network Time Protocol (NTP) server address (primary and secondary) |
| 70 | Post Office Protocol Version 3 (POP3) server address |
| 69 | Simple Mail Transfer Protocol (SMTP) server address |
| 15 | DNS suffix |

## Restrictions to Palo Alto Networks Implementation of DHCP

- The DHCP standard, RFC 2131, is designed to support IPv4 and IPv6 addresses. The Palo Alto Networks implementations of DHCP server and DHCP client support IPv4 addresses only. Its DHCP relay implementation supports IPv4 and IPv6.
- DHCP client is not supported in High Availability active/active mode.
- The firewall supports DHCPv4 Server and DHCPv6 Relay. However, a single interface cannot support both DHCPv4 Server and DHCPv6 Relay.
- DHCP replaces BOOTP; BOOTP is not supported

## Configure an Interface as a DHCP Server

The prerequisites for this task are:

- ❒ You have configured a Layer 3 Ethernet or Layer 3 VLAN interface.
- ❒ The interface is assigned to a virtual router and a zone.
- ❒ You know a valid pool of IP addresses from your network plan that can be designated to be assigned by your DHCP server to clients.

Perform the following task to configure an interface on the firewall to act as a DHCP server. You may configure multiple DHCP servers.

 © Palo Alto Networks, Inc.

| Configure an Interface as a DHCP Server | |
|---|---|
| Step 1 Select an interface to be a DHCP Server. | 1. Select **Network > DHCP > DHCP Server** and click **Add**.<br>2. Enter an **Interface** name or select one from the drop-down.<br>3. For **Mode**, select **enabled** or **auto** mode. Auto mode enables the server and disables it if another DHCP server is detected on the network. The **disabled** setting disables the server.<br>4. Optionally click the **Ping IP when allocating new IP** check box if you want the server to ping the IP address before it assigns that address to its client.<br> If the ping receives a response, that means a different device already has that address, so it is not available. The server assigns the next address from the pool instead. This behavior is similar to Optimistic Duplicate Address Detection (DAD) for IPv6, RFC 4429.<br> After setting options and returning to the DHCP server tab, the **Probe IP** column for the interface indicates if this check box was checked. |

| Configure an Interface as a DHCP Server (Continued) | |
|---|---|
| Step 2 Configure the DHCP Options that the server sends to its clients. | • In the Options section, select a **Lease** type:<br>  • **Unlimited** causes the server to dynamically choose IP addresses from the **IP Pools** and assign them permanently to clients.<br>  • **Timeout** determines how long the lease will last. Enter the number of **Days** and **Hours**, and optionally the number of **Minutes**.<br>• **Inheritance Source**—Leave **None** or select a source DHCP client interface or PPPoE client interface to propagate various server settings into the DHCP server. If you specify an **Inheritance Source**, select one or more options below that you want **inherited** from this source.<br>Benefits of specifying an inheritance source are that it quickly adds DHCP options from the upstream server of the source DHCP client. It also keeps the client's options updated if the source changes an option. For example, if the source replaces its NTP server (which had been identified as the **Primary NTP** server), the client will automatically inherit the new address as its **Primary NTP** server.<br>• **Check inheritance source status**—If your selected an **Inheritance Source**, clicking this link opens the **Dynamic IP Interface Status** window, which displays the options that were inherited from the DHCP client.<br>• **Gateway**—IP address of the network gateway (an interface on the firewall) that is used to reach any device not on the same LAN as this DHCP server.<br>• **Ippool Subnet**—Network mask that applies to the addresses in the **IP Pools**. |

© Palo Alto Networks, Inc.

| Configure an Interface as a DHCP Server (Continued) | | |
|---|---|---|
| | | For the following fields, click the down arrow and select **None**, or **inherited**, or enter a remote server's IP address that your DHCP server will send to clients for accessing that service. If you select **inherited,** the DHCP server inherits the values from the source DHCP client specified as the **Inheritance Source**.<br>The DHCP server sends these settings to its clients.<br>• **Primary DNS, Secondary DNS**—IP address of the preferred and alternate Domain Name System (DNS) servers.<br>• **Primary WINS, Secondary WINS**—IP address of the preferred and alternate Windows Internet Naming Service (WINS) servers.<br>• **Primary NIS, Secondary NIS**—IP address of the preferred and alternate Network Information Service (NIS) servers.<br>• **Primary NTP, Secondary NTP**—IP address of the available Network Time Protocol servers.<br>• **POP3 Server**—IP address of a Post Office Protocol (POP3) server.<br>• **SMTP Server**—IP address of a Simple Mail Transfer Protocol (SMTP) server.<br>• **DNS Suffix**—Suffix for the client to use locally when an unqualified hostname is entered that it cannot resolve. |
| Step 3 | Identify the stateful pool of IP addresses from which the DHCP server chooses an address and assigns it to a DHCP client.<br> If you are not the network administrator for your network, ask the network administrator for a valid pool of IP addresses from the network plan that can be designated to be assigned by your DHCP server. | 1. In the **IP Pools** field, click **Add** and enter the range of IP addresses from which this server assigns an address to a client. Enter an IP subnet and subnet mask (for example, 192.168.1.0/24) or a range of IP addresses (for example, 192.168.1.10-192.168.1.20). At least one IP pool is required.<br>2. Optionally repeat Step 1 to specify another IP address pool. |
| Step 4 | (Optional) Specify an IP address from the IP pools that will not be assigned dynamically. If you also specify a **MAC Address**, the **Reserved Address** is assigned to that device when the device requests an IP address through DHCP.<br> See the DHCP Addressing section for an explanation of allocation of a **Reserved Address**. | 1. In the **Reserved Address** field, click **Add.**<br>2. Enter an IP address from the **IP Pools** (format *x.x.x.x*) that you do not want to be assigned dynamically by the DHCP server.<br>3. Optionally specify the **MAC Address** (format *xx:xx:xx:xx:xx:xx*) of the device to which you want to permanently assign the IP address specified in Step 2.<br>4. Optionally repeat Steps 2-3 to reserve another address. |
| Step 5 | Save the configuration. | Click **OK** and **Commit** the change. |

## Configure an Interface as a DHCP Client

Before configuring a firewall interface as a DHCP client, make sure you have configured a Layer 3 Ethernet or Layer 3 VLAN interface, and the interface is assigned to a virtual router and a zone. Perform this task if you need to use DHCP to request an IPv4 address for an interface on your firewall.

| **Configure an Interface as a DHCP Client** | | |
|---|---|---|
| Step 1 | Configure an interface as a DHCP client. | 1. Select **Network** > **Interfaces**.<br>2. On the **Ethernet** tab or the **VLAN** tab, click **Add** and enter an interface, or click a configured interface, that you want to be a DHCP client.<br>The following shows the **Ethernet Interface** screen:<br> <br>3. Click the **IPv4** tab; for **Type**, select **DHCP Client**.<br>4. Select the **Enable** check box.<br>5. Optionally select the **Automatically create default route pointing to default gateway provided by server** check box. This causes the firewall to create a static route to a default gateway that will be useful when clients are trying to access many destinations that do not need to have routes maintained in a routing table on the firewall.<br>6. Optionally enter a **Default Route Metric** (priority level) for the route between the firewall and the DHCP server. A route with a lower number has higher priority during route selection. For example, a route with a metric of 10 is used before a route with a metric of 100. Range is 1-65535. There is no default metric.<br>7. Optionally click **Show DHCP Client Runtime Info** to see all of the settings the client has inherited from its DHCP server. |
| Step 2 | Save the configuration. | Click **OK** and **Commit** the change.<br>Now the Ethernet interface indicates **Dynamic-DHCP Client** in its **IP Address** field on the **Ethernet** tab. |
| Step 3 | (Optional) See which interfaces on the firewall are configured as DHCP clients. | 1. Select **Network > Interfaces > Ethernet** and look in the **IP Address** field to see which interfaces indicate DHCP Client.<br>2. Select **Network > Interfaces > VLAN** and look in the **IP Address** field to see which interfaces indicate DHCP Client. |

© Palo Alto Networks, Inc.

## Configure an Interface as a DHCP Relay Agent

Before configuring a firewall interface as a DHCP relay agent, make sure you have configured a Layer 3 Ethernet or Layer 3 VLAN interface, and the interface is assigned to a virtual router and a zone. You want that interface be able to pass DHCP messages between clients and servers. The interface can forward messages to a maximum of four external DHCP servers. A client DHCPDISCOVER message is sent to all configured servers, and the DHCPOFFER message of the first server that responds is relayed back to the requesting client.

Perform the following task to configure an interface on the firewall to act as a DHCP relay agent:

| **Configure an Interface as a DHCP Relay Agent** | | |
|---|---|---|
| Step 1 | Select DHCP Relay. | Select **Network** > **DHCP > DHCP Relay**. |
| Step 2 | Specify the IP address of each DHCP server with which the DHCP relay agent will communicate. | 1. In the **Interface** field, select from the drop-down the interface you want to be the DHCP relay agent.<br>2. Check either the **IPv4** or **IPv6** check box, indicating the type of DHCP server address you will specify.<br>3. If you checked **IPv4**, in the **DHCP Server IP Address** field, click **Add**. Enter the address of the DHCP server to and from which you will relay DHCP messages.<br>4. If you checked **IPv6**, in the **DHCP Server IPv6 Address** field, click **Add**. Enter the address of the DHCP server to and from which you will relay DHCP messages. If you specify a *multicast* address, also specify an outgoing **Interface**.<br>5. Optionally repeat Steps 2-4 to enter a maximum of four DHCP server addresses. |
| Step 3 | Save the configuration. | Click **OK** and **Commit** the change. |

## Monitor and Troubleshoot DHCP

You can view the status of dynamic address leases that your DHCP server has assigned or that your DHCP client has been assigned by issuing commands from the CLI. You can also clear leases before they time out and are released automatically. For complete command syntax, see the *PAN-OS Command Line Interface Reference Guide*.

- View DHCP Server Information
- Clear Leases Before They Expire Automatically
- View DHCP Client Information
- Gather Debug Output about DHCP

## View DHCP Server Information

To view DHCP pool statistics, IP addresses the server has assigned, the corresponding MAC address, state and duration of the lease, and time the lease began, use the following command. If the address was configured as a **Reserved Address**, the `state` column indicates `reserved` and there is no `duration` or `lease_time`. If the lease was configured as **Unlimited**, the `duration` column displays a value of `0`.

```
admin@PA-200> show dhcp server lease all
interface: "ethernet1/2"
Allocated IPs: 1, Total number of IPs in pool: 5. 20.0000% used
ip              mac               state      duration    lease_time
192.168.3.11    f0:2f:af:42:70:cf  committed  0           Wed Jul  2 08:10:56 2014
admin@PA-200>
```

To view the options that a DHCP server has assigned to clients, use the following command:

```
admin@PA-200> show dhcp server settings all
Interface       GW            DNS1           DNS2        DNS-Suffix    Inherit source
------------------------------------------------------------------------------------
ethernet1/2     192.168.3.1   10.43.2.10     10.44.2.10                ethernet1/3
admin@PA-200>
```

## Clear Leases Before They Expire Automatically

The following example shows how to release expired DHCP Leases of an interface (server) before the hold timer releases them automatically. Those addresses will be available in the IP pool again.

```
admin@PA-200> clear dhcp lease interface ethernet1/2 expired-only
```

The following example shows how to release the lease of a particular IP address:

```
admin@PA-200> clear dhcp lease interface ethernet1/2 ip 192.168.3.1
```

The following example shows how to release the lease of a particular MAC address:

```
admin@PA-200> clear dhcp lease interface ethernet1/2 mac f0:2c:ae:29:71:34
```

## View DHCP Client Information

To view the status of IP address leases sent to the firewall when it is acting as a DHCP client, use the `show dhcp client state` *`interface_name`* command or the following command:

```
admin@PA-200> show dhcp client state all
Interface       State        IP              Gateway         Leased-until
--------------------------------------------------------------------------
ethernet1/1     Bound        10.43.14.80     10.43.14.1      70315
admin@PA-200>
```

## Gather Debug Output about DHCP

To gather debug output about DHCP, use one of the following commands:

```
admin@PA-200> debug dhcpd
admin@PA-200> debug management-server dhcpd
```

 © Palo Alto Networks, Inc.

# NAT

This section describes Network Address Translation (NAT) and how to configure NAT rules and features.

- Purpose of NAT
- NAT Rules and Security Policies
- Source NAT and Destination NAT
- NAT Rule Capacities
- Dynamic IP and Port NAT Oversubscription
- Dataplane NAT Memory Statistics
- Configure NAT

## Purpose of NAT

NAT was introduced to solve the problem of an organization not having enough public, globally-routable IPv4 addresses assigned to it by the Internet Assigned Numbers Authority (IANA) or a Regional Internet Registry. NAT translates private, non-routable IPv4 addresses to one or more globally-routable IPv4 addresses, thereby conserving an organization's routable IP addresses.

Since its origination, the use of NAT has expanded. For example, NAT is used as a way to not disclose the real IP addresses of hosts that need access to public addresses. It is also used to manage traffic by performing port forwarding. The NAT64 option translates between IPv6 and IPv4 addresses, providing connectivity between networks using disparate IP addressing schemes, and therefore a migration path to IPv6 addressing. PAN-OS supports all of these uses.

If you use private IP addresses within your internal networks, you must use NAT to translate the private addresses to public addresses that can be routed on external networks. In PAN-OS, you create NAT policy rules that instruct the firewall which packet addresses need translation and what the translated addresses are.

## NAT Rules and Security Policies

You configure a NAT rule to match a packet's source zone and destination zone, at a minimum. In addition to zones, you can configure matching criteria based on the packet's destination interface, source and destination address, and service. You can configure multiple NAT rules. The firewall evaluates the rules in order from the top down. Once a packet matches the criteria of a single NAT rule, the packet is not subjected to additional NAT rules. Therefore, your list of NAT rules should be in order from most specific to least specific so that packets are subjected to the most specific rule you created for them.

It is important to understand the firewall's flow logic when it applies NAT rules and security policies so that you can determine what rules you need, based on the zones you have defined.

© Palo Alto Networks, Inc.

Upon ingress, the firewall inspects the packet and does a route lookup to determine the egress interface and zone. Then the firewall determines if the packet matches one of the NAT rules that have been defined, based on source and/or destination zone. It then evaluates and applies any security policies that match the packet based on the original (pre-NAT) source and destination addresses, but the post-NAT zones. Finally, upon egress, for a matching NAT rule, the firewall translates the source and/or destination address and port numbers.

Keep in mind that the translation of the IP address and port do not occur until the packet leaves the firewall. The NAT rules and security policies apply to the original IP address (the pre-NAT address). A NAT rule is configured based on the zone associated with a pre-NAT IP address.

Security policies differ from NAT rules because security policies examine post-NAT zones to determine whether the packet is allowed or not. Because the very nature of NAT is to modify source or destination IP addresses, which can result in modifying the packet's outgoing interface and zone, security policies are enforced on the post-NAT zone.

### Address Pools Identified as Address Objects

When configuring a NAT IP address pool, it is typical to identify it as address object. It can be a host IP address, IP address range, or IP subnet. Because both NAT rules and security policies use address objects, it is a best practice to distinguish between them by naming an address object used for NAT with a prefix, such as "NAT-*name*."

## Source NAT and Destination NAT

The firewall supports both source address and/or port translation and destination address and/or port translation.

- Source NAT
- Destination NAT

### Source NAT

Source NAT is typically used by internal users to access the Internet; the source address is translated and thereby kept private. There are three types of source NAT:

- **Dynamic IP and Port (DIPP)**—Allows multiple hosts to have their source IP addresses translated to the same public IP address with different port numbers. The dynamic translation is to the next available address in the NAT address pool, which you configure as a **Translated Address** pool be to an IP address, range of addresses, a subnet, or a combination of these.

  As an alternative to the next address in the NAT address pool, DIPP allows you to specify the address of the **Interface** itself. The advantage of specifying the interface in the NAT rule is that the NAT rule will be automatically updated to use any address subsequently acquired by the interface.

  DIPP has a default NAT oversubscription rate, which is the number of times that the same translated IP address and port pair can be used concurrently. For more information, see Dynamic IP and Port NAT Oversubscription and Modify the Oversubscription Rate for DIPP NAT.

 © Palo Alto Networks, Inc.

- **Dynamic IP**—Allows the 1-to-1, dynamic translation of a source IP address only (no port number) to the next available address in the NAT address pool. By default, if the source address pool is larger than the NAT address pool and eventually all of the NAT addresses are allocated, new connections that need address translation are dropped. The default behavior can be changed by clicking **Advanced (Dynamic IP/Port Fallback)**, which causes DIPP addresses to be used when necessary. In either event, as sessions terminate and the addresses in the pool become available, they can be allocated to translate new connections.
- **Static IP**—Allows the 1-to-1, static translation of a source IP address, but leaves the source port unchanged. A common scenario for a static IP translation is an internal server that must be available to the Internet.

### Destination NAT

Destination NAT is performed on incoming packets, when the firewall translates a public destination address to a private address. Destination NAT does not use address pools or ranges. It is a 1-to-1, static translation with the option to perform port forwarding or port translation.

- **Static IP**—Allows the 1-to-1, static translation of a destination IP address and optionally the port number.

One common use of destination NAT is to configure several NAT rules that map a single public destination address to several private destination addresses assigned to servers or services. For example:

  - **Port Forwarding**—Can translate a public destination address and port number to a private destination address, but keeps the same port number.
  - **Port Translation**—Can translate a public destination address and port number to a private destination address and a different port number, thus keeping the real port number private. It is configured by entering a **Translated Port** on the **Translated Packet** tab in the NAT policy rule.

## NAT Rule Capacities

The number of NAT rules allowed is based on the firewall platform. Individual rule limits are set for static, Dynamic IP (DIP), and Dynamic IP and Port (DIPP) NAT. The sum of the number of rules used for these NAT types cannot exceed the total NAT rule capacity. For DIPP, the rule limit is based on the device's oversubscription setting (8, 4, 2, or 1) and the assumption of one translated IP address per rule. To see platform-specific NAT rule limits and translated IP address limits, use the Compare Firewalls tool.

Consider the following when working with NAT rules:

- If you run out of pool resources, you cannot create more NAT rules, even if the platform's maximum rule count has not been reached.
- If you consolidate NAT rules, the logging and reporting will also be consolidated. The statistics are provided per the rule, not per all of the addresses within the rule. If you need granular logging and reporting, do not combine the rules.

© Palo Alto Networks, Inc.

## Dynamic IP and Port NAT Oversubscription

Dynamic IP and Port (DIPP) NAT allows you to use each translated IP address and port pair multiple times (8, 4, or 2 times) in concurrent sessions. This reusability of an IP address and port (known as oversubscription) provides scalability for customers who have too few public IP addresses. The design is based on the assumption that hosts are connecting to different destinations, therefore sessions can be uniquely identified and collisions are unlikely. The oversubscription rate in effect multiplies the original size of the address/port pool to 8, 4, or 2 times the size. For example, the default limit of 64K concurrent sessions allowed, when multiplied by an oversubscription rate of 8, results in 512K concurrent sessions allowed.

The oversubscription rates that are allowed vary based on the platform. The oversubscription rate is global; it applies to the device. This oversubscription rate is set by default and consumes memory, even if you have enough public IP addresses available to make oversubscription unnecessary. You can reduce the rate from the default setting to a lower setting or even 1 (which means no oversubscription). By configuring a reduced rate, you decrease the number of source device translations possible, but increase the DIP and DIPP NAT rule capacities. To change the default rate, see Modify the Oversubscription Rate for DIPP NAT.

If you select **Platform Default**, your explicit configuration of oversubscription is turned off and the default oversubscription rate for the platform applies, as shown in the table below. The **Platform Default** setting allows for an upgrade or downgrade of a software release.

The following table lists the default (highest) oversubscription rate for each platform.

| Platform | Default Oversubscription Rate |
|---|---|
| PA-200 | 2 |
| PA-500 | 2 |
| PA-2020 | 2 |
| PA-2050 | 2 |
| PA-3020 | 2 |
| PA-3050 | 2 |
| PA-3060 | 2 |
| PA-4020 | 4 |
| PA-4050 | 8 |
| PA-4060 | 8 |
| PA-5020 | 4 |
| PA-5050 | 8 |
| PA-5060 | 8 |
| PA-7050 | 8 |
| VM-100 | 1 |
| VM-200 | 1 |

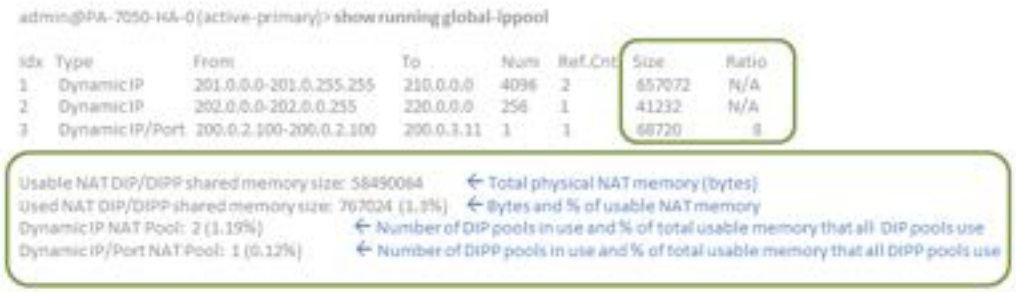
 © Palo Alto Networks, Inc.

| Platform | Default Oversubscription Rate |
|---|---|
| VM-300 | 2 |
| VM-1000-HV | 2 |

The firewall supports a maximum of 256 translated IP addresses per NAT rule, and each platform supports a maximum number of translated IP addresses (for all NAT rules combined). If oversubscription causes the maximum translated addresses per rule (256) to be exceeded, the firewall will automatically reduce the oversubscription ratio in an effort to have the commit succeed. However, if your NAT rules result in translations that exceed the maximum translated addresses for the platform, the commit will fail.

## Dataplane NAT Memory Statistics

The `show running global-ippool` command displays statistics related to NAT memory consumption for a pool. The Size column displays the number of bytes of memory that the resource pool is using. The Ratio column displays the oversubscription ratio (for DIPP pools only). The lines of pool and memory statistics are explained in the following sample output:



For NAT pool statistics for a virtual system, the `show running ippool` command has columns indicating the memory size used per NAT rule and the oversubscription ratio used (for DIPP rules). The following is sample output for the command.

A field in the output of the `show running nat-rule-ippool rule` command shows the memory (bytes) used per NAT rule. The following is sample output for the command, with the memory usage for the rule encircled.

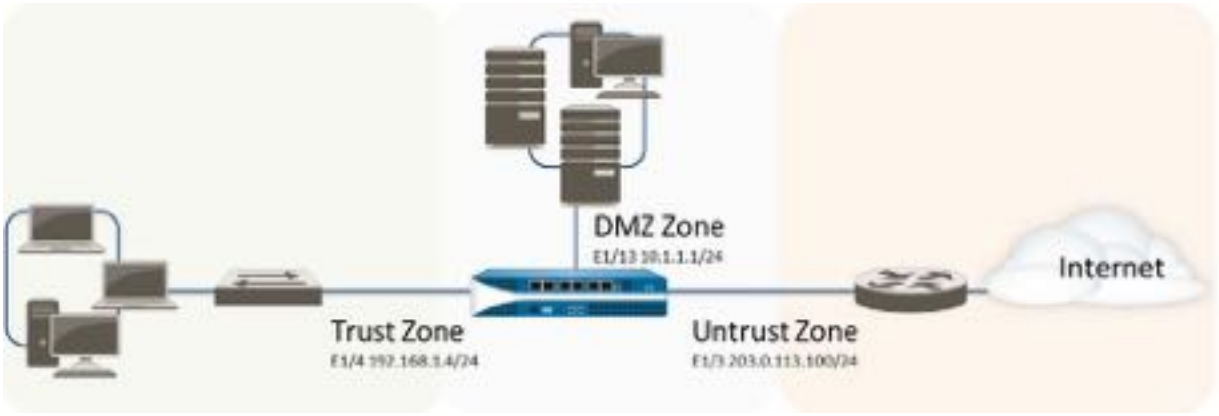
 © Palo Alto Networks, Inc.

## Configure NAT

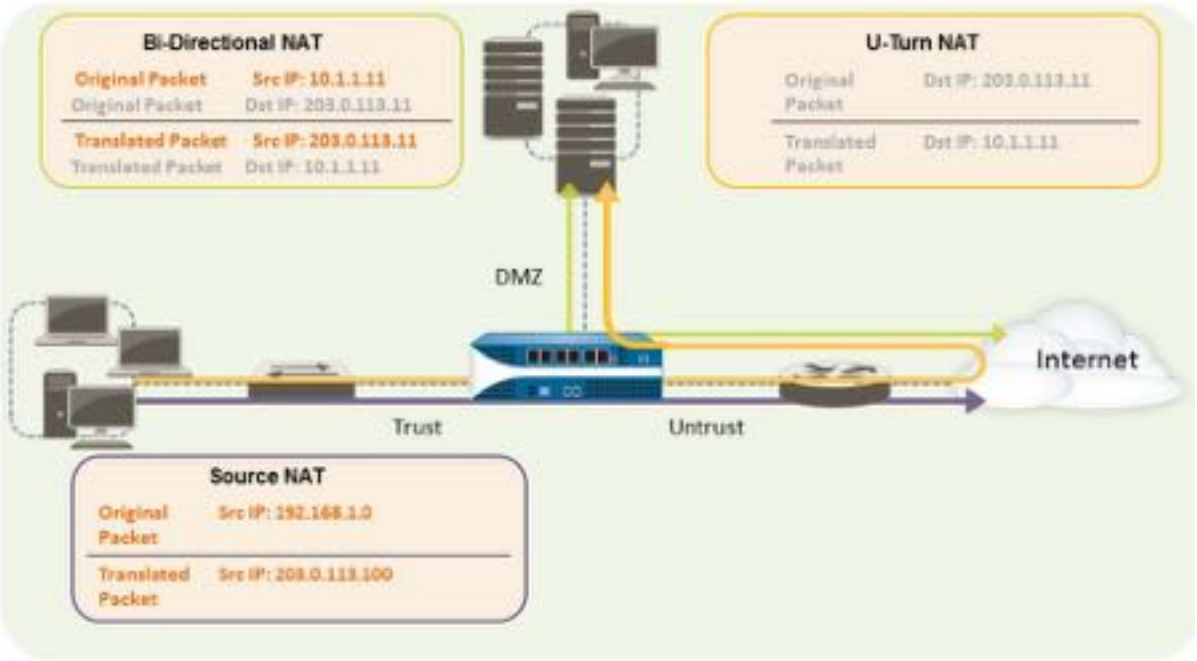
Perform the following tasks to configure various aspects of NAT.

- Translate Internal Client IP Addresses to Your Public IP Address
- Enable Clients on the Internal Network to Access your Public Servers
- Enable Bi-Directional Address Translation for Your Public-Facing Servers
- Modify the Oversubscription Rate for DIPP NAT
- Disable NAT for a Specific Host or Interface

The NAT example in this section is based on the following topology, which was also used in Getting Started for setting up interfaces and zones:



Based on the topology initially used in Getting Started to create the interfaces and zones, there are three NAT policies we need to create as follows:



- To enable the clients on the internal network to access resources on the Internet, the internal 192.168.1.0 addresses will need to be translated to publicly routable addresses. In this case, we will configure source NAT, using the egress interface address, 203.0.113.100, as the source address in all packets that leave the firewall from the internal zone. See Translate Internal Client IP Addresses to Your Public IP Address for instructions.
- To enable clients on the internal network to access the public web server in the DMZ zone, we will need to configure a NAT rule that redirects the packet from the external network, where the original routing table lookup will determine it should go based on the destination address of 203.0.113.11 within the packet, to the actual address of the web server on the DMZ network of 10.1.1.11. To do this you must create a NAT rule from the trust zone (where the source address in the packet is) to the untrust zone (where the original destination address is) to translate the destination address to an address in the DMZ zone. This type of destination NAT is called *U-Turn NAT*. See Enable Clients on the Internal Network to Access your Public Servers for instructions.
- To enable the web server—which has both a private IP address on the DMZ network and a public-facing address for access by external users—to both send and receive requests, the firewall must translate the incoming packets from the public IP address to the private IP address and the outgoing packets from the private IP address to the public IP address. On the firewall, you can accomplish this with a single bi-directional static source NAT policy. See Enable Bi-Directional Address Translation for Your Public-Facing Servers.

 © Palo Alto Networks, Inc.

## Translate Internal Client IP Addresses to Your Public IP Address

When a client on your internal network sends a request, the source address in the packet contains the IP address for the client on your internal network. If you use private IP address ranges internally, the packets from the client will not be able to be routed on the Internet unless you translate the source IP address in the packets leaving the network into a publicly routable address.

On the firewall you can do this by configuring a source NAT policy that translates the source address and optionally the port into a public address. One way to do this is to translate the source address for all packets to the egress interface on your firewall, as shown in the following procedure.

| **Configure Source NAT** | |
|---|---|
| Step 1 Create an address object for the external IP address you plan to use. | 1. Select **Objects > Addresses** and then click **Add**.<br>2. Enter a **Name** and optionally a **Description** for the object.<br>3. Select **IP Netmask** from the **Type** drop-down and then enter the IP address of the external interface on the firewall, 203.0.113.100 in this example.<br> <br>4. To save the address object, click **OK**.<br>Although you do not have to use address objects in your policies, it is a best practice because it simplifies administration by allowing you to make updates in one place rather than having to update every policy where the address is referenced. |

| Configure Source NAT (Continued) | |
|---|---|
| Step 2 Create the NAT policy. | 1. Select **Policies > NAT** and click **Add**.<br>2. On the **General** tab, enter a descriptive **Name** for the policy.<br>3. On the **Original Packet** tab, select the zone you created for your internal network in the **Source Zone** section (click **Add** and then select the zone) and the zone you created for the external network from the **Destination Zone** drop-down.<br> <br>4. On the **Translated Packet** tab, select **Dynamic IP And Port** from the **Translation Type** drop-down in the **Source Address Translation** section of the screen and then click **Add**.<br>5. Select the address object you just created.<br>  <br>6. Click **OK** to save the NAT policy. |
| Step 3 Save the configuration. | Click **Commit**. |

© Palo Alto Networks, Inc.

## Enable Clients on the Internal Network to Access your Public Servers

When a user on the internal network sends a request for access to the corporate web server in the DMZ, the DNS server will resolve to the public IP address. When processing the request, the firewall will use the original destination in the packet (the public IP address) and route the packet to the egress interface for the untrust zone. In order for the firewall to know that it must translate the public IP address of the web server to an address on the DMZ network when it receives requests from users on the trust zone, you must create a destination NAT rule that will enable the firewall to send the request to the egress interface for the DMZ zone as follows.

| **Configure U-Turn NAT** | |
|---|---|
| Step 1 Create an address object for the web server. | 1. Select **Objects > Addresses** and click **Add**.<br>2. Enter a **Name** and optionally a **Description** for the object.<br>3. Select **IP Netmask** from the **Type** drop-down and enter the public IP address of the web server, 203.0.113.11 in this example.<br> <br>4. Click **OK**. |
| Step 1 Create the NAT policy. | 1. Select **Policies > NAT** and click **Add**.<br>2. On the **General** tab, enter a descriptive **Name** for the NAT rule.<br>3. On the **Original Packet** tab, select the zone you created for your internal network in the **Source Zone** section (click **Add** and then select the zone) and the zone you created for the external network from the **Destination Zone** drop-down.<br>4. In the **Destination Address** section, click **Add** and select the address object you created for your public web server.<br> |

| Configure U-Turn NAT (Continued) | |
|---|---|
| | 5. On the **Translated Packet** tab, select the **Destination Address Translation** check box and then enter the IP address that is assigned to the web server interface on the DMZ network, 10.1.1.11 in this example.<br> <br>6. Click **OK** to save the NAT policy. |
| Step 2 Save the configuration. | Click **Commit**. |

## Enable Bi-Directional Address Translation for Your Public-Facing Servers

When your public-facing servers have private IP addresses assigned on the network segment where they are physically located, you need a source NAT rule to translate the source address of the server to the external address upon egress. You create a static NAT rule to translate the internal source address, 10.1.1.11, to the external web server address, 203.0.113.11 in our example.

However, a public-facing server must be able to both send and receive packets. You need a reciprocal policy that translates the public address (the destination IP address in incoming packets from Internet users) into the private address so that the firewall can route the packet to your DMZ network. You create a bi-directional static NAT rule, as described in the following procedure.

| Configure Bi-Directional NAT | |
|---|---|
| Step 1 Create an address object for the web server's internal IP address. | 1. Select **Objects > Addresses** and click **Add**.<br>2. Enter a **Name** and optionally a **Description** for the object.<br>3. Select **IP Netmask** from the **Type** drop-down and enter the IP address of the web server on the DMZ network, 10.1.1.11 in this example.<br> <br>4. Click **OK**.<br>If you did not already create an address object for the *public* address of your web server, you should create that object now. |

 © Palo Alto Networks, Inc.

| Configure Bi-Directional NAT (Continued) | |
|---|---|
| Step 2 Create the NAT policy. | 1. Select **Policies > NAT** and click **Add**.<br>2. On the **General** tab, enter a descriptive **Name** for the NAT rule.<br>3. On the **Original Packet** tab, select the zone you created for your DMZ in the **Source Zone** section (click **Add** and then select the zone) and the zone you created for the external network from the **Destination Zone** drop-down.<br>4. In the **Source Address** section, click **Add** and select the address object you created for your internal web server address.<br>  <br>5. On the **Translated Packet** tab, select **Static IP** from the **Translation Type** drop-down in the **Source Address Translation** section and then select the address object you created for your external web server address from the **Translated Address** drop-down.<br>6. In the **Bi-directional** field, select **Yes**.<br> <br>7. Click **OK** to save the NAT policy. |
| Step 3 Save the configuration. | Click **Commit**. |

## Modify the Oversubscription Rate for DIPP NAT

If you have enough public IP addresses that you do not need to use DIPP NAT oversubscription, you can reduce the oversubscription rate and thereby gain more DIP and DIPP NAT rules allowed.

| **Set NAT Oversubscription** | | |
|---|---|---|
| Step 1 | View the DIPP NAT oversubscription rate. | 1. Select **Device > Setup > Session > Session Settings.** View the **NAT Oversubscription Rate** setting. |
| Step 2 | Set the DIPP NAT oversubscription rate. | 1. Click the Edit icon in the Session Settings section.<br>2. In the **NAT Oversubscription Rate** drop-down, select **1x**, **2x**, **4x**, or **8x**, depending on which ratio you want.<br>The **Platform Default** setting applies the default oversubscription setting for the platform. If you want no oversubscription, select **1x**.<br>3. Click **OK** and **Commit** the change. |

## Disable NAT for a Specific Host or Interface

You may have exceptions where you do not want NAT to occur for a certain host in a subnet or for traffic exiting a specific interface. Source NAT and destination NAT rules can be configured to disable translation in those cases. The following procedure shows how to disable source NAT for a host.

| **Create a Source NAT Exemption** | | |
|---|---|---|
| Step 1 | Create the NAT policy. | 1. Select **Policies > NAT** and click **Add**.<br>2. Enter a descriptive **Name** for the policy.<br>3. On the **Original Packet** tab, select the zone you created for your internal network in the **Source Zone** section (click **Add** and then select the zone) and the zone you created for the external network from the **Destination Zone** drop-down.<br>4. For **Source Address**, click **Add** and enter the host address. Click **OK**.<br>5. On the **Translated Packet** tab, select **None** from the **Translation Type** drop-down in the **Source Address Translation** section of the screen.<br>6. Click **OK** to save the NAT policy. |
| Step 2 | Save the configuration. | Click **Commit**. |

© Palo Alto Networks, Inc.

# LACP

The firewall can now use Link Aggregation Control Protocol (LACP) to detect the physical interfaces between itself and a connected device (peer) and manage those interfaces as a single virtual interface (aggregate group). An aggregate group increases the bandwidth between peers. Enabling LACP provides redundancy within the group: the protocol automatically detects interface failures and performs failover to standby interfaces. Without LACP, you must manually identify interface failures occurring at layers above the physical or occurring between peers that are not directly connected.

The following Palo Alto Networks firewalls support LACP: PA-500, PA-3000 Series, PA-4000 Series, PA-5000 Series, and PA-7050. The firewalls support LACP for HA3 (only on the PA-500, PA-3000 Series, PA-4000 Series, and PA-5000 Series), Layer 2, and Layer 3 interfaces.

The following topics describe LACP and how to configure it for aggregate groups:

- LACP Settings
- Configure LACP

## LACP Settings

To implement LACP, you must configure an aggregate group on each LACP peer that will use the protocol. Before you Configure LACP, determine the optimal settings for each peer, as described in the following topics:

- Mode
- Transmission Rate
- Fast Failover
- Port Priority and System Priority

### Mode

In LACP active mode, a device actively searches the network for peers and queries their status (available or unresponsive). In passive mode, a device only responds to queries from an active peer. Between any two peers, it is recommended that one be active and the other passive. LACP cannot function if both peers are passive.

### Transmission Rate

You can configure a device to detect the state (available or unresponsive) of peers and individual interfaces at fast (every second) or slow (every 30 seconds) intervals. When the device does not receive an LACP update from the peer within a period that is three times the transmission rate (3 seconds or 90 seconds), it flags the peer as unresponsive. Therefore, set the transmission rate according to how much LACP processing your network can support and how quickly a device should detect and resolve interface failures.

© Palo Alto Networks, Inc.

For example, in a network where peers have many redundant links, a single interface failure would not disrupt traffic. In this case, a slow rate would suffice for detecting failures and would avoid the extra processing associated with the fast rate. If the network can support the extra processing and requires high availability (for example, datacenters supporting critical business operations), a fast transmission rate would enable the firewall to substitute failed interfaces quicker.

If devices have different transmission rates, each uses the rate of its peer.

## Fast Failover

When an interface goes down, it fails over to a standby interface. The IEEE 802.1ax standard that defines LACP specifies a failover process that takes at least three seconds. For networks that require quicker failover, the firewall provides an option that performs fast failover within one second. This option is recommended for deployments in which critical data might be lost during the standard failover interval. For example, if the amount of traffic between peers is close to the maximum that the active interfaces can support and one interface fails, the risk of data being lost while a standby interface becomes active is significantly less for fast failover than for standard failover.

Because both peers perform failover when an interface goes down, it is recommended that you configure fast failover on both so that they complete the process within the same time frame.

## Port Priority and System Priority

When you configure an aggregate group, the **Max Ports** parameter determines how many interfaces can be active at any given time. If the number of interfaces you assign to the group exceeds the **Max Ports**, the remaining interfaces are in standby mode. If an active interface fails, a standby interface becomes active. LACP uses the **LACP Port Priority** assigned to each interface to determine which interfaces are initially active and to determine the order in which standby interfaces become active upon failover. (You set port priorities when configuring individual interfaces, not when configuring the aggregate group.)

It is recommended that you assign a unique priority number to each interface in an aggregate group. However, if multiple interfaces have the same priority number, the interface with the lowest port number has the highest priority.

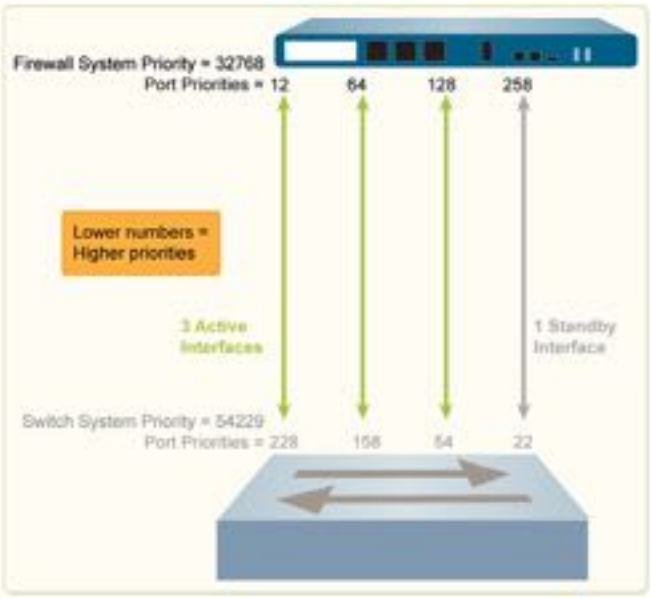
To enable LACP between two peers, each requires an aggregate group configuration. If the port priority values for the member interfaces differ in each peer, the values of the peer with the higher **System Priority** will override the other peer in determining active and standby interfaces.

For port and system priorities, the priority level is the inverse of its numerical value: a priority of 1 designates the highest priority level; a value of 65535 designates the lowest priority level. The default is 32768.

The following figure shows an aggregate group instance configured on a firewall and on a switch. The group has four interfaces and the **Max Ports** parameter is set to three. That means three interfaces are active and one is standby. The firewall administrator assigned port priorities 12, 64, 128, and 258 to the interfaces. The switch administrator assigned port priorities 22, 54, 158, and 228 to the interfaces. LACP uses the port priorities of the firewall instance because the **System Priority** of the firewall is higher than that of the switch.

 © Palo Alto Networks, Inc.

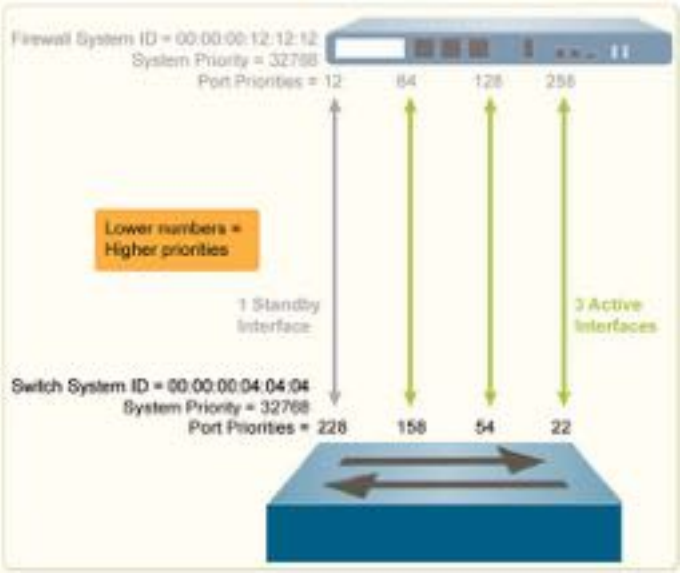
**Figure: LACP System Priority**



It is a best practice to assign a unique system priority to each peer. However, in some cases, peers might have the same value. This could happen if a different administrator configured the aggregate group on each peer. In such cases, the peer for which the *system ID* is a lower numerical value will override the other peer with respect to port priorities. LACP automatically derives the system ID from the system priority and system MAC address. A numerically lower MAC address produces a numerically lower system ID.

The following figure shows the same peers as in Figure: LACP System Priority but with identical system priorities. In this case, LACP uses the system IDs to determine port prioritization: the switch overrides the firewall.

**Figure: LACP System ID**



Firewalls in a high availability (HA) pair have the same system priority value. However, in an active/passive deployment, the system ID for each can be the same or different, depending on whether you assign the same MAC address. (Firewalls in an active/active deployment require unique MAC addresses so PAN-OS automatically assigns them.) When the LACP peers (also in HA mode) are virtualized (appearing to the network as a single device), selecting the **Same System MAC Address for Active-Passive HA** option for the firewalls is a best practice to minimize latency during failover. When the LACP peers are not virtualized, using the unique MAC address of each firewall is the best practice to minimize failover latency. In the latter case, if the HA firewall pair and the LACP peer devices all have the same system priority but each firewall in the HA pair has a unique system ID, one firewall might have a lower system ID than the LACP peers while the other firewall has a higher system ID than the LACP peers. In this case, when failover occurs on the firewalls, port prioritization switches between the LACP peers and the firewall that becomes active.

## Configure LACP

Before starting this procedure:

- Determine which physical interfaces connect the LACP peers. This procedure assumes the cabling is complete.
- Determine the optimal LACP Settings for the peers.

This procedure only covers the configuration steps for an LACP peer that is a Palo Alto Networks firewall. Other devices have proprietary methods for configuring LACP.

Perform the following steps to configure LACP on a firewall. In a high availability deployment, configure the primary (for active/active) or active (for active/passive) firewall; the secondary or passive firewall automatically synchronizes with it.

 © Palo Alto Networks, Inc.

| Configure LACP | |
|---|---|
| Step 1 Add an aggregate group with LACP enabled. | 1. Select **Network > Interfaces > Ethernet** and click **Add Aggregate Group**.<br>2. In the field adjacent to the read-only **Interface Name**, enter a number (1-8) to identify the group.<br>3. For the **Interface Type**, select **HA**, **Layer 2**, or **Layer 3**.<br>Only select **HA** if the interface is an HA3 link between two firewalls in an active/active deployment.<br>4. On the **LACP** tab, select **Enable LACP**.<br>5. For the LACP **Mode**, select whether the firewall is **Passive** (default) or **Active**.<br>6. For the **Transmission Rate**, select **Fast** or **Slow**.<br>7. If desired, select **Fast Failover** (under one second) for when interfaces go down. Otherwise, the standard failover (at least three seconds) applies.<br>8. Enter a **System Priority** number (1-65535, default 32768) that determines whether the firewall or peer overrides the other with respect to port priorities. Note that the lower the number, the higher the priority.<br>9. For the **Max Ports**, enter the number of interfaces (1-8) that are active. The value cannot exceed the number of interfaces you assign to the group. If the number of assigned interfaces exceeds the number of active interfaces, the remaining interfaces will be in standby mode.<br>10. By default, each firewall in an HA pair has a unique MAC address. A **Same System MAC Address for Active-Passive HA** configuration is recommended only when the LACP peers are virtualized (appearing to the network as a single device). In such cases, select the check box and select the system-generated **MAC Address**, or enter your own. You must verify the address is globally unique.<br>If the firewalls are not in active/passive HA mode, PAN-OS ignores your selections for these fields. Firewalls in an active/active deployment require unique MAC addresses so PAN-OS automatically assigns them. If the **Interface Type** is **HA**, these fields do not appear.<br>11. Click **OK**. |

| Configure LACP (Continued) | | |
|---|---|---|
| Step 2 | Assign interfaces to the aggregate group. | Perform the following steps for each physical interface (1-8) that will belong to the aggregate group.<br> During normal operations, assign more than one interface. You would only assign a single interface if a troubleshooting procedure requires it.<br>1. Select **Network > Interfaces** and select the interface name. It must be the same type (HA, Layer 2, or Layer 3) as the aggregate group.<br>2. Change the **Interface Type** to **Aggregate Ethernet**.<br>3. Select the **Aggregate Group** you just defined.<br>4. Select the **Link Speed**, **Link Duplex**, and **Link State**. It is a best practice to set the same link speed and duplex values for every interface in the group. For non-matching values, the commit operation displays a warning and PAN-OS defaults to the higher speed and full duplex.<br>5. Enter an **LACP Port Priority** (1-65535, default 32768). If the number of interfaces you assign exceeds the **Max Ports** value you configured for the group, the port priorities determine which interfaces are active or standby. The lower the numeric value, the higher the priority.<br>6. Click **OK** and **Commit**. |
| Step 3 | Verify the status of the aggregate group. | 1. Select **Network > Interfaces > Ethernet**.<br>2. Verify that the Features column displays an LACP enabled icon for the aggregate group.<br>3. Verify that the Link State column displays a green icon for the aggregate group, indicating that all member interfaces are up. If the icon is yellow, at least one member is down but not all. If the icon is red, all members are down.<br>4. If the Link State icon for the aggregate group is yellow or red, select **Monitor > Logs > System** and review the logs for the LACP subtype to investigate the causes of the interface failures. |
| Step 4 | (Optional) If you selected **HA** as the **Interface Type** for the aggregate group, enable forwarding of packets over the HA3 link. | 1. Select **Device > High Availability > Active/Active Config** and edit the Packet Forwarding section.<br>2. For the **HA3 Interface**, select the aggregate group you configured.<br>3. Click **OK** and **Commit**. |

 © Palo Alto Networks, Inc.

# Policy

Policies allow you to enforce rules and take action. The different types of policy rules that you can create on the firewall are: Security, NAT, Quality of Service (QoS), Policy Based Forwarding (PBF), Decryption, Application Override, Captive Portal, Denial of Service (DoS), and Zone protection policies. All these different policies work together to allow, deny, prioritize, forward, encrypt, decrypt, make exceptions, authenticate access, and reset connections as needed to help secure your network. The following topics describe how to work with policy:

- Policy Types
- Security Policy
- Policy Objects
- Security Profiles
- Enumeration of Rules Within a Rulebase
- Use Tags to Visually Distinguish Objects
- Tips and Tricks for Searching for Objects in Security Policy
- Use a Dynamic Block List in Policy
- Register IP Addresses and Tags Dynamically
- Monitor Changes in the Virtual Environment
- CLI Commands for Dynamic IP Addresses and Tags
- Policy-Based Forwarding
- DoS Protection Against Flooding of New Sessions

# Policy Types

The Palo Alto Networks next-generation firewall supports a variety of policy types that work together to safely enable applications on your network.

| Policy Type | Description |
|---|---|
| Security | Determine whether to block or allow a session based on traffic attributes such as the source and destination security zone, the source and destination IP address, the application, user, and the service. For more details, see Security Policy. |
| NAT | Instruct the firewall which packets need translation and how to do the translation. The firewall supports both source address and/or port translation and destination address and/or port translation. For more details, see NAT. |
| QoS | Identify traffic requiring QoS treatment (either preferential treatment or bandwidth-limiting) using a defined parameter or multiple parameters and assigns it a class. For more details, see Quality of Service. |
| Policy Based Forwarding | Identify traffic that should use a different egress interface than the one that would normally be used based on the routing table. For details, see Policy-Based Forwarding. |
| Decryption | Identify encrypted traffic that you want to inspect for visibility, control, and granular security. For more details, see Decryption. |
| Application Override | Identify sessions that you do not want processed by the App-ID engine, which is a Layer-7 inspection. Traffic matching an application override policy forces the firewall to handle the session as a regular stateful inspection firewall at Layer-4. For more details, see Manage Custom or Unknown Applications. |
| Captive Portal | Identify traffic that requires the user to be known. The captive portal policy is only triggered if other User-ID mechanisms did not identify a user to associate with the source IP address. For more details, see Captive Portal. |
| DoS Protection | Identify potential denial-of-service (DoS) attacks and take protective action in response to rule matches. DoS Protection Profile. |

 © Palo Alto Networks, Inc.

# Security Policy

Security policies protect network assets from threats and disruptions and aid in optimally allocating network resources for enhancing productivity and efficiency in business processes. On the Palo Alto Networks firewall, security policies determine whether to block or allow a session based on traffic attributes such as the source and destination security zone, the source and destination IP address, the application, user, and the service.

All traffic passing through the firewall is matched against a session and each session is matched against a security policy. When a session match occurs, the security policy is applied to bi-directional traffic (client to server and server to client) in that session. For traffic that doesn't match any defined rules, the default rules apply. The default rules—displayed at the bottom of the security rulebase—are predefined to allow all intrazone (within the zone) traffic and deny all interzone (between zones) traffic. Although these rules are part of the pre-defined configuration and are read-only by default, you can override them and change a limited number of settings, including the tags, action (allow or deny), log settings, and security profiles.

Security policies are evaluated left to right and from top to bottom. A packet is matched against the first rule that meets the defined criteria; after a match is triggered the subsequent rules are not evaluated. Therefore, the more specific rules must precede more generic ones in order to enforce the best match criteria. Traffic that matches a rule generates a log entry at the end of the session in the traffic log, if logging is enabled for that rule. The logging options are configurable for each rule, and can for example be configured to log at the start of a session instead of, or in addition to, logging at the end of a session.

- Components of a Security Policy Rule
- Security Policy Best Practices

# Components of a Security Policy Rule

The security policy rule construct permits a combination of the required and optional fields as detailed in the following tables:

- Required Fields
- Optional Fields

## Required Fields

| Required Field | Description |
|---|---|
| **Name** | A label that supports up to 31 characters, used to identify the rule. |
| **Rule Type** | Specifies whether the rule applies to traffic within a zone, between zones, or both:<br>• **universal** (default)—Applies the rule to all matching interzone and intrazone traffic in the specified source and destination zones. For example, if you create a universal role with source zones A and B and destination zones A and B, the rule would apply to all traffic within zone A, all traffic within zone B, and all traffic from zone A to zone B and all traffic from zone B to zone A.<br>• **intrazone**—Applies the rule to all matching traffic within the specified source zones (you cannot specify a destination zone for intrazone rules). For example, if you set the source zone to A and B, the rule would apply to all traffic within zone A and all traffic within zone B, but not to traffic between zones A and B.<br>• **interzone**—Applies the rule to all matching traffic between the specified source and destination zones. For example, if you set the source zone to A, B, and C and the destination zone to A and B, the rule would apply to traffic from zone A to zone B, from zone B to zone A, from zone C to zone A, and from zone C to zone B, but not traffic within zones A, B, or C. |
| **Source Zone** | The zone from which the traffic originates. |
| **Destination Zone** | The zone at which the traffic terminates. If you use NAT, make sure to always reference the post-NAT zone. |
| **Application** | The application which you wish to control. The firewall uses App-ID, the traffic classification technology, to identify traffic on your network. App-ID provides application control and visibility in creating security policies that block unknown applications, while enabling, inspecting, and shaping those that are allowed. |
| **Action** | Specifies an *Allow* or *Deny* action for the traffic based on the criteria you define in the rule. |

 © Palo Alto Networks, Inc.

## Optional Fields

| Optional Field | Description |
|---|---|
| **Tag** | A keyword or phrase that allows you to filter security rules. This is handy when you have defined many rules and wish to then review those that are tagged with a particular keyword, for example *Inbound to DMZ*. |
| **Description** | A text field, up to 255 characters, used to describe the rule. |
| **Source IP Address** | Define host IP or FQDN, subnet, named groups, or country-based enforcement. If you use NAT, make sure to always refer to the original IP addresses in the packet (i.e. the pre-NAT IP address). |
| **Destination IP Address** | The location or destination for the traffic. If you use NAT, make sure to always refer to the original IP addresses in the packet (i.e. the pre-NAT IP address). |
| **User** | The user or group of users for whom the policy applies. You must have User-ID enabled on the zone. To enable User-ID, see User-ID Overview. |
| **URL Category** | Using the URL Category as match criteria allows you to customize security profiles (antivirus, anti-spyware, vulnerability, file-blocking, Data Filtering, and DoS) on a per-URL-category basis. For example, you can prevent.exe file download/upload for URL categories that represent higher risk while allowing them for other categories. This functionality also allows you to attach schedules to specific URL categories (allow social-media websites during lunch & after-hours), mark certain URL categories with QoS (financial, medical, and business), and select different log forwarding profiles on a per-URL-category-basis.<br>Although you can manually configure URL categories on your device, to take advantage of the dynamic URL categorization updates available on the Palo Alto Networks firewalls, you must purchase a URL filtering license.<br>To block or allow traffic based on URL category, you must apply a URL Filtering profile to the security policy rules. Define the URL Category as *Any* and attach a URL Filtering profile to the security policy. See Set Up Basic Security Policies for information on using the default profiles in your security policy and see Control Access to Web Content for more details. |
| **Service** | Allows you to select a Layer 4 (TCP or UDP) port for the application. You can choose *any*, specify a port, or use *application-default* to permit use of the standards-based port for the application. For example, for applications with well- known port numbers such as DNS, the *application-default* option will match against DNS traffic only on TCP port 53. You can also add a custom application and define the ports that the application can use.<br>For inbound allow rules (for example, from untrust to trust), using *application-default* prevents applications from running on unusual ports and protocols. Application-default is the default option; while the device still checks for all applications on all ports, with this configuration, applications are only allowed on their standard ports/protocols. |
| **Security Profiles** | Provide additional protection from threats, vulnerabilities, and data leaks. Security profiles are only evaluated for rules that have an *allow* action. |

| Optional Field | Description (Continued) |
|---|---|
| **HIP Profile** (for GlobalProtect) | Allows you to identify clients with Host Information Profile (HIP) and then enforce access privileges. |
| **Options** | Allow you to define logging for the session, log forwarding settings, change Quality of Service (QoS) markings for packets that match the rule, and schedule when (day and time) the security rule should be in effect. |

 © Palo Alto Networks, Inc.

## Security Policy Best Practices

The task of safely enabling Internet access and preventing misuse of web access privileges, and exposure to vulnerabilities and attacks is a continuous process. The key principle when defining policy on the Palo Alto Networks firewall is to use a positive enforcement approach. Positive enforcement implies that you selectively allow what is required for day-to-day business operations as opposed to a negative enforcement approach where you would selectively block everything that is not allowed. Consider the following suggestions when creating policy:

- If you have two or more zones with identical security requirements, combine them into one security rule.
- The ordering of rules is crucial to ensure the best match criteria. Because policy is evaluated top down, the more specific policy must precede the ones that are more general, so that the more specific rule is not *shadowed*. The term shadow refers to a rule that is not evaluated or is skipped because it is placed lower in the policy list. When the rule is placed lower, it is not evaluated because the match criteria was met by another rule that preceded it, thereby shadowing the rule from policy evaluation.
- To restrict and control access to inbound applications, in the security policy, explicitly define the port that the service/application will be listening on.
- Logging for broad allow rules—for example access to well known servers like DNS—can generate a lot of traffic. Hence it is not recommended unless absolutely necessary.
- By default, the firewall creates a log entry at the end of a session. However, you can modify this default behavior and configure the firewall to log at the start of the session. Because this significantly increases the log volume, logging at session start is recommended only when you are troubleshooting an issue. Another alternative for troubleshooting without enabling logging at session start is to use the session browser (**Monitor > Session Browser**) to view the sessions in real time.

© Palo Alto Networks, Inc.

# Policy Objects

A *policy object* is a single object or a collective unit that groups discrete identities such as IP addresses, URLs, applications, or users. With policy objects that are a collective unit, you can reference the object in security policy instead of manually selecting multiple objects one at a time. Typically, when creating a policy object, you group objects that require similar permissions in policy. For example, if your organization uses a set of server IP addresses for authenticating users, you can group the set of server IP addresses as an *address group* policy object and reference the address group in the security policy. By grouping objects, you can significantly reduce the administrative overhead in creating policies.

You can create the following policy objects on the firewall:

| Policy Object | Description |
|---|---|
| Address/Address Group, Region | Allow you to group specific source or destination addresses that require the same policy enforcement. The address object can include an IPv4 or IPv6 address (single IP, range, subnet) or the FQDN. Alternatively, a region can be defined by the latitude and longitude coordinates or you can select a country and define an IP address or IP range. You can then group a collection of address objects to create an *address group* object.<br>You can also use dynamic address groups to dynamically update IP addresses in environments where host IP addresses change frequently. |
| User/User Group | Allow you to create a list of users from the local database or an external database and group them. |
| Application Group and Application Filter | An *Application Filter* allows you to filter applications dynamically. It allows you to filter, and save a group of applications using the attributes defined in the application database on the firewall. For example, you can filter by one or more attributes—category, sub-category, technology, risk, characteristics—and save your application filter. With an application filter, when a PAN-OS content update occurs, any new applications that match your filter criteria are automatically added to your saved application filter.<br>An *Application Group* allows you to create a static group of specific applications that you wish to group together for a group of users or for a particular service. |
| Service/Service Groups | Allows you to specify the source and destination ports and protocol that a service can use. The firewall includes two pre-defined services—service-http and service-https—that use TCP ports 80 and 8080 for HTTP, and TCP port 443 for HTTPS. You can however, create any custom service on any TCP/UDP port of your choice to restrict application usage to specific ports on your network (in other words, you can define the default port for the application).<br> To view the standard ports used by an application, in **Objects > Applications** search for the application and click the link. A succinct description displays. |

 © Palo Alto Networks, Inc.

# Security Profiles

While security policies enable you to allow or deny traffic on your network, security profiles help you define an *allow but scan* rule, which scan allowed applications for threats, such as viruses, malware, spyware, and DDOS attacks. When traffic matches the allow rule defined in the security policy, the security profile(s) that are attached to the rule are applied for further content inspection rules such as antivirus checks and data filtering.

Security profiles are not used in the match criteria of a traffic flow. The security profile is applied to scan traffic after the application or category is allowed by the security policy.

The firewall provides default security profiles that you can use out of the box to begin protecting your network from threats. See Set Up Basic Security Policies for information on using the default profiles in your security policy. As you get a better understanding about the security needs on your network, you can create custom profiles. See Scan Traffic for Threats for more information.

You can add security profiles that are commonly applied together to a security profile group; this set of profiles can be treated as a unit and added to security policies in one step (or included in security policies by default, if you choose to set up a default security profile group).

The following topics provide more detailed information about each type of security profile and how to set up a security profile group:

- Antivirus Profiles
- Anti-spyware Profiles
- Vulnerability Protection Profiles
- URL Filtering Profiles
- Data Filtering Profiles
- File Blocking Profiles
- DoS Protection Profile
- Zone Protection Profiles
- Security Profile Group

© Palo Alto Networks, Inc.

## Antivirus Profiles

Antivirus profiles protect against viruses, worms, and trojans as well as spyware downloads. Using a stream-based malware prevention engine, which inspects traffic the moment the first packet is received, the Palo Alto Networks antivirus solution can provide protection for clients without significantly impacting the performance of the firewall. This profile scans for a wide variety of malware in executables, PDF files, HTML and JavaScript viruses, including support for scanning inside compressed files and data encoding schemes. If you have enabled Decryption on the firewall, the profile also enables scanning of decrypted content.

The default profile inspects all of the listed protocol decoders for viruses, and generates alerts for SMTP, IMAP, and POP3 protocols while blocking for FTP, HTTP, and SMB protocols. Customized profiles can be used to minimize antivirus inspection for traffic between trusted security zones, and to maximize the inspection of traffic received from untrusted zones, such as the Internet, as well as the traffic sent to highly sensitive destinations, such as server farms.

The Palo Alto Networks WildFire system also provides signatures for persistent threats that are more evasive and have not yet been discovered by other antivirus solutions. As threats are discovered by WildFire, signatures are quickly created and then integrated into the standard antivirus signatures that can be downloaded by Threat Prevention subscribers on a daily basis (sub-hourly for WildFire subscribers).

 © Palo Alto Networks, Inc.

## Anti-spyware Profiles

Anti-spyware profiles blocks spyware on compromised hosts from trying to phone-home or beacon out to external command-and-control (C2) servers, allowing you to detect malicious traffic leaving the network from infected clients. You can apply various levels of protection between zones. For example, you may want to have custom anti-spyware profiles that minimize inspection between trusted zones, while maximizing inspection on traffic received from an untrusted zone, such as Internet facing zones.

You can define your own custom Anti-spyware profiles, or choose one of the following predefined profiles when applying anti-spyware to a security policy:

- **Default**—Uses the default action for every signature, as specified by Palo Alto Networks when the signature is created.
- **Strict**—Overrides the default action of critical, high, and medium severity threats to the block action, regardless of the action defined in the signature file. This profile still uses the default action for medium and informational severity signatures.

In addition, you can enable the DNS Sinkholing action in anti-spyware profiles to enable the firewall to forge a response to a DNS query for a known malicious domain, causing the malicious domain name to resolve to an IP address that you define. This feature helps to identify infected hosts on the protected network using DNS traffic Infected hosts can then be easily identified in the traffic and threat logs because any host that attempts to connect to the sinkhole IP address are most likely infected with malware.

Anti-spyware and vulnerability protection profiles are configured similarly.

## Vulnerability Protection Profiles

Vulnerability protection profiles stop attempts to exploit system flaws or gain unauthorized access to systems. While anti-spyware profiles help identify infected hosts as traffic leaves the network, vulnerability protection profiles protect against threats entering the network. For example, vulnerability protection profiles help protect against buffer overflows, illegal code execution, and other attempts to exploit system vulnerabilities. The default vulnerability protection profile protects clients and servers from all known critical, high, and medium-severity threats. You can also create exceptions, which allow you to change the response to a specific signature.

 © Palo Alto Networks, Inc.

## URL Filtering Profiles

URL Filtering profiles enable you to monitor and control how users access the web over HTTP and HTTPS. The firewall comes with a default profile that is configured to block websites such as known malware sites, phishing sites, and adult content sites. You can use the default profile in a security policy, clone it to be used as a starting point for new URL filtering profiles, or add a new URL profile that will have all categories set to allow for visibility into the traffic on your network. You can then customize the newly added URL profiles and add lists of specific websites that should always be blocked or allowed, which provides more granular control over URL categories.

# Data Filtering Profiles

Data filtering profiles prevent sensitive information such as credit card or social security numbers from leaving a protected network. The data filtering profile also allows you to filter on key words, such as a sensitive project name or the word confidential. It is important to focus your profile on the desired file types to reduce false positives. For example, you may only want to search Word documents or Excel spreadsheets. You may also only want to scan web-browsing traffic, or FTP.

You can use default profiles, or create custom data patterns. There are two default profiles:

- CC# (Credit Card)—Identifies credit card numbers using a hash algorithm. The content must match the hash algorithm in order for data to be detected as a credit card number. This method will reduce false positives.
- SSN# (Social Security Number)—Uses an algorithm to detect nine digit numbers, regardless of format. There are two fields: SSN# and SSN# (no dash).

## Weight and Threshold Values

It is important to understand how the weight of an object (SSN, CC#, pattern) is calculated in order to set the appropriate threshold for a condition you are trying to filter. Each occurrence multiplied by the weight value will be added together in order to reach an action threshold (alert or block).

### Example: Filter for Social Security Numbers Only

For simplicity, if you only want to filter files with Social Security Numbers (SSN) and you define a weight of 3 for SSN#, you would use the following formula: each instance of a SSN x weight = threshold increment. In this case, if a Word document has 10 social security numbers you multiply that by the weight of 3, so 10 x 3 = 30. In order to take action for a file that contains 10 social security numbers you would set the threshold to 30. You may want to set an alert at 30 and then block at 60. You may also want to set a weight in the field SSN# (no dash) for Social Security Numbers that do not contain dashes. If multiple settings are used, they will accumulate to reach a given threshold.

### Example: Filter for Social Security Numbers and a Custom Pattern

In this example, we will filter on files that contain Social Security Numbers and the custom pattern confidential. In other words, if a file has Social Security Numbers in addition to the word confidential and the combined instances of those items hit the threshold, the file will trigger an alert or block, depending on the action setting.

SSN# weight = 3

Custom Pattern confidential weight = 20

The custom pattern is case sensitive.

 © Palo Alto Networks, Inc.

If the file contains 20 Social Security Numbers and a weight of 3 is configured, that is 20 x 3 = 60. If the file also contains one instance of the term confidential and a weight of 20 is configured, that is 1 x 20 = 20 for a total of 80. If your threshold for block is set to 80, this scenario would block the file. The alert or block action will be triggered as soon as the threshold is hit.

© Palo Alto Networks, Inc.

## File Blocking Profiles

The firewall uses file blocking profiles two ways: to forward files to WildFire for analysis or to block specified file types over specified applications and in the specified session flow direction (inbound/outbound/both). You can set the profile to alert or block on upload and/or download and you can specify which applications will be subject to the file blocking profile. You can also configure custom block pages that will appear when a user attempts to download the specified file type. This allows the user to take a moment to consider whether or not they want to download a file.

You can configure a file blocking profile with the following actions:

- **Alert**—When the specified file type is detected, a log is generated in the data filtering log.
- **Block**—When the specified file type is detected, the file is blocked and a customizable block page is presented to the user. A log is also generated in the data filtering log.
- **Continue**—When the specified file type is detected, a customizable response page is presented to the user. The user can click through the page to download the file. A log is also generated in the data filtering log. Because this type of forwarding action requires user interaction, it is only applicable for web traffic.
- **Forward**—When the specified file type is detected, the file is sent to WildFire for analysis. A log is also generated in the data filtering log.
- **Continue-and-forward**—When the specified file type is detected, a customizable continuation page is presented to the user. The user can click through the page to download the file. If the user clicks through the continue page to download the file, the file is sent to WildFire for analysis. A log is also generated in the data filtering log.

 © Palo Alto Networks, Inc.

## DoS Protection Profile

DoS protection profiles provide detailed control for Denial of Service (DoS) protection policies. DoS policies allow you to control the number of sessions between interfaces, zones, addresses, and countries based on aggregate sessions or source and/or destination IP addresses. There are two DoS protection mechanisms that the Palo Alto Networks firewalls support.

- **Flood Protection**—Detects and prevents attacks where the network is flooded with packets resulting in too many half-open sessions and/or services being unable to respond to each request. In this case the source address of the attack is usually spoofed. See DoS Protection Against Flooding of New Sessions.
- **Resource Protection**— Detects and prevent session exhaustion attacks. In this type of attack, a large number of hosts (bots) are used to establish as many fully established sessions as possible to consume all of a system's resources.

You can enable both types of protection mechanisms in a single DoS protection profile.

The DoS profile is used to specify the type of action to take and details on matching criteria for the DoS policy. The DoS profile defines settings for SYN, UDP, and ICMP floods, can enable resource protect and defines the maximum number of concurrent connections. After you configure the DoS protection profile, you then attach it to a DoS policy.

When configuring DoS protection, it is important to analyze your environment in order to set the correct thresholds and due to some of the complexities of defining DoS protection policies, this guide will not go into detailed examples. For more information, refer to the Threat Prevention Tech Note.

## Zone Protection Profiles

Zone protection profiles provide additional protection between specific network zones in order to protect the zones against attack. The profile must be applied to the entire zone, so it is important to carefully test the profiles in order to prevent issues that may arise with the normal traffic traversing the zones. When defining packets per second (pps) thresholds limits for zone protection profiles, the threshold is based on the packets per second that do not match a previously established session. For more information, refer to the Threat Prevention Tech Note.

 © Palo Alto Networks, Inc.

# Security Profile Group

A security profile group is a set of security profiles that can be treated as a unit and then easily added to security policies. Profiles that are often assigned together can be added to profile groups to simplify the creation of security policies. You can also setup a default security profile group—new security policies will use the settings defined in the default profile group to check and control traffic that matches the security policy. Name a security profile group *default* to allow the profiles in that group to be added to new security policies by default. This allows you to consistently include your organization's preferred profile settings in new policies automatically, without administrators having to manually add them each time they create a new policy.

The following sections show how to create a security profile group and how to enable a profile group to be used by default in new security policies:

- Create a Security Profile Group
- Set Up or Override a Default Security Profile Group

## Create a Security Profile Group

Use the following steps to create a security profile group and add it to a security policy.

| **Create a Security Profile Group** | |
|---|---|
| Step 1 Create a security profile group. | 1. Select **Objects > Security Profile Groups** and **Add** a new security profile group.<br>2. Give the profile group a descriptive **Name**, for example, Threats.<br>3. If the firewall is in Multiple Virtual System Mode, enable the profile to be **Shared** by all virtual systems.<br>4. Add existing profiles to the group.<br>  <br>5. Click **OK** to save the profile group. |

| Create a Security Profile Group | | |
|---|---|---|
| Step 2 | Add a security profile group to a security policy. | 1. Select **Policies > Security** and **Add** or modify a security policy rule.<br>2. Select the **Actions** tab.<br>3. In the Profile Setting section, select **Group** for the **Profile Type**.<br>4. In the **Group Profile** drop-down, select the group you created (for example, select the Threats group):<br>  <br>5. Click **OK** to save the policy and **Commit** your changes. |
| Step 3 | Save your changes. | Click **Commit**. |

## Set Up or Override a Default Security Profile Group

Use the following options to set up a default security profile group to be used in new security policies, or to override an existing default group. When an administrator creates a new security policy, the default profile group will be automatically selected as the policy's profile settings, and traffic matching the policy will be checked according to the settings defined in the profile group (the administrator can choose to manually select different profile settings if desired). Use the following options to set up a default security profile group or to override your default settings.

If no default security profile exists, the profile settings for a new security policy are set to **None** by default.

 © Palo Alto Networks, Inc.

| Set Up or Override a Default Security Profile Group | |
|---|---|
| • Create a security profile group. | 1. Select **Objects > Security Profile Groups** and Add a new security profile group.<br>2. Give the profile group a descriptive **Name**, for example, Threats.<br>3. If the firewall is in Multiple Virtual System Mode, enable the profile to be **Shared** by all virtual systems.<br>4. Add existing profiles to the group. For details on creating profiles, see Security Profiles.<br>  <br>5. Click **OK** to save the profile group.<br>6. **Add the security profile group to a security policy.**<br>7. **Add** or modify a security policy rule and select the **Actions** tab.<br>8. Select **Group** for the **Profile Type**.<br>9. In the **Group Profile** drop-down, select the group you created (for example, select the Threats group):<br>  <br>10. Click **OK** to save the policy and **Commit** your changes. |

| Set Up or Override a Default Security Profile Group | |
|---|---|
| • Set up a default security profile group. | 1. Select **Objects > Security Profile Groups** and add a new security profile group or modify an existing security profile group.<br>2. **Name** the security profile group *default*:<br>  <br>3. Click **OK** and **Commit**.<br>4. Confirm that the *default* security profile group is included in new security policies by default:<br>a. Select **Policies > Security** and **Add** a new security policy.<br>b. Select the **Actions** tab and view the **Profile Setting** fields:<br> <br>By default, the new security policy correctly shows the **Profile Type** set to Group and the *default* **Group Profile** is selected. |
| • Override a default security profile group. | If you have an existing default security profile group, and you do not want that set of profiles to be attached to a new security policy, you can continue to modify the Profile Setting fields according to your preference. Begin by selecting a different Profile Type for your policy (**Policies > Security > Security Policy Rule > Actions**). |

 © Palo Alto Networks, Inc.

# Enumeration of Rules Within a Rulebase

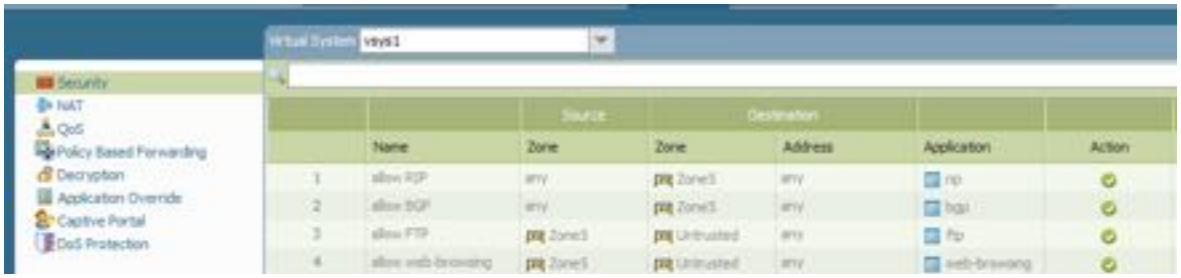
Each rule within a rulebase is automatically numbered and the ordering adjusts as rules are moved or reordered. When filtering rules to find rules that match the specified filter(s), each rule is listed with its number in the context of the complete set of rules in the rulebase and its place in the evaluation order.

On Panorama, pre-rules and post-rules are independently numbered. When rules are pushed from Panorama to a managed firewall, the rule numbering incorporates hierarchy in pre-rules, device rules, and post-rules within a rulebase and reflects the rule sequence and its evaluation order. The **Preview** option in Panorama offers an ordered list view of the total number of rules on a managed device.

**View the Ordered List of Rules Within a Rulebase**

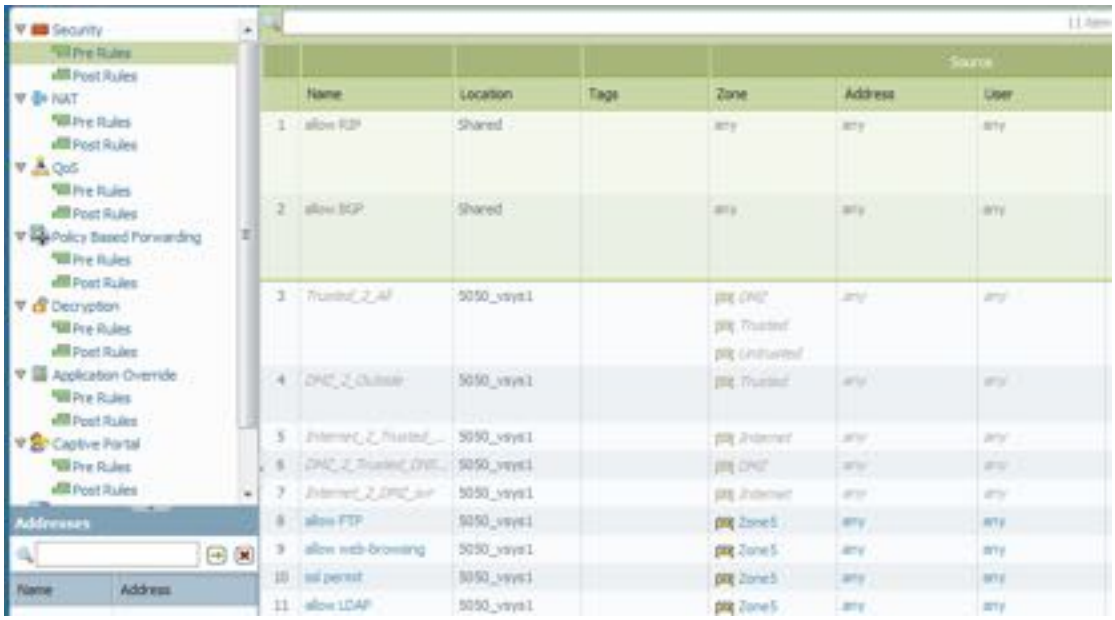
- View the numbered list of rules on the firewall.

  Select **Policies** and any rulebase under it. For example, **Policies > QoS**. The left-most column in the table displays the rule number.



- View the numbered list of rules on Panorama.

  Select **Policies** and any rulebase under it. For example, **Policies > Security> Pre-rules**.



**View the Ordered List of Rules Within a Rulebase (Continued)**

- After you push the rules from Panorama, view the complete list of rules with numbers on the managed device.

  From the web interface of the managed device, select **Policies** and pick any rulebase under it. For example, select **Policies > Security** and view the complete set of numbered rules that will be evaluated on the device.

 © Palo Alto Networks, Inc.

# Use Tags to Visually Distinguish Objects

You can tag objects and add color to the tag in order to visually distinguish tagged objects. Tags can be added to the following objects: address objects, address groups, zones, service groups, and policy rules.

The firewall and Panorama support both static tags and dynamic tags, dynamic tags are registered from a variety of sources and are not displayed with the static tags, because dynamic tags are not part of the device configuration. See Register IP Addresses and Tags Dynamically for information on registering tags dynamically. The tags discussed in this section are statically added and are part of the device configuration.

One or more tags can be applied to objects and to policy rules; a maximum of 64 tags can be applied to an object. Panorama supports a maximum of 10,000 tags that can be apportioned across Panorama (shared and device groups) and the managed devices (including devices with multiple virtual systems).

| **Tag Objects** | |
|---|---|
| Step 1 Create tags.<br><br>To tag a zone, you must create a tag with the same name as the zone. When the zone is attached in policy rules, the tag color automatically displays as the background color against the zone name. | 1. Select **Objects > Tags**.<br>2. On Panorama or a multiple virtual system firewall, select the **Device Group** or the **Virtual System** to which this object must belong.<br>3. Click **Add** and enter a **Name** to identify the tag. The maximum length is 127 characters.<br>4. (Optional) Select **Shared** to create the object in a shared location for access as a shared object in Panorama or for use across all virtual systems in a multiple virtual system firewall.<br>5. (Optional) Assign one of the 16 predefined colors to the tag. By default, no color is selected.<br> <br>6. Click **OK** and **Commit** to save the changes. |
| Step 2 View tags in policy. | 1. Select **Policies** and any rulebase under it.<br>2. Click **Add** to create a policy rule and use the tagged objects you created in Step 1.<br>3. Verify that the tags are in use.<br> |

| Tag Objects (Continued) | |
|---|---|
| Step 3 Working with tags. | • Select **Objects > Tags** to perform any of the following operations with tags:<br>  • Click the link in the **Name** column to edit the properties of a tag.<br>  • Select a tag in the table, and click **Delete** to remove the tag from the firewall.<br>  • Click **Clone** to create a duplicate tag with the same properties. A numerical suffix is added to the tag name. For example, FTP-1.<br>• To apply a tag to an address object, address group, service or service group:<br>  • Create the object. Click **Add**. For example to create a service group, select **Objects > Service Groups > Add**.<br>  • Select the tag(s) from the **Tag** drop-down or enter a phrase to create a new tag.<br> To edit a tag or add color to the tag, select **Objects >Tags**. |

 © Palo Alto Networks, Inc.

# Tips and Tricks for Searching for Objects in Security Policy

The policy filtering mechanism is a powerful tool for searching for objects in even the most complex security policy rulebase. The following topics show examples to help you learn to search the security policy rulebase (**Policies > Security**) efficiently so that you can streamline your management tasks:

- Search Security Policy Rules for Security Profiles
- Search for Disabled Rules in the Security Policy
- Search for Log Forwarding Details in Security Policy
- Search for Log Details in Security Policy
- Search for Scheduled Rules in Security Policy

## Search Security Policy Rules for Security Profiles

- Search for an Antivirus Profile
- Search for a Specific URL Filtering Profile
- Search for an Anti-Spyware Profile
- Search for a Vulnerability Protection Profile
- Search for a File Blocking Profile
- Search for a Data Filtering Profile

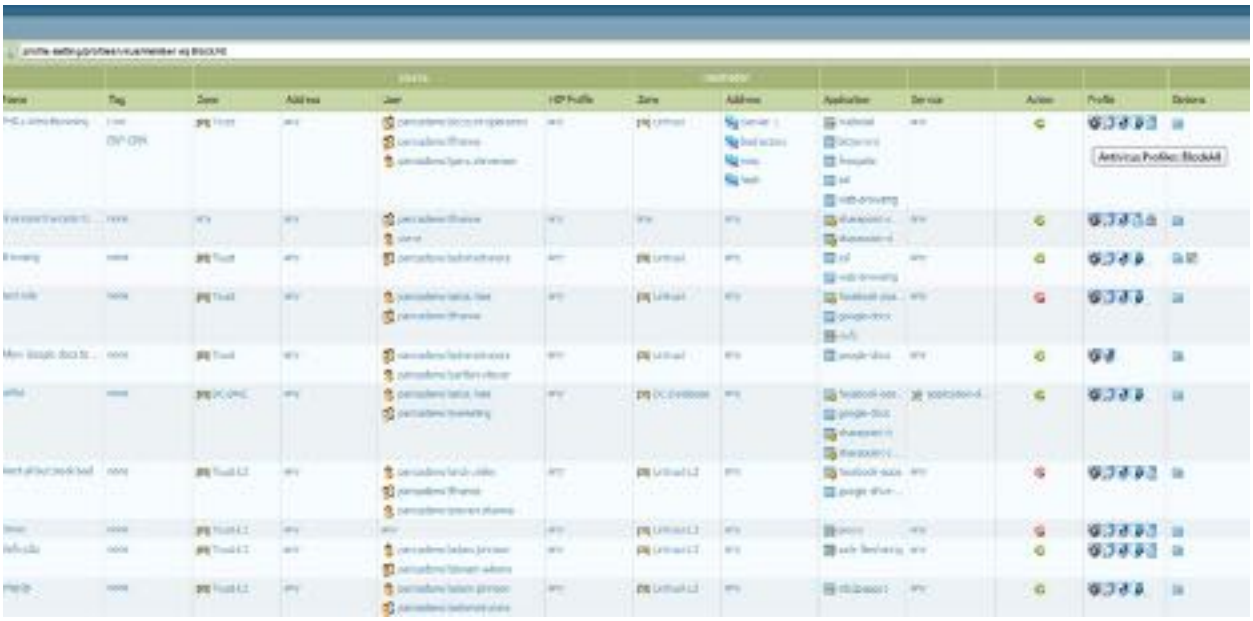
### Search for an Antivirus Profile

Use the `profile-setting/profiles/virus/member` syntax to search for an Antivirus security profile. For example, suppose you have an Antivirus profile named **BlockAll** that you use to block viruses in all FTP, HTTP, IMAP, POP3, SMB, and SMTP application traffic. To search for all security policy rules that include this Antivirus profile you would enter the following search string in the filter text box on the **Policy** tab:

```
profile-setting/profiles/virus/member eq BlockAll
```

The search filter is case sensitive. Therefore, when filtering you must enter the object name exactly as it displays on the **Objects** tab. In this case, filtering on `blockall` or `Blockall` would not yield a match because the exact capitalization of the object is `BlockAll`.

After applying the search filter, the rulebase now only displays security policy rules with the BlockAll Antivirus security profile attached as follows:



## Search for a Specific URL Filtering Profile

Use the `profile-setting/profiles/url-filtering/member` syntax to search for an antivirus security profile. For example, to search for all security policy rules that have a URL Filtering profile named **block malware**, you would enter the following search string in the filter text box:

```
profile-setting/profiles/url-filtering/member eq "block malware"
```

In this case, because the profile name contains a space, you must enclose the name in quotation marks in order for the filter to match policy rules with the block malware URL Filtering profile attached.

After applying the search filter, the rulebase now only displays security policy rules with the block malware URL Filtering security profile attached as follows:

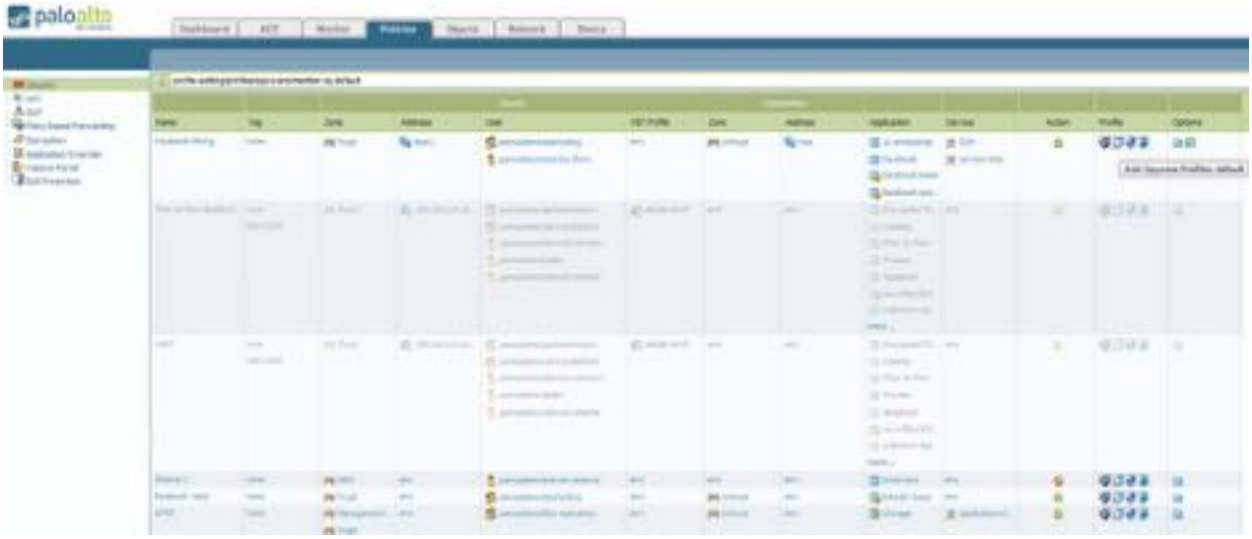
 © Palo Alto Networks, Inc.

## Search for an Anti-Spyware Profile

Use the `profile-setting/profiles/spyware/member` syntax to search for an Anti-Spyware security profile. For example, to search for all security policy rules that have the **default** Anti-Spyware security profile attached, you would enter the following search string in the filter text box:

```
profile-setting/profiles/spyware/member eq default
```

After applying the search filter, the rulebase now only displays security policy rules with the default Anti-Spyware security profile attached as follows:



## Search for a Vulnerability Protection Profile

Use the `profile-setting/profiles/vulnerability/member` syntax to search for a Vulnerability Protection security profile. For example, to search for all security policy rules that have the **strict** Vulnerability Protection security profile attached, you would enter the following search string in the filter text box:

```
profile-setting/profiles/vulnerability/member eq strict
```

After applying the search filter, the rulebase now only displays security policy rules with the strict Vulnerability Protection security profile attached as follows:

## Search for a File Blocking Profile

Use the `profile-setting/profiles/file-blocking/member` syntax to search for a File Blocking security profile. For example, suppose you created a File Blocking profile named Wildfire that you will use to forward all PE files to WildFire for analysis. You can quickly verify that all security policy rules have the File Blocking profile attached by searching for all security policy rules that have the **Wildfire** File Blocking security profile attached by entering the following search string in the filter text box:

```
profile-setting/profiles/file-blocking/member eq Wildfire
```

After applying the search filter, the rulebase now displays all security policy rules that have the Wildfire File Blocking security profile attached as follows:

## Search for a Data Filtering Profile

Use the `profile-setting/profiles/data-filtering/member` syntax to search for security policy rules that have a specific Data Filtering security profile attached. For example, suppose you created a Data Filtering profile named **credit cards**. You can search for all security policy rules have this profile attached by searching for all security policy rules that have the **credit cards** Data Filtering security profile attached by entering the following search string in the filter text box:

```
profile-setting/profiles/data-filtering/member eq "credit cards"
```

Notice once again that the profile name must be enclosed in quotation marks because it contains a space.

After applying the search filter, the rulebase now displays only security policy rules that have the credit cards Data Filtering security profile attached as follows:

 © Palo Alto Networks, Inc.

## Search for Disabled Rules in the Security Policy

If you want to get a quick view of all security rules that are currently disabled in your policy, you can display these by entering the following command on the search bar on the Security Policy:

```
disabled eq yes
```

## Search for Log Forwarding Details in Security Policy

If you want to get a quick view of all security rules that are currently sending their logs using a particular log forwarding profile, you can filter the rulebase using the `logsetting` parameter. For example, to filter for all rules that are forwarding their logs using a log forwarding profile named **panorama**, you would enter the following command on the search bar on the **Policies > Security** page:

```
logsetting eq panorama
```

## Search for Log Details in Security Policy

If you want to get a quick view of all security rules that are currently sending logs, you can filter using the log-end and log-start filters. For example, to view all policy rules that generate logs at the end of a session, you can filter the rulebase using the following filter:

```
log-end eq yes
```

Similarly, to view all policy rules that generate logs at the start and the end of a session, you can filter the rulebase as follows:

```
log-start eq yes
```

 © Palo Alto Networks, Inc.

## Search for Scheduled Rules in Security Policy

If you want to get a quick view of all security rules that are set to be active based on a particular time schedule, such as during Lunch time, you can display these by entering the following command on the search bar on the **Policies > Security** page:

```
schedule eq "Lunch time"
```

The search field is case sensitive, so you must enter the object name exactly as it appears in the firewall configuration. In addition, you must enclose object names that contain a space in quotation marks.

# Use a Dynamic Block List in Policy

The firewall or Panorama typically enforce policy for a source or destination IP address that is defined as a static object on the firewall. If you need agility in enforcing policy for a list of source/destination IP addresses that emerge ad hoc, you can use dynamic block lists.

A dynamic block list is a text file that contains a list of IP addresses, IP ranges, or IP subnets, and is hosted on a web server. The dynamic block list can be used to deny or allow access to the IP addresses (IPv4 and IPv6) included in the list. For example, you can use it as a whitelist for allowing a set of IP addresses or as a blacklist to disallow access to the specified IP addresses. At a configured interval, the firewall dynamically imports the list and enforces policy for the IP addresses included in the list. When you modify the list, the firewall retrieves the updates; a configuration change or commit is not required on the firewall. If the web server is unreachable, the firewall or Panorama will use the last successfully retrieved list for enforcing policy until the connection is restored with the web server that hosts the list.

- View the IP Address Limit For Your Firewall Model
- Formatting Guidelines for Dynamic Block Lists
- Enforce Policy with a Dynamic Block List
- View the List of IP addresses in the Dynamic Block List
- Retrieve a Dynamic Block List from Web Server

## View the IP Address Limit For Your Firewall Model

Irrespective of the firewall model, each firewall supports a maximum of 10 Dynamic Block Lists.

To find the maximum number of addresses, address groups, and IP addresses per group, for your model of the firewall, use the following CLI command:

**show system state | match cfg.general.max-address**

For example:

```
admin@PA-7050> show system state | match cfg.general.max-address
cfg.general.max-address: 80000
cfg.general.max-address-group: 8000
cfg.general.max-address-per-group: 500
```

Each list can contain the maximum number of addresses supported by your firewall model minus 300. Up to 300 IP addresses are reserved for internal use on the firewall and are deducted from the available limit. Therefore, in the example above, the firewall can have a maximum of 79,700 IP addresses.

 © Palo Alto Networks, Inc.

## Formatting Guidelines for Dynamic Block Lists

The dynamic block list can include individual IP addresses, subnet addresses (address/mask), or range of IP addresses. In addition, the block list can include comments and special characters such as `*` , `:` , `;` , `#`, or `/`. The syntax for each line in the list is `[IP address, IP/Mask, or IP start range-IP end range] [space] [comment]`.

Because the firewall ignores incorrectly formatted lines, use these guidelines when defining the list:

- Enter each IP address/range/subnet in a new line; URLs are not supported in this list.
- If you add comments, the comment must be on the same line as the IP address/range/subnet. The space at the end of the IP address is the delimiter that separates a comment from the IP address.

An example:

```
192.168.20.10/32
2001:db8:123:1::1 #test IPv6 address
192.168.20.0/24 ; test internal subnet
2001:db8:123:1::/64 test internal IPv6 range
192.168.20.40-192.168.20.50
```

For an IP address that is blocked, you can display a notification page only if the protocol is HTTP.

## Enforce Policy with a Dynamic Block List

| **Enforce Policy with a Dynamic Block List** | | |
|---|---|---|
| Step 1 | Create the dynamic block list and host it on a web server, so that the firewall can retrieve the list for policy evaluation. | 1. Create a text file and enter the IP addresses for which you want to enforce policy. For syntax, see Formatting Guidelines for Dynamic Block Lists. |
| Step 2 | Create a dynamic block list object on the firewall. | 1. Select **Objects > Dynamic Block Lists**.<br>2. Click **Add** and enter a descriptive **Name** for the list.<br>3. (Optional) Select **Shared**, to share the list with all virtual systems on a device that is enabled for multiple virtual systems. By default, the object is created on the virtual system that is currently selected in the **Virtual Systems** drop-down.<br>4. Enter the **Source** URL (hostname or IP address and the path) for the list you just created on the web server. For example, https://1.2.3.4/DBL_2014<br>5. Click **Test Source URL** to verify that the firewall or Panorama can connect to the web server.<br>6. (Optional) Specify the **Repeat** frequency at which the firewall or Panorama must retrieve the list. By default the list is retrieved ever hour.<br>7. Click **OK** to save the changes. |

| Enforce Policy with a Dynamic Block List | | |
|---|---|---|
| Step 3 | Use the dynamic block list as a source or destination address object in policy.<br> Create separate dynamic block lists if you want to specify allow and deny actions for specific IP addresses.<br>The list can be referenced in any policy type. In this example, we attach it as a destination object in security policy. | 1. Select **Policies > Security**.<br>2. Click **Add** and give the rule a descriptive name in the **General** tab.<br>3. In the **Source** tab, select the **Source Zone**.<br>4. In the **Destination** tab, select the **Destination Zone** and select the dynamic block list as the Destination Address.<br>5. In the **Service/ URL Category** tab, make sure the **Service** is set to **application-default**.<br>6. In the **Actions** tab, set the **Action Setting** to Allow or Deny.<br>7. Leave all the other options at the default values.<br>8. Click **OK** to save the changes.<br>9. **Commit** the changes. |
| Step 4 | Test that the policy action is enforced. | 1. Access a IP address that is included in the dynamic block list and verify that action you defined is enforced.<br>2. Select **Monitor > Logs > Traffic** and see the log entry for the session.<br>3. To verify the policy rule that matches a flow, use the following CLI command:<br>**test security-policy-match source** *<IP_address>* **destination** *<IP_address>* **destination port** *<port_number>* **protocol** *<protocol_number>* |

## View the List of IP addresses in the Dynamic Block List

**View the IP Addresses Included in the Dynamic Block List**

To view the list of IP addresses that the firewall has retrieved from the web server enter the following CLI command:

**request system external-list show name *<name>***

For example, for a list named case DBL_2014, the output is:

```
vsys1/DBL_2014:
  Next update at: Wed Aug 27 16:00:00 2014
  IPs:
  1.1.1.1
  1.2.2.2/20 #test China
  192.168.255.0; test internal
  192.168.254.0/24 test internal range
```

 © Palo Alto Networks, Inc.

## Retrieve a Dynamic Block List from Web Server

The firewall or Panorama can be configured to retrieve the list from the web server on an hourly, daily, weekly, or monthly basis. If you have added or deleted IP addresses on the list and need to trigger an immediate refresh, you must use the Command Line Interface.

**Retrieve a Dynamic Block List**

1. Enter the command: **request system external-list refresh name *<name>***

   For example, `request system external-list refresh name DBL_2014`
2. Get the job ID for the refresh job using the CLI command: **show jobs all**

   Look for the last EBL Refresh job in the list.
3. View the details for the job ID. Use the command **show jobs id *<number>***

   A message indicating the success or failure displays. For example:

```
admin@PA-200> show jobs id 55
Enqueued                    ID             Type    Status Result Completed
------------------------------------------------------------------------------
2014/08/26 15:34:14         55       EBLRefresh       FIN     OK 15:34:40
Warnings:
Details:
```

# Register IP Addresses and Tags Dynamically

To mitigate the challenges of scale, lack of flexibility and performance, the architecture in networks today allows for clients, servers and applications to be provisioned, changed, and deleted on demand. This agility poses a challenge for security administrators because they have limited visibility into the IP addresses of the dynamically provisioned clients, servers and the plethora of applications that can be enabled on these virtual resources.

The firewall (hardware-based platforms and the VM-Series) supports the ability to register IP addresses and tags dynamically. The IP addresses and tags can be registered on the firewall directly or registered on the firewall through Panorama.This dynamic registration process can be enabled using any of the following options:

- **User-ID agent for Windows**—In an environment where you've deployed the User-ID agent, you can enable the User-ID agent to monitor up to 100 VMware ESXi and/or vCenter Servers. As you provision or modify virtual machines on these VMware servers, the agent can retrieve the IP address changes and share them with the firewall.
- **VM Information Sources**—Allows you to monitor VMware ESXi and vCenter Server, and the AWS-VPC to retrieve IP address changes when you provision or modify virtual machines on these sources. VM Information Sources polls for a predefined set of attributes and does not require external scripts to register the IP addresses through the XML API. See Monitor Changes in the Virtual Environment.
- **VMware Service Manager** (only available for the integrated NSX solution)—The integrated NSX solution is designed for automated provisioning and distribution of Palo Alto Networks next-generation security services and the delivery of dynamic context-based security policies using Panorama. The NSX Manager updates Panorama with the latest information on the IP addresses and tags associated with the virtual machines deployed in this integrated solution. For information on this solution, see Set Up a VM-Series NSX Edition Firewall.
- **XML API**—The firewall and Panorama support an XML API that uses standard HTTP requests to send and receive data. You can use this API to register IP addresses and tags with the firewall or Panorama. API calls can be made directly from command line utilities such as cURL or using any scripting or application framework that supports REST-based services. Refer to the PAN-OS XML API Usage Guide for details.

For information on creating and using Dynamic Address Groups, see Use Dynamic Address Groups in Policy.

For the CLI commands for registering tags dynamically, see CLI Commands for Dynamic IP Addresses and Tags.

# Monitor Changes in the Virtual Environment

To secure applications and prevent threats in an environment where new users and servers are constantly emerging, your security policy must be nimble. To be nimble, the firewall must be able to learn about new or modified IP addresses and consistently apply policy without requiring configuration changes on the firewall.

This capability is provided by the coordination between the **VM Information Sources** and **Dynamic Address Groups** features on the firewall. The firewall and Panorama provide an automated way to gather information on the virtual machine (or guest) inventory on each monitored source and create policy objects that stay in sync with the dynamic changes on the network.

- Enable VM Monitoring to Track Changes on the Virtual Network
- Attributes Monitored in the AWS and VMware Environments
- Use Dynamic Address Groups in Policy

## Enable VM Monitoring to Track Changes on the Virtual Network

VM information sources provides an automated way to gather information on the Virtual Machine (VM) inventory on each monitored source (host); the firewall can monitor the VMware ESXi and vCenter Server, and the AWS-VPC. As virtual machines (guests) are deployed or moved, the firewall collects a predefined set of attributes (or metadata elements) as tags; these tags can then be used to define Dynamic Address Groups (see Use Dynamic Address Groups in Policy) and matched against in policy.

Up to 10 VM information sources can be configured on the firewall or pushed using Panorama templates. By default, the traffic between the firewall and the monitored sources uses the management (MGT) port on the firewall.

**VM Information Sources** offers easy configuration and enables you to monitor a predefined set of 16 metadata elements or attributes. See Attributes Monitored in the AWS and VMware Environmentsfor the list.

 © Palo Alto Networks, Inc.

**Set up the VM Monitoring Agent**

Step 1 Enable the VM Monitoring Agent.

Up to 10 sources can be configured for each firewall, or for each virtual system on a multiple virtual systems capable firewall.

If your firewalls are configured in a high availability configuration:

- An active/passive setup, only the active firewall monitors the VM sources.
- An active/active setup, only the firewall with the priority value of primary monitors the VM sources.

1. Select **Device > VM Information Sources**.
2. Click **Add** and enter the following information:
   - A **Name** to identify the VMware ESX(i) or vCenter Server that you want to monitor.
   - Enter the **Host information for the server—**hostname or IP address and the **Port** on which it is listening.
   - Select the **Type** to indicate whether the source is a **VMware ESX(i)** server or a **VMware vCenter** Server.
   - Add the credentials (**Username** and **Password**) to authenticate to the server specified above.
   - Use the credentials of an administrative user to enable access.
   - (Optional) Modify the **Update interval** to a value between 5-600 seconds. By default, the firewall polls every 5 seconds. The API calls are queued and retrieved within every 60 seconds, so updates may take up to 60 seconds plus the configured polling interval.

   - (Optional) Enter the interval in hours when the connection to the monitored source is closed, if the host does not respond. (default: 2 hours, range 2-10 hours)
     To change the default value, select the check box to **Enable timeout when the source is disconnected** and specify the value. When the specified limit is reached or if the host cannot be accessed or does not respond, the firewall will close the connection to the source.
   - Click **OK**, and **Commit** the changes.
   - Verify that the connection **Status** displays as connected .

| Set up the VM Monitoring Agent (Continued) | |
|---|---|
| Step 2 Verify the connection status. | Verify that the connection **Status** displays as connected.<br> <br>If the connection status is pending or disconnected, verify that the source is operational and that the firewall is able to access the source. If you use a port other than the MGT port for communicating with the monitored source, you must change the service route (**Device > Setup > Services**, click the **Service Route Configuration** link and modify the **Source Interface** for the **VM Monitor** service). |

 © Palo Alto Networks, Inc.

## Attributes Monitored in the AWS and VMware Environments

Each VM on a monitored ESXi or vCenter server must have VMware Tools installed and running. VMware Tools provide the capability to glean the IP address(es) and other values assigned to each VM.

In order to collect the values assigned to the monitored VMs, the firewall monitors the following predefined set of attributes:

| Attributes Monitored on a VMware Source | Attributes Monitored on the AWS-VPC |
|---|---|
| • UUID | • Architecture |
| • Name | • Guest OS |
| • Guest OS | • Image ID |
| • VM State — the power state can be poweredOff, poweredOn, standBy, and unknown. | • Instance ID |
| • Annotation | • Instance State |
| • Version | • Instance Type |
| • Network — Virtual Switch Name, Port Group Name, and VLAN ID | • Key Name |
| • Container Name —vCenter Name, Data Center Object Name, Resource Pool Name, Cluster Name, Host, Host IP address. | • Placement—Tenancy, Group Name, Availability Zone |
| | • Private DNS Name |
| | • Public DNS Name |
| | • Subnet ID |
| | • Tag (key, value) (up to5 tags supported per instance |
| | • VPC ID |

## Use Dynamic Address Groups in Policy

Dynamic address groups are used in policy. They allow you to create policy that automatically adapts to changes—adds, moves, or deletions of servers. It also enables the flexibility to apply different rules to the same server based on *tags* that define its role on the network, the operating system, or the different kinds of traffic it processes.

A dynamic address group uses tags as a filtering criteria to determine its members. The filter uses logical *and* and *or* operators. All IP addresses or address groups that match the filtering criteria become members of the dynamic address group. Tags can be defined statically on the firewall and/or registered (dynamically) to the firewall. The difference between static and dynamic tags is that static tags are part of the configuration on the firewall, and dynamic tags are part of the runtime configuration. This implies that a commit is not required to update dynamic tags; the tags must however be used by Dynamic Address Groups that are referenced in policy, and the policy must be committed on the device.

To dynamically register tags, you can use the XML API or the VM Monitoring agent on the firewall or on the User-ID agent. Each tag is a metadata element or attribute-value pair that is registered on the firewall or Panorama. For example, IP1 {tag1, tag2,.....tag32}, where the IP address and the associated tags are maintained as a list; each registered IP address can have up to 32 tags such as the operating system, the datacenter or the virtual switch to which it belongs. Within 60 seconds of the API call, the firewall registers the IP address and associated tags, and automatically updates the membership information for the dynamic address group(s).

The maximum number of IP addresses that can be registered for each platform is different. Use the following table for specifics on your platform:

| Platform | Maximum number of dynamically registered IP addresses |
|---|---|
| PA-7050, PA-5060, VM-1000-HV | 100,000 |
| PA-5050 | 50,000 |
| PA-5020 | 25,000 |
| PA-4000 Series, PA-3000 Series | 5000 |
| PA-2000 Series, PA-500, PA-200, VM-300, VM-200, VM-100 | 1000 |

The following example shows how dynamic address groups can simplify network security enforcement. The example workflow shows how to:

- Enable the VM Monitoring agent on the firewall, to monitor the VMware ESX(i) host or vCenter Server and register VM IP addresses and the associated tags.
- Create dynamic address groups and define the tags to filter. In this example, two address groups are created. One that only filters for dynamic tags and another that filters for both static and dynamic tags to populate the members of the group.
- Validate that the members of the dynamic address group are populated on the firewall.
- Use dynamic address groups in policy. This example uses two different security policies:
  - A security policy for all Linux servers that are deployed as FTP servers; this rule matches on dynamically registered tags.

 © Palo Alto Networks, Inc.

– A security policy for all Linux servers that are deployed as web servers; this rule matches on a dynamic address group that uses static and dynamic tags.

- Validate that the members of the dynamic address groups are updated as new FTP or web servers are deployed. This ensure that the security rules are enforced on these new virtual machines too.

| **Use Dynamic Address Groups in Policy** | |
|---|---|
| Step 1 Enable VM Source Monitoring. | See Enable VM Monitoring to Track Changes on the Virtual Network. |
| Step 2 Create dynamic address groups on the firewall.<br><br>View the tutorial to see a big picture view of the feature. | 1. Log in to the web interface of the firewall.<br>2. Select **Object > Address Groups**.<br>3. Click **Add** and enter a **Name** and a **Description** for the address group.<br>4. Select **Type** as **Dynamic**.<br>5. Define the match criteria. You can select dynamic and static tags as the match criteria to populate the members of the group. Click **Add Match Criteria**, and select the **And** or **Or** operator and select the attributes that you would like to filter for or match against. and then click **OK**.<br> <br><br>6. Click **Commit**. |

The match criteria for each dynamic address group in this example is as follows:

ftp_server: matches on the guest operating system “Linux 64-bit” and annotated as “ftp” ('guestos.Ubuntu Linux 64-bit' and 'annotation.ftp').

web-servers: matches on two criteria—the tag black or if the guest operating system is Linux 64-bit and the name of the server us Web_server_Corp. ('guestos.Ubuntu Linux 64-bit' and 'vmname.WebServer_Corp' or 'black')

**Use Dynamic Address Groups in Policy (Continued)**

Step 3 Use dynamic address groups in policy.

View the tutorial.

1. Select **Policies > Security**.
2. Click **Add** and enter a **Name** and a **Description** for the policy.
3. Add the **Source Zone** to specify the zone from which the traffic originates.
4. Add the **Destination Zone** at which the traffic is terminating.
5. For the **Destination Address**, select the Dynamic address group you created in Step 2 above.
6. Specify the action— **Allow** or **Deny**—for the traffic, and optionally attach the default security profiles to the rule.
7. Repeats Steps 1 through 6 above to create another policy rule.
8. Click **Commit**.

This example shows how to create two policies: one for all access to FTP servers and the other for access to web servers.

Step 4 Validate that the members of the dynamic address group are populated on the firewall.

1. Select **Policies > Security**, and select the rule.
2. Select the drop-down arrow next to the address group link, and select **Inspect**. You can also verify that the match criteria is accurate.

3. Click the **more** link and verify that the list of registered IP addresses is displayed.

Policy will be enforced for all IP addresses that belong to this address group, and are displayed here.

© Palo Alto Networks, Inc.

# CLI Commands for Dynamic IP Addresses and Tags

The Command Line Interface on the firewall and Panorama give you a detailed view into the different sources from which tags and IP addresses are dynamically registered. It also allows you to audit registered and unregistered tags. The following examples illustrate the capabilities in the CLI.

| Example | CLI Command |
|---|---|
| View all registered IP addresses that match the tag, `state.poweredOn` or that are not tagged as `vSwitch0` | `show log iptag tag_name equal state.poweredOn`<br>`show log iptag tag_name not-equal switch.vSwitch0` |
| View all dynamically registered IP addresses that were sourced by VM Information Source with name `vmware1` and tagged as `poweredOn` | `show vm-monitor source source-name vmware1 tag state.poweredOn registered-ip all`<br><br>`registered IP Tags`<br>`---------- ----------`<br>`fe80::20c:29ff:fe69:2f76 "state.poweredOn"`<br>`10.1.22.100 "state.poweredOn"`<br>`2001:1890:12f2:11:20c:29ff:fe69:2f76 "state.poweredOn"`<br>`fe80::20c:29ff:fe69:2f80 "state.poweredOn"`<br>`192.168.1.102 "state.poweredOn"`<br>`10.1.22.105 "state.poweredOn"`<br>`2001:1890:12f2:11:2cf8:77a9:5435:c0d "state.poweredOn"`<br>`fe80::2cf8:77a9:5435:c0d "state.poweredOn"` |
| Clear all IP addresses and tags learned from a specific VM Monitoring source without disconnecting the source. | `debug vm-monitor clear source-name <name>` |
| Display IP addresses registered from all sources. | `show object registered-ip all` |
| Display the count for IP addresses registered from all sources. | `show object registered-ip all option count` |
| Clear IP addresses registered from all sources | `debug object registered-ip clear all` |
| Add or delete tags for a given IP address that was registered using the XML API. | `debug object test registered-ip [<register/unregister>] <ip/netmask> <tag>` |

| Example | CLI Command |
|---|---|
| View all tags registered from a specific information source. | `show vm-monitor source source-name vmware1 tag all`<br>`vlanId.4095`<br>`vswitch.vSwitch1`<br>`host-ip.10.1.5.22`<br>`portgroup.TOBEUSED`<br>`hostname.panserver22`<br>`portgroup.VM Network 2`<br>`datacenter.ha-datacenter`<br>`vlanId.0`<br>`state.poweredOn`<br>`vswitch.vSwitch0`<br>`vmname.Ubuntu22-100`<br>`vmname.win2k8-22-105`<br>`resource-pool.Resources`<br>`vswitch.vSwitch2`<br>`guestos.Ubuntu Linux 32-bit`<br>`guestos.Microsoft Windows Server 2008 32-bit`<br>`annotation.`<br>`version.vmx-08`<br>`portgroup.VM Network`<br>`vm-info-source.vmware1`<br>`uuid.564d362c-11cd-b27f-271f-c361604dfad7`<br>`uuid.564dd337-677a-eb8d-47db-293bd6692f76`<br>`Total: 22` |
| View all tags registered from a specific data source, for example from the VM Monitoring Agent on the firewall, the XML API, Windows User-ID Agent or the CLI. | • To view tags registered from the CLI:<br>`show log iptag datasource_type equal unknown`<br>• To view tags registered from the XML API:<br>`show log iptag datasource_type equal xml-api`<br>• To view tags registered from VM Information sources:<br>`show log iptag datasource_type equal vm-monitor`<br>• To view tags registered from the Windows User-ID agent:<br>`show log iptag datasource_type equal xml-api datasource_subtype equal user-id-agent` |
| View all tags that are registered for a specific IP address (across all sources). | `debug object registered-ip show tag-source ip` *`ip_address`* `tag all` |

 © Palo Alto Networks, Inc.

# Policy-Based Forwarding

Normally, the firewall uses the destination IP address in a packet to determine the outgoing interface. The firewall uses the routing table associated with the virtual router to which the interface is connected to perform the route lookup. Policy-Based Forwarding (PBF) allows you to override the routing table, and specify the outgoing or *egress* interface based on specific parameters such as source or destination IP address, or type of traffic.

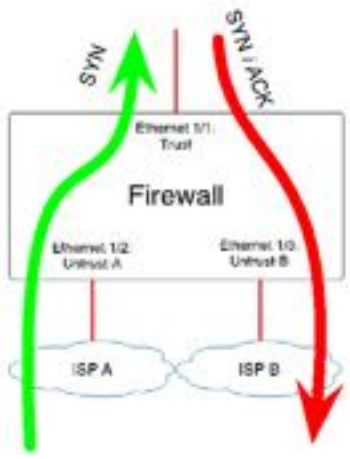
- PBF
- Create a Policy-Based Forwarding Rule
- Use Case: PBF for Outbound Access with Dual ISPs
- Use Case: PBF for Routing Traffic Through Virtual Systems

# PBF

PBF rules allow traffic to take an alternative path from the next hop specified in the route table, and are typically used to specify an egress interface for security or performance reasons. Let's say your company has two links between the corporate office and the branch office: a cheaper Internet link and a more expensive leased line. The leased line is a high-bandwidth, low-latency link. For enhanced security, you can use PBF to send applications that aren't encrypted traffic, such as FTP traffic, over the private leased line and all other traffic over the Internet link. Or, for performance, you can choose to route business-critical applications over the leased line while sending all other traffic, such as web browsing, over the cheaper link.

## Egress Path and Symmetric Return

Using PBF, you can direct traffic to a specific interface on the firewall, drop the traffic, or direct traffic to another virtual system (on systems enabled for multiple virtual systems).



In networks with asymmetric routes, such as in a dual ISP environment, connectivity issues occur when traffic arrives at one interface on the firewall and leaves from another interface. If the route is asymmetrical, where the forward (SYN packet) and return (SYN/ACK) paths are different, the firewall is unable to track the state of the entire session and this causes a connection failure. To ensure that the traffic uses a symmetrical path, which means that the traffic arrives at and leaves from the same interface on which the session was created, you can enable the *Symmetric Return* option.

With symmetric return, the virtual router overrides a routing lookup for return traffic and instead directs the flow back to the MAC address from which it received the SYN packet (or first packet). However, if the destination IP address is on the same subnet as the ingress/egress interface's IP address, a route lookup is performed and symmetric return is not enforced. This behavior prevents traffic from being blackholed.

To determine the next hop for symmetric returns, the firewall uses an Address Resolution Protocol (ARP) table. The maximum number of entries that this ARP table supports is limited by the firewall model and the value is not user configurable. To determine the limit for your model, use the CLI command: **`show pbf return-mac all`**.

## Path Monitoring

Path monitoring allows you to verify connectivity to an IP address so that the firewall can direct traffic through an alternate route, when needed. The firewall uses ICMP pings as *heartbeats* to verify that the specified IP address is reachable.

A monitoring profile allows you to specify the threshold number of heartbeats to determine whether the IP address is reachable. When the monitored IP address is unreachable, you can either disable the PBF rule or specify a *fail-over* or *wait-recover* action. Disabling the PBF rule allows the virtual router to take over the routing decisions.

 © Palo Alto Networks, Inc.

The following table lists the difference in behavior for a path monitoring failure on a new session versus an established session.

| Behavior of a session on a monitoring failure | If the rule stays enabled when the monitored IP address is unreachable<br>☐ Disable this rule if nexthop/monitor ip is unreachable | If rule is disabled when the monitored IP address is unreachable<br>☑ Disable this rule if nexthop/monitor ip is unreachable |
|---|---|---|
| For an established session | **wait-recover**—Continue to use egress interface specified in the PBF rule | **wait-recover**—Continue to use egress interface specified in the PBF rule |
| | **fail-over**—Use path determined by routing table (no PBF) | **fail-over**—Use path determined by routing table (no PBF) |
| For a new session | **wait-recover**—Use path determined by routing table (no PBF) | **wait-recover**—Check the remaining PBF rules. If no match, use the routing table |
| | **fail-over**—Use path determined by routing table (no PBF) | **fail-over**—Check the remaining PBF rules. If no match, use the routing table |

## Service Versus Applications in PBF

PBF rules are applied either on the first packet (SYN) or the first response to the first packet (SYN/ACK). This means that a PBF rule may be applied before the firewall has enough information to determine the application. Therefore, application-specific rules are not recommended for use with PBF. Whenever possible, use a service object, which is the Layer 4 port (TCP or UDP) used by the protocol or application.

However, if you specify an application in a PBF rule, the firewall performs *App-ID caching*. When an application passes through the firewall for the first time, the firewall does not have enough information to identify the application and therefore cannot enforce the PBF rule. As more packets arrive, the firewall determines the application and creates an entry in the App-ID cache and retains this App-ID for the session.When a new session is created with the same destination IP address, destination port, and protocol ID, the firewall could identify the application as the same from the initial session (based on the App-ID cache) and apply the PBF rule. Therefore, a session that is not an exact match and is not the same application, can be forwarded based on the PBF rule.

Further, applications have dependencies and the identity of the application can change as the firewall receives more packets. Because PBF makes a routing decision at the start of a session, the firewall cannot enforce a change in application identity. YouTube, for example, starts as web-browsing but changes to Flash, RTSP, or YouTube based on the different links and videos included on the page. However with PBF, because the firewall identifies the application as web-browsing at the start of the session, the change in application is not recognized thereafter.

PBF rules cannot be based on domain names; only IP addresses are valid; also, you cannot use custom-applications, application-filters or application groups in PBF rules.

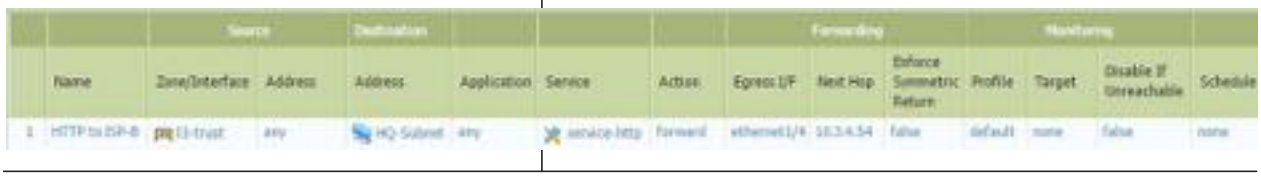
# Create a Policy-Based Forwarding Rule

Use a PBF rule to direct traffic to a specific egress interface on the firewall, and override the default path for the traffic.

| Create a PBF Rule | |
|---|---|
| Step 1 Create a PBF rule.<br><br>When creating a PBF rule you must specify a name for the rule, a source zone or interface, and an egress interface. All other components are either optional or have a default value provided. | 1. Select **Policies > Policy Based Forwarding** and click **Add.**<br>2. Give the rule a descriptive name in the **General** tab.<br>3. In the **Source** tab, select the following:<br>a. Select the **Type**—**Zone** or **Interface**— to which the forwarding policy will be applied, and the relevant zone or interface.<br><br>PBF is only supported on Layer 3 interfaces.<br><br>b. (Optional) Specify the **Source Address** to which PBF will apply. For example, a specific IP address or subnet IP address from which you want to forward traffic to the interface or zone specified in this rule.<br><br>Use the **Negate** option to exclude a one or more source IP addresses from the PBF rule. For example, if your PBF rule directs all traffic from the specified zone to the Internet, **Negate** allows you to exclude internal IP addresses from the PBF rule.<br><br>The evaluation order is top down. A packet is matched against the first rule that meets the defined criteria; after a match is triggered the subsequent rules are not evaluated.<br><br>c. (Optional) **Add** and select the **Source User** or groups of users to whom the policy applies.<br>4. In the **Destination/Application/Service** tab, select the following:<br>a. **Destination Address**. By default the rule applies to **Any** IP address. Use the **Negate** option to exclude one or more destination IP addresses from the PBF rule.<br><br>b. Select the Application(s) or Service(s) that you want to control using PBF.<br><br>Application-specific rules are not recommended for use with PBF. Whenever possible, use a service object, which is the Layer 4 port (TCP or UDP) used by the protocol or application. For more details, see Service Versus Applications in PBF. |

© Palo Alto Networks, Inc.

| Create a PBF Rule | |
|---|---|
| | 5. In the **Forwarding** tab, select the following:<br>a. Set the **Action.** The options are as follows:<br>– **Forward**—Directs the packet to a specific **Egress Interface**. Enter the **Next Hop** IP address for the packet.<br>– **Forward To VSYS**—(On a device enabled for multiple virtual systems) Select the virtual system to which to forward the packet.<br>– **Discard**—Drop the packet.<br>– **No PBF**—Exclude the packets that match the criteria for source/destination/application/service defined in the rule. Matching packets use the route table instead of PBF; the firewall uses the route table to exclude the matched traffic from the redirected port.<br>To trigger the specified action at a daily, weekly or non-recurring frequency, create and attach a **Schedule**.<br>b. (Optional) Enable Monitoring to verify connectivity to a target IP address or to the next hop IP address. Select **Monitor** and attach a monitoring **Profile** (default or custom) that specifies the action when the IP address is unreachable.<br>c. (Optional, required for asymmetric routing environments) Select **Enforce Symmetric Return** and enter one or more IP addresses in the **Next Hop Address List**.<br>Enabling symmetric return ensures that return traffic (say, from the Trust zone on the LAN to the Internet) is forwarded out through the same interface through which traffic ingresses from the Internet. |
| Step 2 Save the policies to the running configuration on the device. | Click **Commit**.<br>The PBF rule is in effect. |



## Use Case: PBF for Outbound Access with Dual ISPs

In this use case, the branch office has a dual ISP configuration and implements PBF for redundant Internet access. The backup ISP is the default route for traffic from the client to the web servers. In order to enable redundant Internet access without using an internetwork protocol such as BGP, we use PBF with destination interface-based source NAT and static routes, and configure the firewall as follows:

- Enable a PBF rule that routes traffic through the primary ISP, and attach a monitoring profile to the rule. The monitoring profile triggers the firewall to use the default route through the backup ISP when the primary ISP is unavailable.
- Define Source NAT rules for both the primary and backup ISP that instruct the firewall to use the source IP address associated with the egress interface for the corresponding ISP. This ensures that the outbound traffic has the correct source IP address.
- Add a static route to the backup ISP, so that when the primary ISP is unavailable, the default route comes into effect and the traffic is directed through the backup ISP.

 © Palo Alto Networks, Inc.

| PBF for Outbound Access with Dual ISPs | | |
|---|---|---|
| Step 1 | Configure the ingress and the egress interfaces on the firewall.<br><br>Egress interfaces can be in the same zone. In this example we assign the egress interfaces to different zones. | 1. Select **Network > Interfaces** and then select the interface you want to configure, for example, Ethernet1/1 and Ethernet1/3.<br>The interface configuration on the firewall used in this example is as follows:<br>• Ethernet 1/1 connected to the primary ISP:<br>– Zone: ISP-East<br>– IP Address:1.1.1.2/30<br>– Virtual Router: Default<br>• Ethernet 1/3 connected to the backup ISP:<br>– Zone: ISP-West<br>– IP Address:2.2.2.2/30<br>– Virtual Router: Default<br>• Ethernet 1/2 is the ingress interface, used by the network clients to connect to the Internet:<br>– Zone: Trust<br>– IP Address:192.168. 54.1/24<br>– Virtual Router: Default<br>2. To save the interface configuration, click **OK**. |
| Step 2 | On the virtual router, add a static route to the backup ISP. | 1. Select **Network > Virtual Router** and then select the **default** link to open the Virtual Router dialog.<br>2. Select the **Static Routes** tab and click **Add**. Enter a **Name** for the route and specify the **Destination** IP address for which you are defining the static route. In this example, we use 0.0.0.0/0 for all traffic.<br>3. Select the **IP Address** radio button and set the **Next Hop** IP address for your router that connects to the backup Internet gateway. In this example, 2.2.2.1.<br>4. Specify a cost metric for the route. In this example, we use 10.<br> <br>5. Click **OK** twice to save the virtual router configuration. |

**PBF for Outbound Access with Dual ISPs**

Step 3 Create a PBF rule that directs traffic to the interface that is connected to the primary ISP.

Make sure to exclude traffic destined to internal servers/IP addresses from PBF. Define a negate rule so that traffic destined to internal IP addresses is not routed through the egress interface defined in the PBF rule.

1. Select **Policies > Policy Based Forwarding** and click **Add.**
2. Give the rule a descriptive **Name** in the **General** tab.
3. In the **Source** tab, set the **Source Zone** to Trust.
4. In the **Destination/Application/Service** tab, set the following:
   a. In the Destination Address section, **Add** the IP addresses or address range for servers on the internal network or create an address object for your internal servers. Select **Negate** to exclude the IP addresses or address object listed above from using this rule.
   b. In the Service section, **Add** the **service-http** and **service-https** services to allow HTTP and HTTPS traffic to use the default ports. For all other traffic that is allowed by security policy, the default route will be used.

   To forward all traffic using PBF, set the Service to **Any**.

5. In the **Forwarding** tab, specify the interface to which you want to forward traffic and enable path monitoring.
   a. To forward traffic, set the **Action** to **Forward**, and select the **Egress Interface** and specify the **Next Hop**. In this example, the egress interface is ethernet1/1, and the next hop IP address is 1.1.1.1.

© Palo Alto Networks, Inc.

**PBF for Outbound Access with Dual ISPs**

b. Enable **Monitor** and attach the default monitoring profile, to trigger a failover to the backup ISP. In this example, we do not specify a target IP address to monitor. The firewall will monitor the next hop IP address; if this IP address is unreachable the firewall will direct traffic to the default route specified on the virtual router.

c. (Required if you have asymmetric routes). Select **Enforce Symmetric Return** to ensure that return traffic from the Trust zone to the Internet is forwarded out on the same interface through which traffic ingressed from the Internet.

NAT ensures that the traffic from the Internet is returned to the correct interface/IP address on the firewall.

d. Click **OK** to save the changes.

**PBF for Outbound Access with Dual ISPs**

Step 4 Create NAT rules based on the egress interface and ISP. These rules ensure that the correct source IP address is used for outbound connections.

1. Select **Policies > NAT** and click **Add**.
2. In this example, the NAT rule we create for each ISP is as follows:

**NAT for Primary ISP**

In the **Original Packet** tab,

- **Source Zone**: Trust
- **Destination Zone**: ISP-West

In the **Translated Packet** tab, under Source Address Translation

- **Translation Type**: Dynamic IP and Port
- **Address Type**: Interface Address
- **Interface**: ethernet1/1
- **IP Address**: 1.1.1.2/30

**NAT for Backup ISP**

In the **Original Packet** tab,

- **Source Zone**: Trust
- **Destination Zone**: ISP-East

In the **Translated Packet** tab, under Source Address Translation

- **Translation Type**: Dynamic IP and Port
- **Address Type**: Interface Address
- **Interface**: ethernet1/3
- **IP Address**: 2.2.2.2/30

 © Palo Alto Networks, Inc.

| PBF for Outbound Access with Dual ISPs | | |
|---|---|---|
| Step 5 | Create security policy to allow outbound access to the Internet. | To safely enable applications, create a simple rule that allows access to the Internet and attach the security profiles available on the firewall.<br>1. Select **Policies > Security** and click **Add**.<br>2. Give the rule a descriptive **Name** in the **General** tab.<br>3. In the **Source** tab, set the **Source Zone** to Trust.<br>4. In the **Destination** tab, Set the **Destination Zone** to ISP-East and ISP-West.<br>5. In the **Service/ URL Category** tab, leave the default **application-default**.<br>6. In the **Actions** tab, complete these tasks:<br>a. Set the **Action Setting** to **Allow**.<br>b. Attach the default profiles for antivirus, anti-spyware, vulnerability protection and URL filtering, under **Profile Setting.**<br>7. Under **Options**, verify that logging is enabled at the end of a session. Only traffic that matches a security rule is logged.<br>  |
| Step 6 | Save the policies to the running configuration on the device. | Click **Commit**. |

**PBF for Outbound Access with Dual ISPs**

**Step 7** Verify that the PBF rule is active and that the primary ISP is used for Internet access.

1. Launch a web browser and access a web server. On the firewall check the traffic log for web-browsing activity.

2. From a client on the network, use the ping utility to verify connectivity to a web server on the Internet. and check the traffic log on the firewall.

```
C:\Users\pm-user1>ping 4.2.2.1
Pinging 4.2.2.1 with 32 bytes of data:
Reply from 4.2.2.1: bytes=32 time=34ms TTL=117
Reply from 4.2.2.1: bytes=32 time=13ms TTL=117
Reply from 4.2.2.1: bytes=32 time=25ms TTL=117
Reply from 4.2.2.1: bytes=32 time=3ms TTL=117
Ping statistics for 4.2.2.1:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
    Minimum = 3ms, Maximum = 34ms, Average = 18ms
```

3. To confirm that the PBF rule is active, use the CLI command **show pbf rule all**

```
admin@PA-NGFW> show pbf rule all
Rule       ID    Rule State Action   Egress IF/VSYS  NextHop
========== === ========== ====== ============== =======
Use ISP-Pr 1     Active     Forward ethernet1/1     1.1.1.1
```

**Step 8** Verify that the failover to the backup ISP occurs and that the Source NAT is correctly applied.

1. Unplug the connection to the primary ISP.
2. Confirm that the PBF rule is inactive with the CLI command **show pbf rule all**

```
admin@PA-NGFW> show pbf rule all
Rule       ID    Rule State Action   Egress IF/VSYS  NextHop
========== === ========== ====== ============== =======
Use ISP-Pr 1   Disabled   Forward   ethernet1/1     1.1.1.1
```

3. Access a web server, and check the traffic log to verify that traffic is being forwarded through the backup ISP.

 © Palo Alto Networks, Inc.

**PBF for Outbound Access with Dual ISPs**

4. View the session details to confirm that the NAT rule is working properly.

```
admin@PA-NGFW> show session all
--------------------------------------------------------------
ID Application    State   Type Flag Src[Sport]/Zone/Proto
  (translated IP[Port]) Vsys Dst[Dport]/Zone (translated
  IP[Port])
--------------------------------------------------------------
87212 ssl ACTIVE  FLOW  NS   192.168.54.56[53236]/Trust/6
  (2.2.2.2[12896]) vsys1 204.79.197.200[443]/ISP-East
  (204.79.197.200[443])
```

5. Obtain the session identification number from the output and view the session details. Note that the PBF rule is not used and hence is not listed in the output.

```
admin@PA-NGFW> show session id 87212

Session           87212

        c2s flow:

# DoS Protection Against Flooding of New Sessions

The following topics describe how to configure DoS protection to better block IP addresses in order to handle high-volume attacks more efficiently.

- DoS Protection Against Flooding of New Sessions
- Configure DoS Protection Against Flooding of New Sessions
- Use the CLI to End a Single Attacking Session
- Identify Sessions That Use an Excessive Percentage of the Packet Buffer
- Discard a Session Without a Commit

 © Palo Alto Networks, Inc.

# DoS Protection Against Flooding of New Sessions

DoS protection against flooding of new sessions is beneficial against high-volume single-session and multiple-session attacks. In a single-session attack, an attacker uses a single session to target a device behind the firewall. If a Security policy rule allows the traffic, the session is established and the attacker initiates an attack by sending packets at a very high rate with the same source IP address and port number, destination IP address and port number, and protocol, trying to overwhelm the target. In a multiple-session attack, an attacker uses multiple sessions (or connections per second [cps]) from a single host to launch a DoS attack.

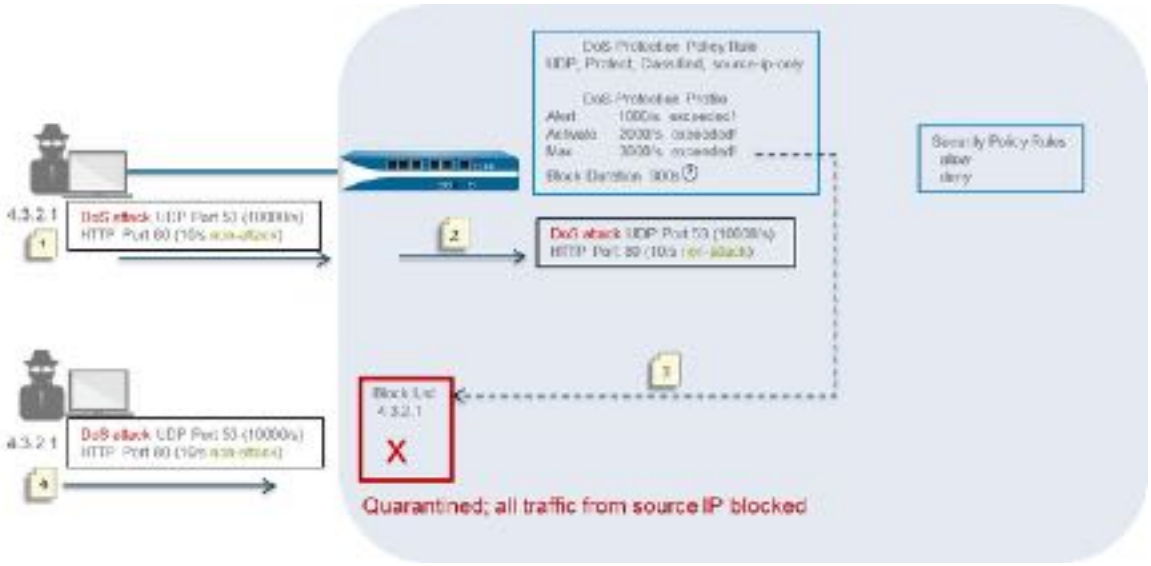
This feature defends only against DoS attacks of new sessions, that is, traffic that has not been offloaded to hardware. An offloaded attack is not protected by this feature. However, this topic describes how you can create a Security policy rule to reset the client; the attacker reinitiates the attack with numerous connections per second and is blocked by the defenses illustrated in this topic.

▲ Multiple-Session DoS Attack
▲ Single-Session DoS Attack

## Multiple-Session DoS Attack

Configure DoS Protection Against Flooding of New Sessions by configuring a DoS Protection policy rule, which determines the criteria that, when matched by incoming packets, trigger the protect action. The DoS Protection profile counts each new connection toward the Alarm Rate, Activate Rate, and Max Rate thresholds. When the incoming new connections per second exceed the Max Rate allowed, the firewall takes the action specified in the DoS Protection policy rule.

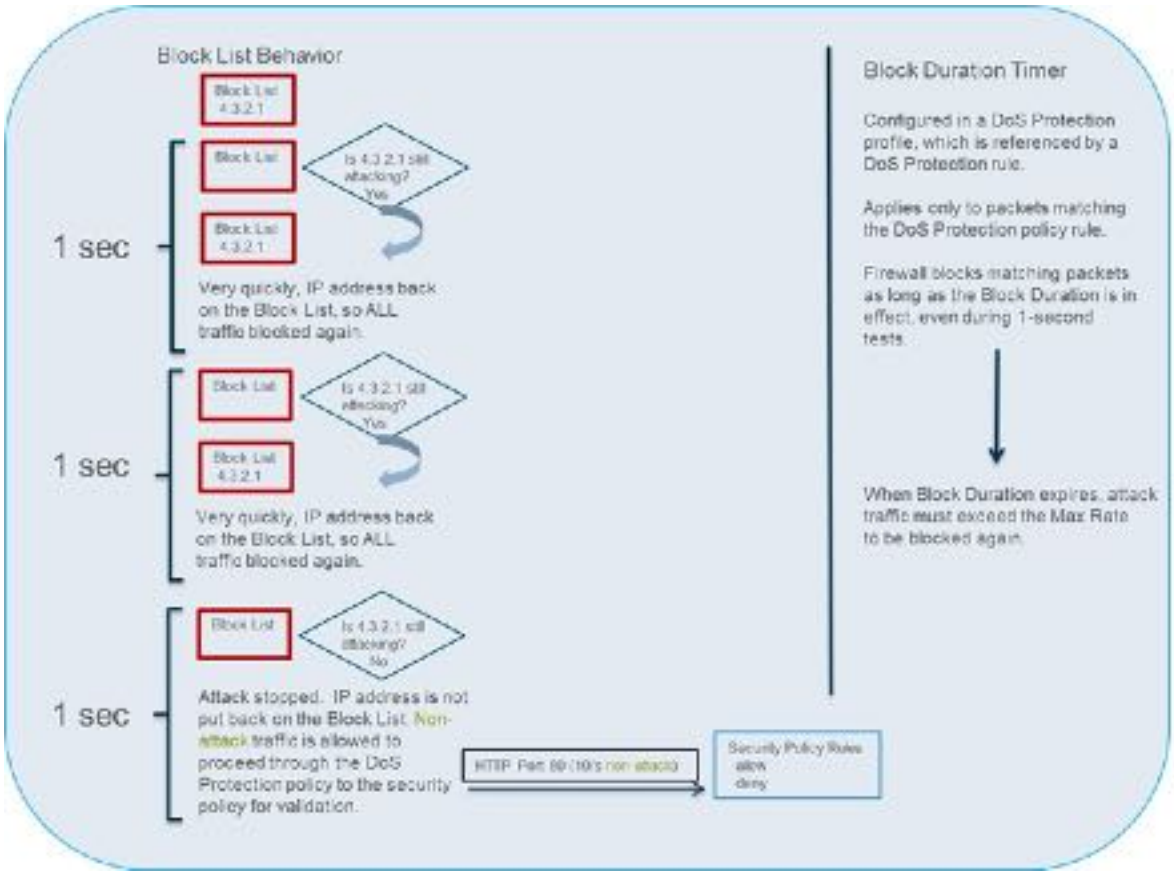
The following figure and table describe how the Security policy rules, DoS Protection policy rules and profile work together in an example.



| Sequence of Events as Firewall Quarantines an IP Address | |
|---|---|
| 1 | In this example, an attacker launches a DoS attack at a rate of 10,000 new connections per second to UDP port 53. The attacker also sends 10 new connections per second to HTTP port 80. |
| 2 | The new connections match criteria in the DoS Protection policy rule, such as a source zone or interface, source IP address, destination zone or interface, destination IP address, or a service, among other settings. In this example, the policy rule specifies UDP.<br>The DoS rule also specifies the Protect action and Classified, two settings that dynamically put the DoS Protection Profile settings into effect. The DoS Protection Profile specifies that a Max Rate of 3000 packets per second is allowed. When incoming packets match the DoS rule, new connections per second are counted toward the Alert, Activate, and Max Rate thresholds.<br>You can also use a Security policy rule to block all traffic from the source IP address if you deem that address to be malicious all the time. |
| 3 | The 10,000 new connections per second exceed the Max Rate threshold. When all of the following occur:<br>• the threshold is exceeded,<br>• a Block Duration is specified, and<br>• Classified is set to includes source IP address,<br>the firewall puts the offending source IP address on the block list. |
| 4 | An IP address on the block list is in quarantine, meaning all traffic from that IP address is blocked. The firewall blocks the offending source IP address before additional attack packets reach the security policy. |

The following figure describes in more detail what happens after an IP address that matches the DoS Protection policy rule is put on the block list. It also describes the Block Duration timer.

 © Palo Alto Networks, Inc.



Every one second, the firewall allows the IP address to come off the Block List so that the firewall can test the traffic patterns and determine if the attack is ongoing. The firewall takes the following action:

- During this one-second test period, the firewall allows packets that do not match the DoS Protection policy criteria (HTTP traffic in this example) through the DoS Protection policy rules to the Security policy for validation. Very few packets, if any, have time to get through because the first attack packet that the firewall receives after the IP address is let off the Block List will match the DoS Protection policy criteria, quickly causing the IP address to be placed back on the block list for another second. The firewall repeats this test each second until the attack stops.
- The firewall blocks all attack traffic from going past the DoS Protection policy rules until the Block Duration expires.

When the attack stops, the firewall does not put the IP address back on the Block List. The firewall allows non-attack traffic to proceed through the DoS Protection policy rules to the Security policy rules for validation. You must configure a Security policy rule because without one, an implicit deny rule denies all traffic.

The block list is based on a source zone and source address combination. This behavior allows duplicate IP addresses to exist as long as they are in different zones belonging to separate virtual routers.

The Block Duration setting in a DoS Protection profile specifies how long the firewall blocks the [offending] packets that exactly match a DoS Protection policy rule. The attack traffic remains blocked until the Block Duration expires, after which the attack traffic must again exceed the Max Rate threshold to be blocked again.

If the attacker uses multiple sessions or bots that initiate multiple attack sessions, the sessions count toward the thresholds in the DoS Protection profile without a Security policy deny rule in place. Hence, a single-session attack requires a Security policy deny rule in order for each packet to count toward the thresholds; a multiple-session attack does not.

Therefore, the DoS protection against flooding of new sessions allows the firewall to efficiently defend against a source IP address while attack traffic is ongoing and to permit non-attack traffic to pass as soon as the attack stops. Putting the offending IP address on the block list allows the DoS protection functionality to take advantage of the block list, which is designed to quarantine all activity. Quarantining the IP address from all activity protects against a modern attacker who attempts a rotating application attack, in which the attacker simply changes applications to start a new attack or uses a combination of different attacks in a hybrid DoS attack.

Beginning with PAN-OS 6.1.7, it is a change in behavior that the firewall places the attacking source IP address on the block list. When the attack stops, non-attack traffic is allowed to proceed to the Security policy rules. The attack traffic that matched the DoS Protection profile and DoS Protection policy rules remains blocked until the Block Duration expires.

## Single-Session DoS Attack

A single-session DoS attack typically will not trigger Zone or DoS Protection profiles because they are attacks that are formed after the session is created. These attacks are allowed by the Security policy because a session is allowed to be created, and after the session is created, the attack drives up the packet volume and takes down the target device.

Configure DoS Protection Against Flooding of New Sessions to protect against flooding of new sessions (single-session and multiple-session flooding). In the event of a single-session attack that is underway, additionally Use the CLI to End a Single Attacking Session.

 © Palo Alto Networks, Inc.

# Configure DoS Protection Against Flooding of New Sessions

| Configure DoS Protection Against Flooding of New Sessions | | |
|---|---|---|
| Step 1 | (Required for single-session attack mitigation or attacks that have not triggered the DoS Protection policy threshold; optional for multiple-session attack mitigation)<br><br>Configure Security policy rules to deny traffic from the attacker's IP address and allow other traffic based on your network needs. You can specify any of the match criteria in a Security policy rule, such as source IP address.<br><br> This step is one of the steps typically performed to stop an existing attack. See Use the CLI to End a Single Attacking Session. | • Set Up Basic Security Policies<br>• Components of a Security Policy Rule |

**Configure DoS Protection Against Flooding of New Sessions (Continued)**

Step 2 Configure a DoS Protection profile for flood protection.

Because flood attacks can occur over multiple protocols, as a best practice, activate protection for all of the flood types in the DoS Protection profile.

1. Select **Objects > Security Profiles > DoS Protection** and **Add** a profile **Name**.
2. Select **Classified** as the **Type**.
3. For **Flood Protection**, select the check boxes for all of the following types of flood protection:
   - **SYN Flood**
   - **UDP Flood**
   - **ICMP Flood**
   - **ICMPv6 Flood**
   - **Other IP Flood**
4. (Optional) On each of the flood tabs, change the following thresholds to suit your environment:
   - **Alarm Rate (packets/s)**—Specify the threshold rate (packets per second [pps]) above which a DoS alarm is generated. (Range is 0-2000000; default is 10000.)
   - **Activate Rate (packets/s)**—Specify the threshold rate (pps) above which a DoS response is activated. The DoS response is configured in the **Action** field of the DoS policy where this profile is referenced. When the **Activate Rate** threshold is reached, **Random Early Drop** occurs. (Range is 0-2000000; default is 10000.)
   - **Max Rate (packets/s)**—Specify the threshold rate of incoming packets per second that the firewall allows. When the threshold is exceeded, new packets that arrive are dropped and the **Action** specified in the DoS Policy rule is triggered. (Range is 2-2000000; default is 40000.)

   The default threshold values in this step are only starting points and might not be appropriate for your network. You must analyze the behavior of your network to properly set initial threshold values.
5. On each of the flood tabs, specify the **Block Duration** (in seconds), which is the length of time the firewall blocks packets that match the DoS Protection policy rule that references this profile. Specify a value greater than zero. (Range is 1-21600; default is 300.)

   Set a low Block Duration value if you are concerned that packets you incorrectly identified as attack traffic will be blocked unnecessarily.

   Set a high Block Duration value if you are more concerned about blocking volumetric attacks than you are about incorrectly blocking packets that are not part of an attack.
6. Click **OK**.

© Palo Alto Networks, Inc.

| Configure DoS Protection Against Flooding of New Sessions (Continued) | | |
|---|---|---|
| Step 3 | Configure a DoS Protection policy rule that specifies the criteria for matching the incoming traffic. | 1. Select **Policies > DoS Protection** and **Add** a **Name** on the **General** tab. The name is case-sensitive and can be a maximum of 31 characters, including letters, numbers, spaces, hyphens, and underscores.<br>2. On the **Source** tab, choose the **Type** to be a **Zone** or **Interface**, and then **Add** the zone(s) or interface(s).<br>3. (Optional) For **Source Address**, select **Any** for any incoming IP address to match the rule or **Add** an address object such as a geographical region.<br>4. (Optional) For **Source User**, select **any** or specify a user.<br>5. (Optional) Select **Negate** to match any sources except those you specify.<br>6. (Optional) On the **Destination** tab, choose the **Type** to be a **Zone** or **Interface**, and then **Add** the destination zone(s) or interface(s). For example, enter the security zone you want to protect.<br>7. (Optional) For **Destination Address**, select **Any** or enter the IP address of the device you want to protect.<br>8. (Optional) On the **Option/Protection** tab, **Add** a **Service**. Select a service or click **Service** and enter a **Name**. Select **TCP** or **UDP**. Enter a **Destination Port**. Not specifying a particular service allows the rule to match a flood of any protocol type without regard to an application-specific port.<br>9. On the **Option/Protection** tab, for **Action**, select **Protect**.<br>10. Select the **Classified** check box.<br>11. For **Profile**, select the name of the **DoS Protection** profile you created in Step 2.<br>12. For **Address**, select **source-ip-only** or **src-dest-ip-both**, which determines the type of IP address to which the rule applies. Choose the setting based on how you want the firewall to identify offending traffic.<br>• Specify **source-ip-only** if you want the firewall to classify only on the source IP address. Because attackers often test the entire network for hosts to attack, **source-ip-only** is the typical setting for a wider examination.<br>• Specify **src-dest-ip-both** if you want to protect only against DoS attacks on the server that has a specific destination address and also ensure that every source IP address will not surpass a specific connections-per-second threshold to that server.<br>13. Click **OK**. |
| Step 4 | Save the configuration. | Click **Commit**. |

## Use the CLI to End a Single Attacking Session

To mitigate a single-session DoS attack, you would still Configure DoS Protection Against Flooding of New Sessions in advance. At some point after you configure the feature, a session might be established before you realize a DoS attack (from the IP address of that session) is underway. When you see a single-session DoS attack, perform the following task to end the session, so that subsequent connection attempts from that IP address trigger the DoS protection against flooding of new sessions.

| Use the CLI to End a Single Attacking Session | |
|---|---|
| Step 1 | Identify the source IP address that is causing the attack.<br>For example, use the firewall Packet Capture feature with a destination filter to collect a sample of the traffic going to the destination IP address. Alternatively, in PAN-OS 7.0 and later, you can use ACC to filter on destination address to view the activity to the target host being attacked. |
| Step 2 | Create a DoS Protection policy rule that will block the attacker's IP address after the attack thresholds are exceeded. |
| Step 3 | Create a Security policy rule to deny the source IP address and its attack traffic. |
| Step 4 | End any existing attacks from the attacking source IP address by executing the `clear session all filter source <ip-address>` operational command.<br>Alternatively, if you know the session ID, you can execute the `clear session id <value>` command to end that session only.<br>If you use the `clear session all filter source <ip-address>` command, all sessions matching the source IP address are discarded, which can include both good and bad sessions. |

After you end the existing attack session, any subsequent attempts to form an attack session are blocked by the Security policy. The DoS Protection policy counts all connection attempts toward the thresholds. When the Max Rate threshold is exceeded, the source IP address is blocked for the Block Duration, as described in Sequence of Events as Firewall Quarantines an IP Address.

 © Palo Alto Networks, Inc.

## Identify Sessions That Use an Excessive Percentage of the Packet Buffer

When a firewall exhibits signs of resource depletion, it might be experiencing an attack that is sending an overwhelming number of packets. In such events, the firewall starts buffering inbound packets. With PAN-OS 6.1.10 and later PAN-OS 6.1 releases, you can quickly identify the sessions that are using an excessive percentage of the packet buffer and mitigate their impact by discarding them.

Perform the following task on any hardware-based firewall platform (not a VM-Series firewall) to identify, for each slot and dataplane, the packet buffer percentage used, the top five sessions using more than two percent of the packet buffer, and the source IP addresses associated with those sessions. Having that information allows you to take appropriate action.

**View Firewall Resource Usage, Top Sessions, and Session Details**

Step 1 View firewall resource usage, top sessions, and session details. Execute the following operational command in the CLI (sample output from the command follows):

```
admin@PA-7050> show running resource-monitor ingress-backlogs

-- SLOT:s1, DP:dp1 --
USAGE - ATOMIC: 92%  TOTAL: 93%

TOP SESSIONS:
SESS-ID      PCT   GRP-ID   COUNT
6            92%   1        156
                   7        1732

SESSION DETAILS
SESS-ID PROTO SZONE SRC           SPORT  DST       DPORT  IGR-IF    EGR-IF       APP
6       6     trust 192.168.2.35 55653  10.1.8.89 80  ethernet1/21 ethernet1/22
undecided
```

The command displays a maximum of the top five sessions that each use 2% or more of the packet buffer.

The sample output above indicates that Session 6 is using 92% of the packet buffers with TCP packets (protocol 6) coming from source IP address 192.168.2.35.

- **GRP-ID**—indicates an internal stage of processing packets.
- **COUNT**—indicates how many packets are in that GRP-ID for that session.
- **SESS-ID**—indicates the global session ID that is used in all other `show session` commands. The global session ID is unique within the firewall.
- **APP**—indicates the application name extracted from the Session information, which can help you determine whether the traffic is legitimate. For example, spoofed packets that use a common TCP or UDP port but indicate an APP of `undecided` are possibly attack traffic.

To restrict the display output:

On a PA-7000 Series platform, you can limit output to a slot, a dataplane, or both. For example:

```
admin@PA-7050> show running resource-monitor ingress-backlogs slot s1
admin@PA-7050> show running resource-monitor ingress-backlogs slot s1 dp dp1
```

On a PA-5000 Series platform, you can limit output to a dataplane. For example:

```
admin@PA-5060> show running resource-monitor ingress-backlogs dp dp1
```

**View Firewall Resource Usage, Top Sessions, and Session Details**

Step 2 Use the command output to determine whether the source at the source IP address using a high percentage of the packet buffer is sending legitimate or attack traffic.

In the sample output above, a single-session attack is likely occurring. A single session (Session ID 6) is using 92% of the packet buffer for Slot 1, DP 1, and the application at that point is `undecided`.

- If you determine a single user is sending an attack and the traffic is in the slow path, you can Use the CLI to End a Single Attacking Session. At a minimum, you can Configure DoS Protection Against Flooding of New Sessions.
- If the traffic is offloaded to hardware (the traffic is in the fast path), clearing the session does not help because the software then has to handle the barrage of packets. You should Discard a Session Without a Commit instead.

To see whether a session is offloaded or not, use the `show session id <session-id>` operational command in the CLI as shown in the following example. The `layer7 processing value indicates completed` for sessions offloaded or `enabled` for sessions not offloaded.

```
admin@PA-5060> show session id 68088184

Session       68088184

        c2s flow:
                source:      1.1.42.15 [trust]
                dst:         1.2.27.99
                proto:       6
                sport:       55993           dport:      6881
                state:       ACTIVE          type:       FLOW
                src user:    unknown
                dst user:    unknown
                offload:     Yes

        s2c flow:
                source:      1.2.27.99 [untrust]
                dst:         1.1.42.15
                proto:       6
                sport:       6881            dport:      55993
                state:       ACTIVE          type:       FLOW
                src user:    unknown
                dst user:    unknown
                offload:     Yes

        DP                                   : 2
        index(local):                        : 979328

        URL filtering enabled                : False
        session via syn-cookies              : False
        session terminated on host           : False
        session traverses tunnel             : False
        captive portal session               : False
        ingress interface                    : ethernet1/21
        egress interface                     : ethernet1/22
        session QoS rule                     : N/A (class 4)
        tracker stage l7proc                 : ctd decoder bypass
        end-reason                           : unknown
```

 © Palo Alto Networks, Inc.

## Discard a Session Without a Commit

With PAN-OS 6.1.10 and later PAN-OS 6.1 releases, you can perform this task to permanently discard a session, such as a session that is overloading the packet buffer. No commit is required; the session is discarded immediately after executing the command. The commands you use for this task apply to both offloaded and non-offloaded sessions.

| Discard a Session Without a Commit | |
|---|---|
| Step 1 | In the CLI, execute the following operational command on any hardware platform:<br>`admin@PA-7050> request session-discard [timeout <seconds>] [reason <reason-string>] id <session-id>`<br>The default timeout is 3600 seconds. |
| Step 2 | Verify that sessions have been discarded:<br>`admin@PA-7050> show session all filter state discard` |

# Virtual Systems Overview

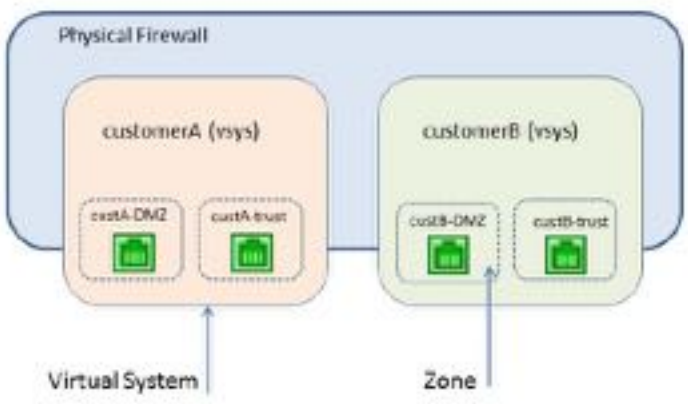
Virtual systems are separate, logical firewall instances within a single physical Palo Alto Networks firewall. Rather than using multiple firewalls, managed service providers and enterprises can use a single pair of firewalls (for high availability) and enable virtual systems on them. Each virtual system (vsys) is an independent, separately-managed firewall with its traffic kept separate from the traffic of other virtual systems.

This topic includes the following:

- Virtual System Components and Segmentation
- Benefits of Virtual Systems
- Use Cases for Virtual Systems
- Platform Support and Licensing for Virtual Systems
- Restrictions on Virtual Systems
- Administrative Roles for Virtual Systems
- Shared Objects for Virtual Systems

## Virtual System Components and Segmentation

A virtual system is an object that creates an administrative boundary, as shown in the following figure.



A virtual system consists of a set of physical and logical interfaces and subinterfaces (including VLANs and virtual wires), virtual routers, and security zones. You choose the deployment mode(s) (any combination of virtual wire, Layer 2, or Layer 3) of each virtual system. By using virtual systems, you can segment any of the following:

- Administrative access
- The management of all policies (security, NAT, QoS, policy-based forwarding, decryption, application override, captive portal, and DoS protection)
- All objects (such as address objects, application groups and filters, dynamic block lists, security profiles, decryption profiles, custom objects, etc.)

 © Palo Alto Networks, Inc.

- User-ID
- Certificate management
- Server profiles
- Logging, reporting, and visibility functions

Virtual systems affect the security functions of the firewall, but virtual systems alone do not affect networking functions such as static and dynamic routing. You can segment routing for each virtual system by creating one or more virtual routers for each virtual system, as in the following use cases:

- If you have virtual systems for departments of one organization, and the network traffic for all of the departments is within a common network, you can create a single virtual router for multiple virtual systems.
- If you want routing segmentation and each virtual system's traffic must be isolated from other virtual systems, you can create one or more virtual routers for each virtual system.

## Benefits of Virtual Systems

Virtual systems provide the same basic functions as a physical firewall, along with additional benefits:

- **Segmented administration**—Different organizations (or customers or business units) can control (and monitor) a separate firewall instance, so that they have control over their own traffic without interfering with the traffic or policies of another firewall instance on the same physical device.
- **Scalability**—After the physical firewall is configured, adding or removing customers or business units can be done efficiently. An ISP, managed security service provider, or enterprise can provide different security services to each customer.
- **Reduced capital and operational expenses**—Virtual systems eliminate the need to have multiple physical firewalls at one location because virtual systems co-exist on one firewall. By not having to purchase multiple firewalls, an organization can save on the hardware expense, electric bills, and rack space, and can reduce maintenance and management expenses.

## Use Cases for Virtual Systems

There are many ways to use virtual systems in a network. One common use case is for an ISP or a managed security service provider (MSSP) to deliver services to multiple customers with a single firewall. Customers can choose from a wide array of services that can be enabled or disabled easily. The firewall's role-based administration allows the ISP or MSSP to control each customer's access to functionality (such as logging and reporting) while hiding or offering read-only capabilities for other functions.

Another common use case is within a large enterprise that requires different firewall instances because of different technical or confidentiality requirements among multiple departments. Like the above case, different groups can have different levels of access while IT manages the firewall itself. Services can be tracked and/or billed back to departments to thereby make separate financial accountability possible within an organization.

© Palo Alto Networks, Inc.

## Platform Support and Licensing for Virtual Systems

Virtual systems are supported on the PA-2000, PA-3000, PA-4000, PA-5000, and PA-7050 Series firewalls. Each firewall series supports a base number of virtual systems; the number varies by platform. A Virtual Systems license is required in the following cases:

- To support multiple virtual systems on PA-2000 or PA-3000 Series firewalls.
- To create more than the base number of virtual systems supported on a platform.

For license information, see Activate Licenses and Subscriptions. For the base and maximum number of virtual systems supported, see Compare Firewalls tool.

Multiple virtual systems are not supported on the PA-200, PA-500 or VM-Series firewalls.

## Restrictions on Virtual Systems

- Within a Palo Alto Networks firewall, a packet may hop from one virtual system to another virtual system or a shared gateway. A packet may not traverse more than two virtual systems or shared gateways. For example, a packet cannot go from one virtual system to a shared gateway to a second virtual system within the firewall.
- Only one Shared Gateway is permitted on a firewall.

## Administrative Roles for Virtual Systems

A **superuser** administrator can create virtual systems and add a **Device Administrator**, **vsysadmin**, or **vsysreader**. A **Device Administrator** can access all virtual systems, but cannot add administrators. The two types of virtual system administrative roles are:

- **vsysadmin**—Grants full access to a virtual system.
- **vsysreader**—Grants read-only access to a virtual system.

A virtual system administrator can view logs of only the virtual systems assigned to that administrator. Someone with **superuser** or **Device Admin** permission can view all of the logs or select a virtual system to view.

Persons with **vsysadmin** permission can commit configurations for only the virtual systems assigned to them.

## Shared Objects for Virtual Systems

If your administrator account extends to multiple virtual systems, you can choose to configure objects (such as an address object) and policies for a specific virtual system or as shared objects, which apply to all of the virtual systems on the firewall. If you try to create a shared object with the same name and type as an existing object in a virtual system, the virtual system object is used.

 © Palo Alto Networks, Inc.

# Communication Between Virtual Systems

There are two typical scenarios where communication between virtual systems (inter-vsys traffic) is desirable. In a multi-tenancy environment, communication between virtual systems can occur by having traffic leave the firewall, go through the Internet, and re-enter the firewall. In a single organization environment, communication between virtual systems can remain within the firewall. This section discusses both scenarios.

- Inter-VSYS Traffic That Must Leave the Firewall
- Inter-VSYS Traffic That Remains Within the Firewall
- Inter-VSYS Communication Uses Two Sessions

## Inter-VSYS Traffic That Must Leave the Firewall

An ISP that has multiple customers on a firewall (known as multi-tenancy) can use a virtual system for each customer, and thereby give each customer control over its virtual system configuration. The ISP grants **vsysadmin** permission to customers. Each customer's traffic and management are isolated from the others. Each virtual system must be configured with its own IP address and one or more virtual routers in order to manage traffic and its own connection to the Internet.

If the virtual systems need to communicate with each other, that traffic goes out the firewall to another Layer 3 routing device and back to the firewall, even though the virtual systems exist on the same physical firewall, as shown in the following figure.

 © Palo Alto Networks, Inc.

# Inter-VSYS Traffic That Remains Within the Firewall

Unlike the preceding multi-tenancy scenario, virtual systems on a firewall can be under the control of a single organization. The organization wants to both isolate traffic between virtual systems and allow communications between virtual systems. This common use case arises when the organization wants to provide departmental separation and still have the departments be able to communicate with each other or connect to the same network(s). In this scenario, the inter-vsys traffic remains within the firewall, as described in the following topics:

- External Zone
- External Zones and Security Policies For Traffic Within a Firewall

## External Zone

The communication desired in the use case above is achieved by configuring security policies that point to or from an *external* zone. An external zone is a security object that is associated with a specific virtual system that it can reach; the zone is external to the virtual system. A virtual system can have only one external zone, regardless of how many security zones the virtual system has within it. External zones are required to allow traffic between zones in different virtual systems, without the traffic leaving the firewall.

The virtual system administrator configures the security policies needed to allow traffic between two virtual systems. Unlike security zones, an external zone is not associated with an interface; it is associated with a virtual system. The security policy allows or denies traffic between the security (internal) zone and the external zone.

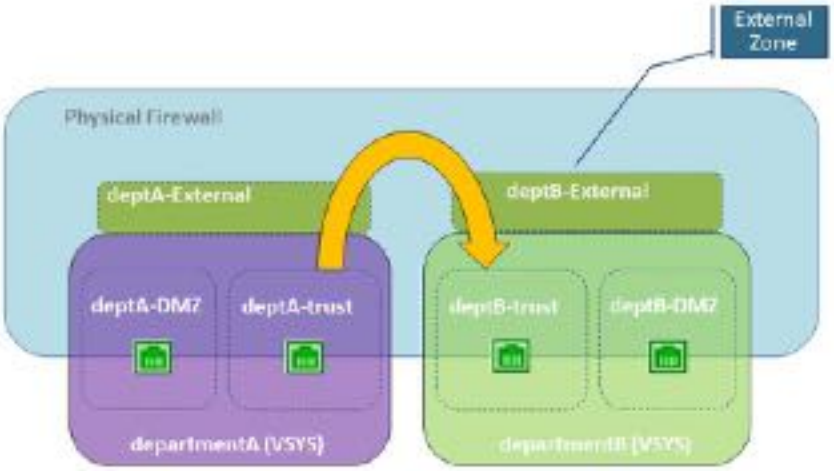
Because external zones do not have interfaces or IP addresses associated with them, some zone protection profiles are not supported on external zones.

Remember that each virtual system is a separate instance of a firewall, which means that each packet moving between virtual systems is inspected for security policy and App-ID evaluation.

## External Zones and Security Policies For Traffic Within a Firewall

In the following example, an enterprise has two separate administrative groups: the departmentA and departmentB virtual systems. The following figure shows the external zone associated with each virtual system, and traffic flowing from one trust zone, out an external zone, into an external zone of another virtual system, and into its trust zone.

© Palo Alto Networks, Inc.



In order to create external zones, the device administrator must configure the virtual systems so that they are *visible* to each other. External zones do not have security policies between them because their virtual systems are visible to each other.

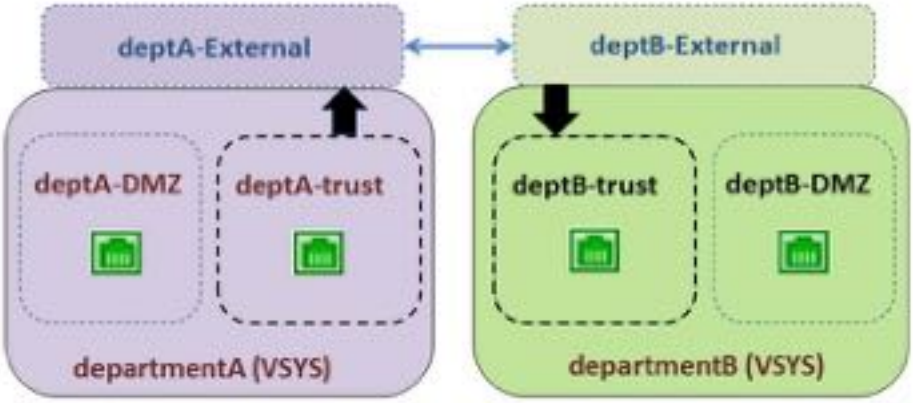
To communicate between virtual systems, the ingress and egress interfaces on the firewall are either assigned to a single virtual router or else they are connected using inter-virtual router static routes. The simpler of these two approaches is to assign all virtual systems that must communicate with each other to a single virtual router.

There might be a reason that the virtual systems need to have their own virtual router, for example, if the virtual systems use overlapping IP address ranges. Traffic can be routed between the virtual systems, but each virtual router must have static routes that point to the other virtual router(s) as the next hop.

Referring to the scenario in the figure above, we have an enterprise with two administrative groups: departmentA and departmentB. The departmentA group manages the local network and the DMZ resources. The departmentB group manages traffic in and out of the sales segment of the network. All traffic is on a local network, so a single virtual router is used. There are two external zones configured for communication between the two virtual systems. The departmentA virtual system has three zones used in security policies: deptA-DMZ, deptA-trust, and deptA-External. The departmentB virtual system also has three zones: deptB-DMZ, deptB-trust, and deptB-External. Both groups can control the traffic passing through their virtual systems.

In order to allow traffic from deptA-trust to deptB-trust, two security policies are required. In the following figure, the two vertical arrows indicate where the security policies (described below the figure) are controlling traffic.

 © Palo Alto Networks, Inc.



- Security Policy 1: In the preceding figure, traffic is destined for the deptB-trust zone. Traffic leaves the deptA-trust zone and goes to the deptA-External zone. A security policy must allow traffic from the source zone (deptA-trust) to the destination zone (deptA-External). A virtual system allows any policy type to be used for this traffic, including NAT.

  No policy is needed between external zones because traffic sent to an external zone appears in and has automatic access to the other external zones that are visible to the original external zone.

- Security Policy 2: In the preceding figure, the traffic from deptB-External is still destined to the deptB-trust zone, and a security policy must be configured to allow it. The policy must allow traffic from the source zone (deptB-External) to the destination zone (deptB-trust).

The departmentB virtual system could be configured to block traffic from the departmentA virtual system, and vice versa. Like traffic from any other zone, traffic from external zones must be explicitly allowed by policy to reach other zones in a virtual system.

In addition to external zones being required for inter-virtual system traffic that does not leave the firewall, external zones are also required if you configure a Shared Gateway, in which case the traffic is intended to leave the firewall.

## Inter-VSYS Communication Uses Two Sessions

It is helpful to understand that communication between two virtual systems uses two sessions, unlike the one session used for a single virtual system. Let's compare the scenarios.

Scenario 1—Vsys1 has two zones: trust1 and untrust1. A host in the trust1 zone initiates traffic when it needs to communicate with a device in the untrust1 zone. The host sends traffic to the firewall, and the firewall creates a new session for source zone trust1 to destination zone untrust1. Only one session is needed for this traffic.

Scenario 2—A host from vsys1 needs to access a server on vsys2. A host in the trust1 zone initiates traffic to the firewall, and the firewall creates the first session: source zone trust1 to destination zone untrust1. Traffic is routed to vsys2, either internally or externally. Then the firewall creates a second session: source zone untrust2 to destination zone trust2. Two sessions are needed for this inter-vsys traffic.

# Shared Gateway

This topic includes the following information about shared gateways:

- External Zones and Shared Gateway
- Networking Considerations for a Shared Gateway

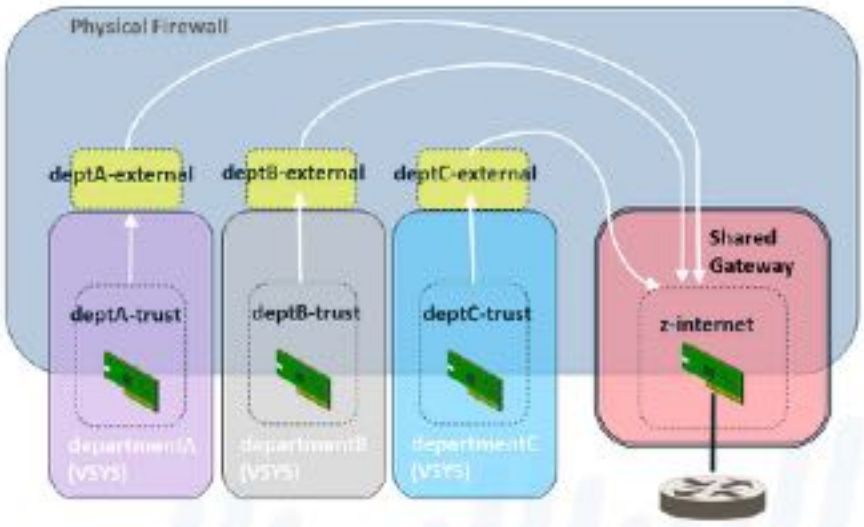
## External Zones and Shared Gateway

A shared gateway is an interface that multiple virtual systems share in order to communicate over the Internet. Each virtual system requires an External Zone, which acts as an intermediary, for configuring security policies that allow or deny traffic from the virtual system's internal zone to the shared gateway.

The shared gateway uses a single virtual router to route traffic for all virtual systems. A shared gateway is used in cases when an interface does not need a full administrative boundary around it, or when multiple virtual systems must share a single Internet connection. This second case arises if an ISP provides an organization with only one IP address (interface), but multiple virtual systems need external communication.

Unlike the behavior between virtual systems, security policy and App-ID evaluations are not performed between a virtual system and a shared gateway. That is why using a shared gateway to access the Internet involves less overhead than creating another virtual system to do so.

In the following figure, three customers share a firewall, but there is only one interface accessible to the Internet. Creating another virtual system would add the overhead of App-ID and security policy evaluation for traffic being sent to the interface through the added virtual system. To avoid adding another virtual system, the solution is to configure a shared gateway, as shown in the following diagram.



The shared gateway has one globally-routable IP address used to communicate with the outside world. Interfaces in the virtual systems have IP addresses too, but they can be private, non-routable IP addresses.

You will recall that an administrator must specify whether a virtual system is visible to other virtual systems. Unlike a virtual system, a shared gateway is always visible to all of the virtual systems on the firewall.

© Palo Alto Networks, Inc.

A shared gateway ID number appears as **sg<ID>** on the web interface. It is recommended that you name your shared gateway with a name that includes its ID number.

When you add objects such as zones or interfaces to a shared gateway, the shared gateway appears as an available virtual system in the vsys drop-down menu.

A shared gateway is a limited version of a virtual system; it supports NAT, policy-based forwarding (PBF), and DoS policies, but does not support security, QoS, decryption, application override, or captive portal policies.

## Networking Considerations for a Shared Gateway

Keep the following in mind while you are configuring a shared gateway.

- The virtual systems in a shared gateway scenario access the Internet through the shared gateway's physical interface, using a single IP address. If the IP addresses of the virtual systems are not globally routable, configure source NAT to translate those addresses to globally-routable IP addresses.
- A virtual router routes the traffic for all of the virtual systems through the shared gateway.
- The default route for the virtual systems should point to the shared gateway.
- Security policies must be configured for each virtual system to allow the traffic between the internal zone and external zone, which is visible to the shared gateway.
- A device administrator should control the virtual router, so that no member of a virtual system can affect the traffic of other virtual systems.

To save configuration time and effort, consider the following advantages of a shared gateway:

- Rather than configure NAT for multiple virtual systems associated with a shared gateway, you can configure NAT for the shared gateway.
- Rather than configure policy-based routing (PBR) for multiple virtual systems associated with a shared gateway, you can configure PBR for the shared gateway.

 © Palo Alto Networks, Inc.

# Configure Virtual Systems

Creating a virtual system requires that you have the following:

- A **superuser** administrative role.
- An interface configured.
- A Virtual Systems license if configuring a PA-2000 or PA-3000 Series firewall, or if creating more than the base number of virtual systems supported on the platform. See Platform Support and Licensing for Virtual Systems.

Perform the following procedure to create and configure virtual systems.

| Configure a Virtual System | |
|---|---|
| Step 1 Enable virtual systems. | 1. Select **Device > Setup > Management** and edit the **General Settings**.<br>2. Select the **Multi Virtual System Capability** check box and click **OK**. This action triggers a commit if you approve it.<br>Only after completing Step 1 will the **Device** tab display the **Virtual Systems** and **Shared Gateways** options. |
| Step 2 Create a virtual system. | 1. Select **Device > Virtual Systems**, click **Add** and enter a virtual system **ID**, which is appended to "vsys." Range: 1-255.<br>The default ID is 1, which makes the default virtual system **vsys1**. This default appears even on platforms that do not support multiple virtual systems.<br>2. Check the **Allow forwarding of decrypted content** check box if you want to allow the firewall to forward decrypted content to an outside service. For example, you must enable this option for the firewall to be able to send decrypted content to WildFire for analysis.<br>3. Enter a descriptive **Name** for the virtual system. A maximum of 31 alphanumeric, space, and underscore characters is allowed. |

| Configure a Virtual System | | |
|---|---|---|
| Step 3 | Assign interfaces to the virtual system.<br>The virtual routers, vwires, or VLANs can either be configured already or you can configure them later, at which point you specify the virtual system associated with it. The procedure to configure a virtual router, for example, is in Step 6 below. | 1. On the **General** tab, select a **DNS Proxy** profile if you want to apply DNS proxy rules to the interface.<br>2. In the **Interfaces** field, click **Add** to enter the interfaces or subinterfaces to assign to the virtual system. An interface can belong to only one virtual system.<br>3. Do any of the following, based on the deployment type(s) you need in the virtual system:<br>• In the **VLANs** field, click **Add** to enter the VLAN(s) to assign to the vsys.<br>• In the **Virtual Wires** field, click **Add** to enter the virtual wire(s) to assign to the vsys.<br>• In the **Virtual Routers** field, click **Add** to enter the virtual router(s) to assign to the vsys.<br>4. In the **Visible Virtual System** field, check all virtual systems that should be made visible to the virtual system being configured. This is required for virtual systems that need to communicate with each other.<br>In a multi-tenancy scenario where strict administrative boundaries are required, no virtual systems would be checked.<br>5. Click **OK**. |
| Step 4 | (Optional) Limit the resource allocations for sessions, rules, and VPN tunnels allowed for the virtual system. The flexibility of being able to allocate limits per virtual system allows you to effectively control device resources. | 1. On the **Resource** tab, optionally set limits for a virtual system. There are no default values.<br>• **Sessions Limit**—Range: 1-262144<br>• **Security Rules**—Range: 0-2500<br>• **NAT Rules**—Range: 0-3000<br>• **Decryption Rules**—Range: 0-250<br>• **QoS Rules**—Range: 0-1000<br>• **Application Override Rules**—Range: 0-250<br>• **Policy Based Forwarding Rules**—Range: 0-500<br>• **Captive Portal Rules**—Range: 0-1000<br>• **DoS Protection Rules**—Range: 0-1000<br>• **Site to Site VPN Tunnels**—Range: 0-1024<br>• **Concurrent SSL VPN Tunnels**—Range: 0-1024<br>2. Click **OK**. |
| Step 5 | Save the configuration. | Click **Commit** and **OK**. The virtual system is now an object accessible from the **Objects** tab. |

 © Palo Alto Networks, Inc.

| Configure a Virtual System | | |
|---|---|---|
| Step 6 | Create at least one virtual router for the virtual system in order to make the virtual system capable of networking functions, such as static and dynamic routing.<br>Alternatively, your virtual system might use a VLAN or a virtual wire, depending on your deployment. | 1. Select **Network > Virtual Routers** and **Add** a **virtual router** by **Name**.<br>2. **Add** the **Interfaces** that belong to the virtual router.<br>3. Click **OK**. |
| Step 7 | Configure a security zone for each interface in the virtual system. | For at least one interface, create a Layer 3 security zone. See Set Up Interfaces and Zones. |
| Step 8 | Configure the security policies allowing or denying traffic to and from the zones in the virtual system. | See Set Up Basic Security Policies. |
| Step 9 | Save the configuration. | Click **Commit** and **OK**.<br>After a virtual system is created, a device administrator can use the CLI to commit a configuration for only a specific virtual system:<br>`PA-5060> commit partial vsys vsys<id>` |
| Step 10 | (Optional) View the security policies configured for a virtual system. | Open an SSH session to use the CLI. To view the security policies for a virtual system, in operational mode, use the following commands:<br>`PA-5060> set system setting target-vsys <vsys-id>`<br>`PA-5060> show running security-policy` |

# Configure Inter-Virtual System Communication within the Firewall

Perform this task if you have a use case, perhaps within a single enterprise, where you want the virtual systems to be able to communicate with each other within the firewall. Such a scenario is described in Inter-VSYS Traffic That Remains Within the Firewall. This task presumes:

- ❒ You completed the task, Configure Virtual Systems.
- ❒ When configuring the virtual systems, in the **Visible Virtual System** field, you checked the boxes of all virtual systems that must communicate with each other to be visible to each other.

| **Configure Inter-Virtual System Communication within the Firewall** | | |
|---|---|---|
| Step 1 | Configure an external zone for each virtual system. | 1. Select **Network > Zones** and **Add** a new zone by **Name**.<br>2. For **Location**, select the virtual system for which you are creating an external zone.<br>3. For **Type**, select **External**.<br>4. For **Virtual Systems**, enter the virtual system that the external zone can reach.<br>5. **Zone Protection Profile**—Optionally select a zone protection profile (or configure one later) that provides flood, reconnaissance, or packet-based attack protection.<br>6. **Log Setting—**Optionally select a log forwarding profile for forwarding zone protection logs to an external system.<br>7. Optionally select the **Enable User Identification** check box to enable User-ID for the external zone.<br>8. Click **OK**. |
| Step 2 | Configure the security policies allowing or denying traffic from the internal zones to the external zone of the virtual system, and vice versa. | • See Set Up Basic Security Policies.<br>• See Inter-VSYS Traffic That Remains Within the Firewall. |
| Step 3 | Save the configuration. | Click **Commit**. |

© Palo Alto Networks, Inc.

# Configure a Shared Gateway

Perform this task if you need multiple virtual systems to share an interface (a Shared Gateway) to the Internet. This task presumes:

- You configured an interface with a globally-routable IP address, which will be the shared gateway.
- You completed the prior task, Configure Virtual Systems. For the interface, you chose the external-facing interface with the globally-routable IP address.
- When configuring the virtual systems, in the **Visible Virtual System** field, you checked the boxes of all virtual systems that must communicate to be visible to each other.

| **Configure a Shared Gateway** | | |
|---|---|---|
| Step 1 | Configure a Shared Gateway. | 1. Select **Device > Shared Gateway** and enter an **ID**.<br>2. Enter a helpful **Name**, preferably including the **ID** of the gateway.<br>3. In the **DNS Proxy** field, select a DNS proxy profile if you want to apply DNS proxy rules to the interface.<br>4. **Add** an **Interface** that connects to the outside world.<br>5. Click **OK**. |
| Step 2 | Configure the zone for the shared gateway.<br> When adding objects such as zones or interfaces to a shared gateway, the shared gateway itself will be listed as an available vsys in the **VSYS** drop-down menu. | 1. Select **Network > Zones** and **Add** a new zone by **Name**.<br>2. For **Location**, select the shared gateway for which you are creating a zone.<br>3. For **Type**, select **Layer3**.<br>4. **Zone Protection Profile**—Optionally select a zone protection profile (or configure one later) that provides flood, reconnaissance, or packet-based attack protection.<br>5. **Log Setting—**Optionally select a log forwarding profile for forwarding zone protection logs to an external system.<br>6. Optionally select the **Enable User Identification** check box to enable User-ID for the shared gateway.<br>7. Click **OK**. |
| Step 3 | Save the configuration. | Click **Commit**. |

# Virtual System Functionality with Other Features

Many of the firewall's features and functionality are capable of being configured, viewed, logged, or reported per virtual system. Therefore, virtual systems are mentioned in other relevant locations in the documentation and that information is not repeated here. Some of the specific chapters are the following:

- If you are configuring Active/Passive HA, the two firewalls must have the same virtual system capability (single or multiple virtual system capability). See High Availability.
- To configure QoS for virtual systems, see Configure QoS for a Virtual System.
- For information about configuring a firewall with virtual systems in a virtual wire deployment that uses subinterfaces (and VLAN tags), see the Networking section, Virtual Wire Subinterfaces.

## About this Guide

This guide takes you through the configuration and maintenance of your Palo Alto Networks next-generation firewall. For additional information, refer to the following resources:

- For information on the additional capabilities and for instructions on configuring the features on the firewall, refer to https://www.paloaltonetworks.com/documentation.
- For access to the knowledge base, complete documentation set, discussion forums, and videos, refer to https://live.paloaltonetworks.com.
- For contacting support, for information on support programs, to manage your account or devices, or to open a support case, refer to https://www.paloaltonetworks.com/support/tabs/overview.html.
- For the most current PAN-OS 7.0 release notes, see https://www.paloaltonetworks.com/documentation/70/pan-os/pan-os-release-notes.html.

To provide feedback on the documentation, please write to us at: documentation@paloaltonetworks.com.

# Getting Started

The following topics provide detailed steps to help you deploy a new Palo Alto Networks next-generation firewall. They provide details for integrating a new firewall into your network and configuring basic security policies and threat prevention features.

After you perform the basic configuration steps required to integrate the firewall into your network, you can use the rest of the topics in this guide to help you deploy the comprehensive enterprise security platform features as necessary to address your network security needs.

- Integrate the Firewall into Your Management Network
- Create the Security Perimeter
- Enable Basic Threat Prevention Features
- Best Practices for Completing the Firewall Deployment

# Integrate the Firewall into Your Management Network

All Palo Alto Networks firewalls provide an out-of-band management port (MGT) that you can use to perform the firewall administration functions. By using the MGT port, you separate the management functions of the firewall from the data processing functions, safeguarding access to the firewall and enhancing performance. When using the web interface, you must perform all initial configuration tasks from the MGT port even if you plan to use an in-band port for managing your device going forward.

Some management tasks, such as retrieving licenses and updating the threat and application signatures on the firewall require access to the Internet. If you do not want to enable external access to your MGT port, you will need to either set up a data port to provide access to required external services or plan to manually upload updates regularly.

The following topics describe how to perform the initial configuration steps that are necessary to integrate a new firewall into the management network and deploy it in a basic security configuration.

- Determine Your Management Strategy
- Perform Initial Configuration
- Set Up Network Access for External Services
- Register the Firewall
- Activate Licenses and Subscriptions
- Manage Content Updates
- Install Software Updates

The following topics describe how to integrate a single Palo Alto Networks next-generation firewall into your network. However, for redundancy, consider deploying a pair of firewalls in a High Availability configuration.

 © Palo Alto Networks, Inc.

## Determine Your Management Strategy

The Palo Alto Networks firewall can be configured and managed locally or it can be managed centrally using Panorama, the Palo Alto Networks centralized security management system. If you have six or more firewalls deployed in your network, use Panorama to achieve the following benefits:

- Reduce the complexity and administrative overhead in managing configuration, policies, software and dynamic content updates. Using device groups and templates on Panorama, you can effectively manage device specific configuration locally on a device and enforce shared policies across all devices or device groups.
- Aggregate data from all managed firewalls and gain visibility across all the traffic on your network. The Application Command Center (ACC) on Panorama provides a single glass pane for unified reporting across all the firewalls, allowing you to centrally analyze, investigate and report on network traffic, security incidents and administrative modifications.

The procedures that follow describe how to manage the firewall using the local web interface. If you want to use Panorama for centralized management, first Perform Initial Configuration and verify that the firewall can establish a connection to Panorama. From that point on you can use Panorama to configure your firewall centrally.

## Perform Initial Configuration

By default, the firewall has an IP address of 192.168.1.1 and a username/password of admin/admin. For security reasons, you must change these settings before continuing with other firewall configuration tasks. You must perform these initial configuration tasks either from the MGT interface, even if you do not plan to use this interface for your firewall management, or using a direct serial connection to the console port on the device.

| **Set Up Network Access to the Firewall** | | |
|---|---|---|
| Step 1 | Gather the required information from your network administrator. | • IP address for MGT port<br>• Netmask<br>• Default gateway<br>• DNS server address |
| Step 2 | Connect your computer to the firewall. | You can connect to the firewall in one of the following ways:<br>• Connect a serial cable from your computer to the Console port and connect to the firewall using terminal emulation software (9600-8-N-1). Wait a few minutes for the boot-up sequence to complete; when the device is ready, the prompt changes to the name of the firewall, for example `PA-500 login`.<br>• Connect an RJ-45 Ethernet cable from your computer to the MGT port on the firewall. From a browser, go to `https://192.168.1.1`. Note that you may need to change the IP address on your computer to an address in the 192.168.1.0 network, such as 192.168.1.2, in order to access this URL. |
| Step 3 | When prompted, log in to the firewall. | You must log in using the default username and password (admin/admin). The firewall will begin to initialize. |
| Step 4 | Configure the MGT interface. | 1. Select **Device > Setup > Management** and then edit the Management Interface Settings.<br>2. Enter the **IP Address**, **Netmask**, and **Default Gateway**.<br> To prevent unauthorized access to the management interface, it is a best practice to **Add** the **Permitted IP Addresses** from which an administrator can access the MGT interface.<br>3. Set the **Speed** to **auto-negotiate**.<br>4. Select which management services to allow on the interface.<br> Make sure **Telnet** and **HTTP** are not selected because these services use plaintext and are not as secure as the other services and could compromise administrator credentials.<br>5. Click **OK**. |

 © Palo Alto Networks, Inc.

| Set Up Network Access to the Firewall (Continued) | | |
|---|---|---|
| Step 5 | Configure general firewall settings as needed.<br> <br>As a best practice, add a login banner that indicates that access to the firewall is restricted to prevent unauthorized users from accessing the management functions. It is a good idea to avoid using welcoming verbiage and to run your messaging by your legal department to ensure that you are providing adequate warning that unauthorized access is prohibited. | 1. Select **Device > Setup > Management** and edit the General Settings.<br>2. Enter a **Hostname** for the firewall and enter your network **Domain** name. The domain name is just a label; it will not be used to join the domain.<br>3. Enter **Login Banner** text that informs users who are attempting to log in that they are that they must have authorization to access the firewall management functions.<br>4. Enter the **Latitude** and **Longitude** to enable accurate placement of the firewall on the world map.<br>5. Click **OK**. |
| Step 6 | Configure DNS, update server, and proxy server settings.<br> <br>You must manually configure at least one DNS server on the firewall or it will not be able to resolve hostnames; it will not use DNS server settings from another source, such as an ISP. | 1. Select **Device > Setup > Services**.<br>• For multi-virtual system platforms, select **Global** and edit the Services section.<br>• For single virtual system platforms, edit the Services section.<br>2. On the **Services** tab, for **DNS**, click one of the following:<br>• **Servers**—Enter the **Primary DNS Server** address and **Secondary DNS Server** address.<br>• **DNS Proxy Object**—From the drop-down, select the **DNS Proxy** that you want to use to configure global DNS services, or click **DNS Proxy** to configure a new DNS proxy object.<br>3. (Optional) For **Update Server**, enter the IP address or host name of the server from which to download updates from Palo Alto Networks. The current value is updates.paloaltonetworks.com. Do not change the Update Server unless instructed by Technical Support.<br>4. (Optional) Click **Verify Update Server Identity** for an extra level of validation. The firewall will check the update server's SSL certificate to ensure that it was signed by a trusted authority.<br>5. (Optional) If the firewall needs to use a proxy server to reach Palo Alto Networks update services, in the **Proxy Server** window, enter:<br>• **Server**—IP address or host name of the proxy server.<br>• **Port**—Port for the proxy server. Range: 1-65535.<br>• **User**—Username to access the server.<br>• **Password**—Password for the user to access the proxy server. Re-enter the password at **Confirm Password**.<br>6. Click **OK**. |

© Palo Alto Networks, Inc.

| Set Up Network Access to the Firewall (Continued) | |
|---|---|
| Step 7 Configure date and time (NTP) settings. | 1. Select **Device > Setup > Services**.<br>• For multi-virtual system platforms, select **Global** and edit the Services section.<br>• For single virtual system platforms, edit the Services section.<br>2. On the **NTP** tab, to use the virtual cluster of time servers on the Internet, enter the hostname **pool.ntp.org** as the **Primary NTP Server** or enter the IP address of your primary NTP server.<br>3. (Optional) Enter a **Secondary NTP Server** address.<br>4. (Optional) To authenticate time updates from the NTP server(s), for **Authentication Type**, select one of the following for each server:<br>• **None**—(Default) Disables NTP authentication.<br>• **Symmetric Key**—Firewall uses symmetric key exchange (shared secrets) to authenticate time updates.<br>– **Key ID**—Enter the Key ID (1-65534).<br>– **Algorithm**—Select the algorithm to use in NTP authentication (**MD5** or **SHA1**).<br>• **Autokey**—Firewall uses autokey (public key cryptography) to authenticate time updates.<br>5. Click **OK**. |
| Step 8 Set a secure password for the admin account. | 1. Select **Device > Administrators.**<br>2. Select the **admin** role.<br>3. Enter the current default password and the new password.<br>4. Click **OK** to save your settings. |
| Step 9 Commit your changes.<br>When the configuration changes are saved, you will lose connectivity to the web interface because the IP address will have changed. | Click **Commit**. The device may take up to 90 seconds to save your changes.<br> |
| Step 10 Connect the firewall to your network. | 1. Disconnect the firewall from your computer.<br>2. Connect the MGT port to a switch port on your management network using an RJ-45 Ethernet cable. Make sure that the switch port you cable the firewall to is configured for auto-negotiation. |
| Step 11 Open an SSH management session to the firewall. | Using a terminal emulation software, such as PuTTY, launch an SSH session to the firewall using the new IP address you assigned to it. |

 © Palo Alto Networks, Inc.

| Set Up Network Access to the Firewall (Continued) | |
|---|---|
| Step 12 Verify network access to external services required for firewall management, such as the Palo Alto Networks Update Server, in one of the following ways:<br>• If you do not want to allow external network access to the MGT interface, you will need to set up a data port to retrieve required service updates. Continue to Set Up Network Access for External Services.<br>• If you do plan to allow external network access to the MGT interface, verify that you have connectivity and then proceed to Register the Firewall and Activate Licenses and Subscriptions. | If you cabled your MGT port for external network access, verify that you have access to and from the firewall by using the ping utility from the CLI. Make sure you have connectivity to the default gateway, DNS server, and the Palo Alto Networks Update Server as shown in the following example:<br>`admin@PA-200> ping host updates.paloaltonetworks.com`<br>`PING updates.paloaltonetworks.com (67.192.236.252) 56(84) bytes of data.`<br>`64 bytes from 67.192.236.252 : icmp_seq=1 ttl=243 time=40.5 ms`<br>`64 bytes from 67.192.236.252 : icmp_seq=1 ttl=243 time=53.6 ms`<br>`64 bytes from 67.192.236.252 : icmp_seq=1 ttl=243 time=79.5 ms`<br>After you have verified connectivity, press Ctrl+C to stop the pings. |

## Set Up Network Access for External Services

By default, the firewall uses the MGT interface to access remote services, such as DNS servers, content updates, and license retrieval. If you do not want to enable external network access to your management network, you must set up a data port to provide access to these required external services.

This task requires familiarity with firewall interfaces, zones, and policies. For more information on these topics, see Create the Security Perimeter.

For information on setting up network access to external services on a virtual system basis rather than a global basis, see Per-Virtual System Service Routes.

| Set Up a Data Port for Access to External Services | | |
|---|---|---|
| Step 1 | Decide which port you want to use for access to external services and connect it to your switch or router port. | The interface you use must have a static IP address. |
| Step 2 | Log in to the web interface. | Using a secure connection (https) from your web browser, log in using the new IP address and password you assigned during initial configuration (https://<IP address>). You will see a certificate warning; that is okay. Continue to the web page. |
| Step 3 | (Optional) The firewall comes preconfigured with a default virtual wire interface between ports Ethernet 1/1 and Ethernet 1/2 (and a corresponding default security policy and zones). If you do not plan to use this virtual wire configuration, you must manually delete the configuration to prevent it from interfering with other interface settings you define. | You must delete the configuration in the following order:<br>1. To delete the default security policy, select **Policies > Security**, select the rule, and click **Delete**.<br>2. Next, delete the default virtual wire by selecting **Network > Virtual Wires**, selecting the virtual wire and clicking **Delete**.<br>3. To delete the default trust and untrust zones, select **Network > Zones**, select each zone and click **Delete**.<br>4. Finally, delete the interface configurations by selecting **Network > Interfaces** and then select each interface (ethernet1/1 and ethernet1/2) and click **Delete**.<br>5. **Commit** the changes. |

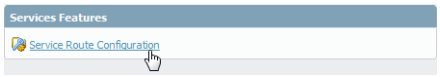
 © Palo Alto Networks, Inc.

| Set Up a Data Port for Access to External Services (Continued) | |
|---|---|
| Step 4 Configure the interface. | 1. Select **Network > Interfaces** and select the interface that corresponds to the port you cabled in Step 1.<br>2. Select the **Interface Type**. Although your choice here depends on your network topology, this example shows the steps for **Layer3**.<br>3. On the **Config** tab, expand the **Security Zone** drop-down and select **New Zone**.<br>4. In the Zone dialog, define a **Name** for new zone, for example L3-trust, and then click **OK**.<br>5. Select the **IPv4** tab, select the **Static** radio button, and click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 192.168.1.254/24.<br>6. Select **Advanced > Other Info**, expand the **Management Profile** drop-down, and select **New Management Profile**.<br>7. Enter a **Name** for the profile, such as allow_ping, and then select the services you want to allow on the interface. For the purposes of allowing access to the external services, you probably only need to enable **Ping** and then click **OK**.<br> These services provide management access to the device, so only select the services that correspond to the management activities you want to allow on this interface. For example, if you plan to use the MGT interface for device configuration tasks through the web interface or CLI, you would not want to enable HTTP, HTTPS, SSH, or Telnet so that you could prevent unauthorized access through this interface (and if you did allow those services, you should limit access to a specific set of **Permitted IP Addresses**).<br>8. To save the interface configuration, click **OK**. |

**Set Up a Data Port for Access to External Services (Continued)**

Step 5 Because the firewall uses the MGT interface by default to access the external services it requires, you must change the interface the firewall uses to send these requests by editing the service routes.

1. Select **Device > Setup > Services > Service Route Configuration**.



For the purposes of activating your licenses and getting the most recent content and software updates, you will want to change the service route for **DNS**, **Palo Alto Updates**, **URL Updates**, and **WildFire**.

2. Click the **Customize** radio button, and select one of the following:
   - For a predefined service, select **IPv4** or **IPv6** and click the link for the service for which you want to modify the **Source Interface** and select the interface you just configured.

     If more than one IP address is configured for the selected interface, the **Source Address** drop-down allows you select an IP address.
   - To create a service route for a custom destination, select **Destination**, and click **Add**. Enter a **Destination** name and select a **Source Interface**. If more than one IP address is configured for the selected interface, the **Source Address** drop-down allows you select an IP address.
3. Click **OK** to save the settings.
4. Repeat steps 2-3 above for each service route you want to modify.
5. **Commit** your changes.

 © Palo Alto Networks, Inc.

| Set Up a Data Port for Access to External Services (Continued) | |
|---|---|
| Step 6 Configure an external-facing interface and an associated zone and then create security and NAT policy rules to allow the firewall to send service requests from the internal zone to the external zone. | 1. Select **Network > Interfaces** and then select your external-facing interface. Select **Layer3** as the **Interface Type**, **Add** the **IP** address (on the **IPv4** or **IPv6** tab), and create the associated **Security Zone** (on the **Config** tab), such as l3-untrust. You do not need to set up management services on this interface.<br>2. To set up a security rule that allows traffic from your internal network to the Palo Alto Networks update server, select **Policies > Security** and click **Add**. For the purposes of initial configuration, you can create a simple rule that allows all traffic from l3-trust to l3-untrust as follows:<br> <br>3. If you are using a private IP address on the internal-facing interface, you will need to create a source NAT rule to translate the address to a publicly routable address. Select **Policies > NAT** and then click **Add**. At a minimum you must define a name for the rule (**General** tab), specify a source and destination zone, l3-trust to l3-untrust in this case (**Original Packet** tab), and define the source address translation settings (**Translated Packet** tab) and then click **OK**.<br> <br>4. **Commit** your changes. |
| Step 7 Verify that you have connectivity from the data port to the external services, including the default gateway, and the Palo Alto Networks Update Server.<br><br>After you verify you have the required network connectivity, continue to Register the Firewall and Activate Licenses and Subscriptions. | Launch the CLI and use the ping utility to verify that you have connectivity. Keep in mind that by default pings are sent from the MGT interface, so in this case you must specify the source interface for the ping requests as follows:<br>`admin@PA-200> ping source 192.168.1.254 host updates.paloaltonetworks.com`<br>`PING updates.paloaltonetworks.com (67.192.236.252) from 192.168.1.254 : 56(84) bytes of data.`<br>`64 bytes from 67.192.236.252: icmp_seq=1 ttl=242 time=56.7 ms`<br>`64 bytes from 67.192.236.252: icmp_seq=2 ttl=242 time=47.7 ms`<br>`64 bytes from 67.192.236.252: icmp_seq=3 ttl=242 time=47.6 ms`<br>`^C`<br>After you have verified connectivity, press Ctrl+C to stop the pings. |

# Register the Firewall

| Register the Firewall | | |
|---|---|---|
| Step 1 | Log in to the web interface. | Using a secure connection (https) from your web browser, log in using the new IP address and password you assigned during initial configuration (https://<IP address>). You will see a certificate warning; that is okay. Continue to the web page. |
| Step 2 | Locate your serial number and copy it to the clipboard. | On the **Dashboard**, locate your **Serial Number** in the General Information section of the screen. |
| Step 3 | Go to the Palo Alto Networks Support site. | In a new browser tab or window, go to https://support.paloaltonetworks.com. |
| Step 4 | Register the device. The way you register depends on whether you already have a login to the support site. | • If this is the first Palo Alto Networks device you are registering and you do not yet have a login, click **Register** on the right side of the page. To register, you must provide your sales order number or customer ID, and the serial number of your firewall (which you can paste from your clipboard) or the authorization code you received with your order. You will also be prompted to set up a username and password for access to the Palo Alto Networks support community.<br> <br>• If you already have a support account, log in and then click **My Devices**. Scroll down to Register Device section at the bottom of the screen and enter the serial number of your firewall (which you can paste from your clipboard), your city and postal code and then click **Register Device**. |

 © Palo Alto Networks, Inc.

## Activate Licenses and Subscriptions

Before you can start using your firewall to secure the traffic on your network, you must activate the licenses for each of the services you purchased. Available licenses and subscriptions include the following:

- Threat Prevention—Provides antivirus, anti-spyware, and vulnerability protection.
- Decryption Mirroring—Provides the ability to create a copy of decrypted traffic from a firewall and send it to a traffic collection tool that is capable of receiving raw packet captures—such as NetWitness or Solera—for archiving and analysis.
- URL Filtering—Allows you create security policy to enforce web access based on dynamic URL categories. You must purchase and install a subscription for one of the supported URL filtering databases: PAN-DB or BrightCloud. With PAN-DB, you can set up access to the PAN-DB public cloud or to the PAN-DB private cloud. For more information about URL filtering, see Control Access to Web Content.
- Virtual Systems—This license is required to enable support for multiple virtual systems on PA-2000 and PA-3000 Series firewalls. In addition, you must purchase a Virtual Systems license if you want to increase the number of virtual systems beyond the base number provided by default on PA-4000 Series, PA-5000 Series, and PA-7000 Series firewalls (the base number varies by platform). The PA-500, PA-200, and VM-Series firewalls do not support virtual systems.
- WildFire—Although basic WildFire support is included as part of the Threat Prevention license, the WildFire subscription service provides enhanced services for organizations that require immediate coverage for threats, frequent WildFire signature updates, advanced file type forwarding (APK, PDF, Microsoft Office, and Java Applet), as well as the ability to upload files using the WildFire API. A WildFire subscription is also required if your firewalls will be forwarding files to a WF-500 appliance.
- GlobalProtect—Provides mobility solutions and/or large-scale VPN capabilities. By default, you can deploy GlobalProtect portals and gateways (without HIP checks) without a license. If you want to use HIP checks, you will also need gateway licenses (subscription) for each gateway.

| **Activate Licenses** | | |
|---|---|---|
| Step 1 | Locate the activation codes for the licenses you purchased. | When you purchased your subscriptions you should have received an email from Palo Alto Networks customer service listing the activation code associated with each subscription. If you cannot locate this email, contact customer support to obtain your activation codes before you proceed. |
| Step 2 | Launch the web interface and go to the license page. | Select **Device > Licenses**. |

| Activate Licenses (Continued) | | |
|---|---|---|
| Step 3 | Activate each license you purchased. | After purchasing your licenses/subscriptions activate them in one of the following ways:<br>• **Retrieve license keys from license server**—Use this option if you activated your license on the support portal.<br>• **Activate feature using authorization code**—Use this option to enable purchased subscriptions using an authorization code for licenses that have not been previously activated on the support portal. When prompted, enter the **Authorization Code** and then click **OK**.<br>• **Manually upload license key**—Use this option if your device does not have connectivity to the Palo Alto Networks support site. In this case, you must download a license key file from the support site on an Internet connected computer and then upload to the device. |
| Step 4 | Verify that the license was successfully activated | On the **Device > Licenses** page, verify that the license was successfully activated. For example, after activating the WildFire license, you should see that the license is valid:<br> |
| Step 5 | (WildFire subscriptions only) Perform a commit to complete WildFire subscription activation. | After activating a WildFire subscription, a commit is required for the firewall to begin forwarding advanced file types:<br>• Commit any pending changes.<br>• Make a minor change and perform a commit. For example, update a rule description and commit the change.<br>Check that the WildFire Analysis profile rules include the advanced file types that are now supported with the WildFire subscription. If no change to any of the rules is required, make a minor edit to a rule description and perform a commit. |

 © Palo Alto Networks, Inc.

## Manage Content Updates

In order to stay ahead of the changing threat and application landscape, Palo Alto Networks maintains a Content Delivery Network (CDN) infrastructure for delivering content updates to the Palo Alto Networks devices. The devices access the web resources in the CDN to perform various App-ID and Content-ID functions. By default, the devices use the management port to access the CDN infrastructure for application updates, threat and antivirus signature updates, BrightCloud and PAN-DB database updates and lookups, and access to the Palo Alto Networks WildFire cloud. To ensure that you are always protected from the latest threats (including those that have not yet been discovered), you must ensure that you keep your devices up-to-date with the latest updates published by Palo Alto Networks.

The following content updates are available, depending on which subscriptions you have:

Although you can manually download and install content updates at any time, as a best practice you should Schedule each update. Scheduled updates occur automatically.

- **Antivirus**—Includes new and updated antivirus signatures, including signatures discovered by the WildFire cloud service. You must have a Threat Prevention subscription to get these updates. New antivirus signatures are published daily.
- **Applications**—Includes new and updated application signatures. This update does not require any additional subscriptions, but it does require a valid maintenance/support contract. New application updates are published weekly. To review the policy impact of new application updates, see Manage New App-IDs Introduced in Content Releases.
- **Applications and Threats**—Includes new and updated application and threat signatures. This update is available if you have a Threat Prevention subscription (and you get it instead of the Applications update). New Applications and Threats updates are published weekly.
- **GlobalProtect Data File**—Contains the vendor-specific information for defining and evaluating host information profile (HIP) data returned by GlobalProtect agents. You must have a GlobalProtect gateway license and create an update schedule in order to receive these updates.
- **BrightCloud URL Filtering**—Provides updates to the BrightCloud URL Filtering database only. You must have a BrightCloud subscription to get these updates. New BrightCloud URL database updates are published daily. If you have a PAN-DB license, scheduled updates are not required as devices remain in-sync with the servers automatically.
- **WildFire**—Provides near real-time malware and antivirus signatures created as a result of the analysis done by the WildFire cloud service. Without the subscription, you must wait 24 to 48 hours for the signatures to roll into the Applications and Threat update.

If your firewall does not have Internet access from the management port, you can download content updates from the Palo Alto Networks Support portal and then Upload them to your firewall.

If your firewall is deployed behind existing firewalls or proxy servers, access to these external resources might be restricted using access control lists that allow the firewall to only access a hostname or an IP address. In such cases, to allow access to the CDN, set the update server address to use the hostname `staticupdates.paloaltonetworks.com` or the IP address `199.167.52.15`. For details on setting up CDN access, see Content Delivery Network Infrastructure for Dynamic Updates.

| Update Content | |
|---|---|
| Step 1 Verify that the firewall points to the CDN infrastructure. | Select **Device > Setup > Services**.<br>• As a best practice, set the **Update Server** to access `updates.paloaltonetworks.com`. This allows the firewall to receive content updates from the server to which it is closest in the CDN infrastructure.<br>• (Optional) If the firewall has restricted access to the Internet, set the update server address to use the hostname `staticupdates.paloaltonetworks.com` or the IP address `199.167.52.15`.<br>• For additional security, select **Verify Update Server Identity**. The firewall verifies that the server from which the software or content package is download has an SSL certificate signed by a trusted authority. |
| Step 2 Launch the web interface and go to the Dynamic Updates page. | Select **Device > Dynamic Updates**. |
| Step 3 Check for the latest updates. | Click **Check Now** (located in the lower left-hand corner of the window) to check for the latest updates. The link in the **Action** column indicates whether an update is available:<br>• **Download**—Indicates that a new update file is available. Click the link to begin downloading the file directly to the firewall. After successful download, the link in the **Action** column changes from **Download** to **Install**.<br> <br>You cannot download the antivirus database until you have installed the Application and Threats database.<br>• **Upgrade**—Indicates that there is a new version of the BrightCloud database available. Click the link to begin the download and installation of the database. The database upgrade begins in the background; when completed a check mark displays in the **Currently Installed** column. Note that if you are using PAN-DB as your URL filtering database you will not see an upgrade link because the PAN-DB database automatically stays in sync with the server.<br> <br>To check the status of an action, click **Tasks** (on the lower right-hand corner of the window).<br>• **Revert**—Indicates that a previously installed version of the content or software version is available. You can choose to revert to the previously installed version. |

 © Palo Alto Networks, Inc.

| Update Content (Continued) | | |
|---|---|---|
| Step 4 | Install the updates.<br><br>Installation can take up to 20 minutes on a PA-200, PA-500, or PA-2000 Series device and up to two minutes on a PA-3000 Series, PA-4000 Series, PA-5000 Series, PA-7000 Series, or VM-Series firewall. | Click the **Install** link in the **Action** column. When the installation completes, a check mark displays in the **Currently Installed** column. |
| | | |
| Step 5 | Schedule each update.<br><br>Repeat this step for each update you want to schedule.<br><br>Stagger the update schedules because the firewall can only download one update at a time. If you schedule the updates to download during the same time interval, only the first download will succeed. | 1. Set the schedule of each update type by clicking the **None** link.<br> <br>2. Specify how often you want the updates to occur by selecting a value from the **Recurrence** drop-down. The available values vary by content type (WildFire updates are available **Every 15 minutes**, **Every 30 minutes** or **Every Hour** whereas all other content types can be scheduled for **Daily** or **Weekly** update).<br>3. Specify the **Time** and (or, minutes past the hour in the case of WildFire), if applicable depending on the **Recurrence** value you selected, **Day** of the week that you want the updates to occur.<br>4. Specify whether you want the system to **Download Only** or, as a best practice, **Download And Install** the update.<br>5. In rare instances, errors in content updates may be found. For this reason, you may want to delay installing new updates until they have been released for a certain number of hours. You can specify how long after a release to wait before performing a content update by entering the number of hours to wait in the **Threshold (Hours)** field.<br>6. Click **OK** to save the schedule settings.<br>7. Click **Commit** to save the settings to the running configuration. |

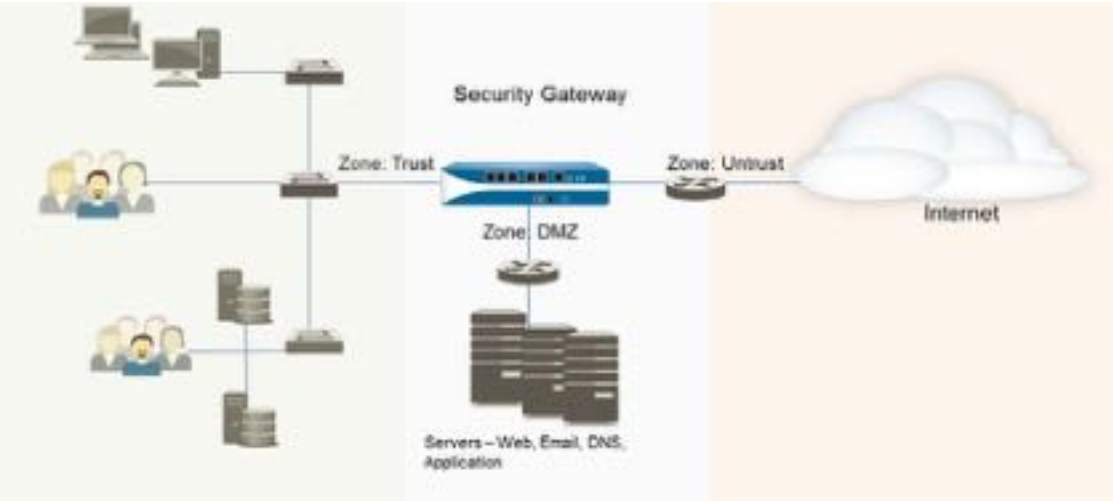
## Install Software Updates

When installing a new firewall, it is a good idea to upgrade to the latest software update (or to the update version that your reseller or Palo Alto Networks Systems Engineer recommends) to take advantage of the latest fixes and security enhancements. Before updating the software, make sure you have the latest content updates as detailed in Manage Content Updates (the Release Notes for a software update specify the minimum content release version supported in the release).

 © Palo Alto Networks, Inc.

# Create the Security Perimeter

Traffic must pass through the firewall in order for the firewall to manage and control it. Physically, traffic enters and exits the firewall through *interfaces*. The firewall determines how to act on a packet based on whether the packet matches a *security policy rule*. At the most basic level, each security policy rule must identify where the traffic came from and where it is going. On a Palo Alto Networks next-generation firewall, security policy rules are applied between zones. A *zone* is a grouping of interfaces (physical or virtual) that provides an abstraction for an area of trust for simplified policy enforcement. For example, in the following topology diagram, there are three zones: Trust, Untrust, and DMZ. Traffic can flow freely within a zone, but traffic will not be able to flow between zones until you define a security policy rule that allows it.



The following topics describe the components of the security perimeter and provide steps for configuring the firewall interfaces, defining zones, and setting up a basic security policy that allows traffic from your internal zone to the Internet and to the DMZ. By initially creating a basic security policy rulebase like this, you will be able to analyze the traffic running through your network and use this information to define more granular policies for safely enabling applications while preventing threats.

- Basic Interface Deployments
- About Security Policy
- Plan the Deployment
- Configure Interfaces and Zones
- Set Up Basic Security Policies

If you use private IP addresses in your internal networks, you will also need to configure network address translation (NAT).

# Basic Interface Deployments

All Palo Alto Networks next-generation firewalls provide a flexible networking architecture that includes support for dynamic routing, switching, and VPN connectivity, enabling you to deploy the firewall into nearly any networking environment. When configuring the Ethernet ports on your firewall, you can choose from virtual wire, Layer 2, or Layer 3 interface deployments. In addition, to allow you to integrate into a variety of network segments, you can configure different types of interfaces on different ports. The following sections provide basic information on each type of deployment.

- Virtual Wire Deployments
- Layer 2 Deployments
- Layer 3 Deployments

For more detailed deployment information, refer to Designing Networks with Palo Alto Networks Firewalls.

## Virtual Wire Deployments

In a virtual wire deployment, the firewall is installed transparently on a network segment by binding two ports together. By using a virtual wire, you can install the firewall in any network environment without reconfiguring adjacent devices. If necessary, a virtual wire can block or allow traffic based on the virtual LAN (VLAN) tag values. You can also create multiple subinterfaces and classify traffic according to an IP Address (address, range, or subnet), VLAN, or a combination of the two.

By default, the virtual wire (named **default-vwire**) binds Ethernet ports 1 and 2 and allows all untagged traffic. Choose this deployment to simplify installation and configuration and/or avoid configuration changes to surrounding network devices.

A virtual wire is the default configuration, and should be used only when no switching or routing is needed. If you do not plan to use the default virtual wire, you should manually delete the configuration before proceeding with interface configuration to prevent it from interfering with other interface settings you define. For instructions on how to delete the default virtual wire and its associated security policy and zones, see Step 3 in Set Up a Data Port for Access to External Services.

## Layer 2 Deployments

In a Layer 2 deployment, the firewall provides switching between two or more interfaces. Each group of interfaces must be assigned to a VLAN object in order for the firewall to switch between them. The firewall will perform VLAN tag switching when Layer 2 subinterfaces are attached to a common VLAN object. Choose this option when switching is required.

For more information on Layer 2 deployments, refer to the Layer 2 Networking Tech Note and/or the Securing Inter VLAN Traffic Tech Note.

 © Palo Alto Networks, Inc.

## Layer 3 Deployments

In a Layer 3 deployment, the firewall routes traffic between ports. An IP address must be assigned to each interface and a virtual router must be defined to route the traffic. Choose this option when routing is required.

You must assign an IP address to each physical Layer 3 interface you configure. You can also create logical subinterfaces for each physical Layer 3 interface that allows you to segregate the traffic on the interface based on VLAN tag (when VLAN trunking is in use) or by IP address, for example for multi-tenancy.

In addition, because the firewall must route traffic in a Layer 3 deployment, you must configure a virtual router. You can configure the virtual router to participate with dynamic routing protocols (BGP, OSPF, or RIP) as well as adding static routes. You can also create multiple virtual routers, each maintaining a separate set of routes that are not shared between virtual routers, enabling you to configure different routing behaviors for different interfaces. For more information on routing integrations on the firewall, see the PAN-OS Admin Guide.

The configuration example in this chapter illustrates how to integrate the firewall into your Layer 3 network using static routes.

# About Security Policy

Security Policy protects network assets from threats and disruptions and aids in optimally allocating network resources for enhancing productivity and efficiency in business processes. On the Palo Alto Networks firewall, security policy rules determine whether to block or allow a session based on traffic attributes such as the source and destination security zone, the source and destination IP address, the application, user, and the service.

For traffic that doesn't match any defined rules, the default rules apply. The default rules—displayed at the bottom of the security rulebase—are predefined to allow all intrazone (within the zone) traffic and deny all interzone (between zones) traffic. Although these rules are part of the pre-defined configuration and are read-only by default, you can override them and change a limited number of settings, including the tags, action (allow or deny), log settings, and security profiles.

Security policies rules are evaluated left to right and from top to bottom. A packet is matched against the first rule that meets the defined criteria; after a match is triggered the subsequent rules are not evaluated. Therefore, the more specific rules must precede more generic ones in order to enforce the best match criteria. Traffic that matches a rule generates a log entry at the end of the session in the traffic log, if logging is enabled for that rule. The logging options are configurable for each rule, and can for example be configured to log at the start of a session instead of, or in addition to, logging at the end of a session.

- Actions in Security Policy
- About Policy Objects
- About Security Profiles

## Actions in Security Policy

For traffic that matches the attributes defined in a security policy, you can apply the following actions:

| Action | Description |
|---|---|
| **Allow** (default action) | Allows the traffic. |
| **Deny** | Blocks traffic, and enforces the default *Deny Action* defined for the application that is being denied. To view the deny action defined by default for an application, view the application details in **Objects > Applications** or check the application details in Applipedia. |
| **Drop** | Silently drops the traffic; for an application, it overrides the default deny action. A TCP reset is not sent to the host/application.<br>For Layer 3 interfaces, to optionally send an ICMP unreachable response to the client, set Action: **Drop** and enable the **Send ICMP Unreachable** check box. When enabled, the firewall sends the ICMP code for *communication with the destination is administratively prohibited*— ICMPv4: Type 3, Code 13; ICMPv6: Type 1, Code 1. |
| **Reset client** | Sends a TCP reset to the client-side device. |
| **Reset server** | Sends a TCP reset to the server-side device. |
| **Reset both** | Sends a TCP reset to both the client-side and server-side devices. |

 © Palo Alto Networks, Inc.

A reset is sent only after a session is formed. If the session is blocked before a 3-way handshake is completed, the firewall will not send the reset.

For a TCP session with a reset action, the firewall does not send an ICMP Unreachable response.

For a UDP session with a drop or reset action, if the **ICMP Unreachable** check box is selected, the firewall sends an ICMP message to the client.

## About Policy Objects

A *policy object* is a single object or a collective unit that groups discrete identities such as IP addresses, URLs, applications, or users. With Policy Objects that are a collective unit, you can reference the object in security policy instead of manually selecting multiple objects one at a time. Typically, when creating a policy object, you group objects that require similar permissions in policy. For example, if your organization uses a set of server IP addresses for authenticating users, you can group the set of server IP addresses as an *address group* policy object and reference the address group in the security policy. By grouping objects, you can significantly reduce the administrative overhead in creating policies.

Some examples of address and application policy objects are shown in the security policies that are included in Create Security Rules. For information on the other policy objects, see Enable Basic Threat Prevention Features.

## About Security Profiles

While security policies enable you to allow or deny traffic on your network, security profiles help you define an *allow but scan* rule, which scan allowed applications for threats. When traffic matches the allow rule defined in the security policy, the Security Profiles that are attached to the rule are applied for further content inspection rules such as antivirus checks and data filtering.

Security profiles are not used in the match criteria of a traffic flow. The security profile is applied to scan traffic after the application or category is allowed by the security policy.

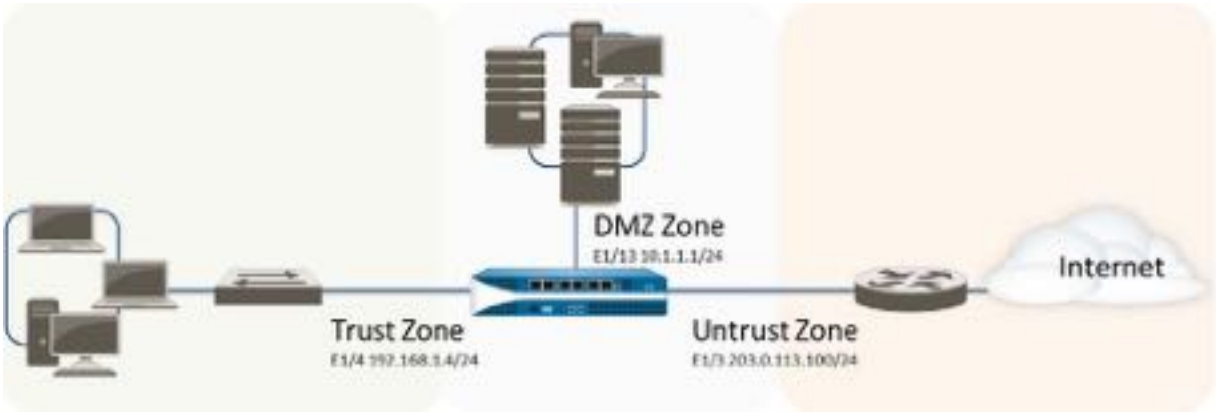
The different types of security profiles that can be attached to security policies are: Antivirus, Anti-Spyware, Vulnerability Protection, URL Filtering, File Blocking, and Data Filtering. The firewall provides default security profiles that you can use out of the box to begin protecting your network from threats. See Create Security Rules for information on using the default profiles in your security policy. As you get a better understanding about the security needs on your network, you can create custom profiles. See Scan Traffic for Threats for more information.

 © Palo Alto Networks, Inc.

## Plan the Deployment

Before you begin configuring interfaces and zones, take some time to plan the zones you will need based on the different usage requirements within your organization. In addition, you should gather all of the configuration information you will need ahead of time. At a basic level, you should plan which interfaces will belong to which zones. For Layer 3 deployments you'll also need to obtain the required IP addresses and network configuration information from your network administrator, including information on how to configure the routing protocol or static routes required for the virtual router configuration. The example in this chapter will be based on the following topology:

**Figure: Layer 3 Topology Example**



The following table shows the information we will use to configure the Layer 3 interfaces and their corresponding zones as shown in the sample topology.

| Zone | Deployment Type | Interface(s) | Configuration Settings |
|---|---|---|---|
| Untrust | L3 | Ethernet1/3 | **IP address:** 203.0.113.100/24<br>**Virtual router:** default<br>**Default route:** 0.0.0.0/0<br>**Next hop:** 203.0.113.1 |
| Trust | L3 | Ethernet1/4 | **IP address:** 192.168.1.4/24<br>**Virtual router:** default |
| DMZ | L3 | Ethernet1/13 | **IP address:** 10.1.1.1/24<br>**Virtual router:** default |

## Configure Interfaces and Zones

After you plan your zones and the corresponding interfaces, you can configure them on the device. The way you configure each interface depends on your network topology.

The following procedure shows how to configure a Layer 3 deployment as depicted in Figure: Layer 3 Topology Example.

The firewall comes preconfigured with a default virtual wire interface between ports Ethernet 1/1 and Ethernet 1/2 (and a corresponding default security policy and virtual router). If you do not plan to use the default virtual wire, you must manually delete the configuration and commit the change before proceeding to prevent it from interfering with other settings you define. For instructions on how to delete the default virtual wire and its associated security policy and zones, see Step 3 in Set Up a Data Port for Access to External Services.

| **Set Up Interfaces and Zones** | | |
|---|---|---|
| Step 1 | Configure a default route to your Internet router. | 1. Select **Network > Virtual Router** and then select the **default** link to open the Virtual Router dialog.<br>2. Select the **Static Routes** tab and click **Add**. Enter a **Name** for the route and enter the route in the **Destination** field (for example, 0.0.0.0/0).<br>3. Select the **IP Address** radio button in the **Next Hop** field and then enter the IP address and netmask for your Internet gateway (for example, 203.00.113.1).<br>4. Click **OK** twice to save the virtual router configuration. |
| Step 2 | Configure the external interface (the interface that connects to the Internet). | 1. Select **Network > Interfaces** and then select the interface you want to configure. In this example, we are configuring Ethernet1/3 as the external interface.<br>2. Select the **Interface Type**. Although your choice here depends on your network topology, this example shows the steps for **Layer3**.<br>3. On the **Config** tab, select **New Zone** from the **Security Zone** drop-down. In the Zone dialog, define a **Name** for new zone, for example Untrust, and then click **OK**.<br>4. In the **Virtual Router** drop-down, select **default**.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 208.80.56.100/24.<br>6. To enable you to ping the interface, select **Advanced > Other Info**, expand the **Management Profile** drop-down, and select **New Management Profile**. Enter a **Name** for the profile, select **Ping** and then click **OK**.<br>7. To save the interface configuration, click **OK**. |

 © Palo Alto Networks, Inc.

| Set Up Interfaces and Zones (Continued) | | |
|---|---|---|
| Step 3 | Configure the interface that connects to your internal network.<br><br>In this example, the interface connects to a network segment that uses private IP addresses. Because private IP addresses cannot be routed externally, you will have to configure NAT. | 1. Select **Network > Interfaces** and select the interface you want to configure. In this example, we are configuring Ethernet1/4 as the internal interface.<br>2. Select **Layer3** from the **Interface Type** drop-down.<br>3. On the **Config** tab, expand the **Security Zone** drop-down and select **New Zone**. In the Zone dialog, define a **Name** for new zone, for example Trust, and then click **OK**.<br>4. Select the same Virtual Router you used in Step 2, default in this example.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 192.168.1.4/24.<br>6. To enable you to ping the interface, select the management profile that you created in Step 2-6.<br>7. To save the interface configuration, click **OK**. |
| Step 4 | Configure the interface that connects to the DMZ. | 1. Select the interface you want to configure.<br>2. Select **Layer3** from the **Interface Type** drop-down. In this example, we are configuring Ethernet1/13 as the DMZ interface.<br>3. On the **Config** tab, expand the **Security Zone** drop-down and select **New Zone**. In the Zone dialog, define a **Name** for new zone, for example DMZ, and then click **OK**.<br>4. Select the Virtual Router you used in Step 2, default in this example.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 10.1.1.1/24.<br>6. To enable you to ping the interface, select the management profile that you created in Step 2-6.<br>7. To save the interface configuration, click **OK**. |
| Step 5 | Save the interface configuration. | Click **Commit**. |
| Step 6 | Cable the firewall. | Attach straight through cables from the interfaces you configured to the corresponding switch or router on each network segment. |
| Step 7 | Verify that the interfaces are active. | From the web interface, select **Network > Interfaces** and verify that icon in the Link State column is green. You can also monitor link state from the **Interfaces** widget on the **Dashboard**.<br><br>  |

# Set Up Basic Security Policies

Policies allow you to enforce rules and take action. The different types of policy rules that you can create on the firewall are: Security, NAT, Quality of Service (QoS), Policy Based Forwarding (PBF), Decryption, Application Override, Captive Portal, Denial of Service, and Zone protection policies. All these different policies work together to allow, deny, prioritize, forward, encrypt, decrypt, make exceptions, authenticate access, and reset connections as needed to help secure your network. This section covers basic security policies and the default security profiles:

- Create Security Rules
- Test Your Security Policies
- Monitor Network Traffic

## Create Security Rules

Security policies reference security zones and enable you to allow, restrict, and track traffic on your network. Because each zone implies a level of trust, the implicit rule for passing traffic between two different zones is deny, and the traffic within a zone is permitted. To allow traffic between two different zones, you must create a security rule that allows traffic to flow between them.

While setting up the basic framework for securing the enterprise perimeter, it's good idea to start with a simple security policy that allows traffic between the different zones without being too restrictive. As illustrated in the following section, our objective is to minimize the likelihood of breaking applications that users on the network need access to, while providing visibility into the applications and the potential threats for your network.

When defining policies make sure that you do not create a policy that denies all traffic from *any* source zone to *any* destination zone as this will break intra-zone traffic that is implicitly allowed. By default, intra-zone traffic is permitted because the source and destination zones are the same and therefore share the same level of trust.

 © Palo Alto Networks, Inc.

## Define Basic Security Rules

**Step 1** Permit Internet access for all users on the enterprise network.

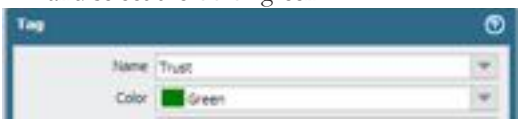
Zone: Trust to Untrust

By default, the firewall includes a security rule named *rule1* that allows all traffic from Trust zone to Untrust zone. You can either delete the rule or modify the rule to reflect your zone-naming convention.

To safely enable applications that are required for day-to-day business operations we will create a simple rule that allows access to the Internet. To provide basic threat protection, we will attach the default security profiles available on the firewall.

1. Select **Policies > Security** and click **Add.**
2. Give the rule a descriptive name in the **General** tab.
3. In the **Source** tab, set the **Source Zone** to Trust.
4. In the **Destination** tab, Set the **Destination Zone** to Untrust.

   To scan policy rules and visually identify the zones on each rule, create a tag with the same name as the zone. For example, to color code the Trust zone as green, select **Objects > Tags,** click **Add** and **Name** the tag Trust, and select the **Color** green.



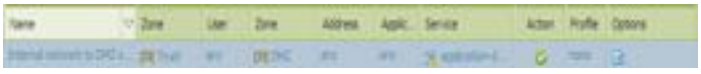
5. In the **Service/ URL Category** tab, select service-http and service-https.
6. In the **Actions** tab, complete these tasks:
   a. Set the **Action Setting** to **Allow**.
   b. Attach the default profiles for antivirus, anti-spyware, vulnerability protection and URL filtering, under **Profile Setting.**
7. Verify that logging is enabled at the end of a session under **Options**. Only traffic that matches a security rule will be logged.

**Step 2** Permit users on the internal network to access the servers in the DMZ.

Zone: Trust to DMZ

If using IP addresses for configuring access to the servers in the DMZ, make sure to always refer to the original IP addresses in the packet (i.e. the pre-NAT addresses), and the post-NAT zone.

1. Click **Add** in the **Policies > Security** section.
2. Give the rule a descriptive name in the **General** tab.
3. In the **Source** tab, set the **Source Zone** to Trust.
4. In the **Destination** tab, set the **Destination Zone** to DMZ.
5. In the **Service/ URL Category** tab, make sure the **Service** is set to **application-default**.
6. In the **Actions** tab, set the **Action Setting** to Allow.
7. Leave all the other options at the default values.



**Define Basic Security Rules (Continued)**

**Step 3** Restrict access from the Internet to the servers on the DMZ to specific server IP addresses only.

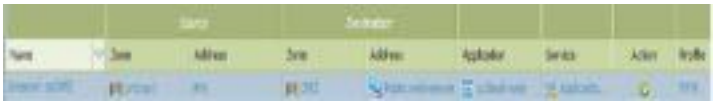
For example, you might only allow users to access the webmail servers from outside.

Zone: Untrust to DMZ

To restrict inbound access to the DMZ from the Internet, configure a rule that allows access only to specific servers IP addresses and on the default ports that the applications use.

1. Click **Add** to add a new rule, and give it a descriptive name.
2. In the **Source** tab, set the **Source Zone** to Untrust.
3. In the **Destination** tab, set the **Destination Zone** to DMZ.
4. Set the **Destination Address** to the **Public web server** address object you created earlier. The public web server address object references the public IP address—208.80.56.11/24—of the web server that is accessible on the DMZ.
5. Select the webmail application in the **Application** tab.

   The **Service** is set to **application-default** by default.



6. Set the **Action Setting** to **Allow**.

**Step 4** Allow access from the DMZ to your internal network (Trust zone). To minimize risk, you will allow traffic only between specific servers and destination addresses. For example, if you have an application server on the DMZ that needs to communicate with a specific database server in your Trust zone, create a rule to allow traffic between a specific source to a specific destination.

Zone: DMZ to Trust

1. Click **Add** to add a new rule, and give it a descriptive name.
2. Set the **Source Zone** to DMZ.
3. Set the **Destination Zone** to Trust.
4. Create a an address object that specifies the server(s) on your Trust zone that can be accessed from the DMZ.

5. In the **Destination** tab on the Security Policy rule, set the **Destination Address** to the Address object you created above.
6. In the **Actions** tab, complete these tasks:
   a. Set the **Action Setting** to **Allow**.
   b. Attach the default profiles for antivirus, anti-spyware, vulnerability protection, under **Profile Setting.**
   c. In the Other Settings section, select the option to **Disable Server Response Inspection**. This setting disables the antivirus and anti-spyware scanning on the server-side responses, and thus reduces the load on the firewall.

 © Palo Alto Networks, Inc.

| Define Basic Security Rules (Continued) | | |
|---|---|---|
| Step 5 | Enable the servers on the DMZ to obtain updates and hot fixes from the Internet. Say, for example, you would like to allow the Microsoft Update service.<br><br>Zone: DMZ to Untrust | 1. Add a new rule and give it a descriptive label.<br>2. Set the **Source Zone** to DMZ.<br>3. Set the **Destination Zone** to Untrust.<br>4. Create an application group to specify the applications that you would like to allow. In this example, we allow Microsoft updates (ms-updates) and dns.<br>  <br>The **Service** is set to **application-default** by default. This allows the firewall to permit the applications only when they use the standard ports associated with these applications.<br>5. Set the **Action Setting** to **Allow**.<br>6. Attach the default profiles for antivirus, anti-spyware, and vulnerability protection, under **Profiles**.<br> |
| Step 6 | Save your policies to the running configuration on the device. | Click **Commit**. |

## Test Your Security Policies

To verify that you have set up your basic policies effectively, test whether your security policies are being evaluated and determine which security rule applies to a traffic flow.

| Verify Policy Match Against a Flow | |
|---|---|
| To verify the policy rule that matches a flow, use the following CLI command:<br>**test security-policy-match source** <IP_address> **destination** <IP_address> **destination port** <port_number> **protocol** <protocol_number><br>The output displays the best rule that matches the source and destination IP address specified in the CLI command. | For example, to verify the policy rule that will be applied for a server on the DMZ with the IP address 208.90.56.11 when it accesses the Microsoft update server, you will try the following command:<br>`test security-policy-match source 208.80.56.11 destination 176.9.45.70 destination-port 80 protocol 6`<br>`"Updates-DMZ to Internet" { from dmz; source any; source-region any; to untrust; destination any; destination-region any; user any; category any; application/service[dns/tcp/any/53 dns/udp/any/53 dns/udp/any/5353 ms-update/tcp/any/80 ms-update/tcp/any/443]; action allow; terminal yes;` |

## Monitor Network Traffic

Now that you have a basic security policy, you can review the statistics and data in the Application Command Center (ACC), traffic logs, and the threat logs to observe trends on your network, to identify where you need to create more granular policies.

| Monitor Network Traffic | |
|---|---|
| • Use the Application Command Center and Use the Automated Correlation Engine. | In the ACC, review the most used applications and the high-risk applications on your network. The ACC graphically summarizes the log information to highlight the applications traversing the network, who is using them (with User-ID enabled), and the potential security impact of the content to help you identify what is happening on the network in real time. You can then use this information to create appropriate security policy rules that block unwanted applications, while allowing and enabling applications in a secure manner.<br>The Compromised Hosts widget in **ACC > Threat Activity** displays potentially compromised hosts on your network and the logs and match evidence that corroborates the events. |

 © Palo Alto Networks, Inc.

| Monitor Network Traffic | |
|---|---|
| • Determine what updates/modifications are required for your network security policy rules and implement the changes. | For example:<br>• Evaluate whether to allow content based on schedule, users, or groups.<br>• Allow or control certain applications or functions within an application.<br>• Decrypt and inspect content.<br>• Allow but scan for threats and exploits.<br>For information on refining your security policies and for attaching custom security profiles, see Enable Basic Threat Prevention Features. |
| • View the Log Files. | Specifically, view the traffic and threat logs (**Monitor > Logs**).<br> Traffic logs are dependent on how your security policies are defined and set up to log traffic. The Application Usage widget in the **ACC**, however, records applications and statistics regardless of policy configuration; it shows all traffic that is allowed on your network, therefore it includes the inter-zone traffic that is allowed by policy and the same zone traffic that is allowed implicitly |
| • Monitor Web Activity of Network Users. | Review the URL filtering logs to scan through alerts, denied categories/URLs. URL logs are generated when a traffic matches a security rule that has a URL filtering profile attached with an action of alert, continue, override or block. |

# Enable Basic Threat Prevention Features

The Palo Alto Networks next-generation firewall has unique threat prevention capabilities that allow it to protect your network from attack despite evasive, tunneled, or circumvention techniques. The threat prevention features on the firewall include the WildFire service, the Security Profiles that support Antivirus, Anti-Spyware, Vulnerability Protection, URL Filtering, File Blocking and Data Filtering capabilities and the Denial of Service (DoS) and Zone protection functionality.

Before you can apply threat prevention features, you must first configure zones—to identify one or more source or destination interfaces—and security policy rules. To configure interfaces, zones, and the policies that are needed to apply threat prevention features, see Configure Interfaces and Zones and Set Up Basic Security Policies.

To begin protecting your network from threats start here:

- Enable WildFire
- Scan Traffic for Threats
- Control Access to Web Content

 © Palo Alto Networks, Inc.

## Enable WildFire

The WildFire service is included as part of the base product. The WildFire service enables the firewall to forward attachments to a sandbox environment where applications are run to detect any malicious activity. As new malware is detected by the WildFire service, malware signatures are automatically generated and are made available within 24-48 hours in the antivirus daily downloads. Your threat prevention subscription entitles you to antivirus signature updates that include signatures discovered by WildFire.

Consider purchasing the WildFire subscription service for these additional benefits:

- Sub-hourly (as often as every 15 minutes) WildFire signature updates.
- Advanced file type forwarding for APKs, Flash files, PDFs, Microsoft Office files, Java Applets, Java files (.jar and .class), and HTTP/HTTPS email links contained in SMTP and POP3 email messages. Portable Executable (PE) files can be forwarded for WildFire analysis both with and without a WildFire subscription.
- Ability to upload files using the WildFire API.
- Ability to forward files to a private WF-500 WildFire appliance. When using a WildFire appliance, you can also set up a WildFire hybrid cloud, enabling the WildFire appliance to analyze sensitive file types locally, while other files less sensitive file types (such as PEs) or file types not supported for WildFire appliance analysis (such as APKs) can be forwarded to the WildFire cloud.

| **Enable WildFire** | | |
|---|---|---|
| Step 1 | Confirm that your device is registered and that you have a valid support account as well as any subscriptions you require. | 1. Go to the Palo Alto Networks Support Site, log in, and select **My Devices**.<br>2. Verify that the firewall is listed. If it is not listed, see Register the Firewall.<br>3. (Optional) Activate Licenses and Subscriptions. |
| Step 2 | Set the WildFire forwarding options.<br> If you do not have a WildFire subscription you can only forward PEs. | 1. Select **Device > Setup > WildFire** and edit the General Settings.<br>2. (Optional) Specify the WildFire cloud or WildFire appliance (or both) to which the firewall will forward files for analysis. By default, the firewall will forward files to the public WildFire cloud hosted in the United States (wildfire.paloaltonetworks.com). To forward files to the WildFire cloud hosted in Japan or to enable file-forwarding to a WildFire appliance, update the following fields:<br>• **WildFire Public Cloud**—To forward files to the public WildFire cloud running in Japan, enter `wildfire.paloaltonetworks.jp`.<br>• **WildFire Private Cloud**—To forward files to a private WildFire cloud, enter the IP address or FQDN of your WF-500 WildFire appliance.<br>3. (Optional) If you want to change the maximum file size that the firewall can forward for a specific type of file, modify the value in the corresponding field.<br>4. Click **OK** to save your changes. |

| Enable WildFire (Continued) | | |
|---|---|---|
| Step 3 | Set up a WildFire Analysis profile to forward files to WildFire. | 1. Select **Objects > Security Profiles > WildFire Analysis** and click **Add**.<br>2. Enter a **Name** and optionally a **Description** for the profile.<br>3. Click **Add** to create a forwarding rule and enter a name.<br>4. Define traffic to be forwarded to the WildFire service based on **Applications**, **File Types,** or transmission **Direction**.<br>5. In the **Analysis** column, select **public-cloud** to forward the defined files to the WildFire cloud or select **private-cloud** to forward files to the WildFire appliance.<br>6. (Optional) Add additional forwarding rules as necessary.<br>7. Click **OK** to save the profile. |
| Step 4 | Attach the WildFire Analysis profile to the security policies that allow access to the Internet. | 1. Select **Policies > Security** and either select an existing policy or create a new policy as described in Create Security Rules.<br>2. Click the **Actions** tab within the security policy.<br>3. In the Profile Settings section, click the drop-down and select the WildFire Analysis profile you created for WildFire forwarding. (If you don't see a drop-down for selecting a profile, select **Profiles** from the **Profile Type** drop-down. |
| Step 5 | Save the configuration. | Click **Commit**. |
| Step 6 | Verify that the firewall is forwarding files to the WildFire cloud or the WildFire appliance. | 1. Select **Monitor > Logs > WildFire Submissions** to WildFire logs. For each log entry displayed, the firewall has successfully forwarded the file to WildFire and WildFire has returned a file analysis report.<br>2. Check the **WildFire Cloud** column to view if a file was forwarded to the WildFire cloud or the WildFire appliance for analysis. |

 © Palo Alto Networks, Inc.

# Scan Traffic for Threats

Security Profiles provide threat protection in security policies. For example, you can apply an antivirus profile to a security policy and all traffic that matches the security policy will be scanned for viruses.

The following sections provide steps for setting up a basic threat prevention configuration:

- Set Up Antivirus, Anti-Spyware, and Vulnerability Protection
- Set Up File Blocking

## Set Up Antivirus, Anti-Spyware, and Vulnerability Protection

Every Palo Alto Networks next-generation firewall comes with predefined Antivirus, Anti-Spyware, and Vulnerability Protection profiles that you can attach to security policies. There is one predefined Antivirus profile, **default**, which uses the default action for each protocol (block HTTP, FTP, and SMB traffic and alert on SMTP, IMAP, and POP3 traffic). There are two predefined Anti-Spyware and Zone Protection profiles:

- **default**—Applies the default action to all client and server critical, high, and medium severity spyware/vulnerability protection events. It does not detect low and informational events.
- **strict**—Applies the block response to all client and server critical, high and medium severity spyware/vulnerability protection events and uses the default action for low and informational events.

To ensure that the traffic entering your network is free from threats, attach the predefined profiles to your basic web access policies. As you monitor the traffic on your network and expand your policy rulebase, you can then design more granular profiles to address your specific security needs.

| **Set up Antivirus/Anti-Spyware/Vulnerability Protection** | | |
|---|---|---|
| Step 1 | Verify that you have a Threat Prevention license. | • The Threat Prevention license bundles the Antivirus, Anti-Spyware, and the Vulnerability Protection features in one license.<br>• Select **Device > Licenses** to verify that the **Threat Prevention** license is installed and valid (check the expiration date). |
| Step 2 | Download the latest antivirus threat signatures. | 1. Select **Device > Dynamic Updates** and click **Check Now** at the bottom of the page to retrieve the latest signatures.<br>2. In the **Actions** column, click **Download** to install the latest Antivirus, and Applications and Threats signatures. |

**Set up Antivirus/Anti-Spyware/Vulnerability Protection (Continued)**

Step 3 Schedule signature updates.

Perform a **download-and-install** on a daily basis for antivirus updates and weekly for applications and threats updates.

1. From **Device > Dynamic Updates**, click the text to the right of **Schedule** to automatically retrieve signature updates for **Antivirus** and **Applications and Threats**.
2. Specify the frequency and timing for the updates and whether the update will be downloaded and installed or only downloaded. If you select **Download Only**, you would need to manually go in and click the **Install** link in the **Action** column to install the signature. When you click **OK**, the update is scheduled. No commit is required.
3. (Optional) You can also enter the number of hours in the **Threshold** field to indicate the minimum age of a signature before a download will occur. For example, if you entered **10**, the signature must be at least 10 hours old before it will be downloaded, regardless of the schedule.
4. In an HA configuration, you can also click the **Sync To Peer** option to synchronize the content update with the HA peer after download/install. This will not push the schedule settings to the peer device, you need to configure the schedule on each device.

Recommendations for HA Configurations:

- **Active/Passive HA**—If the MGT port is used for antivirus signature downloads, you should configure a schedule on both devices and both devices will download/install independently. If you are using a data port for downloads, the passive device will not perform downloads while it is in the passive state. In this case you would set a schedule on both devices and then select the **Sync To Peer** option. This will ensure that whichever device is active, the updates will occur and will then push to the passive device.
- **Active/Active HA**—If the MGT port is used for antivirus signature downloads on both devices, then schedule the download/install on both devices, but do not select the **Sync To Peer** option. If you are using a data port, schedule the signature downloads on both devices and select **Sync To Peer**. This will ensure that if one device in the active/active configuration goes into the active-secondary state, the active device will download/install the signature and will then push it to the active-secondary device.

 © Palo Alto Networks, Inc.

| Set up Antivirus/Anti-Spyware/Vulnerability Protection (Continued) | |
|---|---|
| Step 4 Attach the security profiles to a security policy.<br><br>Attach a clone of a predefined security profile to your basic security policies. That way, if you want to customize the profile you can do so without deleting the read-only predefined **strict** or **default** profile and attaching a customized profile. | 1. Select **Policies > Security**, select the desired policy to modify it and then click the **Actions** tab.<br>2. In **Profile Settings**, click the drop-down next to each security profile you would like to enable. In this example we choose default for **Antivirus, Vulnerability Protection,** and **Anti-Spyware**.<br><br>If you don't see drop-downs for selecting profiles, select **Profiles** from the **Profile Type** drop-down.<br><br>  |
| Step 5 Save the configuration. | Click **Commit**. |

## Set Up File Blocking

File Blocking Profiles allow you to identify specific file types that you want to want to block or monitor. The following workflow shows how to set up a basic file blocking profile that prevents users from downloading executable files from the Internet.

| Configure File Blocking | |
|---|---|
| Step 1 Create the file blocking profile. | 1. Select **Objects > Security Profiles > File Blocking** and click **Add**.<br>2. Enter a **Name** for the file blocking profile, for example `Block_EXE`.<br>3. Optionally enter a **Description**, such as `Block users from downloading exe files from websites`. |
| Step 2 Configure the file blocking options. | 1. Click **Add** to define the profile settings.<br>2. Enter a **Name**, such as `BlockEXE`.<br>3. Set the **Applications** to which to apply file blocking, or leave it set to **any**.<br>4. Set **File Types** to block. For example, to block download of executables, you would select **exe**.<br>5. Specify the **Direction** in which to block files: **download**, **upload**, or **both**.<br>6. Set the **Action** to one of the following:<br>• **continue**—(web traffic only) Files matching the selected criteria will trigger a customizable response page that requires users to click **Continue** in order to proceed with the download/upload. You must enable response pages on the associated interfaces if you plan to use this option (Step 4).<br>• **block**—Files matching the selected criteria will be blocked from download/upload.<br>• **alert**—Files matching the selected criteria will be allowed, but will generate a log entry in the data filtering log.<br> <br>7. Click **OK** to save the profile. |
| Step 3 Attach the file blocking profile to the security policies that allow access to content. | 1. Select **Policies > Security** and either select an existing policy or create a new policy as described in Create Security Rules.<br>2. Click the **Actions** tab within the security policy.<br>3. In the Profile Settings section, click the drop-down and select the file blocking profile you created.<br>If you don't see drop-downs for selecting profiles, select **Profiles** from the **Profile Type** drop-down. |

 © Palo Alto Networks, Inc.

| Configure File Blocking (Continued) | | |
|---|---|---|
| Step 4 | Enable response pages in the management profile for each interface on which you are attaching file blocking profile with a **continue** action. | 1. Select **Network > Network Profiles > Interface Mgmt** and then select an interface profile to edit or click **Add** to create a new profile.<br>2. Select **Response Pages**, as well as any other management services required on the interface.<br>3. Click **OK** to save the interface management profile.<br>4. Select **Network > Interfaces** and select the interface to which to attach the profile.<br>5. On the **Advanced > Other Info** tab, select the interface management profile you just created.<br>6. Click **OK** to save the interface settings. |
| Step 5 | Test the file blocking configuration. | Access a client PC in the trust zone of the firewall and attempt to download an.exe file from a website in the untrust zone. Make sure the file is blocked as expected based on the action you defined in the file blocking profile:<br>• If you selected **alert** as the action, check the data filtering log to make sure you see a log entry for the request.<br>• If you selected **block** as the action, the File Blocking Block Page response page should display.<br>• If you selected the **continue** action, the File Blocking Continue Page response page should display. Click **Continue** to download the file. The following shows the default File Blocking Continue Page.<br> |

## Control Access to Web Content

URL Filtering provides visibility and control over web traffic on your network. With URL filtering enabled, the firewall can categorize web traffic into one or more (from approximately 60) categories. You can then create policies that specify whether to allow, block, or log (alert) traffic based on the category to which it belongs. The following workflow shows how to enable PAN-DB for URL filtering, create security profiles, and attach them to security policies to enforce a basic URL filtering policy.

| **Configure URL Filtering** | | |
|---|---|---|
| Step 1 | Confirm license information for URL Filtering. | 1. Obtain and install a URL Filtering license. See Activate Licenses and Subscriptions for details.<br>2. Select **Device > Licenses** and verify that the URL Filtering license is valid.<br> |
| Step 2 | Download the seed database and activate the license. | 1. To download the seed database, click **Download** next to **Download Status** in the PAN-DB URL Filtering section of the Licenses page.<br>2. Choose a region (North America, Europe, APAC, Japan) and then click **OK** to start the download.<br>3. After the download completes, click **Activate**.<br> |
| Step 3 | Create a URL filtering profile.<br>Because the default URL filtering profile blocks risky and threat-prone content, clone this profile when creating a new profile in order to preserve the default settings. | 1. Select **Objects > Security Profiles > URL Filtering**.<br>2. Select the default profile and then click **Clone**. The new profile will be named default-1.<br>3. Select the new profile and rename it. |

 © Palo Alto Networks, Inc.

| Configure URL Filtering (Continued) | |
|---|---|
| Step 4 Define how to control access to web content.<br><br>If you are not sure what traffic you want to control, consider setting the categories (except for those blocked by default) to alert. You can then use the visibility tools on the firewall, such as the ACC and App Scope, to determine which web categories to restrict to specific groups or to block entirely. You can then go back and modify the profile to block and allow categories as desired.<br><br>You can also define specific sites to always allow or always block regardless of category and enable the safe search option to filter search results when defining the URL Filtering profile. | 1. For each category that you want visibility into or control over, select a value from the **Action** column as follows:<br>• If you do not care about traffic to a particular category (that is you neither want to block it nor log it), select **allow**.<br>• For visibility into traffic to sites in a category, select **alert**.<br>• To present a response page to users attempting to access a particular category to alert them to the fact that the content they are accessing might not be work appropriate, select **continue**.<br>• To prevent access to traffic that matches the associated policy, select **block** (this also generates a log entry).<br> <br>2. Click **OK** to save the URL filtering profile. |
| Step 5 Attach the URL filtering profile to a security policy. | 1. Select **Policies > Security**.<br>2. Select the desired policy to modify it and then click the **Actions** tab.<br>3. If this is the first time you are defining a security profile, select **Profiles** from the **Profile Type** drop-down.<br>4. In the **Profile Settings** list, select the profile you just created from the **URL Filtering** drop-down. (If you don't see drop-downs for selecting profiles, select **Profiles** from the **Profile Type** drop-down.)<br>5. Click **OK** to save the profile.<br>6. **Commit** the configuration. |

| Configure URL Filtering (Continued) | | |
|---|---|---|
| Step 6 | Enable Response Pages in the management profile for each interface on which you are filtering web traffic. | 1. Select **Network > Network Profiles > Interface Mgmt** and then select an interface profile to edit or click **Add** to create a new profile.<br>2. Select **Response Pages**, as well as any other management services required on the interface.<br>3. Click **OK** to save the interface management profile.<br>4. Select **Network > Interfaces** and select the interface to which to attach the profile.<br>5. On the **Advanced > Other Info** tab, select the interface management profile you just created.<br>6. Click **OK** to save the interface settings. |
| Step 7 | Save the configuration. | Click **Commit**. |
| Step 8 | Test the URL filtering configuration. | Access a client PC in the trust zone of the firewall and attempt to access a site in a blocked category. Make sure URL filtering is applied based on the action you defined in the URL filtering profile:<br>• If you selected **alert** as the action, check the data filtering log to make sure you see a log entry for the request.<br>• If you selected the **continue** action, the URL Filtering Continue and Override Page response page should display. **Continue** to the site.<br>• If you selected **block** as the action, the URL Filtering and Category Match Block Page response page should display as follows:<br> |

## For More Information

For more detailed information on how to protect your enterprise from threats, see Threat Prevention. For details on how to scan encrypted (SSH or SSL) traffic for threats, see Decryption.

For information about the threats and applications that Palo Alto Networks products can identify, visit the following links:

- Applipedia—Provides details on the applications that Palo Alto Networks can identify.
- Threat Vault—Lists threats that Palo Alto Networks products can identify. You can search by Vulnerability, Spyware, or Virus. Click the Details icon next to the ID number for more information about a threat.

 © Palo Alto Networks, Inc.

# Best Practices for Completing the Firewall Deployment

Now that you have integrated the firewall into your network and enabled the basic security features, you can begin configuring more advanced features. Here are some things to consider next:

- Learn about the different Management Interfaces that are available to you and how to access and use them.
- Set up High Availability—High availability (HA) is a configuration in which two firewalls are placed in a group and their configuration is synchronized to prevent a single point to failure on your network. A heartbeat connection between the firewall peers ensures seamless failover in the event that a peer goes down. Setting up the firewalls in a two-device cluster provides redundancy and allows you to ensure business continuity.
- Configure the Master Key—Every Palo Alto Networks firewall has a default master key that encrypts private keys that are used to authenticate administrators when they access management interfaces on the firewall. As a best practice to safeguard the keys, configure the master key on each firewall to be unique.
- Manage Firewall Administrators—Every Palo Alto Networks firewall and appliance is preconfigured with a default administrative account (admin) that provides full read-write access (also known as superuser access) to the device. As a best practice, create a separate administrative account for each person who needs access to the administrative or reporting functions of the firewall. This allows you to better protect the device from unauthorized configuration (or modification) and to enable logging of the actions of each individual administrator.
- Enable User Identification (User-ID)—User-ID is a Palo Alto Networks next-generation firewall feature that allows you to create policies and perform reporting based on users and groups rather than individual IP addresses.
- Enable Decryption—Palo Alto Networks firewalls provide the capability to decrypt and inspect traffic for visibility, control, and granular security. Use decryption on a firewall to prevent malicious content from entering your network or sensitive content from leaving your network concealed as encrypted or tunneled traffic.
- Enable Passive DNS Collection for Improved Threat Intelligence—Enable this opt-in feature to enable the firewall to act as a passive DNS sensor and send select DNS information to Palo Alto Networks for analysis in order to improve threat intelligence and threat prevention capabilities.
- Follow the Best Practices for Securing Your Network from Layer 4 and Layer 7 Evasions.

© Palo Alto Networks, Inc.

 © Palo Alto Networks, Inc.

# Device Management

Administrators can configure, manage, and monitor the Palo Alto Networks firewalls using the web interface, the CLI, and the API management interface. Role-based administrative access to the management interfaces can be customized in order to delegate specific tasks or permissions to certain administrators. See the following topics for information on device management options, including how to begin using the management interfaces and how to customize administrator roles:

- Management Interfaces
- Manage Firewall Administrators
- Reference: Web Interface Administrator Access
- Reference: Port Numbers Used by Palo Alto Networks Devices
- Reset the Firewall to Factory Default Settings

# Management Interfaces

PAN-OS firewalls and Panorama provide three user interfaces: a web interface, a command line interface (CLI), and a XML-based management API. See the following topics for how to access and begin using each of the device management interfaces:

- Use the Web Interface to complete administrative tasks and generate reports from the web interface with relative ease. This graphical interface allows you to access the firewall using HTTPS and it is the best way to perform administrative tasks.
- Use the Command Line Interface (CLI) to type through the commands in rapid succession to complete a series of tasks. The CLI is a no-frills interface that supports two command modes and each mode has its own hierarchy of commands and statements. When you get familiar with the nesting structure and the syntax of the commands, the CLI allows quick response times and offers administrative efficiency.
- Use the XML API to streamline your operations and integrate with existing, internally developed applications and repositories. The XML API is provided as a web service that is implemented using HTTP/HTTPS requests and responses.

 © Palo Alto Networks, Inc.

# Use the Web Interface

The following topics describes how to begin using the firewall web interface. For detailed information about the tabs and fields that are available in the web interface, refer to the Web Interface Reference Guide.

- Launch the Web Interface
- Navigate the Web Interface
- Commit or Validate Changes
- Global Find
- Use Configuration Pages
- Required Fields
- Lock Transactions

## Launch the Web Interface

The following web browsers are supported for access to the web interface for PAN-OS firewalls and Panorama:

- Internet Explorer 7+
- Firefox 3.6+
- Safari 5+
- Chrome 11+

Launch an Internet browser and enter the firewall's IP address. Enter your user credentials. If logging in to the firewall for the first time, type the default **admin** into both the **Name** and **Password** fields.

To view information on how to use a specific page and an explanation of the fields and options on the page, click the **Help** icon

in the upper right area of the page to open the online help system. In addition to displaying context-sensitive help for a page, clicking the **Help** icon displays a help navigation pane with options to browse and search all help content.

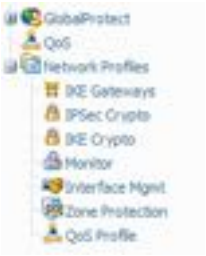
## Navigate the Web Interface

The following conventions apply when using the web interface.

- To display the menu items for a general functional category, click the tab, such as **Objects** or **Device**, near the top of the browser window.

- Click an item on the side menu to display a panel.

- To display submenu items, click the ⊞ icon to the left of an item. To hide submenu items, click the ⊟ icon to the left of the item.



- To search the candidate configuration on a firewall or on Panorama for a particular string, click the **Search** icon to start a Global Find search.

- On most configuration pages, you can click **Add** to create a new item.

- To delete one or more items, select their check boxes and click **Delete**. In most cases, the system prompts you to confirm by clicking **OK** or to cancel the deletion by clicking **Cancel**.

- On some configuration pages, you can select the check box for an item and click **Clone** to create a new item with the same information as the selected item.

- To modify an item, click its underlined link.

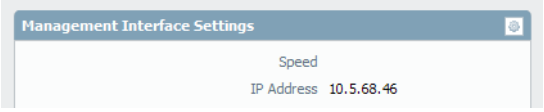
 © Palo Alto Networks, Inc.

- To view the current list of tasks, click the **Tasks** icon in the lower right corner of the page. The Task Manager window opens to show the list of tasks, along with status, start times, associated messages, and actions. Use the **Show** drop-down to filter the list of tasks.

- The web interface language is controlled by the current language of the computer that is managing the device if a specific language preference has not been defined. For example, if the computer you use to manage the firewall has a locale of Spanish, when you log in to the firewall, the web interface will be in Spanish.

- To specify a language that will always be used for a given account regardless of the locale of the computer, click the **Language** icon in the lower right corner of the page and the Language Preference window opens. Click the drop-down to select the desired language and then click **OK** to save your change.

- On pages that list information you can modify (for example, the **Setup** page on the **Devices** tab), click the icon in the upper right corner of a section to edit the settings.



- After you configure settings, you must click **OK** or **Save** to store the changes. When you click **OK**, the current *candidate* configuration is updated.

## Commit or Validate Changes

Click **Commit** at the top of the web interface to open the Commit dialog box, which displays the following options. Certain options only display if you click **Advanced**.

If dependencies between the configuration changes you included and excluded cause a validation error, perform the commit with all the changes included. For example, if your changes introduce a new Log Forwarding profile (an object) that references a new Syslog server profile (a device setting), the commit must include both policy and object configurations and device and network configurations.

- **Include Device and Network configuration**—Include the device and network configuration changes in the commit operation.
- **Include Shared Object configuration**—(Multi-virtual system firewalls only) Include the shared object configuration changes in the commit operation.
- **Include Policy and Object configuration**—(Non-multi-virtual system firewalls only) Include the policy and object configuration changes in the commit operation.
- **Include Virtual System configuration**—Include all virtual systems or choose **Select one or more virtual systems**.
- **Preview Changes**—Click this button to display a two-pane window that shows proposed changes in the candidate configuration compared to the current running configuration. You can choose the number of lines of context to display, or show all lines. Changes are color coded based on items that you and other administrators added (green), modified (yellow), or deleted (red) since the last commit.

Because the preview results display in a new window, your browser must allow pop-ups. If the preview window does not open, refer to your browser documentation for the steps to unblock pop-ups.

- **Validate Changes**—Click this button to perform a syntactic validation (of configuration syntax) and semantic validation (whether the configuration is complete and makes sense) of a firewall or Panorama candidate configuration before committing it. The results display all of the errors and warnings of a full commit or virtual system commit, including rule shadowing and application dependency warnings. Possible errors could be an invalid route destination or a missing account and password that are required to query a server. Such validation significantly reduces failures at commit time.

## Global Find

Global Find enables you to search the candidate configuration on a firewall or on Panorama for a particular string, such as an IP address, object name, policy rule name, threat ID, or application name. The search results are grouped by category and provide links to the configuration location in the web interface, so that you can easily find all of the places where the string is referenced. The search results also help you identify other objects that depend on or make reference to the search term or string. For example, when deprecating a security profile enter the profile name in Global Find to locate all instances of the profile and then click each instance to navigate to the configuration page and make the necessary change. After all references are removed, you can then delete the profile. You can do this for any configuration item that has dependencies.

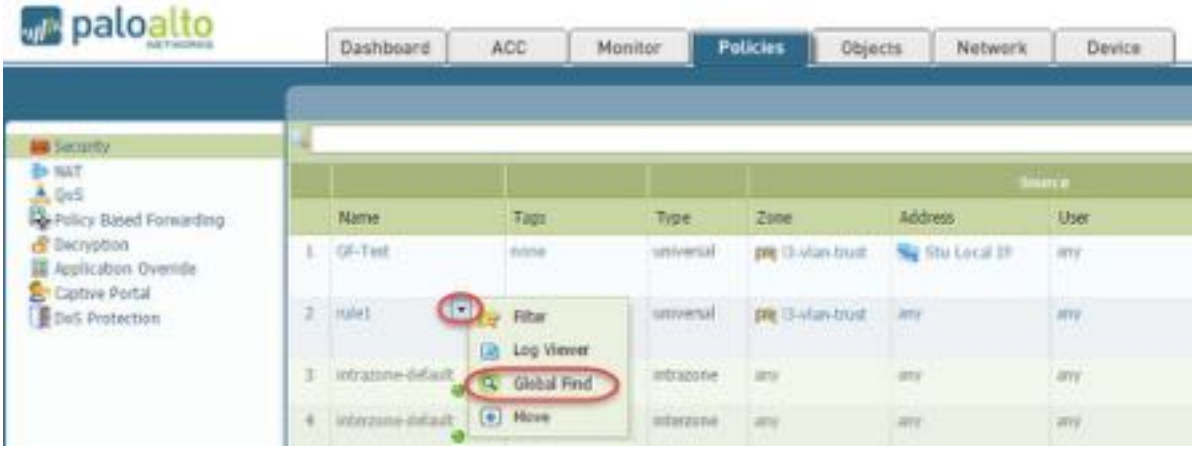
Global Find will not search dynamic content (such as logs, address ranges, or allocated DHCP addresses). In the case of DHCP, you can search on a DHCP server attribute, such as the DNS entry, but you cannot search for individual addresses allocated to users. Global Find also does not search for individual user or group names identified by User-ID unless the user/group is defined in a policy. In general, you can only search content that the firewall writes to the configuration.

 © Palo Alto Networks, Inc.

**Use Global Find**

- Launch Global Find by clicking the **Search** icon located on the upper right of the web interface.

- To access the Global Find from within a configuration area, click the drop-down next to an item and click **Global Find** as follows:



**Use Global Find (Continued)**

For example, click **Global Find** on a zone named **`l3-vlan-trust`** to search the candidate configuration for each location where the zone is referenced. The following screen capture shows the search results for the zone l3-vlan-trust:

**Search tips:**

- If you initiate a search on a firewall that has multiple virtual systems enabled or if custom Administrative Roles are defined, Global Find will only return results for areas of the firewall in which the administrator has permissions. The same applies to Panorama device groups.
- Spaces in search terms are handled as AND operations. For example, if you search on `corp policy`, the search results include instances where **corp** and **policy** exist in the configuration.
- To find an exact phrase, enclose the phrase in quotation marks.
- To rerun a previous search, click the Search icon located on the upper right of the web interface and a list of the last 20 searches will be displayed. Click an item in the list to rerun that search. The search history list is unique to each administrator account.

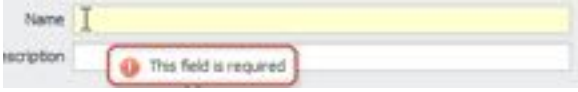
## Use Configuration Pages

The tables on configuration pages include sorting and column chooser options. Click a column header to sort on that column, and click again to change the sort order. Click the arrow to the right of any column and select check boxes to choose the columns to display.

## Required Fields

Required fields are shown with a light yellow background. A message indicating that the field is required appears when you hover over or click in the field entry area.

 © Palo Alto Networks, Inc.



## Lock Transactions

The web interface provides support for multiple administrators by allowing an administrator to lock a current set of transactions, thereby preventing configuration changes or commit operations by another administrator until the lock is removed. The following types of locks are supported:

- **Config lock**—Blocks other administrators from making changes to the configuration. This type of lock can be set globally or for a virtual system. It can be removed only by the administrator who set it or by a superuser on the system.
- **Commit Lock**—Blocks other administrators from committing changes until all of the locks have been released. This type of lock prevents collisions that can occur when two administrators are making changes at the same time and the first administrator finishes and commits changes before the second administrator has finished. The lock is released when the current changes are committed by the administrator who applied the lock, or it can be released manually.

Any administrator can open the lock window to view the current transactions that are locked, along with a time stamp for each.

To lock a transaction, click the unlocked icon on the top bar to open the Locks dialog box. Click **Take a Lock**, select the scope of the lock from the drop-down, and click **OK**. Add additional locks as needed, and then click **Close** to close the Lock dialog box.

The transaction is locked, and the icon on the top bar changes to a locked icon that shows the number of locked items in parentheses.

To unlock a transaction, click the locked icon on the top bar to open the Locks window. Click the icon for the lock that you want to remove, and click **Yes** to confirm. Click **Close** to close the Lock dialog box.

You can arrange to automatically acquire a commit lock by selecting the **Automatically acquire commit lock** check box in the Management area of the **Device Setup** page.

# Use the Command Line Interface (CLI)

The PAN-OS CLI allows you to access Firewall and Panorama devices, view status and configuration information, and modify configurations. Access to the PAN-OS CLI is provided through SSH, Telnet, or direct console access.

The following topics describe how to access and begin using the PAN-OS CLI:

- Access the PAN-OS CLI
- Operational and Configuration Modes

## Access the PAN-OS CLI

Use a terminal emulator, such as PuTTY, to connect to the CLI in one of the following ways:

- **SSH Connection**—If you Perform Initial Configuration, you can establish a CLI connection over the network using a secure shell (SSH) connection.
- **Serial Connection**—If you have not yet completed initial configuration or if you chose not to enable SSH on the firewall, you can establish a direct serial connection from a serial interface on your management computer to the Console port on the firewall.

| **Access the PAN-OS CLI** | |
|---|---|
| Step 1 | Launch the terminal emulation software and select the type of connection (Serial or SSH).<br>• To establish an SSH connection, enter the hostname or IP address of the firewall or Panorama you want to connect to and set the port to 22.<br>• To establish a Serial connection, connect a serial interface on management computer to the Console port on the firewall. Configure the Serial connection settings in the terminal emulation software as follows:<br>  • Data rate: 9600<br>  • Data bits: 8<br>  • Parity: none<br>  • Stop bits: 1<br>  • Flow control: none |
| Step 2 | When prompted to log in, enter your administrative username.<br>The default superuser username is `admin`. To set up CLI access for other administrative users, Configure an Administrative Account. |
| Step 3 | Enter the administrative password.<br>The default superuser password is `admin`. However, for security reasons you should immediately change the admin password.<br>The CLI opens in Operational mode, and the CLI prompt is displayed:<br>username@hostname><br>You can tell you are in Operational mode because the command prompt ends with a >. |

 © Palo Alto Networks, Inc.

## Operational and Configuration Modes

When you log in, the PAN-OS CLI opens in operational mode. You can move between operational and configuration modes at any time. Use operational mode to view the state of the system, navigate the PAN-OS CLI, and enter configuration mode. Use configuration mode to view and modify the configuration hierarchy.

- To enter configuration mode from operational mode, use the `configure` command:

```
username@hostname> configure
Entering configuration mode
[edit]
username@hostname#
```

- To leave configuration mode and return to operational mode, use the `quit` or `exit` command:

```
username@hostname# quit
Exiting configuration mode
username@hostname>
```

- To enter an operational mode command while in configuration mode, use the `run` command, for example:

```
username@hostname# run ping host 10.1.1.2
PING 10.1.1.2 (10.1.1.2) 56(84) bytes of data
...
username@hostname#
```

- To direct an Operational mode command to a particular VSYS, specify the target VSYS with the following command:

```
username@hostname# set system setting target-vsys <vsys_name>
```

# Use the XML API

Palo Alto Networks XML API uses standard HTTP requests to send and receive data, allowing access to several types of data on the device so the data can be easily integrated with and used in other systems. Use the XML-based Management API to view a firewall or Panorama's configuration, extract report data in XML format, and execute operational commands. API calls can be made directly from command line utilities such as cURL or wget, or using any scripting or application framework that supports RESTful services. When using the API with command lines tools, both HTTP GET and POST methods are supported.

You must generate an API key in order to use the XML API. The API key authenticates the user to the firewall, application, or Panorama. After you have generated an API key, you can use the key to perform device configuration and operational tasks, retrieve reports and logs, and import and export files. See Generate an API Key for steps to generate an API key.

The following table shows the URL structure for API requests:

| PAN-OS Version | XML API URL Structure |
|---|---|
| Prior to PAN-OS 4.1.0 | http(s)://hostname/esp/restapi.esp?request-parameters-values |
| PAN-OS 4.1.0 and later | http(s)://hostname/api/?request-parameters-values |

URL structure item definitions:

- **hostname**—Device's IP address or Domain name.
- **request-parameters-values**—A series of multiple 'parameter=value' pairs separated by the ampersand character (&). These values can either be keywords or data-values in standard or XML format (response data is always in XML format).

There are APIs for PAN-OS, User-ID, and WildFire products. For more information on how to use the API interface, refer to the PAN-OS XML API Usage Guide.

## Generate an API Key

In order to use the API to manage a firewall or application, an API key is required to authenticate all API calls. Admin account credentials are used to generate API keys.

As a best practice, create a separate admin account for XML-based administration.

| Generate an API key | |
|---|---|
| Step 1 Create an administrator account. | 1. In the web interface, on the **Device > Administrators** tab, click **Add**.<br>2. Enter a login **Name** for the admin.<br>3. Enter and confirm a **Password** for the admin.<br>4. Click **OK** and **Commit**. |

 © Palo Alto Networks, Inc.

| Generate an API key (Continued) | | |
|---|---|---|
| Step 2 | Request an API key. | Replace the hostname, username and password parameters in the following URL with the appropriate values from your administrator account credentials:<br>http(s)://hostname/api/?type=keygen&user=username&password=password<br>The API key is displayed in an XML block. For example:<br><response status="success"><br><result><br><key>0RgWc42Oi0vDx2WRUIUM6A</key><br></result><br></response> |
| Step 3 | (Optional) Revoke or change an API key.<br>For PAN-OS 4.1.0 and later releases, generating an API key using the same administrator account credentials returns unique API keys every time, and all of the keys are valid.<br>You can choose to revoke and then change an API key associated with an administrator account by changing the password associated with the administrator account. Any API keys that were generated using the previous credentials would no longer be valid. | 1. On the **Device > Adminstrators** tab, open the administrator account associated with the API key.<br>2. Enter and confirm a new **Password** for the administrator account.<br>3. Click **OK** and **Commit**.<br>Any API keys associated with the admin account prior to the password change are revoked upon Commit.<br>4. (Optional) Use the updated administrator account credentials to generate a new API key. See Step 2. |

Example work flow using an API key:

Request an API key by entering the URL with the appropriate values in a web browser:

```
https://10.xx.10.50/esp/restapi.esp?type=keygen&user=admin&password=admin
```

Entering the URL displays an XML block that contains the API key:

```
<response status="success">
  <result>
    <key>0RgWc42Oi0vDx2WRUIUM6A</key>
  </result>
</response>
```

Continue to use the API key to create API requests. For example, to generate a report:

```
https://10.xx.10.50/esp/restapi.esp?type=report&reporttype=dynamic&reportname
=top-app-summary&period=last-hour&topn=5&key=0RgWc42Oi0vDx2WRUIUM6A=
```

# Manage Firewall Administrators

Administrative accounts specify roles and authentication methods for the administrators of Palo Alto Networks firewalls. Every Palo Alto Networks firewall has a predefined default administrative account (admin) that provides full read-write access (also known as superuser access) to the firewall.

As a best practice, create a separate administrative account for each person who needs access to the administrative or reporting functions of the firewall. This enables you to better protect the firewall from unauthorized configuration and enables logging of the actions of individual administrators.

- Administrative Roles
- Administrative Authentication
- Configure Administrative Accounts and Authentication

 © Palo Alto Networks, Inc.

# Administrative Roles

A *role* defines the type of access that an administrator has to the firewall.

▲ Administrative Role Types
▲ Configure an Admin Role Profile

## Administrative Role Types

The role types are:

- **Dynamic Roles**—These are built-in roles that provide access to the firewall. When new features are added, the firewall automatically updates the definitions of dynamic roles; you never need to manually update them. The following table lists the access privileges associated with dynamic roles.

| Dynamic Role | Privileges |
|---|---|
| Superuser | Full access to the firewall, including defining new administrator accounts and virtual systems. You must have superuser privileges to create an administrative user with superuser privileges. |
| Superuser (read-only) | Read-only access to the firewall. |
| Virtual system administrator | Full access to a selected virtual system (vsys) on the firewall. |
| Virtual system administrator (read-only) | Read-only access to a selected vsys on the firewall. |
| Device administrator | Full access to all firewall settings except for defining new accounts or virtual systems. |
| Device administrator (read-only) | Read-only access to all firewall settings except password profiles (no access) and administrator accounts (only the logged in account is visible). |

- **Admin Role Profiles**—Custom roles you can configure for more granular access control over the functional areas of the web interface, CLI, and XML API. For example, you can create an Admin Role profile for your operations staff that provides access to the firewall and network configuration areas of the web interface and a separate profile for your security administrators that provides access to security policy definitions, logs, and reports. On a multi-vsys firewall, you can select whether the role defines access for all virtual systems or for a specific vsys. When new features are added to the product, you must update the roles with corresponding access privileges: the firewall does not automatically add new features to custom role definitions. For details on the privileges you can configure for custom administrator roles, see Reference: Web Interface Administrator Access.

## Configure an Admin Role Profile

Admin Role profiles enable you to define granular administrative access privileges to ensure protection for sensitive company information and privacy for end users. As a best practice, create Admin Role profiles that allow administrators to access only the areas of the management interfaces that they require to perform their jobs.

© Palo Alto Networks, Inc.

| Configure an Admin Role Profile | |
|---|---|
| Step 1 | Select **Device > Admin Roles** and click **Add**. |
| Step 2 | Enter a **Name** to identify the role. |
| Step 3 | For the scope of the **Role**, select **Device** or **Virtual System**. |
| Step 4 | In the **Web UI** and **XML API** tabs, click the icon for each functional area to toggle it to the desired setting: Enable, Read Only, or Disable. For details on the **Web UI** options, see Web Interface Access Privileges. |
| Step 5 | Select the **Command Line** tab and select a CLI access option. The **Role** scope controls the available options:<br>• **Device** role—**superuser**, **superreader**, **deviceadmin**, **devicereader**, or **None**<br>• **Virtual System** role—**vsysadmin**, **vsysreader**, or **None** |
| Step 6 | Click **OK** to save the profile. |
| Step 7 | Assign the role to an administrator. See Configure an Administrative Account. |

© Palo Alto Networks, Inc.

## Administrative Authentication

You can configure the following types of administrator authentication:

| Account Type | Authentication Method | Description |
|---|---|---|
| Local | Local database | Both the administrator account credentials and the authentication mechanisms are local to the firewall. You can further secure a local administrator account by creating a password profile that defines a validity period for passwords and by setting firewall-wide password complexity settings. If your network supports Kerberos single sign-on (SSO), you can configure local authentication as a fallback in case SSO fails. For details, see Configure Kerberos SSO and External or Local Authentication for Administrators. |
| Local | SSL-based | The administrator accounts are local to the firewall, but authentication is based on SSH certificates (for CLI access) or client certificates (for web interface access). For details, see Configure SSH Key-Based Administrator Authentication to the CLI and Configure Certificate-Based Administrator Authentication to the Web Interface. |
| Local | External service | The administrator accounts are local to the firewall, but external services (LDAP, Kerberos, TACACS+, or RADIUS) handle the authentication functions. If your network supports Kerberos single sign-on (SSO), you can configure external authentication as a fallback in case SSO fails. For details, see Configure Kerberos SSO and External or Local Authentication for Administrators. |
| External | External service | An external RADIUS server handles account management and authentication. You must define Vendor-Specific Attributes (VSAs) on your RADIUS server that map to the administrator role, access domain, user group (if applicable), and virtual system (if applicable). For details, see Configure RADIUS Vendor-Specific Attributes for Administrator Authentication. |

## Configure Administrative Accounts and Authentication

- Configure an Administrative Account
- Configure Kerberos SSO and External or Local Authentication for Administrators
- Configure Certificate-Based Administrator Authentication to the Web Interface
- Configure SSH Key-Based Administrator Authentication to the CLI
- Configure RADIUS Vendor-Specific Attributes for Administrator Authentication

## Configure an Administrative Account

Administrative accounts specify roles and authentication methods for the administrators of Palo Alto Networks firewalls.

| Configure an Administrative Account | |
|---|---|
| Step 1 | Select **Device > Administrators** and click **Add**. |
| Step 2 | Enter a user **Name**. |
| Step 3 | Select an **Authentication Profile** or sequence if you configured either for the user. The default option **None** specifies that the firewall will locally manage and authenticate the account without a local database; you must enter and confirm the **Password**. |
| Step 4 | Select the **Administrator Type**. If you configured a custom role for the user, select **Role Based** and select the Admin Role **Profile**. Otherwise, select **Dynamic** (the default) and select a dynamic role. |
| Step 5 | Click **OK** and **Commit**. |

# Configure Kerberos SSO and External or Local Authentication for Administrators

You can configure the firewall to first try Kerberos single sign-on (SSO) authentication and, if that fails, fall back to External service or Local database authentication.

| Configure Kerberos SSO and External or Local Authentication for Administrators | | |
|---|---|---|
| Step 1 | Configure a Kerberos keytab for the firewall.<br><br>Required for Kerberos SSO authentication. | Create a Kerberos keytab. A keytab is a file that contains Kerberos account information (principal name and hashed password) for the firewall. |
| Step 2 | Configure an Admin Role profile.<br><br>Required if you are assigning a custom role to the administrator. | Configure an Admin Role Profile. |
| Step 3 | Create the local database.<br><br>Required for local database authentication. | 1. Add the user account:<br>a. Select **Device > Local User Database > Users** and click **Add**.<br>b. Enter a user **Name** for the administrator.<br>c. Enter a **Password** and **Confirm Password**.<br>d. Be sure the **Enable** check box is selected and click **OK**.<br>2. (Optional) If the user is a member of a group, assign the user to that group:<br>a. Select **Device > Local User Database > User Groups** and click the Name of an existing group to edit it, or click **Add** to create a new group.<br>b. Enter a **Name** to identify the group.<br>c. Click **Add**, select the user you just created, and click **OK**. |
| Step 4 | Configure access to an external authentication service.<br><br>Required for external authentication. | Configure a server profile for the authentication service type:<br>• Configure a RADIUS Server Profile.<br>• Configure a TACACS+ Server Profile.<br>• Configure an LDAP Server Profile.<br>• Configure a Kerberos Server Profile. |
| Step 5 | Configure an authentication profile.<br><br>If your users are in multiple Kerberos realms, create an authentication profile for each realm and assign all the profiles to an authentication sequence. You can then assign the same authentication sequence to all user accounts (Step 6). | Configure an Authentication Profile and Sequence. |

 © Palo Alto Networks, Inc.

| Configure Kerberos SSO and External or Local Authentication for Administrators (Continued) | |
|---|---|
| Step 6 Configure an administrator account. | Configure an Administrative Account.<br>• For local database authentication, specify the **Name** of the user you defined in Step 3.<br>• Assign the **Authentication Profile** or sequence and the Admin Role **Profile** that you just created. |

# Configure Certificate-Based Administrator Authentication to the Web Interface

As a more secure alternative to password-based authentication to the web interface of a Palo Alto Networks firewall, you can configure certificate-based authentication for administrator accounts that are local to the firewall. Certificate-based authentication involves the exchange and verification of a digital signature instead of a password.

Configuring certificate-based authentication for any administrator disables the username/password logins for all administrators on the firewall; administrators thereafter require the certificate to log in.

| Configure Certificate-Based Administrator Authentication to the Web Interface | | |
|---|---|---|
| Step 1 | Generate a certificate authority (CA) certificate on the firewall.<br>You will use this CA certificate to sign the client certificate of each administrator. | Create a Self-Signed Root CA Certificate.<br>Alternatively, you can Import a Certificate and Private Key from your enterprise CA. |
| Step 2 | Configure a certificate profile for securing access to the web interface. | Configure a Certificate Profile.<br>• Set the **Username Field** to **Subject**.<br>• Select **Add** in the CA Certificates section and select the **CA Certificate** you just created or imported. |
| Step 3 | Configure the firewall to use the certificate profile for authenticating administrators. | 1. Select **Device > Setup > Management** and edit the Authentication Settings.<br>2. Select the **Certificate Profile** you just created and click **OK**. |
| Step 4 | Configure the administrator accounts to use client certificate authentication. | For each administrator who will access the firewall web interface, Configure an Administrative Account. Select the **Use only client certificate authentication** check box.<br>If you have already deployed client certificates that your enterprise CA generated, skip to Step 8. Otherwise, go to Step 5. |
| Step 5 | Generate a client certificate for each administrator. | Generate a Certificate on the Device. In the **Signed By** drop-down, select the CA certificate you created. |
| Step 6 | Export the client certificate. | 1. Export a Certificate and Private Key.<br>2. **Commit** your changes. The firewall restarts and terminates your login session. Thereafter, administrators can access the web interface only from client systems that have the client certificate you generated. |
| Step 7 | Import the client certificate into the client system of each administrator who will access the web interface. | Refer to your web browser documentation. |

© Palo Alto Networks, Inc.

| Configure Certificate-Based Administrator Authentication to the Web Interface (Continued) | | |
|---|---|---|
| Step 8 | Verify that administrators can access the web interface. | 1. Open the firewall IP address in a browser on the computer that has the client certificate.<br>2. When prompted, select the certificate you imported and click **OK**. The browser displays a certificate warning.<br>3. Add the certificate to the browser exception list.<br>4. Click **Login**. The web interface should appear without prompting you for a username or password. |

## Configure SSH Key-Based Administrator Authentication to the CLI

For administrators who use Secure Shell (SSH) to access the CLI of a Palo Alto Networks firewall, SSH keys provide a more secure authentication method than passwords. SSH keys almost eliminate the risk of brute-force attacks, provide the option for two-factor authentication (private key and passphrase), and don't send passwords over the network. SSH keys also enable automated scripts to access the CLI.

| Configure SSH Key-Based Administrator Authentication to the CLI | | |
|---|---|---|
| Step 1 | Use an SSH key generation tool to create an asymmetric keypair on the client system of the administrator.<br>The supported key formats are IETF SECSH and Open SSH. The supported algorithms are DSA (1,024 bits) and RSA (768-4,096 bits). | For the commands to generate the keypair, refer to your SSH client documentation.<br>The public key and private key are separate files. Save both to a location that the firewall can access. For added security, enter a passphrase to encrypt the private key. The firewall prompts the administrator for this passphrase during login. |
| Step 2 | Configure the administrator account to use public key authentication. | 1. Configure an Administrative Account.<br>• Configure the authentication method to use as a fallback if SSH key authentication fails. If you configured an **Authentication Profile** for the administrator, select it in the drop-down. If you select **None**, you must enter a **Password** and **Confirm Password**.<br>• Select the **Use Public Key Authentication (SSH)** check box, click **Import Key**, **Browse** to the public key you just generated, and click **OK**.<br>2. **Commit** your changes. |
| Step 3 | Configure the SSH client to use the private key to authenticate to the firewall. | Perform this task on the client system of the administrator. For the steps, refer to your SSH client documentation. |

| Configure SSH Key-Based Administrator Authentication to the CLI (Continued) | |
|---|---|
| Step 4 Verify that the administrator can access the firewall CLI using SSH key authentication. | 1. Use a browser on the client system of the administrator to go to the firewall IP address.<br>2. Log in to the firewall CLI as the administrator. After entering a username, you will see the following output (the key value is an example):<br>`Authenticating with public key "dsa-key-20130415"`<br>3. If prompted, enter the passphrase you defined when creating the keys. |

## Configure RADIUS Vendor-Specific Attributes for Administrator Authentication

The following procedure provides an overview of the tasks required to use RADIUS Vendor-Specific Attributes (VSAs) for administrator authentication to Palo Alto Networks firewalls. For detailed instructions, refer to the following Knowledge Base articles:

- For Windows 2003 Server, Windows 2008 (and later), and Cisco ACS 4.0—RADIUS Vendor-Specific Attributes (VSAs)
- For Cisco ACS 5.2—Configuring Cisco ACS 5.2 for use with Palo Alto VSA

Before starting this procedure, you must:

- ❒ Create the administrative accounts in the directory service that your network uses (for example, Active Directory).
- ❒ Set up a RADIUS server that can communicate with that directory service.

 © Palo Alto Networks, Inc.

| Use RADIUS Vendor-Specific Attributes for Account Authentication | |
|---|---|
| Step 1 Configure the firewall. | 1. Configure an Admin Role Profile if the administrator will use a custom role.<br>2. Configure an access domain if the firewall has more than one virtual system (vsys):<br>a. Select **Device > Access Domain**, **Add** and access domain and enter a **Name** to identify it.<br>b. **Add** each vsys that the administrator will access, and then click **OK**.<br>3. Configure a RADIUS Server Profile.<br>4. Configure an authentication profile. Set the authentication **Type** to **RADIUS** and assign the RADIUS **Server Profile**.<br>5. Configure the firewall to use the authentication profile for administrator access—Select **Device > Setup > Management**, edit the Authentication Settings, and select the **Authentication Profile**.<br>6. Click **OK** and **Commit**. |
| Step 2 Configure the RADIUS server. | 1. Add the firewall IP address or hostname as the RADIUS client.<br>2. Define the VSAs for administrator authentication. You must specify the vendor code (25461 for Palo Alto Networks firewalls) and the VSA name, number, and value: see RADIUS Vendor-Specific Attributes for Palo Alto Networks Devices. |

# Reference: Web Interface Administrator Access

You can configure privileges for an entire device or for one or more virtual systems (on platforms that support multiple virtual systems). Within that **Device** or **Virtual System** designation, you can configure privileges for custom administrator roles, which are more granular than the fixed privileges associated with a dynamic administrator role.

Configuring privileges at a granular level ensures that lower level administrators cannot access certain information. You can create custom roles for firewall administrators (see Configure an Administrative Account), Panorama administrators, or Device Group and Template administrators (refer to the Panorama Administrator's Guide). The following topics describe the privileges you can configure for custom administrator roles.

▲ Web Interface Access Privileges

▲ Panorama Web Interface Access

## Web Interface Access Privileges

If you want to prevent a role-based administrator from accessing specific tabs on the web interface, you can disable the tab and the administrator will not even see it when logging in using the associated role-based administrative account. For example, you could create an Admin Role Profile for your operations staff that provides access to the **Device** and **Network** tabs only and a separate profile for your security administrators that provides access to the **Object**, **Policy**, and **Monitor** tabs.

An admin role can apply at the **Device** level or **Virtual System** level; the choice is made in the Admin Role Profile by clicking the **Device** or **Virtual System** radio button. If the **Virtual System** button is selected, the admin assigned this profile is restricted to the virtual system(s) he or she is assigned to. Furthermore, only the **Device > Setup > Services > Virtual Systems** tab is available to that admin, not the **Global** tab.

The following table describes the tab-level access privileges you can assign to the admin role profile at the **Device** level. It also provides cross-references to additional tables that detail granular privileges within a tab.

You can also configure an admin role profile to:

- Define User Privacy Settings in the Admin Role Profile
- Restrict Admin Access to Commit Functions
- Restrict Admin Access to Validate Functions
- Provide Granular Access to Global Settings

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Dashboard | Controls access to the **Dashboard** tab. If you disable this privilege, the administrator will not see the tab and will not have access to any of the Dashboard widgets. | Yes | No | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| ACC | Controls access to the Application Command Center (ACC). If you disable this privilege, the **ACC** tab will not display in the web interface. Keep in mind that if you want to protect the privacy of your users while still providing access to the ACC, you can disable the **Privacy > Show Full Ip Addresses** option and/or the **Show User Names In Logs And Reports** option. | Yes | No | Yes |
| Monitor | Controls access to the **Monitor** tab. If you disable this privilege, the administrator will not see the **Monitor** tab and will not have access to any of the logs, packet captures, session information, reports or to App Scope. For more granular control over what monitoring information the admin can see, leave the Monitor option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Monitor Tab. | Yes | No | Yes |
| Policies | Controls access to the **Policies** tab. If you disable this privilege, the administrator will not see the **Policies** tab and will not have access to any policy information. For more granular control over what policy information the admin can see, for example to enable access to a specific type of policy or to enable read-only access to policy information, leave the **Policies** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Policy Tab. | Yes | No | Yes |
| Objects | Controls access to the **Objects** tab. If you disable this privilege, the administrator will not see the **Objects** tab and will not have access to any objects, security profiles, log forwarding profiles, decryption profiles, or schedules. For more granular control over what objects the admin can see, leave the **Objects** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Objects Tab. | Yes | No | Yes |
| Network | Controls access to the **Network** tab. If you disable this privilege, the administrator will not see the **Network** tab and will not have access to any interface, zone, VLAN, virtual wire, virtual router, IPsec tunnel, DHCP, DNS Proxy, GlobalProtect, or QoS configuration information or to the network profiles. For more granular control over what objects the admin can see, leave the **Network** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Network Tab. | Yes | No | Yes |

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Device | Controls access to the **Device** tab. If you disable this privilege, the administrator will not see the **Device** tab and will not have access to any device-wide configuration information, such as User-ID, High Availability, server profile or certificate configuration information. For more granular control over what objects the admin can see, leave the **Objects** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Device Tab.<br>You cannot enable access to the **Admin Roles** or **Administrators** nodes for a role-based administrator even if you enable full access to the **Device** tab. | Yes | No | Yes |

## Provide Granular Access to the Monitor Tab

In some cases you might want to enable the administrator to view some but not all areas of the **Monitor** tab. For example, you might want to restrict operations administrators to the Config and System logs only, because they do not contain sensitive user data. Although this section of the admin role definition specifies what areas of the **Monitor** tab the administrator can see, you can also couple privileges in this section with privacy privileges, such as disabling the ability to see usernames in logs and reports. One thing to keep in mind, however, is that any system-generated reports will still show usernames and IP addresses even if you disable that functionality in the role. For this reason, if you do not want the administrator to see any of the private user information, disable access to the specific reports as detailed in the following table.

The following table lists the **Monitor** tab access levels and the administrator roles for which they are available.

Device Group and Template roles can see log data only for the device groups that are within the access domains assigned to those roles.

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Monitor | Enables or disables access to the **Monitor** tab. If disabled, the admin will not see this tab or any of the associated logs or reports. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Logs | Enables or disables access to all log files. You can also leave this privilege enabled and then disable specific logs that you do not want the admin to see. Keep in mind that if you want to protect the privacy of your users while still providing access to one or more of the logs, you can disable the **Privacy > Show Full Ip Addresses** option and/or the **Show User Names In Logs And Reports** option. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Traffic | Specifies whether the admin can see the traffic logs. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Threat | Specifies whether the admin can see the threat logs. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| URL Filtering | Specifies whether the admin can see the URL filtering logs. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| WildFire Submissions | Specifies whether the admin can see the WildFire logs. These logs are only available if you have a WildFire subscription. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Data Filtering | Specifies whether the admin can see the data filtering logs. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| HIP Match | Specifies whether the admin can see the HIP Match logs. HIP Match logs are only available if you have a GlobalProtect portal license and gateway subscription. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Configuration | Specifies whether the admin can see the configuration logs. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |

© Palo Alto Networks, Inc.

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Alarms | Specifies whether the admin can see system-generated alarms. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Automated Correlation Engine | Enables or disables access to the correlation objects and correlated event logs generated on the firewall. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Correlation Objects | Specifies whether the admin can view and enable/disable the correlation objects. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Correlated Events | Specifies whether the admin | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Packet Capture | Specifies whether the admin can see packet captures (pcaps) from the **Monitor** tab. Keep in mind that packet captures are raw flow data and as such may contain user IP addresses. Disabling the **Show Full IP Addresses** privileges will not obfuscate the IP address in the pcap and you should therefore disable the Packet Capture privilege if you are concerned about user privacy. | Firewall: Yes<br>Panorama: No<br>Device Group/Template: No | Yes | Yes | Yes |
| App Scope | Specifies whether the admin can see the App Scope visibility and analysis tools. Enabling App Scope enables access to all of the **App Scope** charts. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Session Browser | Specifies whether the admin can browse and filter current running sessions on the firewall. Keep in mind that the session browser shows raw flow data and as such may contain user IP addresses. Disabling the **Show Full IP Addresses** privileges will not obfuscate the IP address in the session browser and you should therefore disable the **Session Browser** privilege if you are concerned about user privacy. | Firewall: Yes<br>Panorama: No<br>Device Group/Template: No | Yes | No | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Botnet | Specifies whether the admin can generate and view botnet analysis reports or view botnet reports in read-only mode. Disabling the **Show Full IP Addresses** privileges will not obfuscate the IP address in scheduled botnet reports and you should therefore disable the **Botnet** privilege if you are concerned about user privacy. | Firewall: Yes<br>Panorama: No<br>Device Group/Template: No | Yes | Yes | Yes |
| PDF Reports | Enables or disables access to all PDF reports. You can also leave this privilege enabled and then disable specific PDF reports that you do not want the admin to see. Keep in mind that if you want to protect the privacy of your users while still providing access to one or more of the reports, you can disable the **Privacy > Show Full Ip Addresses** option and/or the **Show User Names In Logs And Reports** option. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Manage PDF Summary | Specifies whether the admin can view, add or delete PDF summary report definitions. With read-only access, the admin can see PDF summary report definitions, but not add or delete them. If you disable this option, the admin can neither view the report definitions nor add/delete them. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | Yes | Yes |
| PDF Summary Reports | Specifies whether the admin can see the generated PDF Summary reports in **Monitor > Reports**. If you disable this option, the **PDF Summary Reports** category will not display in the **Reports** node. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| User Activity Report | Specifies whether the admin can view, add or delete User Activity report definitions and download the reports. With read-only access, the admin can see User Activity report definitions, but not add, delete, or download them. If you disable this option, the admin cannot see this category of PDF report. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | Yes | Yes |
| Report Groups | Specifies whether the admin can view, add or delete report group definitions. With read-only access, the admin can see report group definitions, but not add or delete them. If you disable this option, the admin cannot see this category of PDF report. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | Yes | Yes |

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Email Scheduler | Specifies whether the admin can schedule report groups for email. Because the generated reports that get emailed may contain sensitive user data that is not removed by disabling the **Privacy > Show Full Ip Addresses** option and/or the **Show User Names In Logs And Reports** options and because they may also show log data to which the admin does not have access, you should disable the **Email Scheduler** option if you have user privacy requirements. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | Yes | Yes |
| Manage Custom Reports | Enables or disables access to all custom report functionality. You can also leave this privilege enabled and then disable specific custom report categories that you do not want the admin to be able to access. Keep in mind that if you want to protect the privacy of your users while still providing access to one or more of the reports, you can disable the **Privacy > Show Full Ip Addresses** option and/or the **Show User Names In Logs And Reports** option.<br> Reports that are scheduled to run rather than run on demand will show IP address and user information. In this case, be sure to restrict access to the corresponding report areas. In addition, the custom report feature does not restrict the ability to generate reports that contain log data contained in logs that are excluded from the admin role. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Application Statistics | Specifies whether the admin can create a custom report that includes data from the application statistics database. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Data Filtering Log | Specifies whether the admin can create a custom report that includes data from the Data Filtering logs. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |
| Threat Log | Specifies whether the admin can create a custom report that includes data from the Threat logs. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Threat Summary | Specifies whether the admin can create a custom report that includes data from the Threat Summary database. | Firewall: Yes<br>Panorama: Yes<br>Device Group/Template: Yes | Yes | No | Yes |

## Provide Granular Access to the Policy Tab

If you enable the Policy option in the admin role profile, you can then enable, disable, or provide read-only access to specific nodes within the tab as necessary for the admin role you are defining. By enabling access to a specific policy type, you enable the ability to view, add, or delete policy rules. By enabling read-only access to a specific policy, you enable the admin to view the corresponding policy rule base, but not add or delete rules. Disabling access to a specific type of policy prevents the admin from seeing the policy rule base.

Because policy that is based on specific users (by user name or IP address) must be explicitly defined, privacy settings that disable the ability to see full IP addresses or user names do not apply to the Policy tab. Therefore, you should only allow access to the Policy tab to administrators that are excluded from user privacy restrictions.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Security | Enable this privilege to allow the admin to view, add, and/or delete security rules. Set the privilege to read-only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the security rulebase, disable this privilege. | Yes | Yes | Yes |
| NAT | Enable this privilege to allow the admin to view, add, and/or delete NAT rules. Set the privilege to read-only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the NAT rulebase, disable this privilege. | Yes | Yes | Yes |
| QoS | Enable this privilege to allow the admin to view, add, and/or delete QoS rules. Set the privilege to read-only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the QoS rulebase, disable this privilege. | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Policy Based Forwarding | Enable this privilege to allow the admin to view, add, and/or delete Policy-Based Forwarding (PBF) rules. Set the privilege to read-only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the PBF rulebase, disable this privilege. | Yes | Yes | Yes |
| Decryption | Enable this privilege to allow the admin to view, add, and/or delete decryption rules. Set the privilege to read-only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the decryption rulebase, disable this privilege. | Yes | Yes | Yes |
| Application Override | Enable this privilege to allow the admin to view, add, and/or delete application override policy rules. Set the privilege to read-only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the application override rulebase, disable this privilege. | Yes | Yes | Yes |
| Captive Portal | Enable this privilege to allow the admin to view, add, and/or delete Captive Portal rules. Set the privilege to read-only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the Captive Portal rulebase, disable this privilege. | Yes | Yes | Yes |
| DoS Protection | Enable this privilege to allow the admin to view, add, and/or delete DoS protection rules. Set the privilege to read-only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the DoS protection rulebase, disable this privilege. | Yes | Yes | Yes |

## Provide Granular Access to the Objects Tab

An *object* is a container that groups specific policy filter values—such as IP addresses, URLs, applications, or services—for simplified rule definition. For example, an address object might contain specific IP address definitions for the web and application servers in your DMZ zone.

When deciding whether to allow access to the objects tab as a whole, determine whether the admin will have policy definition responsibilities. If not, the admin probably does not need access to the tab. If, however, the admin will need to create policy, you can enable access to the tab and then provide granular access privileges at the node level.

By enabling access to a specific node, you give the admin the privilege to view, add, and delete the corresponding object type. Giving read-only access allows the admin to view the already defined objects, but not create or delete any. Disabling a node prevents the admin from seeing the node in the web interface.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Addresses | Specifies whether the admin can view, add, or delete address objects for use in security policy. | Yes | Yes | Yes |
| Address Groups | Specifies whether the admin can view, add, or delete address group objects for use in security policy. | Yes | Yes | Yes |
| Regions | Specifies whether the admin can view, add, or delete regions objects for use in security, decryption, or DoS policy. | Yes | Yes | Yes |
| Applications | Specifies whether the admin can view, add, or delete application objects for use in policy. | Yes | Yes | Yes |
| Application Groups | Specifies whether the admin can view, add, or delete application group objects for use in policy. | Yes | Yes | Yes |
| Application Filters | Specifies whether the admin can view, add, or delete application filters for simplification of repeated searches. | Yes | Yes | Yes |
| Services | Specifies whether the admin can view, add, or delete service objects for use in creating policy rules that limit the port numbers an application can use. | Yes | Yes | Yes |
| Service Groups | Specifies whether the admin can view, add, or delete service group objects for use in security policy. | Yes | Yes | Yes |
| Tags | Specifies whether the admin can view, add, or delete tags that have been defined on the device. | Yes | Yes | Yes |
| GlobalProtect | Specifies whether the admin can view, add, or delete HIP objects and profiles. You can restrict access to both types of objects at the GlobalProtect level, or provide more granular control by enabling the GlobalProtect privilege and restricting HIP Object or HIP Profile access. | Yes | No | Yes |
| HIP Objects | Specifies whether the admin can view, add, or delete HIP objects, which are used to define HIP profiles. HIP Objects also generate HIP Match logs. | Yes | Yes | Yes |
| HIP Profiles | Specifies whether the admin can view, add, or delete HIP Profiles for use in security policy and/or for generating HIP Match logs. | Yes | Yes | Yes |
| Dynamic Block Lists | Specifies whether the admin can view, add, or delete dynamic block lists for use in security policy. | Yes | Yes | Yes |
| Custom Objects | Specifies whether the admin can see the custom spyware and vulnerability signatures. You can restrict access to either enable or disable access to all custom signatures at this level, or provide more granular control by enabling the Custom Objects privilege and then restricting access to each type of signature. | Yes | No | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Data Patterns | Specifies whether the admin can view, add, or delete custom data pattern signatures for use in creating custom Vulnerability Protection profiles. | Yes | Yes | Yes |
| Spyware | Specifies whether the admin can view, add, or delete custom spyware signatures for use in creating custom Vulnerability Protection profiles. | Yes | Yes | Yes |
| Vulnerability | Specifies whether the admin can view, add, or delete custom vulnerability signatures for use in creating custom Vulnerability Protection profiles. | Yes | Yes | Yes |
| URL Category | Specifies whether the admin can view, add, or delete custom URL categories for use in policy. | Yes | Yes | Yes |
| Security Profiles | Specifies whether the admin can see security profiles. You can restrict access to either enable or disable access to all security profiles at this level, or provide more granular control by enabling the Security Profiles privilege and then restricting access to each type of profile. | Yes | No | Yes |
| Antivirus | Specifies whether the admin can view, add, or delete antivirus profiles. | Yes | Yes | Yes |
| Anti-Spyware | Specifies whether the admin can view, add, or delete Anti-Spyware profiles. | Yes | Yes | Yes |
| Vulnerability Protection | Specifies whether the admin can view, add, or delete Vulnerability Protection profiles. | Yes | Yes | Yes |
| URL Filtering | Specifies whether the admin can view, add, or delete URL filtering profiles. | Yes | Yes | Yes |
| File Blocking | Specifies whether the admin can view, add, or delete file blocking profiles. | Yes | Yes | Yes |
| Data Filtering | Specifies whether the admin can view, add, or delete data filtering profiles. | Yes | Yes | Yes |
| DoS Protection | Specifies whether the admin can view, add, or delete DoS protection profiles. | Yes | Yes | Yes |
| Security Profile Groups | Specifies whether the admin can view, add, or delete security profile groups. | Yes | Yes | Yes |
| Log Forwarding | Specifies whether the admin can view, add, or delete log forwarding profiles. | Yes | Yes | Yes |
| Decryption Profile | Specifies whether the admin can view, add, or delete decryption profiles. | Yes | Yes | Yes |
| Schedules | Specifies whether the admin can view, add, or delete schedules for limiting a security policy to a specific date and/or time range. | Yes | Yes | Yes |

© Palo Alto Networks, Inc.

## Provide Granular Access to the Network Tab

When deciding whether to allow access to the **Network** tab as a whole, determine whether the admin will have network administration responsibilities, including GlobalProtect administration. If not, the admin probably does not need access to the tab.

You can also define access to the **Network** tab at the node level. By enabling access to a specific node, you give the admin the privilege to view, add, and delete the corresponding network configurations. Giving read-only access allows the admin to view the already-defined configuration, but not create or delete any. Disabling a node prevents the admin from seeing the node in the web interface.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Interfaces | Specifies whether the admin can view, add, or delete interface configurations. | Yes | Yes | Yes |
| Zones | Specifies whether the admin can view, add, or delete zones. | Yes | Yes | Yes |
| VLANs | Specifies whether the admin can view, add, or delete VLANs. | Yes | Yes | Yes |
| Virtual Wires | Specifies whether the admin can view, add, or delete virtual wires. | Yes | Yes | Yes |
| Virtual Routers | Specifies whether the admin can view, add, modify or delete virtual routers. | Yes | Yes | Yes |
| IPSec Tunnels | Specifies whether the admin can view, add, modify, or delete IPSec Tunnel configurations. | Yes | Yes | Yes |
| DHCP | Specifies whether the admin can view, add, modify, or delete DHCP server and DHCP relay configurations. | Yes | Yes | Yes |
| DNS Proxy | Specifies whether the admin can view, add, modify, or delete DNS proxy configurations. | Yes | Yes | Yes |
| GlobalProtect | Specifies whether the admin can view, add, modify GlobalProtect portal and gateway configurations. You can disable access to the GlobalProtect functions entirely, or you can enable the GlobalProtect privilege and then restrict the role to either the portal or gateway configuration areas. | Yes | No | Yes |
| Portals | Specifies whether the admin can view, add, modify, or delete GlobalProtect portal configurations. | Yes | Yes | Yes |
| Gateways | Specifies whether the admin can view, add, modify, or delete GlobalProtect gateway configurations. | Yes | Yes | Yes |
| MDM | Specifies whether the admin can view add, modify, or delete GlobalProtect MDM server configurations. | Yes | Yes | Yes |
| QoS | Specifies whether the admin can view add, modify, or delete QoS configurations. | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| LLDP | Specifies whether the admin can view add, modify, or delete LLDP configurations. | Yes | Yes | Yes |
| Network Profiles | Sets the default state to enable or disable for all of the Network settings described below. | Yes | No | Yes |
| IKE Gateways | Controls access to the **Network Profiles > IKE Gateways** node. If you disable this privilege, the administrator will not see the **IKE Gateways** node or define gateways that include the configuration information necessary to perform IKE protocol negotiation with peer gateway.<br>If the privilege state is set to read-only, you can view the currently configured IKE Gateways but cannot add or edit gateways. | Yes | Yes | Yes |
| GlobalProtect IPSec Crypto | Controls access to the **Network Profiles > GlobalProtect IPSec Crypto** node.<br>If you disable this privilege, the administrator will not see that node, or configure algorithms for authentication and encryption in VPN tunnels between a GlobalProtect gateway and clients.<br>If you set the privilege to read-only, the administrator can view existing GlobalProtect IPSec Crypto profiles but cannot add or edit them. | Yes | Yes | Yes |
| IPSec Crypto | Controls access to the **Network Profiles > IPSec Crypto** node. If you disable this privilege, the administrator will not see the **Network Profiles > IPSec Crypto** node or specify protocols and algorithms for identification, authentication, and encryption in VPN tunnels based on IPSec SA negotiation.<br>If the privilege state is set to read-only, you can view the currently configured IPSec Crypto configuration but cannot add or edit a configuration. | Yes | Yes | Yes |
| IKE Crypto | Controls how devices exchange information to ensure secure communication. Specify the protocols and algorithms for identification, authentication, and encryption in VPN tunnels based on IPsec SA negotiation (IKEv1 Phase-1). | Yes | Yes | Yes |

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Monitor | Controls access to the **Network Profiles > Monitor** node. If you disable this privilege, the administrator will not see the **Network Profiles > Monitor** node or be able to create or edit a monitor profile that is used to monitor IPSec tunnels and monitor a next-hop device for policy-based forwarding (PBF) rules.<br>If the privilege state is set to read-only, you can view the currently configured monitor profile configuration but cannot add or edit a configuration. | Yes | Yes | Yes |
| Interface Mgmt | Controls access to the **Network Profiles > Interface Mgmt** node. If you disable this privilege, the administrator will not see the **Network Profiles > Interface Mgmt** node or be able to specify the protocols that are used to manage the firewall.<br>If the privilege state is set to read-only, you can view the currently configured Interface management profile configuration but cannot add or edit a configuration. | Yes | Yes | Yes |
| Zone Protection | Controls access to the **Network Profiles > Zone Protection** node. If you disable this privilege, the administrator will not see the **Network Profiles > Zone Protection** node or be able to configure a profile that determines how the firewall responds to attacks from specified security zones.<br>If the privilege state is set to read-only, you can view the currently configured Zone Protection profile configuration but cannot add or edit a configuration. | Yes | Yes | Yes |
| QoS Profile | Controls access to the **Network Profiles > QoS** node. If you disable this privilege, the administrator will not see the **Network Profiles > QoS** node or be able to configure a QoS profile that determines how QoS traffic classes are treated.<br>If the privilege state is set to read-only, you can view the currently configured QoS profile configuration but cannot add or edit a configuration. | Yes | Yes | Yes |
| LLDP Profile | Controls access to the **Network Profiles > LLDP** node. If you disable this privilege, the administrator will not see the **Network Profiles > LLDP** node or be able to configure an LLDP profile that controls whether the interfaces on the firewall can participate in the Link Layer Discovery Protocol.<br>If the privilege state is set to read-only, you can view the currently configured LLDP profile configuration but cannot add or edit a configuration. | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

## Provide Granular Access to the Device Tab

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Setup | Controls access to the **Setup** node. If you disable this privilege, the administrator will not see the **Setup** node or have access to device-wide setup configuration information, such as Management, Operations, Service, Content-ID, Wildfire or Session setup information.<br>If the privilege state is set to read-only, you can view the current configuration but cannot make any changes. | Yes | Yes | Yes |
| Config Audit | Controls access to the **Config Audit** node. If you disable this privilege, the administrator will not see the **Config Audit** node or have access to any device-wide configuration information. | Yes | No | Yes |
| Admin Roles | Controls access to the **Admin Roles** node. This function can only be allowed for read-only access.<br>If you disable this privilege, the administrator will not see the **Admin Roles** node or have access to any device-wide information concerning admin roles configuration.<br>If you set this privilege to read-only, you can view the configuration information for all admin roles configured on the device. | No | Yes | Yes |
| Administrators | Controls access to the **Administrators** node. This function can only be allowed for read-only access.<br>If you disable this privilege, the administrator will not see the **Administrators** node or have access to information about their own admin account.<br>If you set this privilege to read-only, the administrator can view the configuration information for their own admin account. They will not see any information about other admin accounts configured on the device. | No | Yes | Yes |
| Virtual Systems | Controls access to the **Virtual Systems** node. If you disable this privilege, the administrator will not see or be able to configure virtual systems.<br>If the privilege state is set to read-only, you can view the currently configured virtual systems but cannot add or edit a configuration. | Yes | Yes | Yes |

© Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Shared Gateways | Controls access to the **Shared Gateways** node. Shared gateways allow virtual systems to share a common interface for external communications.<br>If you disable this privilege, the administrator will not see or be able to configure shared gateways.<br>If the privilege state is set to read-only, you can view the currently configured shared gateways but cannot add or edit a configuration. | Yes | Yes | Yes |
| User Identification | Controls access to the **User Identification** node. If you disable this privilege, the administrator will not see the **User Identification** node or have access to device-wide User Identification configuration information, such as User Mapping, User-ID Agents, Service, Terminal Services Agents, Group Mappings Settings or Captive Portal Settings.<br>If you set this privilege to read-only, the administrator can view configuration information for the device but is not allowed to perform any configuration procedures. | Yes | Yes | Yes |
| VM Information Source | Controls access to the **VM Information Source** node that allows you to configure the firewall/Windows User-ID agent to collect VM inventory automatically. If you disable this privilege, the administrator will not see the **VM Information Source** node.<br>If you set this privilege to read-only, the administrator can view the VM information sources configured but cannot add, edit, or delete any sources.<br>This privilege is not available to Device Group and Template administrators. | Yes | Yes | Yes |
| High Availability | Controls access to the **High Availability** node. If you disable this privilege, the administrator will not see the **High Availability** node or have access to device-wide high availability configuration information such as General setup information or Link and Path Monitoring.<br>If you set this privilege to read-only, the administrator can view High Availability configuration information for the device but is not allowed to perform any configuration procedures. | Yes | Yes | Yes |
| Certificate Management | Sets the default state to enable or disable for all of the Certificate settings described below. | Yes | No | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Certificates | Controls access to the **Certificates** node. If you disable this privilege, the administrator will not see the **Certificates** node or be able to configure or access information regarding Device Certificates or Default Trusted Certificate Authorities.<br>If you set this privilege to read-only, the administrator can view Certificate configuration information for the device but is not allowed to perform any configuration procedures. | Yes | Yes | Yes |
| Certificate Profile | Controls access to the **Certificate Profile** node. If you disable this privilege, the administrator will not see the **Certificate Profile** node or be able to create certificate profiles.<br>If you set this privilege to read-only, the administrator can view Certificate Profiles that are currently configured for the device but is not allowed to create or edit a certificate profile. | Yes | Yes | Yes |
| OCSP Responder | Controls access to the **OCSP Responder** node. If you disable this privilege, the administrator will not see the **OCSP Responder** node or be able to define a server that will be used to verify the revocation status of certificates issues by the PAN-OS device.<br>If you set this privilege to read-only, the administrator can view the **OCSP Responder** configuration for the device but is not allowed to create or edit an OCSP responder configuration. | Yes | Yes | Yes |
| SSL/TLS Service Profile | Controls access to the **SSL/TLS Service Profile** node.<br>If you disable this privilege, the administrator will not see the node or configure a profile that specifies a certificate and a protocol version or range of versions for device services that use SSL/TLS.<br>If you set this privilege to read-only, the administrator can view existing SSL/TLS Service profiles but cannot create or edit them. | Yes | Yes | Yes |
| Response Pages | Controls access to the **Response Pages** node. If you disable this privilege, the administrator will not see the **Response Page** node or be able to define a custom HTML message that is downloaded and displayed instead of a requested web page or file.<br>If you set this privilege to read-only, the administrator can view the **Response Page** configuration for the device but is not allowed to create or edit a response page configuration. | Yes | Yes | Yes |

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Log Settings | Sets the default state to enable or disable for all of the Log settings described below. | Yes | No | Yes |
| System | Controls access to the **Log Settings > System** node. If you disable this privilege, the administrator will not see the **Log Settings > System** node or be able to specify the severity levels of the system log entries that are logged remotely with Panorama and sent as SNMP traps, syslog messages, and/or email notifications.<br>If you set this privilege to read-only, the administrator can view the **Log Settings > System** configuration for the device but is not allowed to create or edit a configuration. | Yes | Yes | Yes |
| Config | Controls access to the **Log Settings > Config** node. If you disable this privilege, the administrator will not see the **Log Settings > Config** node or be able to specify the configuration log entries that are logged remotely with Panorama, and sent as syslog messages and/or email notification.<br>If you set this privilege to read-only, the administrator can view the **Log Settings > Config** configuration for the device but is not allowed to create or edit a configuration. | Yes | Yes | Yes |
| HIP Match | Controls access to the **Log Settings > HIP Match** node. If you disable this privilege, the administrator will not see the **Log Settings > HIP Match** node or be able to specify the Host Information Profile (HIP) match log settings that are used to provide information on security rules that apply to GlobalProtect clients<br>If you set this privilege to read-only, the administrator can view the **Log Settings > HIP** configuration for the device but is not allowed to create or edit a configuration. | Yes | Yes | Yes |
| Alarms | Controls access to the **Log Settings > Alarms** node. If you disable this privilege, the administrator will not see the **Log Settings > Alarms** node or be able to configure notifications that are generated when a security rule (or group of rules) has been hit repeatedly in a set period of time.<br>If you set this privilege to read-only, the administrator can view the **Log Settings > Alarms** configuration for the device but is not allowed to create or edit a configuration. | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Manage Logs | Controls access to the **Log Settings > Manage Logs** node. If you disable this privilege, the administrator will not see the **Log Settings > Manage Logs** node or be able to clear the indicated logs.<br>If you set this privilege to read-only, the administrator can view the **Log Settings > Manage Logs** information but cannot clear any of the logs. | Yes | Yes | Yes |
| Server Profiles | Sets the default state to enable or disable for all of the Server Profiles settings described below. | Yes | No | Yes |
| SNMP Trap | Controls access to the **Server Profiles > SNMP Trap** node. If you disable this privilege, the administrator will not see the **Server Profiles > SNMP Trap** node or be able to specify one or more SNMP trap destinations to be used for system log entries.<br>If you set this privilege to read-only, the administrator can view the **Server Profiles > SNMP Trap Logs** information but cannot specify SNMP trap destinations. | Yes | Yes | Yes |
| Syslog | Controls access to the **Server Profiles > Syslog** node. If you disable this privilege, the administrator will not see the **Server Profiles > Syslog** node or be able to specify one or more syslog servers.<br>If you set this privilege to read-only, the administrator can view the **Server Profiles > Syslog** information but cannot specify syslog servers. | Yes | Yes | Yes |
| Email | Controls access to the **Server Profiles > Email** node. If you disable this privilege, the administrator will not see the **Server Profiles > Email** node or be able to configure an email profile that can be used to enable email notification for system and configuration log entries<br>If you set this privilege to read-only, the administrator can view the **Server Profiles > Email** information but cannot configure and email profile. | Yes | Yes | Yes |
| Netflow | Controls access to the **Server Profiles > Netflow** node. If you disable this privilege, the administrator will not see the **Server Profiles > Netflow** node or be able to define a NetFlow server profile, which specifies the frequency of the export along with the NetFlow servers that will receive the exported data.<br>If you set this privilege to read-only, the administrator can view the **Server Profiles > Netflow** information but cannot define a Netflow profile. | Yes | Yes | Yes |

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| RADIUS | Controls access to the **Server Profiles > RADIUS** node. If you disable this privilege, the administrator will not see the **Server Profiles > RADIUS** node or be able to configure settings for the RADIUS servers that are identified in authentication profiles.<br>If you set this privilege to read-only, the administrator can view the **Server Profiles > RADIUS** information but cannot configure settings for the RADIUS servers. | Yes | Yes | Yes |
| TACACS+ | Controls access to the **Server Profiles > TACACS+** node.<br>If you disable this privilege, the administrator will not see the node or configure settings for the TACACS+ servers that authentication profiles reference.<br>If you set this privilege to read-only, the administrator can view existing TACACS+ server profiles but cannot add or edit them. | Yes | Yes | Yes |
| LDAP | Controls access to the **Server Profiles > LDAP** node. If you disable this privilege, the administrator will not see the **Server Profiles > LDAP** node or be able to configure settings for the LDAP servers to use for authentication by way of authentication profiles.<br>If you set this privilege to read-only, the administrator can view the **Server Profiles > LDAP** information but cannot configure settings for the LDAP servers. | Yes | Yes | Yes |
| Kerberos | Controls access to the **Server Profiles > Kerberos** node. If you disable this privilege, the administrator will not see the **Server Profiles > Kerberos** node or configure a Kerberos server that allows users to authenticate natively to a domain controller.<br>If you set this privilege to read-only, the administrator can view the **Server Profiles > Kerberos** information but cannot configure settings for Kerberos servers. | Yes | Yes | Yes |
| Local User Database | Sets the default state to enable or disable for all of the Local User Database settings described below. | Yes | No | Yes |
| Users | Controls access to the **Local User Database > Users** node. If you disable this privilege, the administrator will not see the **Local User Database > Users** node or set up a local database on the firewall to store authentication information for remote access users, device administrators, and captive portal users.<br>If you set this privilege to read-only, the administrator can view the **Local User Database > Users** information but cannot set up a local database on the firewall to store authentication information. | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| User Groups | Controls access to the **Local User Database > Users** node. If you disable this privilege, the administrator will not see the **Local User Database > Users** node or be able to add user group information to the local database.<br>If you set this privilege to read-only, the administrator can view the **Local User Database > Users** information but cannot add user group information to the local database. | Yes | Yes | Yes |
| Authentication Profile | Controls access to the **Authentication Profile** node. If you disable this privilege, the administrator will not see the **Authentication Profile** node or be able to create or edit authentication profiles that specify local database, RADIUS, TACACS+, LDAP, or Kerberos settings that can be assigned to administrator accounts.<br>If you set this privilege to read-only, the administrator can view the **Authentication Profile** information but cannot create or edit an authentication profile. | Yes | Yes | Yes |
| Authentication Sequence | Controls access to the **Authentication Sequence** node. If you disable this privilege, the administrator will not see the **Authentication Sequence** node or be able to create or edit an authentication sequence.<br>If you set this privilege to read-only, the administrator can view the **Authentication Profile** information but cannot create or edit an authentication sequence. | Yes | Yes | Yes |
| Access Domain | Controls access to the **Access Domain** node. If you disable this privilege, the administrator will not see the **Access Domain** node or be able to create or edit an access domain.<br>If you set this privilege to read-only, the administrator can view the **Access Domain** information but cannot create or edit an access domain. | Yes | Yes | Yes |
| Scheduled Log Export | Controls access to the **Scheduled Log Export** node. If you disable this privilege, the administrator will not see the **Scheduled Log Export** node or be able schedule exports of logs and save them to a File Transfer Protocol (FTP) server in CSV format or use Secure Copy (SCP) to securely transfer data between the device and a remote host.<br>If you set this privilege to read-only, the administrator can view the **Scheduled Log Export Profile** information but cannot schedule the export of logs. | Yes | No | Yes |

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Software | Controls access to the **Software** node. If you disable this privilege, the administrator will not see the **Software** node or view the latest versions of the PAN-OS software available from Palo Alto Networks, read the release notes for each version, and select a release to download and install.<br>If you set this privilege to read-only, the administrator can view the **Software** information but cannot download or install software. | Yes | Yes | Yes |
| GlobalProtect Client | Controls access to the **GlobalProtect Client** node. If you disable this privilege, the administrator will not see the **GlobalProtect Client** node or view available GlobalProtect releases, download the code or activate the GlobalProtect agent.<br>If you set this privilege to read-only, the administrator can view the available **GlobalProtect Client** releases but cannot download or install the agent software. | Yes | Yes | Yes |
| Dynamic Updates | Controls access to the **Dynamic Updates** node. If you disable this privilege, the administrator will not see the **Dynamic Updates** node or be able to view the latest updates, read the release notes for each update, or select an update to upload and install.<br>If you set this privilege to read-only, the administrator can view the available **Dynamic Updates** releases, read the release notes but cannot upload or install the software. | Yes | Yes | Yes |
| Licenses | Controls access to the **Licenses** node. If you disable this privilege, the administrator will not see the **Licenses** node or be able to view the licenses installed or activate licenses.<br>If you set this privilege to read-only, the administrator can view the installed **Licenses**, but cannot perform license management functions. | Yes | Yes | Yes |
| Support | Controls access to the **Support** node. If you disable this privilege, the administrator will not see the **Support** node or be able to access product and security alerts from Palo Alto Networks or generate tech support or stats dump files.<br>If you set this privilege to read-only, the administrator can view the **Support** node and access product and security alerts but cannot generate tech support or stats dump files. | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Master Key and Diagnostics | Controls access to the **Master Key and Diagnostics** node. If you disable this privilege, the administrator will not see the **Master Key and Diagnostics** node or be able to specify a master key to encrypt private keys on the firewall.<br>If you set this privilege to read-only, the administrator can view the **Master Key and Diagnostics** node and view information about master keys that have been specified but cannot add or edit a new master key configuration. | Yes | Yes | Yes |

## Define User Privacy Settings in the Admin Role Profile

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Privacy | Sets the default state to enable or disable for all of the privacy settings described below. | Yes | N/A | Yes |
| Show Full IP addresses | When set to disable, full IP addresses obtained by traffic running through the Palo Alto firewall are not shown in logs or reports. In place of the IP addresses that are normally displayed, the relevant subnet is displayed.<br> Scheduled reports that are displayed in the interface through **Monitor > Reports** and reports that are sent via scheduled emails will still display full IP addresses. Because of this exception, we recommend that the following settings within the **Monitor** tab be set to disable: Custom Reports, Application Reports, Threat Reports, URL Filtering Reports, Traffic Reports and Email Scheduler. | Yes | N/A | Yes |
| Show User Names in Logs and Reports | When set to disable, user names obtained by traffic running through the Palo Alto Networks firewall are not shown in logs or reports. Columns where the user names would normally be displayed are empty.<br> Scheduled reports that are displayed in the interface through **Monitor > Reports** or reports that are sent via the email scheduler will still display user names. Because of this exception, we recommend that the following settings within the Monitor tab be set to disable: Custom Reports, Application Reports, Threat Reports, URL Filtering Reports, Traffic Reports and Email Scheduler. | Yes | N/A | Yes |

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| View Pcap Files | When set to disable, packet capture files that are normally available within the Traffic, Threat and Data Filtering logs are not displayed. | Yes | N/A | Yes |

## Restrict Admin Access to Commit Functions

**Restrict User Access Using the Commit Setting**

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Commit | When set to disable, an admin cannot commit any changes to a configuration. | Yes | N/A | Yes |

## Restrict Admin Access to Validate Functions

**Restrict User Access Using the Validate Setting**

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Validate | When set to disable, an admin cannot validate a configuration. | Yes | N/A | Yes |

## Provide Granular Access to Global Settings

**Restrict User Access Using the Global Settings**

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Global | Sets the default state to enable or disable for all of the global settings described below. In effect, this setting is only for System Alarms at this time. | Yes | N/A | Yes |
| System Alarms | When set to disable, an admin cannot view or acknowledge alarms that are generated. | Yes | N/A | Yes |

## Provide Granular Access to the Panorama Tab

The following table lists the **Panorama** tab access levels and the custom Panorama administrator roles for which they are available. Firewall administrators cannot access any of these privileges.

 © Palo Alto Networks, Inc.

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Setup | Specifies whether the administrator can view or edit Panorama setup information, such as **Management**, **Operations**, **Services**, **WildFire**, or **HSM**.<br>If you set the privilege to:<br>• read-only, the administrator can see the information but cannot edit it.<br>• disable this privilege, the administrator cannot see or edit the information. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| High Availability | Specifies whether the administrator can view and manage high availability (HA) settings for the Panorama management server.<br>If you set this privilege to read-only, the administrator can view HA configuration information for the Panorama management server but can't manage the configuration.<br>If you disable this privilege, the administrator can't see or manage HA configuration settings for the Panorama management server. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Config Audit | Specifies whether the administrator can run Panorama configuration audits. If you disable this privilege, the administrator can't run Panorama configuration audits. | Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| Administrators | Specifies whether the administrator can view Panorama administrator account details.<br>You can't enable full access to this function: just read-only access. (Only Panorama administrators with a dynamic role can add, edit, or delete Panorama administrators.) With read-only access, the administrator can see information about his or her own account but no other Panorama administrator accounts.<br>If you disable this privilege, the administrator can't see information about any Panorama administrator account, including his or her own. | Panorama: Yes<br>Device Group/Template: No | No | Yes | Yes |

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Admin Roles | Specifies whether the administrator can view Panorama administrator roles.<br>You can't enable full access to this function: just read-only access. (Only Panorama administrators with a dynamic role can add, edit, or delete custom Panorama roles.) With read-only access, the administrator can see Panorama administrator role configurations but can't manage them.<br>If you disable this privilege, the administrator can't see or manage Panorama administrator roles. | Panorama: Yes<br>Device Group/Template: No | No | Yes | Yes |
| Access Domain | Specifies whether the administrator can view, add, edit, delete, or clone access domain configurations for Panorama administrators. (This privilege controls access only to the configuration of access domains, not access to the device groups, templates, and firewall contexts that are assigned to access domains.)<br>If you set this privilege to read-only, the administrator can view Panorama access domain configurations but can't manage them.<br>If you disable this privilege, the administrator can't see or manage Panorama access domain configurations. | Panorama: Yes<br>Device Group/Template: No<br> You assign access domains to Device Group and Template administrators so they can access the configuration and monitoring data within the device groups, templates, and firewall contexts that are assigned to those access domains. | Yes | Yes | Yes |
| Authentication Profile | Specifies whether the administrator can view, add, edit, delete, or clone authentication profiles for Panorama administrators.<br>If you set this privilege to read-only, the administrator can view Panorama authentication profiles but can't manage them.<br>If you disable this privilege, the administrator can't see or manage Panorama authentication profiles. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Authentication Sequence | Specifies whether the administrator can view, add, edit, delete, or clone authentication sequences for Panorama administrators.<br>If you set this privilege to read-only, the administrator can view Panorama authentication sequences but can't manage them.<br>If you disable this privilege, the administrator can't see or manage Panorama authentication sequences. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Managed Devices | Specifies whether the administrator can view, add, edit, tag, or delete firewalls as managed devices, and install software or content updates on them.<br>If you set this privilege to read-only, the administrator can see managed firewalls but can't add, delete, tag, or install updates on them.<br>If you disable this privilege, the administrator can't view, add, edit, tag, delete, or install updates on managed firewalls.<br>This privilege applies only to the **Panorama > Managed Devices** page. An administrator with Device Deployment privileges can still use the **Panorama > Device Deployment** pages to install updates on managed firewalls. | Panorama: Yes<br>Device Group/Template: Yes | Yes<br>(No for Device Group and Template roles) | Yes | Yes |
| Templates | Specifies whether the administrator can view, edit, add, or delete templates and template stacks.<br>If you set the privilege to read-only, the administrator can see template and stack configurations but can't manage them.<br>If you disable this privilege, the administrator can't see or manage template and stack configurations. | Panorama: Yes<br>Device Group/Template: Yes<br>Device Group and Template administrators can see only the templates and stacks that are within the access domains assigned to those administrators. | Yes<br>(No for Device Group and Template admins) | Yes | Yes |

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Device Groups | Specifies whether the administrator can view, edit, add, or delete device groups.<br>If you set this privilege to read-only, the administrator can see device group configurations but can't manage them.<br>If you disable this privilege, the administrator can't see or manage device group configurations. | Panorama: Yes<br>Device Group/Template: Yes<br>Device Group and Template administrators can access only the device groups that are within the access domains assigned to those administrators. | Yes | Yes | Yes |
| Managed Collectors | Specifies whether the administrator can view, edit, add, or delete managed collectors.<br>If you set this privilege to read-only, the administrator can see managed collector configurations but can't manage them.<br>If you disable this privilege, the administrator can't view, edit, add, or delete managed collector configurations.<br>This privilege applies only to the **Panorama > Managed Collectors** page. An administrator with Device Deployment privileges can still use the **Panorama > Device Deployment** pages to install updates on managed collectors. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Collector Groups | Specifies whether the administrator can view, edit, add, or delete Collector Groups.<br>If you set this privilege to read-only, the administrator can see Collector Groups but can't manage them.<br>If you disable this privilege, the administrator can't see or manage Collector Groups. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| VMware Service Manager | Specifies whether the administrator can view and edit VMware Service Manager settings.<br>If you set this privilege to read-only, the administrator can see the settings but can't perform any related configuration or operational procedures.<br>If you disable this privilege, the administrator can't see the settings or perform any related configuration or operational procedures. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Certificate Management | Sets the default state, enabled or disabled, for all of the Panorama certificate management privileges. | Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| Certificates | Specifies whether the administrator can view, edit, generate, delete, revoke, renew, or export certificates. This privilege also specifies whether the administrator can import or export HA keys.<br>If you set this privilege to read-only, the administrator can see Panorama certificates but can't manage the certificates or HA keys.<br>If you disable this privilege, the administrator can't see or manage Panorama certificates or HA keys. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Certificate Profile | Specifies whether the administrator can view, add, edit, delete or clone Panorama certificate profiles.<br>If you set this privilege to read-only, the administrator can see Panorama certificate profiles but can't manage them.<br>If you disable this privilege, the administrator can't see or manage Panorama certificate profiles. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| SSL/TLS Service Profile | Specifies whether the administrator can view, add, edit, delete or clone SSL/TLS Service profiles.<br>If you set this privilege to read-only, the administrator can see SSL/TLS Service profiles but can't manage them.<br>If you disable this privilege, the administrator can't see or manage SSL/TLS Service profiles. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Log Settings | Sets the default state, enabled or disabled, for all the log setting privileges. | Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| System | Specifies whether the administrator can see and configure the settings that control the forwarding of System logs to external services (syslog, email, or SNMP trap servers).<br>If you set this privilege to read-only, the administrator can see the System log forwarding settings but can't manage them.<br>If you disable this privilege, the administrator can't see or manage the settings.<br>On a Panorama M-Series appliance, this privilege pertains only to System logs that Panorama generates. On a Panorama virtual appliance, this privilege applies to System logs that Panorama generates and to System logs that Panorama collects from firewalls. The **Panorama > Collector Groups** page controls the forwarding of System logs that an M-Series appliance collects from firewalls. The **Device > Log Settings** page controls the forwarding of System logs directly from firewalls to external services (without aggregation on Panorama). | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Config | Specifies whether the administrator can see and configure the settings that control the forwarding of Config logs to external services (syslog, email, or SNMP trap servers).<br>If you set this privilege to read-only, the administrator can see the Config log forwarding settings but can't manage them.<br>If you disable this privilege, the administrator can't see or manage the settings.<br> On a Panorama M-Series appliance, this privilege pertains only to Config logs that Panorama generates. On a Panorama virtual appliance, this privilege applies to Config logs that Panorama generates and to Config logs that Panorama collects from firewalls. The **Panorama > Collector Groups** page controls the forwarding of Config logs that an M-Series appliance collects from firewalls. The **Device > Log Settings** page controls the forwarding of Config logs directly from firewalls to external services (without aggregation on Panorama). | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| HIP Match | Specifies whether the administrator can see and configure the settings that control the forwarding of HIP Match logs from a Panorama virtual appliance to external services (syslog, email, or SNMP trap servers).<br>If you set this privilege to read-only, the administrator can see the forwarding settings of HIP Match logs but can't manage them.<br>If you disable this privilege, the administrator can't see or manage the settings.<br> The **Panorama > Collector Groups** page controls the forwarding of HIP Match logs from a Panorama M-Series appliance. The **Device > Log Settings** page controls the forwarding of HIP Match logs directly from firewalls to external services (without aggregation on Panorama). | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Correlation | Specifies whether the administrator can see and configure the settings that control the forwarding of Correlation logs to external services (syslog, email, or SNMP trap servers).<br>If you set this privilege to read-only, the administrator can see the Correlation log forwarding settings but can't manage them.<br>If you disable this privilege, the administrator can't see or manage the settings.<br> The **Panorama > Collector Groups** page controls the forwarding of Correlation logs from a Panorama M-Series appliance. The **Device > Log Settings** page controls the forwarding of Correlation logs directly from firewalls to external services (without aggregation on Panorama). | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Traffic | Specifies whether the administrator can see and configure the settings that control the forwarding of Traffic logs from a Panorama virtual appliance to external services (syslog, email, or SNMP trap servers).<br>If you set this privilege to read-only, the administrator can see the forwarding settings of Traffic logs but can't manage them.<br>If you disable this privilege, the administrator can't see or manage the settings.<br> The **Panorama > Collector Groups** page controls the forwarding of Traffic logs from a Panorama M-Series appliance. The **Objects > Log Forwarding** page controls the forwarding of Traffic logs directly from firewalls to external services (without aggregation on Panorama). | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Threat | Specifies whether the administrator can see and configure the settings that control the forwarding of Threat logs from a Panorama virtual appliance to external services (syslog, email, or SNMP trap servers).<br>If you set this privilege to read-only, the administrator can see the forwarding settings of Threat logs but can't manage them.<br>If you disable this privilege, the administrator can't see or manage the settings.<br> The **Panorama > Collector Groups** page controls the forwarding of Threat logs from a Panorama M-Series appliance. The **Objects > Log Forwarding** page controls the forwarding of Threat logs directly from firewalls to external services (without aggregation on Panorama). | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Wildfire | Specifies whether the administrator can see and configure the settings that control the forwarding of WildFire logs from a Panorama virtual appliance to external services (syslog, email, or SNMP trap servers).<br>If you set this privilege to read-only, the administrator can see the forwarding settings of WildFire logs but can't manage them.<br>If you disable this privilege, the administrator can't see or manage the settings.<br> The **Panorama > Collector Groups** page controls the forwarding of WildFire logs from a Panorama M-Series appliance. The **Objects > Log Forwarding** page controls the forwarding of WildFire logs directly from firewalls to external services (without aggregation on Panorama). | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Server Profiles | Sets the default state, enabled or disabled, for all the server profile privileges.<br> These privileges pertain only to the server profiles that are used for forwarding logs that Panorama generates or collects from firewalls and the server profiles that are used for authenticating Panorama administrators. The **Device > Server Profiles** pages control the server profiles that are used for forwarding logs directly from firewalls to external services (without aggregation on Panorama) and for authenticating firewall administrators. | Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |
| SNMP Trap | Specifies whether the administrator can see and configure SNMP trap server profiles.<br>If you set this privilege to read-only, the administrator can see SNMP trap server profiles but can't manage them.<br>If you disable this privilege, the administrator can't see or manage SNMP trap server profiles. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| Syslog | Specifies whether the administrator can see and configure Syslog server profiles.<br>If you set this privilege to read-only, the administrator can see Syslog server profiles but can't manage them.<br>If you disable this privilege, the administrator can't see or manage Syslog server profiles. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Email | Specifies whether the administrator can see and configure email server profiles.<br>If you set this privilege to read-only, the administrator can see email server profiles but can't manage them.<br>If you disable this privilege, the administrator can't see or manage email server profiles. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| RADIUS | Specifies whether the administrator can see and configure the RADIUS server profiles that are used to authenticate Panorama administrators.<br>If you set this privilege to read-only, the administrator can see the RADIUS server profiles but can't manage them.<br>If you disable this privilege, the administrator can't see or manage the RADIUS server profiles. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| TACACS+ | Specifies whether the administrator can see and configure the TACACS+ server profiles that are used to authenticate Panorama administrators.<br>If you disable this privilege, the administrator can't see the node or configure settings for the TACACS+ servers that authentication profiles reference.<br>If you set this privilege to read-only, the administrator can view existing TACACS+ server profiles but can't add or edit them. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |

| Access Level | Description | Admin Role Availability | Enable | Read Only | Disable |
|---|---|---|---|---|---|
| LDAP | Specifies whether the administrator can see and configure the LDAP server profiles that are used to authenticate Panorama administrators.<br>If you set this privilege to read-only, the administrator can see the LDAP server profiles but can't manage them.<br>If you disable this privilege, the administrator can't see or manage the LDAP server profiles. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Kerberos | Specifies whether the administrator can see and configure the Kerberos server profiles that are used to authenticate Panorama administrators.<br>If you set this privilege to read-only, the administrator can see the Kerberos server profiles but can't manage them.<br>If you disable this privilege, the administrator can't see or manage the Kerberos server profiles. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |
| Scheduled Config Export | Specifies whether the administrator can view, add, edit, delete, or clone scheduled Panorama configuration exports.<br>If you set this privilege to read-only, the administrator can view the scheduled exports but can't manage them.<br>If you disable this privilege, the administrator can't see or manage the scheduled exports. | Panorama: Yes<br>Device Group/Template: No | Yes | No | Yes |

|---|---|---|---|---|---|
| Dynamic Updates | Specifies whether the administrator can: view information about the content updates (for example, Applications updates) installed on firewalls and Dedicated Log Collectors; download, upload, or install the updates; and view the associated release notes.<br>If you set this privilege to read-only, the administrator can see information about the content updates and view the associated release notes but can't deploy the updates to firewalls or Dedicated Log Collectors.<br>If you disable this privilege, the administrator can't see information about the content updates, see the associated release notes, or deploy the updates to firewalls or Dedicated Log Collectors. | Panorama: Yes<br>Device Group/Template: Yes | Yes | Yes | Yes |
| Licenses | Specifies whether the administrator can view, refresh, and activate firewall licenses.<br>If you set this privilege to read-only, the administrator can view firewall licenses but can't refresh or activate those licenses.<br>If you disable this privilege, the administrator can't view, refresh, or activate firewall licenses. | Panorama: Yes<br>Device Group/Template: Yes | Yes | Yes | Yes |
| Master Key and Diagnostics | Specifies whether the administrator can view and configure a master key by which to encrypt private keys on Panorama.<br>If you set this privilege to read-only, the administrator can view the Panorama master key configuration but can't change it.<br>If you disable this privilege, the administrator can't see or edit the Panorama master key configuration. | Panorama: Yes<br>Device Group/Template: No | Yes | Yes | Yes |

## Panorama Web Interface Access

The custom Panorama administrator roles allow you to define access to the options on Panorama and the ability to only allow access to Device Groups and Templates (**Policies**, **Objects**, **Network**, **Device** tabs).

 © Palo Alto Networks, Inc.

The admin roles you can create are **Panorama** and **Device Group and Template**. You can't assign CLI access privileges to a **Device Group and Template** admin role. If you assign superuser privileges for the CLI to a **Panorama** admin role, administrators with that role can access all features regardless of the web interface privileges you assign.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Dashboard | Controls access to the **Dashboard** tab. If you disable this privilege, the administrator will not see the tab and will not have access to any of the Dashboard widgets. | Yes | No | Yes |
| ACC | Controls access to the Application Command Center (ACC). If you disable this privilege, the **ACC** tab will not display in the web interface. Keep in mind that if you want to protect the privacy of your users while still providing access to the ACC, you can disable the **Privacy > Show Full Ip Addresses** option and/or the **Show User Names In Logs And Reports** option. | Yes | No | Yes |
| Monitor | Controls access to the **Monitor** tab. If you disable this privilege, the administrator will not see the **Monitor** tab and will not have access to any of the logs, packet captures, session information, reports or to App Scope. For more granular control over what monitoring information the admin can see, leave the Monitor option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Monitor Tab. | Yes | No | Yes |
| Policies | Controls access to the **Policies** tab. If you disable this privilege, the administrator will not see the **Policies** tab and will not have access to any policy information. For more granular control over what policy information the admin can see, for example to enable access to a specific type of policy or to enable read-only access to policy information, leave the **Policies** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Policy Tab. | Yes | No | Yes |
| Objects | Controls access to the **Objects** tab. If you disable this privilege, the administrator will not see the **Objects** tab and will not have access to any objects, security profiles, log forwarding profiles, decryption profiles, or schedules. For more granular control over what objects the admin can see, leave the **Objects** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Objects Tab. | Yes | No | Yes |

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Network | Controls access to the **Network** tab. If you disable this privilege, the administrator will not see the **Network** tab and will not have access to any interface, zone, VLAN, virtual wire, virtual router, IPsec tunnel, DHCP, DNS Proxy, GlobalProtect, or QoS configuration information or to the network profiles. For more granular control over what objects the admin can see, leave the **Network** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Network Tab. | Yes | No | Yes |
| Device | Controls access to the **Device** tab. If you disable this privilege, the administrator will not see the **Device** tab and will not have access to any device-wide configuration information, such as User-ID, High Availability, server profile or certificate configuration information. For more granular control over what objects the admin can see, leave the **Device** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Device Tab.<br>You can't enable access to the **Admin Roles** or **Administrators** nodes for a role-based administrator even if you enable full access to the **Device** tab. | Yes | No | Yes |
| Panorama | Controls access to the **Panorama** tab. If you disable this privilege, the administrator will not see the **Panorama** tab and will not have access to any Panorama-wide configuration information, such as Managed Devices, Managed Collectors, or Collector Groups.<br>For more granular control over what objects the admin can see, leave the **Panorama** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Panorama Tab. | Yes | No | Yes |
| Validate | When set to disable, an admin cannot validate a configuration. | Yes | N/A | Yes |

 © Palo Alto Networks, Inc.

# Reference: Port Numbers Used by Palo Alto Networks Devices

The following tables list the ports that Palo Alto Networks devices use to communicate with each other, or with other services on the network.

- Ports Used for Management Functions
- Ports Used for HA
- Ports Used for Panorama
- Ports Used for User-ID

## Ports Used for Management Functions

| Destination Port | Protocol | Description |
|---|---|---|
| 22 | TCP | Used for communication from a client system to the firewall CLI interface. |
| 80 | TCP | The port the firewall listens on for Online Certificate Status Protocol (OCSP) updates when acting as an OCSP responder. |
| 123 | UDP | Port the firewall uses for NTP updates. |
| 443 | TCP | Used for communication from a client system to the firewall web interface. This is also the port the firewall and User-ID agent listens on for VM Information source updates.<br>For monitoring an AWS environment, this is the only port that is used.<br>For monitoring a VMware vCenter/ESXi environment, the listening port defaults to 443, but it is configurable. |
| 162 | UDP | Port the firewall, Panorama, or a Log Collector uses to Forward Traps to an SNMP Manager.<br>This port doesn't need to be open on the Palo Alto Networks device. You must configure the Simple Network Management Protocol (SNMP) manager to listen on this port. For details, refer to the documentation of your SNMP management software. |
| 161 | UDP | Port the firewall listens on for polling requests (GET messages) from the SNMP manager. |
| 514<br>514<br>6514 | TCP<br>UDP<br>SSL | Port that the firewall, Panorama, or a Log Collector uses to send logs to a syslog server if you Configure Syslog Monitoring, and the ports that the PAN-OS integrated User-ID agent or Windows-based User-ID agent listens on for authentication syslog messages if you Configure User-ID to Receive User Mappings from a Syslog Sender. |
| 2055 | UDP | Default port the firewall uses to send NetFlow records to a NetFlow collector if you Configure NetFlow Exports, but this is configurable. |

| Destination Port | Protocol | Description |
|---|---|---|
| 5008 | TCP | Port the GlobalProtect Mobile Security Manager listens on for HIP requests from the GlobalProtect gateways.<br>If you are using a third-party MDM system, you can configure the gateway to use a different port as required by the MDM vendor. |
| 6080<br>6081<br>6082 | TCP<br>TCP<br>TCP | Ports used for Captive Portal: 6080 for NT LAN Manager (NTLM) authentication, 6081 for Captive Portal in transparent mode, and 6082 for Captive Portal in redirect mode. |

## Ports Used for HA

Firewalls configured as High Availability (HA) peers must be able to communicate with each other to maintain state information (HA1 control link) and synchronize data (HA2 data link). In Active/Active HA deployments the peer firewalls must also forward packets to the HA peer that owns the session. The HA3 link is a Layer 2 (MAC-in-MAC) link and it does not support Layer 3 addressing or encryption.

| Destination Port | Protocol | Description |
|---|---|---|
| 28769<br>28260 | TCP<br>TCP | Used for the HA1 control link for clear text communication between the HA peer firewalls. The HA1 link is a Layer 3 link and requires an IP address. |
| 28 | TCP | Used for the HA1 control link for encrypted communication (SSH over TCP) between the HA peer firewalls. |
| 28770 | TCP | Listening port for HA1 backup links. |
| 28771 | TCP | Used for heartbeat backups. Palo Alto Networks recommends enabling heartbeat backup on the MGT interface if you use an in-band port for the HA1 or the HA1 backup links. |
| 99<br>29281 | IP<br>UDP | Used for the HA2 link to synchronize sessions, forwarding tables, IPSec security associations and ARP tables between firewalls in an HA pair. Data flow on the HA2 link is always unidirectional (except for the HA2 keep-alive); it flows from the active device (Active/Passive) or active-primary (Active/Active) to the passive device (Active/Passive) or active-secondary (Active/Active). The HA2 link is a Layer 2 link, and it uses ether type 0x7261 by default.<br>The HA data link can also be configured to use either IP (protocol number 99) or UDP (port 29281) as the transport, and thereby allow the HA data link to span subnets. |

 © Palo Alto Networks, Inc.

## Ports Used for Panorama

| Destination Port | Protocol | Description |
|---|---|---|
| 22 | TCP | Used for communication from a client system to the Panorama CLI interface. |
| 443 | TCP | Used for communication from a client system to the Panorama web interface. |
| 3978 | TCP | Used for communication between Panorama and managed devices (firewalls and Log Collectors) as well as for communication among Log Collectors in a Collector Group:<br>• For communication between Panorama and firewalls, this is a bi-directional connection on which the firewalls forward logs to Panorama and Panorama pushes configuration changes to the firewalls. Context switching commands are sent over the same connection.<br>• Log Collectors use this destination port to forward logs to Panorama.<br>• For communication with the default Log Collector on an M-Series appliance in Panorama mode and with Dedicated Log Collectors (M-Series appliances in Log Collector mode). |
| 28769 (5.1 and later)<br>28260 (5.0 and later)<br>49160 (5.0 and earlier) | TCP<br>TCP<br>TCP | Used for the HA connectivity and synchronization between Panorama HA peers using clear text communication. Communication can be initiated by either peer. |
| 28 | TCP | Used for the HA connectivity and synchronization between Panorama HA peers using encrypted communication (SSH over TCP). Communication can be initiated by either peer. |
| 28270 (6.0 and later)<br>49190 (5.1 and earlier) | TCP | Used for communication among Log Collectors in a Collector Group for log distribution. |
| 2049 | TCP | Used by the Panorama virtual appliance to write logs to the NFS datastore. |

## Ports Used for User-ID

User-ID is a feature that enables mapping of user IP addresses to usernames and group memberships, enabling user- or group-based policy and visibility into user activity on your network (for example, to be able to quickly track down a user who may be the victim of a threat). To perform this mapping, the firewall, the User-ID agent (either installed on a Windows-based system or the PAN-OS integrated agent running on the firewall), and/or the Terminal Services agent must be able to connect to directory services on your network to perform Group Mapping and User Mapping. Additionally, if the agents are running on systems external to the firewall, they must be able to connect to the firewall to communicate the IP address to username mappings to the firewall. The following table lists the communication requirements for User-ID along with the port numbers required to establish connections.

| Destination Port | Protocol | Description |
|---|---|---|
| 389 | TCP | Port the firewall uses to connect to an LDAP server (plaintext or Start Transport Layer Security (Start TLS) to Map Users to Groups. |
| 3268 | TCP | Port the firewall uses to connect to an Active Directory global catalog server (plaintext or Start TLS) to Map Users to Groups. |
| 636 | TCP | Port the firewall uses for LDAP over SSL connections with an LDAP server to Map Users to Groups. |
| 3269 | TCP | Port the firewall uses for LDAP over SSL connections with an Active Directory global catalog server to Map Users to Groups. |
| 514<br>514<br>6514 | TCP<br>UDP<br>SSL | Port the PAN-OS integrated User-ID agent or Windows-based User-ID agent listens on for authentication syslog messages if you Configure User-ID to Receive User Mappings from a Syslog Sender. |
| 5007 | TCP | Port the firewall listens on for user mapping information from the User-ID or Terminal Services agent. The agent sends the IP address and username mapping along with a timestamp whenever it learns of a new or updated mapping. In addition, it connects to the firewall at regular intervals to refresh known mappings. |
| 5006 | TCP | Port the User-ID agent listens on for User-ID XML API requests. The source for this communication is typically the system running a script that invokes the API. |
| 88 | UDP/TCP | Port the User-ID agent uses to authenticate to a Kerberos server. The device tries UDP first and falls back to TCP. |
| 1812 | UDP | Port the User-ID agent uses to authenticate to a RADIUS server. |
| 49 | TCP | Port the User-ID agent uses to authenticate to a TACACS+ server. |

 © Palo Alto Networks, Inc.

| Destination Port | Protocol | Description |
|---|---|---|
| 135 | TCP | Port the User-ID agent uses to establish TCP-based WMI connections with the Microsoft Remote Procedure Call (RPC) Endpoint Mapper. The Endpoint Mapper then assigns the agent a randomly assigned port in the 49152-65535 port range. The agent uses this connection to make RPC queries for Exchange Server or AD server security logs, session tables. This is also the port used to access Terminal Services.<br>The User-ID agent also uses this port to connect to client systems to perform Windows Management Instrumentation (WMI) probing. |
| 139 | TCP | Port the User-ID agent uses to establish TCP-based NetBIOS connections to the AD server so that it can send RPC queries for security logs and session information.<br>The User-ID agent also uses this port to connect to client systems for NetBIOS probing (supported on the Windows-based User-ID agent only). |
| 445 | TCP | Port the User-ID agent uses to connect to the Active Directory (AD) using TCP-based SMB connections to the AD server for access to user logon information (print spooler and Net Logon). |

# Reset the Firewall to Factory Default Settings

Resetting the firewall to factory defaults will result in the loss of all configuration settings and logs.

| Reset the Firewall to Factory Default Settings | |
|---|---|
| Step 1 Set up a console connection to the firewall. | 1. Connect a serial cable from your computer to the Console port and connect to the firewall using terminal emulation software (9600-8-N-1).<br>If your computer does not have a 9-pin serial port, use a USB-to-serial port connector.<br>2. Enter your login credentials.<br>3. Enter the following CLI command:<br>`debug system maintenance-mode`<br>The firewall will reboot in the maintenance mode. |
| Step 2 Reset the system to factory default settings. | 1. When the device reboots, press `Enter` to continue to the maintenance mode menu.<br> <br>2. Select `Factory Reset` and press `Enter`.<br>3. Select `Factory Reset` and press `Enter` again.<br>The firewall will reboot without any configuration settings. The default username and password to log in to the firewall is admin/admin.<br>To perform initial configuration on the firewall and to set up network connectivity, see Integrate the Firewall into Your Management Network. |

 © Palo Alto Networks, Inc.

# Authentication

Many of the services that Palo Alto Networks devices provide require authentication, including administrator access to the web interface and end user access to Captive Portal, GlobalProtect portals, and GlobalProtect gateways. The authentication methods that you can configure vary by service, and can include Kerberos single sign-on (SSO), external authentication services, certificates and certificate profiles, local database accounts, RADIUS Vendor-Specific Attributes (VSAs), and NT LAN Manager (NTLM).

The following topics describe authentication methods that are common to most device services, procedures to configure them, how to test authentication profiles, and how to troubleshoot authentication issues:

- Configure Kerberos Single Sign-On
- Configure External Authentication
- Test Authentication Server Connectivity
- Troubleshoot Authentication Issues

# Configure Kerberos Single Sign-On

Palo Alto Networks devices support Kerberos V5 single sign-on (SSO) to authenticate administrators to the web interface and end users to Captive Portal. A network that supports Kerberos SSO prompts a user to log in only for initial access to the network (for example, logging in to Microsoft Windows). After this initial login, the user can access any browser-based service in the network (for example, the firewall web interface) without having to log in again until the SSO session expires. (Your Kerberos administrator sets the duration of SSO sessions.) If you enable both Kerberos SSO and external authentication services (for example, a RADIUS server), the device first tries SSO and, only if that fails, falls back to the external service for authentication.

To support Kerberos SSO, your network requires:

- A Kerberos infrastructure, including a key distribution center (KDC) with an authentication server (AS) and ticket-granting service (TGS).
- A Kerberos account for each Palo Alto Networks device that will authenticate users. An account is required to create a Kerberos keytab, which is a file that contains the principal name and hashed password of the device. The SSO process requires the keytab.

| Configure Kerberos Single Sign-On | | |
|---|---|---|
| Step 1 | Create a Kerberos keytab. | 1. Log in to the KDC and open a command prompt.<br>2. Enter the following command, where <principal_name>, <password>, and <algorithm> are variables. The Kerberos principal name and password are of the device, not the user.<br>**ktpass /princ** <principal_name> **/pass** <password> **/crypto** <algorithm> **/ptype KRB5_NT_PRINCIPAL /out** <file_name>**.keytab**<br>If the device is in FIPS or CC mode, the algorithm must be `aes128-cts-hmac-sha1-96` or `aes256-cts-hmac-sha1-96`. Otherwise, you can also use `des3-cbc-sha1` or `arcfour-hmac`. To use an Advanced Encryption Standard (AES) algorithm, the functional level of the KDC must be Windows Server 2008 or later and you must enable AES encryption for the device account.<br>The algorithm in the keytab must match the algorithm in the service ticket that the TGS issues to clients. Your Kerberos administrator determines which algorithms the service tickets use. |
| Step 2 | Import the keytab into an authentication profile. | Configure an authentication profile.<br>1. Enter the **Kerberos Realm** (usually the DNS domain of the users, except that the realm is uppercase).<br>2. **Import** the **Kerberos Keytab** that you created for the device. |
| Step 3 | Assign the authentication profile to the user account or device service. | • Configure an administrator account.<br>• Configure Captive Portal. |

 © Palo Alto Networks, Inc.

# Configure External Authentication

Palo Alto Networks devices can use external servers for many services that require authentication, including administrator access to the web interface and end user access to Captive Portal, GlobalProtect portals and GlobalProtect gateways. The server protocols that Palo Alto Networks devices support include Lightweight Directory Access Protocol (LDAP), Kerberos, Terminal Access Controller Access-Control System Plus (TACACS+), and Remote Authentication Dial-In User Service (RADIUS). If you enable both external authentication and Kerberos single sign-on (SSO), the device first tries SSO and, only if that fails, falls back to the external server for authentication. To configure external authentication, you create an authentication server profile, assign it to an authentication profile, and then enable authentication for an administrator account or device service by assigning the authentication profile to it.

- Configure Authentication Server Profiles
- Configure an Authentication Profile and Sequence
- Enable External Authentication for Users and Services

## Configure Authentication Server Profiles

- Configure a RADIUS Server Profile
- RADIUS Vendor-Specific Attributes for Palo Alto Networks Devices
- Configure a TACACS+ Server Profile
- Configure an LDAP Server Profile
- Configure a Kerberos Server Profile
- Set CHAP and PAP Authentication for RADIUS and TACACS+ Servers

 © Palo Alto Networks, Inc.

## Configure a RADIUS Server Profile

You can configure Palo Alto Networks devices to use a RADIUS server for authenticating users, managing administrator accounts (if they are not local), and collecting RADIUS Vendor-Specific Attributes (VSAs) from GlobalProtect clients. To use a RADIUS server for managing administrator accounts or collecting GlobalProtect clients VSAs, you must define VSAs on the RADIUS server. For details, see the list of supported RADIUS Vendor-Specific Attributes for Palo Alto Networks Devices.

By default, when authenticating to the RADIUS server, the firewall or Panorama first tries Challenge-Handshake Authentication Protocol (CHAP) and falls back to Password Authentication Protocol (PAP) under certain conditions. Optionally, you can override this automatic protocol selection and configure the firewall or Panorama to always use a specific protocol. For details, see Set CHAP and PAP Authentication for RADIUS and TACACS+ Servers.

| Configure a RADIUS Server Profile | |
|---|---|
| Step 1 | Select **Device > Server Profiles > RADIUS** and click **Add**. |
| Step 2 | Enter a **Profile Name** to identify the server profile. |
| Step 3 | For a firewall with more than one virtual system (vsys), select the **Location** (vsys or **Shared**) where the profile is available. |
| Step 4 | For the **Timeout**, enter an interval in seconds after which an authentication request times out (range is 1-30, default is 3). |
| Step 5 | Enter the number of automatic **Retries** following a **Timeout** before the request fails (range is 1-5, default is 3). |
| Step 6 | For each RADIUS server, click **Add** and enter a **Name** (to identify the server), server IP address or FQDN (**RADIUS Server** field), **Secret**/**Confirm Secret** (a key to encrypt passwords), and server **Port** for authentication requests (default is 1812). |
| Step 7 | Click **OK** and **Commit**. |

## RADIUS Vendor-Specific Attributes for Palo Alto Networks Devices

Palo Alto Networks devices support the following RADIUS Vendor-Specific Attributes (VSAs). To define VSAs on a RADIUS server, you must specify the vendor code (25461 for Palo Alto Networks devices) and the VSA name and number. Some VSAs also require a value.

| Name | Number | Value |
|---|---|---|
| VSAs for administrator account management and authentication | | |
| PaloAlto-Admin-Role | 1 | A default (dynamic) administrative role name or a custom administrative role name on the firewall. |
| PaloAlto-Admin-Access-Domain | 2 | The name of an access domain for firewall administrators (configured in the **Device > Access Domains** page). Define this VSA if the firewall has multiple virtual systems. |
| PaloAlto-Panorama-Admin-Role | 3 | A default (dynamic) administrative role name or a custom administrative role name on Panorama. |
| PaloAlto-Panorama-Admin-Access-Domain | 4 | The name of an access domain for Device Group and Template administrators (configured in the **Panorama > Access Domains** page). |
| PaloAlto-User-Group | 5 | The name of a user group that an authentication profile references. |
| VSAs forwarded from GlobalProtect clients to the RADIUS server | | |
| PaloAlto-User-Domain | 6 | Don't specify a value when you define these VSAs. |
| PaloAlto-Client-Source-IP | 7 | |
| PaloAlto-Client-OS | 8 | |
| PaloAlto-Client-Hostname | 9 | |
| PaloAlto-GlobalProtect-Client-Version | 10 | |

 © Palo Alto Networks, Inc.

## Configure a TACACS+ Server Profile

Terminal Access Controller Access-Control System Plus (TACACS+) protocol provides better Authentication security than RADIUS because it encrypts usernames and passwords (instead of just passwords), and is also more reliable (it uses TCP instead of UDP).

By default, when authenticating to the TACACS+ server, the firewall or Panorama first tries Challenge-Handshake Authentication Protocol (CHAP) and falls back to Password Authentication Protocol (PAP) under certain conditions. Optionally, you can override this automatic protocol selection and configure the firewall or Panorama to always use a specific protocol. For details, see Set CHAP and PAP Authentication for RADIUS and TACACS+ Servers.

| Configure a TACACS+ Server Profile | |
|---|---|
| Step 1 | Select **Device > Server Profiles > TACACS+** and click **Add**. |
| Step 2 | Enter a **Profile Name** to identify the server profile. |
| Step 3 | For a firewall with more than one virtual system (vsys), select the **Location** (vsys or **Shared**) where the profile is available. |
| Step 4 | For the **Timeout**, enter an interval in seconds after which an authentication request times out (range is 1-20, default is 3). |
| Step 5 | Select the **Use single connection for all authentication** check box to use the same TCP session for all authentications that use this profile. This option improves performance by avoiding the need to start and end a separate TCP session for each authentication. The check box is cleared by default. |
| Step 6 | For each TACACS+ server, click **Add** and enter a **Name** (to identify the server), server IP address or FQDN (**TACACS+ Server** field), **Secret**/**Confirm Secret** (a key to encrypt usernames and passwords), and server **Port** for authentication requests (default is 49). |
| Step 7 | Click **OK** and **Commit**. |

## Configure an LDAP Server Profile

An LDAP server profile enables you to:

- Authenticate administrators and end users of Palo Alto Networks devices.
- Define security rules based on user or group. The LDAP server profile instructs the firewall how to connect and authenticate to the server and how to search the directory for user and group information. You must also configure User-ID to Map Users to Groups. Then you can select users or groups when defining policy rules.

| Configure an LDAP Server Profile | |
|---|---|
| Step 1 | Select **Device > Server Profiles > LDAP** and click **Add**. |
| Step 2 | Enter a **Profile Name** to identify the server profile. |
| Step 3 | For a firewall with more than one virtual system (vsys), select the **Location** (vsys or **Shared**) where the profile is available. |
| Step 4 | For each LDAP server (up to four), click **Add** and enter a **Name** (to identify the server), server IP address (**LDAP Server** field), and server **Port** (default 389). |
| Step 5 | Select the server **Type** from the drop-down: **active-directory**, **e-directory**, **sun**, or **other**. |
| Step 6 | If you want the device to use SSL or TLS for a more secure connection with the directory server, select the **Require SSL/TLS secured connection** check box (it is selected by default). The protocol that the device uses depends on the server **Port**:<br>• 389 (default)—TLS (Specifically, the device uses the Start TLS operation, which upgrades the initial plaintext connection to TLS.)<br>• 636—SSL<br>• Any other port—The device first tries to use TLS. If the directory server doesn't support TLS, the device falls back to SSL. |
| Step 7 | To improve security, you can select the **Verify Server Certificate for SSL sessions** check box (it is cleared by default) so that the device verifies the certificate that the directory server presents for SSL/TLS connections. If the verification fails, the connection fails. To enable verification, you must also select the **Require SSL/TLS secured connection** check box. The device verifies the certificate in two respects:<br>• The certificate is trusted and valid. For the device to trust the certificate, its root certificate authority (CA) and any intermediate certificates must be in the certificate store under **Device > Certificate Management > Certificates > Device Certificates**. Import the certificate if necessary: see Import a Certificate and Private Key.<br>• The certificate name must match the host **Name** of the LDAP server. The device first checks the certificate attribute Subject AltName for matching, then tries the attribute Subject DN. If the certificate uses the FQDN of the directory server, you must enter that FQDN in the **LDAP Server** field for the name matching to succeed. |
| Step 8 | Click **OK** and **Commit**. |

 © Palo Alto Networks, Inc.

## Configure a Kerberos Server Profile

A Kerberos server profile enables users to natively authenticate to an Active Directory domain controller or a Kerberos V5-compliant authentication server. This authentication method is interactive, requiring users to enter usernames and passwords, in contrast with Kerberos single sign-on (SSO), which involves transparent authentication.

To use a Kerberos server for authentication, the server must be accessible over an IPv4 address. IPv6 addresses are not supported.

| Configure a Kerberos Server Profile | |
|---|---|
| Step 1 | Select **Device > Server Profiles > Kerberos** and click **Add**. |
| Step 2 | Enter a **Profile Name** to identify the server profile. |
| Step 3 | For a firewall with more than one virtual system (vsys), select the **Location** (vsys or **Shared**) where the profile is available. |
| Step 4 | For each Kerberos server, click **Add** and enter a **Name** (to identify the server), server IPv4 address or FQDN (**Kerberos Server** field), and an optional **Port** number for communication with the server (default 88). |
| Step 5 | Click **OK** and **Commit**. |

## Set CHAP and PAP Authentication for RADIUS and TACACS+ Servers

When you configure a Palo Alto Networks device to use RADIUS or TACACS+ server authentication for a particular service (for example, Captive Portal), the device first tries to authenticate to the server using Challenge-Handshake Authentication Protocol (CHAP). The device falls back to Password Authentication Protocol (PAP) if the server rejects the CHAP request. This will happen if, for example, the server doesn't support CHAP or isn't configured for CHAP. CHAP is the preferred protocol because it is more secure than PAP. After the device falls back to PAP for a particular RADIUS or TACACS+ server, the device uses only PAP in subsequent attempts to authenticate to that server. PAN-OS records a fall back to PAP as a medium severity event in the System logs. If you modify any fields in the RADIUS or TACACS+ server profile and then commit the changes, the device reverts to first trying CHAP for that server.

In Release 7.0.6 and later releases, you can force the firewall or Panorama to always use a specific protocol for authenticating to the RADIUS or TACACS+ server by entering the following operational CLI command (the `auto` option reverts to the default automatic selection):

```
set authentication radius-auth-type [ auto | chap | pap ]
```

When configuring a RADIUS or TACACS+ server for CHAP, you must define user accounts with reversibly encrypted passwords. Otherwise, CHAP authentication will fail.

 © Palo Alto Networks, Inc.

## Configure an Authentication Profile and Sequence

An authentication profile specifies the authentication service that validates the credentials of an administrator during login and defines how a Palo Alto Networks device accesses the service. If you create a local administrator account on the device, you can authenticate the administrator to the local database, use an external service (RADIUS, TACACS+, LDAP, or Kerberos server), or use Kerberos single sign-on (SSO).

Some networks have multiple databases for different users and user groups. To authenticate to multiple authentication sources (for example, local database and LDAP), configure an authentication sequence. An authentication sequence is a ranked order of authentication profiles that the device matches an administrator against during login. The device checks against the local database first, and then checks each profile in sequence until one successfully authenticates the administrator. An administrator is denied access only if an authentication failure occurs for all the profiles in the authentication sequence.

| **Configure an Authentication Profile and Sequence** | | |
|---|---|---|
| Step 1 | Create a Kerberos keytab.<br><br>Required if the device will use Kerberos SSO authentication. | Create a Kerberos keytab. A keytab is a file that contains Kerberos account information (principal name and hashed password) for the device. |
| Step 2 | Configure an external server profile.<br><br>Required if the device will use an external service for authentication. | • Configure a RADIUS Server Profile.<br>• Configure a TACACS+ Server Profile.<br>• Configure an LDAP Server Profile.<br>• Configure a Kerberos Server Profile. |

**Configure an Authentication Profile and Sequence (Continued)**

Step 3 Configure an authentication profile.

Define one or both of the following authentication phases:

- Kerberos SSO—The device first tries SSO authentication. If that fails, the device falls back to authentication of the **Type** specified in the profile.
- Local database or external authentication—The device prompts the user to enter login credentials, and uses its local database or an external service to authenticate the user.

1. Select **Device > Authentication Profile** and click **Add**.
2. Enter a **Name** to identify the authentication profile.
3. If the firewall has more than one virtual system (vsys), select a **Location** (a vsys or **Shared**) where the profile is available.
4. In the **Authentication** tab, select the authentication **Type**. If you select **RADIUS**, **TACACS+**, **LDAP**, or **Kerberos**, select the authentication **Server Profile** from the drop-down.

   If the **Type** is **LDAP**, define the **Login Attribute**. For Active Directory, enter **sAMAccountName** as the value.
5. (Optional) Specify **User Domain** and **Username Modifier** values to modify the domain/username string that the user will enter during login. This is useful when the authentication service requires the string in a particular format and you don't want to rely on users to correctly enter the domain. Select from the following options:
   - To send only the unmodified user input, leave the **User Domain** blank (the default) and set the **Username Modifier** to the variable **%USERINPUT%** (the default).
   - To prepend a domain to the user input, enter a **User Domain** and set the **Username Modifier** to **%USERDOMAIN%\%USERINPUT%**.
   - To append a domain to the user input, enter a **User Domain** and set the **Username Modifier** to **%USERINPUT%@%USERDOMAIN%**.
6. If you want to enable Kerberos SSO, enter the **Kerberos Realm** (usually the DNS domain of the users, except that the realm is uppercase) and **Import** the **Kerberos Keytab** that you created for the device.
7. Select the **Advanced** tab and, in the Allow List, click **Add** to select the users and groups that can authenticate with this profile. You can select users/groups from the local database or, if you configured an LDAP server profile, from an LDAP-based directory service such as Active Directory. Selecting **all** allows every user to authenticate. By default, the list is empty, meaning no users can authenticate.

   You can also create and allow custom groups based on LDAP filters: see Map Users to Groups.
8. Enter the number of **Failed Attempts** (0-10) to log in that the device allows before locking out the user. The default value 0 means there is no limit.
9. Enter the **Lockout Time** (0-60), which is the number of minutes for which the device locks out the user after reaching the **Failed Attempts** limit. The default value 0 means the lockout applies until an administrator unlocks the user account.
10. Click **OK** to save the authentication profile.

© Palo Alto Networks, Inc.

| Configure an Authentication Profile and Sequence (Continued) | | |
|---|---|---|
| Step 4 | Configure an authentication sequence.<br><br>Required if you want the device to try multiple authentication profiles to authenticate users. The device evaluates the profiles in top-to-bottom order—applying the Kerberos SSO, authentication service, allow list, and account lockout values for each—until one profile successfully authenticates the user. The device denies access only if all the profiles in the sequence fail to authenticate. | 1. Select **Device > Authentication Sequence** and click **Add**.<br>2. Enter a **Name** to identify the authentication sequence.<br>3. If the firewall has more than one virtual system (vsys), select a **Location** (a vsys or **Shared**) where the sequence is available.<br><br>To expedite the authentication process, the best practice is to select the **Use domain to determine authentication profile** check box: the device will match the domain name that a user enters during login with the **User Domain** or **Kerberos Realm** of an authentication profile in the sequence, and then use that profile to authenticate the user. If the device doesn't find a match, or if you clear the check box, the device tries the profiles in the top-to-bottom sequence.<br><br>4. For each authentication profile to include, click **Add** and select from the drop-down. To change the evaluation order of the profiles, select a profile and click **Move Up** or **Move Down**.<br>5. Click **OK** to save the authentication sequence. |
| Step 5 | Assign the authentication profile or sequence. | Assign the authentication profile or sequence to a user or device service. |

## Enable External Authentication for Users and Services

Palo Alto Networks devices can use external services to authenticate administrators, end users, and other devices.

| Enable External Authentication | | |
|---|---|---|
| Step 1 | Configure an external server profile. | • Configure a RADIUS Server Profile.<br>• Configure a TACACS+ Server Profile.<br>• Configure an LDAP Server Profile.<br>• Configure a Kerberos Server Profile. |
| Step 2 | Assign the server profile to an authentication profile.<br>Optionally, you can assign multiple authentication profiles to an authentication sequence. | Configure an Authentication Profile and Sequence. |
| Step 3 | Assign the authentication profile or sequence to a user or device service. | • Administrators: Configure an Administrative Account.<br>• End users:<br>  • Configure Captive Portal.<br>  • Configure the GlobalProtect portal.<br>  • Configure the GlobalProtect gateway.<br>• Device services:<br>  • Configure Routing Information Protocol (RIP).<br>  • Configure Open Shortest Path First (OSPF).<br>  • Configure Border Gateway Protocol (BGP). |

© Palo Alto Networks, Inc.

# Test Authentication Server Connectivity

After you configure an authentication profile on a Palo Alto Networks firewall or Panorama manager, you can use the test authentication feature to determine if the device can communicate with the back-end authentication server and if the authentication request was successful. You can additionally test authentication profiles used for GlobalProtect and Captive Portal authentication. You can perform authentication tests on the candidate configuration, so that you know the configuration is correct before committing.

Authentication server connectivity testing is supported for local database, RADIUS, TACACS+, LDAP, and Kerberos authentication.

The following topics describe how to use the test authentication command and provides use case examples:

- Run the Test Authentication Command
- Local Database Authentication Profile Use Case
- RADIUS Authentication Profile Use Case
- TACACS+ Authentication Profile Use Case
- LDAP Authentication Profile Use Case
- Kerberos Authentication Profile Use Case

© Palo Alto Networks, Inc.

# Run the Test Authentication Command

| Run the Test Authentication Command | |
|---|---|
| Step 1 | On the PAN-OS firewall or Panorama server, Configure an authentication profile. You do not need to commit the authentication or server profile configuration prior to testing. |
| Step 2 | Using a terminal emulation application, such as PuTTY, launch an SSH session to the firewall. |
| Step 3 | (Firewalls with virtual systems configured) Define the target virtual system that the test command will access.<br>This is required on firewalls with multiple virtual systems (vsys) configured, so the test authentication command can locate the user (Global Protect or Captive Portal, for example) in the correct vsys.<br>To define the target vsys:<br>`admin@PA-3060> set system setting target-vsys <vsys-name>`<br>For example, if the user is defined in vsys2, run the following command:<br>`admin@PA-3060> set system setting target-vsys vsys2`<br>The `target-vsys` command is per-login session, so the system clears the option when you log off. |
| Step 4 | Test an authentication profile by entering the following command:<br>`admin@PA-3060> test authentication authentication-profile <authentication-profile-name> username <username> password`<br>For example, to test an authentication profile named my-profile for a user named bsimpson, run the following command:<br>`admin@PA-3060> test authentication authentication-profile my-profile username bsimpson password`<br>When entering authentication profile names and server profile names in the test command, the names are case sensitive. Also, if the authentication profile has a username modifier defined, you must enter the modifier with the username. For example, if you add the username modifier %USERINPUT%@%USERDOMAIN% for a user named bsimpson and the domain name is mydomain.com, enter bsimpson@mydomain.com as the username. This will ensure that the correct credentials are sent to the authentication server. In this example, mydomain.com is the domain that you define in the User Domain field in the Authentication profile. |
| Step 5 | View the output of the test results.<br>If the authentication profile is configured correctly, the output displays `Authentication succeeded`. If there is a configuration issue, the output displays information to help you troubleshoot the configuration.<br>For example use cases on the supported authentication profile types, see Local Database Authentication Profile Use Case.<br>The output results vary based on several factors related to the authentication type that you are testing as well as the type of issue. For example, RADIUS and TACACS+ use different underlying libraries, so the same issue that exists for both of these types will produce different errors. Also, if there is a network problem, such as using an incorrect port or IP address in the authentication server profile, the output error is not specific. This is because the test command cannot perform the initial handshake between the firewall and the authentication server to determine details about the issue. |

 © Palo Alto Networks, Inc.

## Local Database Authentication Profile Use Case

The following example shows how to test a Local Database authentication profile named LocalDB for a user named User1-LocalDB and how to troubleshoot error conditions that arise. For details on using the test authentication command, see Run the Test Authentication Command.

| Local Database Authentication Profile Test Example | |
|---|---|
| Step 1 | On the PAN-OS firewall, ensure that you have an administrator configured with the type Local Database. For information on administrator accounts, refer to Manage Firewall Administrators. |
| Step 2 | Using a terminal emulation application, such as PuTTY, launch an SSH session to the firewall. |
| Step 3 | (Firewalls with virtual systems configured) Define the target virtual system that the test command will access.<br>This is required on firewalls with multiple virtual systems (vsys) configured, so the test authentication command can locate the user (Global Protect or Captive Portal, for example) in the correct vsys.<br>To define the target vsys:<br>`admin@PA-3060> set system setting target-vsys <vsys-name>`<br>For example, if the user is defined in vsys2, run the following command:<br>`admin@PA-3060> set system setting target-vsys vsys2`<br>The `target-vsys` command is per-login session, so the system clears the option when you log off. |
| Step 4 | Run the following CLI command:<br>`admin@PA-3060> test authentication authentication-profile LocalDB-Profile username User1-LocalDB password` |
| Step 5 | When prompted, enter the password for the User1-LocalDB account. The following output shows that the test failed:<br>`Allow list check error:`<br>`Do allow list check before sending out authentication request...`<br>`User User1-LocalDB is not allowed with authentication profile LocalDB-Profile`<br>In this case, the last line of the output shows that the user is not allowed, which indicates a configuration problem in the authentication profile. |
| Step 6 | To resolve this issue, modify the authentication profile and add the user to the Allow List.<br>1. On the firewall, select **Device > Authentication Profile** and modify the profile named LocalDB-Profile.<br>2. Click the **Advanced** tab and add User1-LocalDB to the Allow List.<br>3. Click **OK** to save the change. |
| Step 7 | Run the test command again. The following output shows that the test is successful:<br>`Do allow list check before sending out authentication request...`<br>`name "User1-LocalDB" has an exact match in allow list`<br>`Authentication by Local User Database for user "User1-LocalDB"`<br>`Authentication succeeded for Local User Database user "User1-LocalDB"` |

## RADIUS Authentication Profile Use Case

The following example shows how to test a RADIUS profile named RADIUS-Profile for a user named User2-RADIUS and how to troubleshoot error conditions that arise. For details on using the test authentication command, see Run the Test Authentication Command.

| RADIUS Authentication Profile Test Example | |
|---|---|
| Step 1 | On the PAN-OS firewall, Configure a RADIUS Server Profile and Configure an authentication profile. In the authentication profile, you select the new RADIUS server profile in the **Server Profile** drop-down. |
| Step 2 | Using a terminal emulation application, such as PuTTY, launch an SSH session to the firewall. |
| Step 3 | (Firewalls with virtual systems configured) Define the target virtual system that the test command will access.<br>This is required on firewalls with multiple virtual systems (vsys) configured, so the test authentication command can locate the user (Global Protect or Captive Portal, for example) in the correct vsys.<br>To define the target vsys:<br>`admin@PA-3060> set system setting target-vsys <vsys-name>`<br>For example, if the user is defined in vsys2, run the following command:<br>`admin@PA-3060> set system setting target-vsys vsys2`<br>The `target-vsys` command is per-login session, so the system clears the option when you log off. |
| Step 4 | Run the following CLI command:<br>`admin@PA-3060> test authentication authentication-profile RADIUS-Profile username User2-RADIUS password` |
| Step 5 | When prompted, enter the password for the User2-RADIUS account. The following output shows that the test failed:<br>`Do allow list check before sending out authentication request...`<br>`name "User2-RADIUS" is in group "all"`<br>`Authentication to RADIUS server at 10.5.104.99:1812 for user "User2-RADIUS"`<br>`Egress: 10.5.104.98`<br>`Authentication type: CHAP`<br>`Now send request to remote server ...`<br>`RADIUS error: Invalid RADIUS response received - Bad MD5`<br>`Authentication failed against RADIUS server at 10.5.104.99:1812 for user "User2-RADIUS"`<br>In this case, the output shows `Bad MD5`, which indicates that there may be an issue with the secret defined in the RADIUS server profile. |

 © Palo Alto Networks, Inc.

**RADIUS Authentication Profile Test Example**

Step 6 To resolve this issue, modify the RADIUS server profile and ensure that the secret defined on the RADIUS server matches the secret in the server profile.

1. On the firewall, select **Device > Server Profiles > RADIUS** and modify the profile named RADIUS-Profile.
2. In the Servers section, locate the RADIUS server and modify the **Secret** field.
3. Type in the correct secret and then retype to confirm.
4. Click **OK** to save the change.

Step 7 Run the test command again. The following output shows that the test is successful:

```
Do allow list check before sending out authentication request...

name "User2-RADIUS" is in group "all"

Authentication to RADIUS server at 10.5.104.99:1812 for user "User2-RADIUS"

Egress: 10.5.104.98

Authentication type: CHAP

Now send request to remote server ...

RADIUS CHAP auth request is NOT accepted, try PAP next

Authentication type: PAP

Now send request to remote server ...

Authentication succeeded against RADIUS server at 10.5.104.99:1812 for user "User2-RADIUS"

Authentication succeeded for user "User2-RADIUS"
```

## TACACS+ Authentication Profile Use Case

The following example shows how to test a TACACS+ profile named TACACS-Profile for a user named User3-TACACS and how to troubleshoot error conditions that arise. For details on using the test authentication command, see Run the Test Authentication Command.

| TACACS+ Authentication Profile Test Example | |
|---|---|
| Step 1 | On the PAN-OS firewall, Configure a TACACS+ Server Profile and Configure an authentication profile. In the authentication profile, you select the new TACACS+ server profile in the **Server Profile** drop-down. |
| Step 2 | Using a terminal emulation application, such as PuTTY, launch an SSH session to the firewall. |
| Step 3 | (Firewalls with virtual systems configured) Define the target virtual system that the test command will access.<br>This is required on firewalls with multiple virtual systems (vsys) configured, so the test authentication command can locate the user (Global Protect or Captive Portal, for example) in the correct vsys.<br>To define the target vsys:<br>`admin@PA-3060> set system setting target-vsys <vsys-name>`<br>For example, if the user is defined in vsys2, run the following command:<br>`admin@PA-3060> set system setting target-vsys vsys2`<br>The `target-vsys` command is per-login session, so the system clears the option when you log off. |
| Step 4 | Run the following CLI command:<br>`admin@PA-3060> test authentication authentication-profile TACACS-Profile username User3-TACACS password` |

 © Palo Alto Networks, Inc.

**TACACS+ Authentication Profile Test Example**

Step 5 When prompted, enter the password for the User3-TACASC account. The following output shows that the test failed:

```
Do allow list check before sending out authentication request...

name "User2-TACACS" is in group "all"

Authentication to TACACS+ server at '10.5.196.62' for user 'User2-TACACS'

Server port: 49, timeout: 30, flag: 0

Egress: 10.5.104.98

Attempting CHAP authentication ...

CHAP authentication request is created

Sending credential: xxxxxx

Failed to send CHAP authentication request: Network read timed out

Attempting PAP authentication ...

PAP authentication request is created

Failed to send PAP authentication request: Network read timed out

Returned status: -1

Authentication failed against TACACS+ server at 10.5.196.62:49 for user User2-TACACS

Authentication failed for user "User2-TACACS"
```

The output shows error `Network read timed out,` which indicates that the TACACS+ server could not decrypt the authentication request. In this case, there may be an issue with the secret defined in the TACACS+ server profile.

Step 6 To resolve this issue, modify the TACACS+ server profile and ensure that the secret defined on the TACACS+ server matches the secret in the server profile.

1. On the firewall, select **Device > Server Profiles > TACACS+** and modify the profile named TACACS-Profile.
2. In the Servers section, locate the TACACS+ server and modify the **Secret** field.
3. Type in the correct secret and then retype to confirm.
4. Click **OK** to save the change.

**TACACS+ Authentication Profile Test Example**

Step 7 Run the test command again. The following output shows that the test is successful:

```
Do allow list check before sending out authentication request...
name "User2-TACACS" is in group "all"
Authentication to TACACS+ server at '10.5.196.62' for user 'User2-TACACS'
Server port: 49, timeout: 30, flag: 0
Egress: 10.5.104.98
Attempting CHAP authentication ...
CHAP authentication request is created
Sending credential: xxxxxx
CHAP authentication request is sent
Authentication succeeded!
Authentication succeeded for user "User2-TACACS"
```

 © Palo Alto Networks, Inc.

## LDAP Authentication Profile Use Case

The following example shows how to test a LDAP authentication profile named LDAP-Profile for a user named User4-LDAP and how to troubleshoot error conditions that arise. For details on using the test authentication command, see Run the Test Authentication Command.

| LDAP Authentication Profile Test Example | |
|---|---|
| Step 1 | On the PAN-OS firewall, Configure an LDAP Server Profile and Configure an authentication profile. In the authentication profile, you select the new LDAP server profile in the **Server Profile** drop-down. |
| Step 2 | Using a terminal emulation application, such as PuTTY, launch an SSH session to the firewall. |
| Step 3 | (Firewalls with virtual systems configured) Define the target virtual system that the test command will access.<br>This is required on firewalls with multiple virtual systems (vsys) configured, so the test authentication command can locate the user (Global Protect or Captive Portal, for example) in the correct vsys.<br>To define the target vsys:<br>`admin@PA-3060> set system setting target-vsys <vsys-name>`<br>For example, if the user is defined in vsys2, run the following command:<br>`admin@PA-3060> set system setting target-vsys vsys2`<br>The `target-vsys` command is per-login session, so the system clears the option when you log off. |
| Step 4 | Run the following CLI command:<br>`admin@PA-3060> test authentication authentication-profile LDAP-Profile username User4-LDAP password` |
| Step 5 | When prompted, enter the password for the User4-LDAP account. The following output shows that the test failed:<br>`Do allow list check before sending out authentication request...`<br>`name "User4-LDAP" is in group "all"`<br>`Authentication to LDAP server at 10.5.104.99 for user "User4-LDAP"`<br>`Egress: 10.5.104.98`<br>`Type of authentication: plaintext`<br>`Starting LDAP connection...`<br>`Succeeded to create a session with LDAP server`<br>`parse error of dn and attributes for user "User4-LDAP"`<br>`Authentication failed against LDAP server at 10.5.104.99:389 for user "User4-LDAP"`<br>`Authentication failed for user "User4-LDAP"`<br>The output shows `parse error of dn and attributes for user User4-LDAP,` which indicates a BIND DN value issues in the LDAP server profile. In this case, a Domain Component (DC) value is incorrect. |

**LDAP Authentication Profile Test Example**

Step 6 To resolve this issue, modify the LDAP server profile and ensure that the Bind DN DC value is correct by comparing the DC value with the DC value of the LDAP server.

1. On the firewall, select **Device > Server Profiles > LDAP** and modify the profile named LDAP-Profile.
2. In the Server settings section, enter the correct value for the DC in the `Bind DN` field. In this case, the correct value for the DC is MGMT-GROUP
3. Click **OK** to save the change.

Step 7 Run the test command again. The following output shows that the test is successful:

```
Do allow list check before sending out authentication request...

name "User4-LDAP" is in group "all"

Authentication to LDAP server at 10.5.104.99 for user "User4-LDAP"

Egress: 10.5.104.98

Type of authentication: plaintext

Starting LDAP connection...

Succeeded to create a session with LDAP server

DN sent to LDAP server: CN=User4-LDAP,CN=Users,DC=MGMT-GROUP,DC=local

User expires in days: never

Authentication succeeded for user "User4-LDAP"
```

 © Palo Alto Networks, Inc.

## Kerberos Authentication Profile Use Case

The following example shows how to test a Kerberos profile named Kerberos-Profile for a user named User5-Kerberos and how to troubleshoot error conditions that arise. For details on using the test authentication command, see Run the Test Authentication Command.

| Kerberos Authentication Profile Test Example | |
|---|---|
| Step 1 | On the PAN-OS firewall, Configure a Kerberos Server Profile and Configure an authentication profile. In the authentication profile, you select the new Kerberos server profile in the **Server Profile** drop-down. |
| Step 2 | Using a terminal emulation application, such as PuTTY, launch an SSH session to the firewall. |
| Step 3 | (Firewalls with virtual systems configured) Define the target virtual system that the test command will access.<br>This is required on firewalls with multiple virtual systems (vsys) configured, so the test authentication command can locate the user (Global Protect or Captive Portal, for example) in the correct vsys.<br>To define the target vsys:<br>`admin@PA-3060> set system setting target-vsys <vsys-name>`<br>For example, if the user is defined in vsys2, run the following command:<br>`admin@PA-3060> set system setting target-vsys vsys2`<br>The `target-vsys` command is per-login session, so the system clears the option when you log off. |
| Step 4 | Run the following CLI command:<br>`admin@PA-3060> test authentication authentication-profile Kerberos-Profile username User5-Kerberos password` |
| Step 5 | When prompted, enter the password for the User5-Kerberos account. The following output shows that the test failed:<br>`Do allow list check before sending out authentication request...`<br>`name "User5-Kerberos" is in group "all"`<br>`Authentication to KERBEROS server at '10.5.104.99' for user 'User5-Kerberos'`<br>`Realm: 'Bad-MGMT-GROUP.LOCAL'`<br>`Egress: 10.5.104.98`<br>`KERBEROS configuration file is created`<br>`KERBEROS authcontext is created. Now authenticating ...`<br>`Kerberos principal is created`<br>`Sending authentication request to KDC...`<br>`Authentication failure: Wrong realm: 'Bad-MGMT-GROUP.LOCAL' (code: -1765328316)`<br>`Authentication failed against KERBEROS server at 10.5.104.99:88 for user "User5-Kerberos"`<br>`Authentication failed for user "User5-Kerberos"`<br>In this case, the output shows `Wrong realm`, which indicates that the Kerberos realm has an incorrect value. |

**Kerberos Authentication Profile Test Example**

Step 6 To resolve this issue, modify the Kerberos server profile and ensure that the Realm value is correct by comparing the realm name on the Kerberos server.

1. On the firewall, select **Device > Authentication Profiles** and modify the profile named Kerberos-Profile.
2. In the Kerberos Realm field, enter the correct value. In this case, the correct realm is mgmt-group.local.
3. Click **OK** to save the change.

Step 7 Run the test command again. The following output shows that the test is successful:

```
Do allow list check before sending out authentication request...

name "User5-Kerberos" is in group "all"

Authentication to KERBEROS server at '10.5.104.99' for user 'User5-Kerberos'

Realm: 'MGMT-GROUP.LOCAL'

Egress: 10.5.104.98

KERBEROS configuration file is created

KERBEROS authcontext is created. Now authenticating ...

Kerberos principal is created

Sending authentication request to KDC...

Authentication succeeded!

Authentication succeeded for user "User5-Kerberos"
```

 © Palo Alto Networks, Inc.

# Troubleshoot Authentication Issues

When users fail to authenticate to a Palo Alto Networks device, or the Authentication process takes longer than expected, analyzing authentication-related information can help you determine whether the failure or delay resulted from:

- User behavior—For example, users are locked out after entering the wrong credentials or a high volume of users are simultaneously attempting access.
- System or network issues—For example, an authentication server is inaccessible.
- Configuration issues—For example, the Allow List of an authentication profile doesn't have all the users it should have.

The following CLI commands display information that can help you troubleshoot these issues:

| Task | Command |
|---|---|
| Use the `show authentication locked-users` command to display the number of locked user accounts associated with the authentication profile (`auth-profile` option), authentication sequence (`is-seq` option), or virtual system (`vsys` option).<br> To unlock administrator users, use the command: **`set management-server unlock admin`** `<user_name>` | `show authentication locked-users`<br>`{`<br>`vsys <value> \|`<br>`auth-profile <value> \|`<br>`is-seq`<br>`{yes \| no}`<br>`{auth-profile \| vsys} <value>`<br>`}` |

| Task | Command |
|---|---|

# Certificate Management

The following topics describe the different keys and certificates that Palo Alto Networks® devices use, and how to obtain and manage them:

- Keys and Certificates
- Certificate Revocation
- Certificate Deployment
- Set Up Verification for Certificate Revocation Status
- Configure the Master Key
- Obtain Certificates
- Export a Certificate and Private Key
- Configure a Certificate Profile
- Configure an SSL/TLS Service Profile
- Configure the Key Size for SSL Forward Proxy Server Certificates
- Revoke and Renew Certificates
- Secure Keys with a Hardware Security Module

# Keys and Certificates

To ensure trust between parties in a secure communication session, Palo Alto Networks devices use digital certificates. Each certificate contains a cryptographic key to encrypt plaintext or decrypt cyphertext. Each certificate also includes a digital signature to authenticate the identity of the issuer. The issuer must be in the list of trusted certificate authorities (CAs) of the authenticating party. Optionally, the authenticating party verifies the issuer did not revoke the certificate (see Certificate Revocation).

Palo Alto Networks devices use certificates in the following applications:

- User authentication for Captive Portal, GlobalProtect™, Mobile Security Manager, and web interface access to a Palo Alto Networks device.
- Device authentication for GlobalProtect VPN (remote user-to-site or large scale).
- Device authentication for IPSec site-to-site VPN with Internet Key Exchange (IKE).
- Decrypting inbound and outbound SSL traffic.

  A firewall decrypts the traffic to apply policy rules, then re-encrypts it before forwarding the traffic to the final destination. For outbound traffic, the firewall acts as a forward proxy server, establishing an SSL/TLS connection to the destination server. To secure a connection between itself and the client, the firewall uses a *signing certificate* to automatically generate a copy of the destination server certificate.

The following table describes the keys and certificates that Palo Alto Networks devices use. As a best practice, use different keys and certificates for each usage.

**Table: Palo Alto Networks Device Keys/Certificates**

| Key/Certificate Usage | Description |
|---|---|
| Administrative Access | Secure access to device administration interfaces (HTTPS access to the web interface) requires a server certificate for the MGT interface (or a designated interface on the dataplane if the device does not use MGT) and, optionally, a certificate to authenticate the administrator. |
| Captive Portal | In deployments where Captive Portal identifies users who access HTTPS resources, designate a server certificate for the Captive Portal interface. If you configure Captive Portal to use certificates (instead of, or in addition to, username/password credentials) for user identification, designate a user certificate also. For more information on Captive Portal, see Map IP Addresses to Usernames Using Captive Portal. |
| Forward Trust | For outbound SSL/TLS traffic, if a firewall acting as a forward proxy trusts the CA that signed the certificate of the destination server, the firewall uses the forward trust CA certificate to generate a copy of the destination server certificate to present to the client. To set the key size, see Configure the Key Size for SSL Forward Proxy Server Certificates. For added security, store the key on a hardware security module (for details, see Secure Keys with a Hardware Security Module). |
| Forward Untrust | For outbound SSL/TLS traffic, if a firewall acting as a forward proxy does not trust the CA that signed the certificate of the destination server, the firewall uses the forward untrust CA certificate to generate a copy of the destination server certificate to present to the client. |

 © Palo Alto Networks, Inc.

| Key/Certificate Usage | Description |
|---|---|
| SSL Inbound Inspection | The keys that decrypt inbound SSL/TLS traffic for inspection and policy enforcement. For this application, import onto the firewall a private key for each server that is subject to SSL/TLS inbound inspection. See Configure SSL Inbound Inspection. |
| SSL Exclude Certificate | Certificates for servers to exclude from SSL/TLS decryption. For example, if you enable SSL decryption but your network includes servers for which the firewall should not decrypt traffic (for example, web services for your HR systems), import the corresponding certificates onto the firewall and configure them as SSL Exclude Certificates. See Configure Decryption Exceptions. |
| GlobalProtect | All interaction among GlobalProtect components occurs over SSL/TLS connections. Therefore, as part of the GlobalProtect deployment, deploy server certificates for all GlobalProtect portals, gateways, and Mobile Security Managers. Optionally, deploy certificates for authenticating users also.<br>Note that the GlobalProtect Large Scale VPN (LSVPN) feature requires a CA signing certificate. |
| Site-to-Site VPNs (IKE) | In a site-to-site IPSec VPN deployment, peer devices use Internet Key Exchange (IKE) gateways to establish a secure channel. IKE gateways use certificates or preshared keys to authenticate the peers to each other. You configure and assign the certificates or keys when defining an IKE gateway on a firewall. See Site-to-Site VPN Overview. |
| Master Key | The firewall uses a master key to encrypt all private keys and passwords. If your network requires a secure location for storing private keys, you can use an encryption (wrapping) key stored on a hardware security module (HSM) to encrypt the master key. For details, see Encrypt a Master Key Using an HSM. |
| Secure Syslog | The certificate to enable secure connections between the firewall and a syslog server. See Syslog Field Descriptions. |
| Trusted Root CA | The designation for a root certificate issued by a CA that the firewall trusts. The firewall can use a self-signed root CA certificate to automatically issue certificates for other applications (for example, SSL Forward Proxy).<br>Also, if a firewall must establish secure connections with other firewalls, the root CA that issues their certificates must be in the list of trusted root CAs on the firewall. |

# Certificate Revocation

Palo Alto Networks devices use digital certificates to ensure trust between parties in a secure communication session. Configuring a device to check the revocation status of certificates provides additional security. A party that presents a revoked certificate is not trustworthy. When a certificate is part of a chain, the device checks the status of every certificate in the chain except the root CA certificate, for which the device cannot verify revocation status.

Various circumstances can invalidate a certificate before the expiration date. Some examples are a change of name, change of association between subject and certificate authority (for example, an employee terminates employment), and compromise (known or suspected) of the private key. Under such circumstances, the certificate authority that issued the certificate must revoke it.

Palo Alto Networks devices support the following methods for verifying certificate revocation status. If you configure both, the devices first try the OCSP method; if the OCSP server is unavailable, the devices use the CRL method.

- Certificate Revocation List (CRL)
- Online Certificate Status Protocol (OCSP)

In PAN-OS, certificate revocation status verification is an optional feature. It is a best practice to enable it for certificate profiles, which define user and device authentication for Captive Portal, GlobalProtect, site-to-site IPSec VPN, and web interface access to Palo Alto Network devices.

## Certificate Revocation List (CRL)

Each certificate authority (CA) periodically issues a certificate revocation list (CRL) to a public repository. The CRL identifies revoked certificates by serial number. After the CA revokes a certificate, the next CRL update will include the serial number of that certificate.

The Palo Alto Networks firewall downloads and caches the last-issued CRL for every CA listed in the trusted CA list of the firewall. Caching only applies to validated certificates; if a firewall never validated a certificate, the firewall cache does not store the CRL for the issuing CA. Also, the cache only stores a CRL until it expires.

The firewall supports CRLs only in Distinguished Encoding Rules (DER) format. If the firewall downloads a CRL in any other format—for example, Privacy Enhanced Mail (PEM) format—any revocation verification process that uses that CRL will fail when a user performs an activity that triggers the process (for example, sending outbound SSL data). The firewall will generate a system log for the verification failure. If the verification was for an SSL certificate, the firewall will also display the SSL Certificate Errors Notify response page to the user.

To use CRLs for verifying the revocation status of certificates used for the decryption of inbound and outbound SSL/TLS traffic, see Configure Revocation Status Verification of Certificates Used for SSL/TLS Decryption.

To use CRLs for verifying the revocation status of certificates that authenticate users and devices, configure a certificate profile and assign it to the interfaces that are specific to the application: Captive Portal, GlobalProtect (remote user-to-site or large scale), site-to-site IPSec VPN, or web interface access to Palo Alto Networks devices. For details, see Configure Revocation Status Verification of Certificates Used for User/Device Authentication.

 © Palo Alto Networks, Inc.

## Online Certificate Status Protocol (OCSP)

When establishing an SSL/TLS session, clients can use Online Certificate Status Protocol (OCSP) to check the revocation status of the authentication certificate. The authenticating client sends a request containing the serial number of the certificate to the OCSP responder (server). The responder searches the database of the certificate authority (CA) that issued the certificate and returns a response containing the status (*good*, *revoked* or *unknown*) to the client. The advantage of the OCSP method is that it can verify status in real-time, instead of depending on the issue frequency (hourly, daily, or weekly) of CRLs.

The Palo Alto Networks firewall downloads and caches OCSP status information for every CA listed in the trusted CA list of the firewall. Caching only applies to validated certificates; if a firewall never validated a certificate, the firewall cache does not store the OCSP information for the issuing CA. If your enterprise has its own public key infrastructure (PKI), you can configure the firewall as an OCSP responder (see Configure an OCSP Responder).

To use OCSP for verifying the revocation status of certificates when the firewall functions as an SSL forward proxy, perform the steps under Configure Revocation Status Verification of Certificates Used for SSL/TLS Decryption.

The following applications use certificates to authenticate users and/or devices: Captive Portal, GlobalProtect (remote user-to-site or large scale), site-to-site IPSec VPN, and web interface access to Palo Alto Networks devices. To use OCSP for verifying the revocation status of the certificates:

- Configure an OCSP responder.
- Enable the HTTP OCSP service on the firewall.
- Create or obtain a certificate for each application.
- Configure a certificate profile for each application.
- Assign the certificate profile to the relevant application.

To cover situations where the OCSP responder is unavailable, configure CRL as a fall-back method. For details, see Configure Revocation Status Verification of Certificates Used for User/Device Authentication.

# Certificate Deployment

The basic approaches to deploy certificates for Palo Alto Networks devices are:

- **Obtain certificates from a trusted third-party CA**—The benefit of obtaining a certificate from a trusted third-party certificate authority (CA) such as VeriSign or GoDaddy is that end clients will already trust the certificate because common browsers include root CA certificates from well-known CAs in their trusted root certificate stores. Therefore, for applications that require end clients to establish secure connections with a Palo Alto Network device, purchase a certificate from a CA that the end clients trust to avoid having to pre-deploy root CA certificates to the end clients. (Some such applications are a GlobalProtect portal or GlobalProtect Mobile Security Manager.) However, note that most third-party CAs cannot issue signing certificates. Therefore, this type of certificate is not appropriate for applications (for example, SSL/TLS decryption and large-scale VPN) that require the firewall to issue certificates. See Obtain a Certificate from an External CA.

- **Obtain certificates from an enterprise CA**—Enterprises that have their own internal CA can use it to issue certificates for firewall applications and import them onto the firewall. The benefit is that end clients probably already trust the enterprise CA. You can either generate the needed certificates and import them onto the firewall, or generate a certificate signing request (CSR) on the firewall and send it to the enterprise CA for signing. The benefit of this method is that the private key does not leave the firewall. An enterprise CA can also issue a signing certificate, which the firewall uses to automatically generate certificates (for example, for GlobalProtect large-scale VPN or sites requiring SSL/TLS decryption). See Import a Certificate and Private Key.

- **Generate self-signed certificates**—You can Create a Self-Signed Root CA Certificate on the firewall and use it to automatically issue certificates for other firewall applications. Note that if you use this method to generate certificates for an application that requires an end client to trust the certificate, end users will see a certificate error because the root CA certificate is not in their trusted root certificate store. To prevent this, deploy the self-signed root CA certificate to all end user systems. You can deploy the certificates manually or use a centralized deployment method such as an Active Directory Group Policy Object (GPO).

 © Palo Alto Networks, Inc.

# Set Up Verification for Certificate Revocation Status

To verify the revocation status of certificates, the firewall uses Online Certificate Status Protocol (OCSP) and/or certificate revocation lists (CRLs). For details on these methods, see Certificate Revocation If you configure both methods, the firewall first tries OCSP and only falls back to the CRL method if the OCSP responder is unavailable. If your enterprise has its own public key infrastructure (PKI), you can configure the firewall to function as the OCSP responder.

The following topics describe how to configure the firewall to verify certificate revocation status:

- Configure an OCSP Responder
- Configure Revocation Status Verification of Certificates Used for User/Device Authentication
- Configure Revocation Status Verification of Certificates Used for SSL/TLS Decryption

## Configure an OCSP Responder

To use Online Certificate Status Protocol (OCSP) for verifying the revocation status of certificates, you must configure the firewall to access an OCSP responder (server). The entity that manages the OCSP responder can be a third-party certificate authority (CA) or, if your enterprise has its own public key infrastructure (PKI), the firewall itself. For details on OCSP, see Certificate Revocation

| **Configure an OCSP Responder** | | |
|---|---|---|
| Step 1 | Define an OCSP responder. | 1. Select **Device > Certificate Management > OCSP Responder** and click **Add**.<br>2. Enter a **Name** to identify the responder (up to 31 characters). The name is case-sensitive. It must be unique and use only letters, numbers, spaces, hyphens, and underscores.<br>3. If the device has more than one virtual system (vsys), select a **Location** (vsys or **Shared**) for the certificate.<br>4. In the **Host Name** field, enter the host name (recommended) or IP address of the OCSP responder. From this value, PAN-OS automatically derives a URL and adds it to the certificate being verified.<br>If you configure the firewall itself as an OCSP responder, the host name must resolve to an IP address in the interface that the firewall uses for OCSP services (specified in Step 3).<br>5. Click **OK**. |
| Step 2 | Enable OCSP communication on the firewall. | 1. Select **Device > Setup > Management**.<br>2. In the Management Interface Settings section, edit to select the **HTTP OCSP** check box, then click **OK**. |

| Configure an OCSP Responder | | |
|---|---|---|
| Step 3 | Optionally, to configure the firewall itself as an OCSP responder, add an Interface Management Profile to the interface used for OCSP services. | 1. Select **Network > Network Profiles > Interface Mgmt**.<br>2. Click **Add** to create a new profile or click the name of an existing profile.<br>3. Select the **HTTP OCSP** check box and click **OK**.<br>4. Select **Network > Interfaces** and click the name of the interface that the firewall will use for OCSP services. The OCSP **Host Name** specified in Step 1 must resolve to an IP address in this interface.<br>5. Select **Advanced > Other info** and select the Interface Management Profile you configured.<br>6. Click **OK** and **Commit**. |

## Configure Revocation Status Verification of Certificates Used for User/Device Authentication

The firewall uses certificates to authenticate users and devices for such applications as Captive Portal, GlobalProtect, site-to-site IPSec VPN, and web interface access to Palo Alto Networks devices. To improve security, it is a best practice to configure the firewall to verify the revocation status of certificates that it uses for device/user authentication.

| Configure Revocation Status Verification of Certificates Used for User/Device Authentication | | |
|---|---|---|
| Step 1 | Configure a Certificate Profile for each application. | Assign one or more root CA certificates to the profile and select how the firewall verifies certificate revocation status. The common name (FQDN or IP address) of a certificate must match an interface to which you apply the profile in Step 2.<br>For details on the certificates that various applications use, see Keys and Certificates |
| Step 2 | Assign the certificate profiles to the relevant applications. | The steps to assign a certificate profile depend on the application that requires it. |

## Configure Revocation Status Verification of Certificates Used for SSL/TLS Decryption

The firewall decrypts inbound and outbound SSL/TLS traffic to apply security rules and rules, then re-encrypts the traffic before forwarding it. (For details, see SSL Inbound Inspection and SSL Forward Proxy.) You can configure the firewall to verify the revocation status of certificates used for decryption as follows.

Enabling revocation status verification for SSL/TLS decryption certificates will add time to the process of establishing the session. The first attempt to access a site might fail if the verification does not finish before the session times out. For these reasons, verification is disabled by default.

 © Palo Alto Networks, Inc.

| Configure Revocation Status Verification of Certificates Used for SSL/TLS Decryption | | |
|---|---|---|
| Step 1 | Define the service-specific timeout intervals for revocation status requests. | 1. Select **Device > Setup > Session** and, in the Session Features section, select **Decryption Certificate Revocation Settings**.<br>2. Perform one or both of the following steps, depending on whether the firewall will use Online Certificate Status Protocol (OCSP) or the Certificate Revocation List (CRL) method to verify the revocation status of certificates. If the firewall will use both, it first tries OCSP; if the OCSP responder is unavailable, the firewall then tries the CRL method.<br>• In the CRL section, select the **Enable** check box and enter the **Receive Timeout**. This is the interval (1-60 seconds) after which the firewall stops waiting for a response from the CRL service.<br>• In the OCSP section, select the **Enable** check box and enter the **Receive Timeout**. This is the interval (1-60 seconds) after which the firewall stops waiting for a response from the OCSP responder.<br>Depending on the **Certificate Status Timeout** value you specify in Step 2, the firewall might register a timeout before either or both of the **Receive Timeout** intervals pass. |
| Step 2 | Define the total timeout interval for revocation status requests. | Enter the **Certificate Status Timeout**. This is the interval (1-60 seconds) after which the firewall stops waiting for a response from any certificate status service and applies the session-blocking logic you optionally define in Step 3. The **Certificate Status Timeout** relates to the OCSP/CRL **Receive Timeout** as follows:<br>• If you enable both OCSP and CRL—The firewall registers a request timeout after the lesser of two intervals passes: the **Certificate Status Timeout** value or the aggregate of the two **Receive Timeout** values.<br>• If you enable only OCSP—The firewall registers a request timeout after the lesser of two intervals passes: the **Certificate Status Timeout** value or the OCSP **Receive Timeout** value.<br>• If you enable only CRL—The firewall registers a request timeout after the lesser of two intervals passes: the **Certificate Status Timeout** value or the CRL **Receive Timeout** value. |
| Step 3 | Define the blocking behavior for *unknown* certificate status or a revocation status request timeout. | If you want the firewall to block SSL/TLS sessions when the OCSP or CRL service returns a certificate revocation status of *unknown*, select the **Block Session With Unknown Certificate Status** check box. Otherwise, the firewall proceeds with the session.<br>If you want the firewall to block SSL/TLS sessions after it registers a request timeout, select the **Block Session On Certificate Status Check Timeout** check box. Otherwise, the firewall proceeds with the session. |
| Step 4 | Save and apply your entries. | Click **OK** and **Commit**. |

# Configure the Master Key

Every firewall has a default master key that encrypts private keys and other secrets (such as passwords and shared keys). The private keys authenticate users when they access administrative interfaces on the firewall. As a best practice to safeguard the keys, configure the master key on each firewall to be unique and periodically change it. For added security, use a *wrapping key* stored on a hardware security module (HSM) to encrypt the master key. For details, see Encrypt a Master Key Using an HSM.

In a high availability (HA) configuration, ensure both devices in the pair use the same master key to encrypt private keys and certificates. If the master keys differ, HA configuration synchronization will not work properly.

When you export a firewall configuration, the master key encrypts the passwords of users managed on external servers. For locally managed users, the firewall hashes the passwords but the master key does not encrypt them.

| **Configure a Master Key** | |
|---|---|
| Step 1 | Select **Device > Master Key and Diagnostics** and, in the Master Key section, click the Edit icon. |
| Step 2 | Enter the **Current Master Key** if one exists. |
| Step 3 | Define a new **New Master Key** and then **Confirm New Master Key**. The key must contain exactly 16 characters. |
| Step 4 | (Optional) To specify the master key **Life Time**, enter the number of **Days** and/or **Hours** after which the key will expire. If you set a life time, create a new master key before the old key expires. |
| Step 5 | (Optional) If you set a key life time, enter a **Time for Reminder** that specifies the number of **Days** and **Hours** preceding master key expiration when the firewall emails you a reminder. |
| Step 6 | (Optional) Select whether to use an **HSM** to encrypt the master key. For details, see Encrypt a Master Key Using an HSM. |
| Step 7 | Click **OK** and **Commit**. |

© Palo Alto Networks, Inc.

# Obtain Certificates

- Create a Self-Signed Root CA Certificate
- Generate a Certificate on the Device
- Import a Certificate and Private Key
- Obtain a Certificate from an External CA

© Palo Alto Networks, Inc.

## Create a Self-Signed Root CA Certificate

A self-signed root certificate authority (CA) certificate is the top-most certificate in a certificate chain. A firewall can use this certificate to automatically issue certificates for other uses. For example, the firewall issues certificates for SSL/TLS decryption and for satellite devices in a GlobalProtect large-scale VPN.

When establishing a secure connection with the firewall, the remote client must trust the root CA that issued the certificate. Otherwise, the client browser will display a warning that the certificate is invalid and might (depending on security settings) block the connection. To prevent this, after generating the self-signed root CA certificate, import it into the client systems.

On a Palo Alto Networks device, you can generate self-signed certificates only if they are CA certificates.

| Generate a Self-signed Root CA Certificate | |
|---|---|
| Step 1 | Select **Device > Certificate Management > Certificates > Device Certificates**. |
| Step 2 | If the device has more than one virtual system (vsys), select a **Location** (vsys or **Shared**) for the certificate. |
| Step 3 | Click **Generate**. |
| Step 4 | Enter a **Certificate Name**, such as *GlobalProtect_CA*. The name is case-sensitive and can have up to 31 characters. It must be unique and use only letters, numbers, hyphens, and underscores. |
| Step 5 | In the **Common Name** field, enter the FQDN (recommended) or IP address of the interface where you will configure the service that will use this certificate. |
| Step 6 | If the device has more than one vsys and you want the certificate to be available to every vsys, select the **Shared** check box. |
| Step 7 | Leave the **Signed By** field blank to designate the certificate as self-signed. |
| Step 8 | (Required) Select the **Certificate Authority** check box. |
| Step 9 | Leave the **OCSP Responder** field blank; revocation status verification doesn't apply to root CA certificates. |
| Step 10 | Click **Generate** and **Commit**. |

 © Palo Alto Networks, Inc.

## Generate a Certificate on the Device

Palo Alto Networks devices use certificates to authenticate clients, servers, users, and devices in several applications, including SSL/TLS decryption, Captive Portal, GlobalProtect, site-to-site IPSec VPN, and device web interface access. Generate certificates for each usage: for details, see Keys and Certificates.

To generate a certificate, you must first Create a Self-Signed Root CA Certificate or import one (Import a Certificate and Private Key) to sign it. To use Online Certificate Status Protocol (OCSP) for verifying certificate revocation status, Configure an OCSP Responder before generating the certificate.

| Generate a Certificate on the Device | |
|---|---|
| Step 1 | Select **Device > Certificate Management > Certificates > Device Certificates**. |
| Step 2 | If the device has more than one virtual system (vsys), select a **Location** (vsys or **Shared**) for the certificate. |
| Step 3 | Click **Generate**. |
| Step 4 | Enter a **Certificate Name**. The name is case-sensitive and can have up to 31 characters. It must be unique and use only letters, numbers, hyphens, and underscores. |
| Step 5 | In the **Common Name** field, enter the FQDN (recommended) or IP address of the interface where you will configure the service that will use this certificate. |
| Step 6 | If the device has more than one vsys and you want the certificate to be available to every vsys, select the **Shared** check box. |
| Step 7 | In the **Signed By** field, select the root CA certificate that will issue the certificate. |
| Step 8 | (Optional) Select an **OCSP Responder**. |
| Step 9 | For the key generation **Algorithm**, select **RSA** (default) or **Elliptical Curve DSA** (ECDSA). ECDSA is recommended for client browsers and operating systems that support it.<br> Firewalls that run PAN-OS 6.1 and earlier releases will delete any ECDSA certificates that you push from Panorama™, and any RSA certificates signed by an ECDSA certificate authority (CA) will be invalid on those firewalls. |
| Step 10 | Select the **Number of Bits** to define the certificate key length. Higher numbers are more secure but require more processing time. |
| Step 11 | Select the **Digest** algorithm. From most to least secure, the options are: **sha512**, **sha384**, **sha256** (default), **sha1**, and **md5**. |
| Step 12 | For the **Expiration**, enter the number of days (default is 365) for which the certificate is valid. |
| Step 13 | (Optional) **Add** the **Certificate Attributes** to uniquely identify the firewall and the service that will use the certificate.<br> If you add a **Host Name** (DNS name) attribute, it is a best practice for it to match the **Common Name**. The host name populates the Subject Alternative Name field of the certificate. |
| Step 14 | Click **Generate** and, in the Device Certificates page, click the certificate Name.<br> Regardless of the time zone on the firewall, it always displays the corresponding Greenwich Mean Time (GMT) for certificate validity and expiration dates/times. |

| Generate a Certificate on the Device (Continued) | |
|---|---|
| Step 15 | Select the check boxes that correspond to the intended use of the certificate on the firewall.<br>For example, if the firewall will use this certificate to secure forwarding of syslogs to an external syslog server, select the **Certificate for Secure Syslog** check box. |
| Step 16 | Click **OK** and **Commit**. |

 © Palo Alto Networks, Inc.

## Import a Certificate and Private Key

If your enterprise has its own public key infrastructure (PKI), you can import a certificate and private key into the firewall from your enterprise certificate authority (CA). Enterprise CA certificates (unlike most certificates purchased from a trusted, third-party CA) can automatically issue CA certificates for applications such as SSL/TLS decryption or large-scale VPN.

On a Palo Alto Networks device, you can import self-signed certificates only if they are CA certificates.

Instead of importing a self-signed root CA certificate into all the client systems, it is a best practice to import a certificate from the enterprise CA because the clients will already have a trust relationship with the enterprise CA, which simplifies the deployment.

If the certificate you will import is part of a certificate chain, it is a best practice to import the entire chain.

| Import a Certificate and Private Key | |
|---|---|
| Step 1 | From the enterprise CA, export the certificate and private key that the firewall will use for authentication.<br><br>When exporting a private key, you must enter a passphrase to encrypt the key for transport. Ensure the management system can access the certificate and key files. When importing the key onto the firewall, you must enter the same passphrase to decrypt it. |
| Step 2 | Select **Device > Certificate Management > Certificates > Device Certificates**. |
| Step 3 | If the device has more than one virtual system (vsys), select a **Location** (vsys or **Shared**) for the certificate. |
| Step 4 | Click **Import** and enter a **Certificate Name**. The name is case-sensitive and can have up to 31 characters. It must be unique and use only letters, numbers, hyphens, and underscores. |
| Step 5 | To make the certificate available to all virtual systems, select the **Shared** check box. This check box appears only if the device supports multiple virtual systems. |
| Step 6 | Enter the path and name of the **Certificate File** received from the CA, or **Browse** to find the file. |
| Step 7 | Select a **File Format**:<br>• **Encrypted Private Key and Certificate (PKCS12)**—This is the default and most common format, in which the key and certificate are in a single container (**Certificate File**). If a hardware security module (HSM) will store the private key for this certificate, select the **Private key resides on Hardware Security Module** check box.<br>• **Base64 Encoded Certificate (PEM)**—You must import the key separately from the certificate. If a hardware security module (HSM) stores the private key for this certificate, select the **Private key resides on Hardware Security Module** check box and skip Step 8. Otherwise, select the **Import Private Key** check box, enter the **Key File** or **Browse** to it, then perform Step 8. |
| Step 8 | Enter and re-enter (confirm) the **Passphrase** used to encrypt the private key. |
| Step 9 | Click **OK**. The Device Certificates page displays the imported certificate. |

## Obtain a Certificate from an External CA

The advantage of obtaining a certificate from an external certificate authority (CA) is that the private key does not leave the firewall. To obtain a certificate from an external CA, generate a certificate signing request (CSR) and submit it to the CA. After the CA issues a certificate with the specified attributes, import it onto the firewall. The CA can be a well-known, public CA or an enterprise CA.

To use Online Certificate Status Protocol (OCSP) for verifying the revocation status of the certificate, Configure an OCSP Responder *before* generating the CSR.

| **Obtain a Certificate from an External CA** | |
|---|---|
| Step 1 Request the certificate from an external CA. | 1. Select **Device > Certificate Management > Certificates > Device Certificates**.<br>2. If the device has more than one virtual system (vsys), select a **Location** (vsys or **Shared**) for the certificate.<br>3. Click **Generate**.<br>4. Enter a **Certificate Name**. The name is case-sensitive and can have up to 31 characters. It must be unique and use only letters, numbers, hyphens, and underscores.<br>5. In the **Common Name** field, enter the FQDN (recommended) or IP address of the interface where you will configure the service that will use this certificate.<br>6. If the device has more than one vsys and you want the certificate to be available to every vsys, select the **Shared** check box.<br>7. In the **Signed By** field, select **External Authority (CSR)**.<br>8. If applicable, select an **OCSP Responder**.<br>9. (Optional) **Add** the **Certificate Attributes** to uniquely identify the firewall and the service that will use the certificate.<br>If you add a **Host Name** attribute, it is a best practice for it to match the **Common Name** (this is mandatory for GlobalProtect). The host name populates the Subject Alternative Name field of the certificate.<br>10. Click **Generate**. The Device Certificates tab displays the CSR with a Status of *pending*. |
| Step 2 Submit the CSR to the CA. | 1. Select the CSR and click **Export** to save the .csr file to a local computer.<br>2. Upload the .csr file to the CA. |

© Palo Alto Networks, Inc.

| Obtain a Certificate from an External CA | |
|---|---|
| Step 3 Import the certificate. | 1. After the CA sends a signed certificate in response to the CSR, return to the **Device Certificates** tab and click **Import**.<br>2. Enter the **Certificate Name** used to generate the CSR in Step 1-4.<br>3. Enter the path and name of the PEM **Certificate File** that the CA sent, or **Browse** to it.<br>4. Click **OK**. The **Device Certificates** tab displays the certificate with a Status of *valid*. |
| Step 4 Configure the certificate. | 1. Click the certificate **Name**.<br>2. Select the check boxes that correspond to the intended use of the certificate on the firewall. For example, if the firewall will use this certificate to secure forwarding of syslogs to an external syslog server, select the **Certificate for Secure Syslog** check box.<br>3. Click **OK** and **Commit**. |

# Export a Certificate and Private Key

Palo Alto Networks recommends that you use your enterprise public key infrastructure (PKI) to distribute a certificate and private key in your organization. However, if necessary, you can also export a certificate and private key from the firewall or Panorama. You can use an exported certificate and private key in the following cases:

- Administrator authentication to the device web interface
- GlobalProtect agent/app authentication to portals and gateways
- SSL Forward Proxy decryption
- Certificate signing requests (CSRs)

| Export a Certificate and Private Key | |
|---|---|
| Step 1 | Select **Device > Certificate Management > Certificates > Device Certificates**. |
| Step 2 | If the device has more than one virtual system (vsys), select a **Location** (a specific vsys or **Shared**) for the certificate. |
| Step 3 | Select the certificate, click **Export**, and select a **File Format**:<br>• **Base64 Encoded Certificate (PEM)**—This is the default format. It is the most common and has the broadest support on the Internet. If you want the exported file to include the private key, select the **Export Private Key** check box.<br>• **Encrypted Private Key and Certificate (PKCS12)**—This format is more secure than PEM but is not as common or as broadly supported. The exported file will automatically include the private key.<br>• **Binary Encoded Certificate (DER)**—More operating system types support this format than the others. You can export only the certificate, not the key: ignore the **Export Private Key** check box and passphrase fields. |
| Step 4 | Enter a **Passphrase** and **Confirm Passphrase** to encrypt the private key if the **File Format** is PKCS12 or if it is PEM and you selected the **Export Private Key** check box. You will use this passphrase when importing the certificate and key into client systems. |
| Step 5 | Click **OK** and save the certificate/key file to your computer. |

© Palo Alto Networks, Inc.

# Configure a Certificate Profile

Certificate profiles define user and device authentication for Captive Portal, GlobalProtect, site-to-site IPSec VPN, Mobile Security Manager, and web interface access to Palo Alto Networks devices. The profiles specify which certificates to use, how to verify certificate revocation status, and how that status constrains access. Configure a certificate profile for each application.

It is a best practice to enable Online Certificate Status Protocol (OCSP) and/or Certificate Revocation List (CRL) status verification for certificate profiles. For details on these methods, see Certificate Revocation.

| Configure a Certificate Profile | | |
|---|---|---|
| Step 1 | Obtain the certificate authority (CA) certificates you will assign. | Perform one of the following steps to obtain the CA certificates you will assign to the profile. You must assign at least one.<br>• Generate a Certificate on the Device.<br>• Export a certificate from your enterprise CA and then import it onto the firewall (see Step 3). |
| Step 2 | Identify the certificate profile. | 1. Select **Device > Certificate Management > Certificates Profile** and click **Add**.<br>2. Enter a **Name** to identify the profile. The name is case-sensitive, must be unique and can use up to 31 characters that include only letters, numbers, spaces, hyphens, and underscores.<br>3. If the device has more than one virtual system (vsys), select a **Location** (vsys or **Shared**) for the certificate. |
| Step 3 | Assign one or more certificates. | Perform the following steps for each CA certificate:<br>1. In the CA Certificates table, click **Add**.<br>2. Select a **CA Certificate**. Alternatively, to import a certificate, click **Import**, enter a **Certificate Name**, **Browse** to the **Certificate File** you exported from your enterprise CA, and click **OK**.<br>3. Optionally, if the firewall uses OCSP to verify certificate revocation status, configure the following fields to override the default behavior. For most deployments, these fields do not apply.<br>• By default, the firewall uses the OCSP responder URL that you set in the procedure Configure an OCSP Responder. To override that setting, enter a **Default OCSP URL** (starting with *http://* or *https://*).<br>• By default, the firewall uses the certificate selected in the **CA Certificate** field to validate OCSP responses. To use a different certificate for validation, select it in the **OCSP Verify CA Certificate** field.<br>4. Click **OK**. The CA Certificates table displays the assigned certificate. |

| Configure a Certificate Profile | |
|---|---|
| Step 4 Define the methods for verifying certificate revocation status and the associated blocking behavior. | 1. Select **Use CRL** and/or **Use OCSP**. If you select both, the firewall first tries OCSP and falls back to the CRL method only if the OCSP responder is unavailable.<br>2. Depending on the verification method, enter the **CRL Receive Timeout** and/or **OCSP Receive Timeout**. These are the intervals (1-60 seconds) after which the firewall stops waiting for a response from the CRL/OCSP service.<br>3. Enter the **Certificate Status Timeout**. This is the interval (1-60 seconds) after which the firewall stops waiting for a response from any certificate status service and applies any session-blocking logic you define. The **Certificate Status Timeout** relates to the OCSP/CRL **Receive Timeout** as follows:<br>• If you enable both OCSP and CRL—The firewall registers a request timeout after the lesser of two intervals passes: the **Certificate Status Timeout** value or the aggregate of the two **Receive Timeout** values.<br>• If you enable only OCSP—The firewall registers a request timeout after the lesser of two intervals passes: the **Certificate Status Timeout** value or the OCSP **Receive Timeout** value.<br>• If you enable only CRL—The firewall registers a request timeout after the lesser of two intervals passes: the **Certificate Status Timeout** value or the CRL **Receive Timeout** value.<br>4. If you want the firewall to block sessions when the OCSP or CRL service returns a certificate revocation status of *unknown*, select the **Block session if certificate status is unknown** check box. Otherwise, the firewall proceeds with the session.<br>5. If you want the firewall to block sessions after it registers an OCSP or CRL request timeout, select the **Block session if certificate status cannot be retrieved within timeout** check box. Otherwise, the firewall proceeds with the session. |
| Step 5 Save and apply your entries. | Click **OK** and **Commit**. |

© Palo Alto Networks, Inc.

# Configure an SSL/TLS Service Profile

SSL/TLS service profiles specify a certificate and the allowed protocol versions for the SSL/TLS services of Palo Alto Networks devices. The devices use SSL/TLS for Captive Portal, GlobalProtect portals and gateways, inbound traffic on the management (MGT) interface, the URL Admin Override feature, and the User-ID™ syslog listening service. By defining the protocol versions, you can use a profile to restrict the cipher suites that are available for securing communication with the clients requesting the services. This improves network security by enabling devices to avoid SSL/TLS versions that have known weaknesses: if a service request involves a protocol version that is outside the specified range, the device downgrades or upgrades the connection to a supported version.

| Configure an SSL/TLS Service Profile | |
|---|---|
| Step 1 | For each desired service, generate or import a certificate on the firewall (see Obtain Certificates).<br> Use only signed certificates, not certificate authority (CA) certificates, for SSL/TLS services. |
| Step 2 | Select **Device > Certificate Management > SSL/TLS Service Profile**. |
| Step 3 | If the device has more than one virtual system (vsys), select the **Location** (vsys or **Shared**) where the profile is available. |
| Step 4 | Click **Add** and enter a **Name** to identify the profile. |
| Step 5 | Select the **Certificate** you just obtained. |
| Step 6 | Define the range of protocols that the service can use:<br>• For the **Min Version**, select the earliest allowed TLS version: **TLSv1.0** (default), **TLSv1.1**, or **TLSv1.2**.<br>• For the **Max Version**, select the latest allowed TLS version: **TLSv1.0**, **TLSv1.1**, **TLSv1.2**, or **Max** (latest available version). The default is **Max**. |
| Step 7 | Click **OK** and **Commit**. |

# Configure the Key Size for SSL Forward Proxy Server Certificates

When responding to a client in an SSL Forward Proxy session, the firewall creates a copy of the certificate that the destination server presents and uses the copy to establish a connection with the client. By default, the firewall generates certificates with the same key size as the certificate that the destination server presented. However, you can change the key size for the firewall-generated certificate as follows:

**Configure the Key Size for SSL Forward Proxy Server Certificates**

Step 1 Select **Device > Setup > Session** and, in the Decryption Settings section, click **SSL Forward Proxy Settings**.

Step 2 Select a **Key Size**:

- **Defined by destination host**—The firewall determines the key size for the certificates it generates to establish SSL proxy sessions with clients based on the key size of the destination server certificate. If the destination server uses a 1,024-bit RSA key, the firewall generates a certificate with that key size and an SHA-1 hashing algorithm. If the destination server uses a key size larger than 1,024 bits (for example, 2,048 bits or 4,096 bits), the firewall generates a certificate that uses a 2,048-bit RSA key and SHA-256 algorithm. This is the default setting.
- **1024-bit RSA**—The firewall generates certificates that use a 1,024-bit RSA key and SHA-1 hashing algorithm regardless of the key size of the destination server certificates. As of December 31, 2013, public certificate authorities (CAs) and popular browsers have limited support for X.509 certificates that use keys of fewer than 2,048 bits. In the future, depending on security settings, when presented with such keys the browser might warn the user or block the SSL/TLS session entirely.
- **2048-bit RSA**—The firewall generates certificates that use a 2,048-bit RSA key and SHA-256 hashing algorithm regardless of the key size of the destination server certificates. Public CAs and popular browsers support 2,048-bit keys, which provide better security than the 1,024-bit keys.

Changing the key size setting clears the current certificate cache.

Step 3 Click **OK** and **Commit**.

 © Palo Alto Networks, Inc.

# Revoke and Renew Certificates

▲ Revoke a Certificate
▲ Renew a Certificate

## Revoke a Certificate

Various circumstances can invalidate a certificate before the expiration date. Some examples are a change of name, change of association between subject and certificate authority (for example, an employee terminates employment), and compromise (known or suspected) of the private key. Under such circumstances, the certificate authority (CA) that issued the certificate must revoke it. The following task describes how to revoke a certificate for which the firewall is the CA.

| **Revoke a Certificate** | |
|---|---|
| Step 1 | Select **Device > Certificate Management > Certificates > Device Certificates**. |
| Step 2 | If the device supports multiple virtual systems, the tab displays a **Location** drop-down. Select the virtual system to which the certificate belongs. |
| Step 3 | Select the certificate to revoke. |
| Step 4 | Click **Revoke**. PAN-OS immediately sets the status of the certificate to revoked and adds the serial number to the Online Certificate Status Protocol (OCSP) responder cache or certificate revocation list (CRL). You need not perform a commit. |

## Renew a Certificate

If a certificate expires, or soon will, you can reset the validity period. If an external certificate authority (CA) signed the certificate and the firewall uses the Online Certificate Status Protocol (OCSP) to verify certificate revocation status, the firewall uses the OCSP responder information to update the certificate status (see Configure an OCSP Responder). If the firewall is the CA that issued the certificate, the firewall replaces it with a new certificate that has a different serial number but the same attributes as the old certificate.

| **Renew a Certificate** | |
|---|---|
| Step 1 | Select **Device > Certificate Management > Certificates > Device Certificates**. |
| Step 2 | If the device has more than one virtual system (vsys), select a **Location** (vsys or **Shared**) for the certificate. |
| Step 3 | Select a certificate to renew and click **Renew**. |
| Step 4 | Enter a **New Expiration Interval** (in days). |
| Step 5 | Click **OK** and **Commit**. |

© Palo Alto Networks, Inc.

# Secure Keys with a Hardware Security Module

A hardware security module (HSM) is a physical device that manages digital keys. An HSM provides secure storage and generation of digital keys. It provides both logical and physical protection of these materials from non-authorized use and potential adversaries.

HSM clients integrated with Palo Alto Networks devices enable enhanced security for the private keys used in SSL/TLS decryption (both SSL forward proxy and SSL inbound inspection). In addition, you can use the HSM to encrypt device master keys.

The following topics describe how to integrate an HSM with your Palo Alto Networks devices:

- Set up Connectivity with an HSM
- Encrypt a Master Key Using an HSM
- Store Private Keys on an HSM
- Manage the HSM Deployment

 © Palo Alto Networks, Inc.

# Set up Connectivity with an HSM

HSM clients are integrated with PA-3000 Series, PA-4000 Series, PA-5000 Series, PA-7000 Series, and VM-Series firewalls and on Panorama (virtual appliance and M-Series appliance) for use with the following HSMs:

- SafeNet Network 5.2.1 or later
- Thales Nshield Connect 11.62 or later

The HSM server version must be compatible with these client versions. Refer to the HSM vendor documentation for the client-server version compatibility matrix.

The following topics describe how to set up connectivity between the Palo Alto Networks device and one of the supported HSMs:

▲ Set Up Connectivity with a SafeNet Network HSM

▲ Set Up Connectivity with a Thales Nshield Connect HSM

## Set Up Connectivity with a SafeNet Network HSM

To set up connectivity between the Palo Alto Networks device and a SafeNet Network HSM, you must specify the address of the HSM server and the password for connecting to it in the firewall configuration. In addition, you must register the firewall with the HSM server. Prior to beginning the configuration, make sure you have created a partition for the Palo Alto Networks devices on the HSM server.

HSM configuration is not synced between high availability firewall peers. Consequently, you must configure the HSM module separately on each of the peers.

In Active-Passive HA deployments, you must manually perform one failover to configure and authenticate each HA peer individually to the HSM. After this manual failover has been performed, user interaction is not required for the failover function.

| **Set up a Connectivity with a SafeNet Network HSM** | |
|---|---|
| Step 1 Configure the firewall to communicate with the SafeNet Network HSM. | 1. Log in to the firewall web interface and select **Device > Setup > HSM**.<br>2. Edit the Hardware Security Module Provider section and select **Safenet Luna SA** (SafeNet Network) as the **Provider Configured**.<br>3. Click **Add** and enter a **Module Name**. This can be any ASCII string up to 31 characters in length.<br>4. Enter the IPv4 address of the HSM module as the **Server Address**.<br>If you are configuring a high availability HSM configuration, enter module names and IP addresses for the additional HSM devices.<br>5. (Optional) If configuring a high availability HSM configuration, select the **High Availability** check box and add the following: a value for **Auto Recovery Retry** and a **High Availability Group Name**.<br>If two HSM servers are configured, you should configure high availability. Otherwise the second HSM server is not used.<br>6. Click **OK** and **Commit.** |

| Set up a Connectivity with a SafeNet Network HSM (Continued) | | |
|---|---|---|
| Step 2 | (Optional) Configure a service route to enable the firewall to connect to the HSM.<br><br>By default, the firewall uses the Management Interface to communicate with the HSM. To use a different interface, you must configure a service route. | 1. Select **Device > Setup > Services.**<br>2. Select **Service Route Configuration** from the Services Features area.<br>3. Select **Customize** from the Service Route Configuration area.<br>4. Select the **IPv4** tab.<br>5. Select **HSM** from the **Service** column.<br>6. Select an interface to use for HSM from the **Source Interface** drop-down.<br><br>If you select a dataplane connected port for HSM, issuing the `clear session all` CLI command will clear all existing HSM sessions, causing all HSM states to be brought down and then up. During the several seconds required for HSM to recover, all SSL/TLS operations will fail.<br><br>7. Click **OK** and **Commit.** |
| Step 3 | Configure the firewall to authenticate to the HSM. | 1. Select **Device > Setup > HSM**.<br>2. Select **Setup Hardware Security Module** in the Hardware Security Operations area.<br>3. Select the HSM **Server Name** from the drop-down.<br>4. Enter the **Administrator Password** to authenticate the firewall to the HSM.<br>5. Click **OK.**<br><br>The firewall attempts to perform an authentication with the HSM and displays a status message.<br><br>6. Click **OK.** |
| Step 4 | Register the firewall (the HSM client) with the HSM and assign it to a partition on the HSM.<br><br>If the HSM already has a firewall with the same `<cl-name>` registered, you must remove the duplicate registration using the following command before registration will succeed:<br><br>`client delete -client <cl-name>`<br><br>where `<cl-name>` is the name of the client (firewall) registration you want to delete. | 1. Log in to the HSM from a remote system.<br>2. Register the firewall using the following command:<br>`client register -c <cl-name> -ip <fw-ip-addr>`<br>where `<cl-name>` is a name that you assign to the firewall for use on the HSM and `<fw-ip-addr>` is the IP address of the firewall that is being configured as an HSM client.<br>3. Assign a partition to the firewall using the following command:<br>`client assignpartition -c <cl-name> -p <partition-name>`<br>where `<cl-name>` is the name assigned to the firewall in the `client register` command and `<partition-name>` is the name of a previously configured partition that you want to assign to the firewall. |

 © Palo Alto Networks, Inc.

| Set up a Connectivity with a SafeNet Network HSM (Continued) | | |
|---|---|---|
| Step 5 | Configure the firewall to connect to the HSM partition. | 1. Select **Device > Setup > HSM**.<br>2. Click the **Refresh** icon.<br>3. Select the **Setup HSM Partition** in the Hardware Security Operations area.<br>4. Enter the **Partition Password** to authenticate the firewall to the partition on the HSM.<br>5. Click **OK**. |
| Step 6 | (Optional) Configure an additional HSM for high availability (HA). | 1. Follow Step 1 through Step 5 to add an additional HSM for high availability (HA).<br>This process adds a new HSM to the existing HA group.<br>2. If you remove an HSM from your configuration, repeat Step 5.<br>This will remove the deleted HSM from the HA group. |
| Step 7 | Verify connectivity with the HSM. | 1. Select **Device > Setup > HSM**.<br>2. Check the **Status** of the HSM connection:<br>Green—HSM is authenticated and connected.<br>Red—HSM was not authenticated or network connectivity to the HSM is down.<br>3. View the following columns in Hardware Security Module Status area to determine authentication status:<br>**Serial Number**—The serial number of the HSM partition if the HSM was successfully authenticated.<br>**Partition—**The partition name on the HSM that was assigned on the firewall.<br>**Module State**—The current operating state of the HSM. It always has the value Authenticated if the HSM is displayed in this table. |

## Set Up Connectivity with a Thales Nshield Connect HSM

The following workflow describes how to configure the firewall to communicate with a Thales Nshield Connect HSM. This configuration requires that you set up a remote filesystem (RFS) to use as a *hub* to sync key data for all firewalls in your organization that are using the HSM.

HSM configuration is not synced between high availability firewall peers. Consequently, you must configure the HSM module separately on each of the peers.

If the high availability firewall configuration is in Active-Passive mode, you must manually perform one failover to configure and authenticate each HA peer individually to the HSM. After this manual failover has been performed, user interaction is not required for the failover function.

| Set up Connectivity with a Thales Nshield Connect HSM | | |
|---|---|---|
| Step 1 | Configure the Thales Nshield Connect server as the firewall's HSM provider. | 1. From the firewall web interface, select **Device > Setup > HSM** and edit the Hardware Security Module Provider section.<br>2. Select **Thales Nshield Connect** as the **Provider Configured**.<br>3. Click **Add** and enter a **Module Name**. This can be any ASCII string up to 31 characters in length.<br>4. Enter the IPv4 address as the **Server Address** of the HSM module.<br>If you are configuring a high availability HSM configuration, enter module names and IP addresses for the additional HSM devices.<br>5. Enter the IPv4 address of the **Remote Filesystem Address**.<br>6. Click **OK** and **Commit**. |
| Step 2 | (Optional) Configure a service route to enable the firewall to connect to the HSM.<br>By default, the firewall uses the Management Interface to communicate with the HSM. To use a different interface, you must configure a service route. | 1. Select **Device > Setup > Services.**<br>2. Select **Service Route Configuration** from the Services Features area.<br>3. Select **Customize** from the Service Route Configuration area.<br>4. Select the **IPv4** tab.<br>5. Select **HSM** from the **Service** column.<br>6. Select an interface to use for HSM from the **Source Interface** drop-down.<br>If you select a dataplane connected port for HSM, issuing the `clear session all` CLI command will clear all existing HSM sessions, causing all HSM states to be brought down and then up. During the several seconds required for HSM to recover, all SSL/TLS operations will fail.<br>7. Click **OK** and **Commit.** |
| Step 3 | Register the firewall (the HSM client) with the HSM server.<br>This step briefly describes the procedure for using the front panel interface of the Thales Nshield Connect HSM. For more details, consult the Thales documentation. | 1. Log in to the front panel display of the Thales Nshield Connect HSM unit.<br>2. On the unit front panel, use the right-hand navigation button to select **System > System configuration > Client config > New client**.<br>3. Enter the IP address of the firewall.<br>4. Select **System > System configuration > Client config > Remote file system** and enter the IP address of the client computer where you set up the remote file system. |

 © Palo Alto Networks, Inc.

| Set up Connectivity with a Thales Nshield Connect HSM (Continued) | | |
|---|---|---|
| Step 4 | Set up the remote filesystem to accept connections from the firewall. | 1. Log in to the remote filesystem (RFS) from a Linux client.<br>2. Obtain the electronic serial number (ESN) and the hash of the $K_{NETI}$ key. The $K_{NETI}$ key authenticates the module to clients:<br>`anonkneti <ip-address>`<br>where `<ip-address>` is the IP address of the HSM.<br>The following is an example:<br>`anonkneti 192.0.2.1`<br>`B1E2-2D4C-E6A2 5a2e5107e70d525615a903f6391ad72b1c03352c`<br>In this example, **`B1E2-2D4C-E6A2`** is the ESM and 5a2e5107e70d525615a903f6391ad72b1c03352c is the hash of the $K_{NETI}$ key.<br>3. Use the following command from a superuser account to perform the remote filesystem setup:<br>`rfs-setup --force <ip-address> <ESN> <hash-Kneti-key>`<br>where `<ip-address>` is the IP address of the HSM,<br>`<ESN>` is the electronic serial number (ESN) and<br>`<hash-Kneti-key>` is the hash of the KNETI key.<br>The following example uses the values obtained in this procedure:<br>`rfs-setup --force <192.0.2.1> <B1E2-2D4C-E6A2>`<br>`<5a2e5107e70d525615a903f6391ad72b1c03352c>`<br>4. Use the following command to permit client submit on the Remote Filesystem:<br>`rfs-setup --gang-client --write-noauth <FW-IPaddress>`<br>where `<FW-IPaddress>` is the IP address of the firewall. |
| Step 5 | Configure the firewall to authenticate to the HSM. | 1. From the firewall web interface, select **Device > Setup > HSM**.<br>2. Select **Setup Hardware Security Module** in the Hardware Security Operations area.<br>3. Click **OK.**<br>The firewall attempts to perform an authentication with the HSM and displays a status message.<br>4. Click **OK.** |
| Step 6 | Synchronize the firewall with the remote filesystem. | 1. Select the **Device > Setup > HSM**.<br>2. Select **Synchronize with Remote Filesystem** in the Hardware Security Operations section. |

| Set up Connectivity with a Thales Nshield Connect HSM (Continued) | | |
|---|---|---|
| Step 7 | Verify that the firewall can connect to the HSM. | 1. Select **Device > Setup > HSM**.<br>2. Check the Status indicator to verify that the firewall is connected to the HSM:<br>Green—HSM is authenticated and connected.<br>Red—HSM was not authenticated or network connectivity to the HSM is down.<br>3. View the following columns in Hardware Security Module Status section to determine authentication status.<br>**Name**: The name of the HSM attempting to be authenticated.<br>**IP address:** The IP address of the HSM that was assigned on the firewall.<br>**Module State**: The current operating state of the HSM: **Authenticated** or **Not Authenticated**. |

© Palo Alto Networks, Inc.

# Encrypt a Master Key Using an HSM

A master key is configured on a Palo Alto Networks firewall to encrypt all private keys and passwords. If you have security requirements to store your private keys in a secure location, you can encrypt the master key using an encryption key that is stored on an HSM. The firewall then requests the HSM to decrypt the master key whenever it is required to decrypt a password or private key on the firewall. Typically, the HSM is located in a highly secure location that is separate from the firewall for greater security.

The HSM encrypts the master key using a wrapping key. To maintain security, this encryption key must occasionally be changed. For this reason, a command is provided on the firewall to rotate the wrapping key which changes the master key encryption. The frequency of this wrapping key rotation depends on your application.

Master key encryption using an HSM is not supported on firewalls configured in FIPS or CC mode.

The following topics describe how to encrypt the master key initially and how to refresh the master key encryption:

- Encrypt the Master Key
- Refresh the Master Key Encryption

## Encrypt the Master Key

If you have not previously encrypted the master key on a device, use the following procedure to encrypt it. Use this procedure for first time encryption of a key, or if you define a new master key and you want to encrypt it. If you want to refresh the encryption on a previously encrypted key, see Refresh the Master Key Encryption.

| Encrypt a Master Key Using an HSM | |
|---|---|
| Step 1 | Select **Device > Master Key and Diagnostics.** |
| Step 2 | Specify the key that is currently used to encrypt all of the private keys and passwords on the firewall in the **Master Key** field. |
| Step 3 | If changing the master key, enter the new master key and confirm. |
| Step 4 | Select the **HSM** check box.<br>**Life Time:** The number of days and hours after which the master key expires (range 1-730 days).<br>**Time for Reminder:** The number of days and hours before expiration when the user is notified of the impending expiration (range 1-365 days). |
| Step 5 | Click **OK**. |

## Refresh the Master Key Encryption

As a best practice, refresh the master key encryption on a regular basis by rotating the master key wrapping key on the HSM. This command is the same for both the SafeNet Network and Thales Nshield Connect HSMs.

**Refresh the Master Key Encryption**

Step 1 Use the following CLI command to rotate the wrapping key for the master key on an HSM:

```
> request hsm mkey-wrapping-key-rotation
```

If the master key is encrypted on the HSM, the CLI command will generate a new wrapping key on the HSM and encrypt the master key with the new wrapping key.

If the master key is not encrypted on the HSM, the CLI command will generate new wrapping key on the HSM for future use.

The old wrapping key is not deleted by this command.

 © Palo Alto Networks, Inc.

## Store Private Keys on an HSM

For added security, you can use an HSM to secure the private keys used in SSL/TLS decryption for:

- **SSL forward proxy**—The HSM can store the private key of the CA certificate that is used to sign certificates in SSL/TLS forward proxy operations. The firewall will then send the certificates that it generates during such operations to the HSM for signing before forwarding them to the client.
- **SSL inbound inspection**—The HSM can store the private keys for the internal servers for which you are performing SSL/TLS inbound inspection.

| Store Private Keys on an HSM | | |
|---|---|---|
| Step 1 | On the HSM, import or generate the private key used in your SSL forward proxy or SSL inbound inspection deployment. | For instructions on importing or generating a private key on the HSM, refer to your HSM documentation. |
| Step 2 | (Thales Nshield Connect only) Synchronize the key data from the HSM remote file system to the firewall. | 1. Access the firewall web interface and select **Device > Setup > HSM**.<br>2. Select **Synchronize with Remote Filesystem** in the Hardware Security Operations section. |
| Step 3 | Import the certificate that corresponds to the HSM-stored key onto the firewall. | 1. Select **Device > Certificate Management > Certificates > Device Certificates** and click **Import**.<br>2. Enter the **Certificate Name**.<br>3. Enter the filename of the **Certificate File** you imported to the HSM.<br>4. Select a **File Format**.<br>5. Select the **Private Key resides on Hardware Security Module** check box.<br>6. Click **OK** and **Commit**. |
| Step 4 | (Forward trust certificates only) Enable the certificate for use in SSL/TLS Forward Proxy. | 1. Select **Device > Certificate Management > Certificates > Device Certificates**.<br>2. Open the certificate you imported in Step 3 for editing.<br>3. Select the **Forward Trust Certificate** check box.<br>4. Click **OK** and **Commit**. |
| Step 5 | Verify that you successfully imported the certificate onto the firewall. | 1. Select **Device > Certificate Management > Certificates > Device Certificates**.<br>2. Locate the certificate you imported in Step 3 and check the icon in the Key column:<br>• Lock icon—The private key for the certificate is on the HSM.<br>• Error icon—The private key is not on the HSM or the HSM is not properly authenticated or connected. |

## Manage the HSM Deployment

| Manage HSM | |
|---|---|
| • View the HSM configuration settings. | Select **Device > Setup > HSM**. |
| • Display detailed HSM information. | Select **Show Detailed Information** from the Hardware Security Operations section.<br>Information regarding the HSM servers, HSM HA status, and HSM hardware is displayed. |
| • Export Support file. | Select **Export Support File** from the Hardware Security Operations section.<br>A test file is created to help customer support when addressing a problem with an HSM configuration on the firewall. |
| • Reset HSM configuration. | Select **Reset HSM Configuration** from the Hardware Security Operations section.<br>Selecting this option removes all HSM connections. All authentication procedures must be repeated after using this option. |

© Palo Alto Networks, Inc.

# High Availability

High availability (HA) is a configuration in which two firewalls are placed in a group and their configuration is synchronized to prevent a single point of failure on your network. A heartbeat connection between the firewall peers ensures seamless failover in the event that a peer goes down. Setting up two firewalls in an HA pair provides redundancy and allows you to ensure business continuity.

The Palo Alto Networks firewalls support stateful active/passive or active/active high availability with session and configuration synchronization. Some models of the Palo Alto Networks firewall, such as the PA-200 only support HA lite without session synchronization capability, and the VM-Series firewall in AWS only supports active/passive HA. The following topics provide more information about high availability and how to configure it in your environment.

- HA Overview
- HA Concepts
- Set Up Active/Passive HA
- Reference: HA Synchronization
- HA Resources

# HA Overview

On Palo Alto Networks firewalls, you can set up two firewalls as an HA pair. HA allows you to minimize downtime by making sure that an alternate firewall is available in the event that the peer firewall fails. The firewalls in an HA pair use dedicated or in-band HA ports on the firewall to synchronize data—network, object, and policy configurations—and to maintain state information. Firewall-specific configuration such as management interface IP address or administrator profiles, HA specific configuration, log data, and the Application Command Center (ACC) information is not shared between peers. For a consolidated application and log view across the HA pair, you must use Panorama, the Palo Alto Networks centralized management system.

When a failure occurs on a firewall in an HA pair and the peer firewall takes over the task of securing traffic, the event is called a *failover*. The conditions that trigger a failover are:

- One or more of the monitored interfaces fail. (Link Monitoring)
- One or more of the destinations specified on the firewall cannot be reached. (Path Monitoring)
- The firewall does not respond to heartbeat polls. (Heartbeat Polling and Hello messages)

After you understand the HA Concepts, continue to Set Up Active/Passive HA.

 © Palo Alto Networks, Inc.

# HA Concepts

The following topics provide conceptual information about how HA works on a Palo Alto Networks firewall:

- HA Modes
- HA Links and Backup Links
- Device Priority and Preemption
- Failover Triggers
- HA Timers

## HA Modes

You can set up the firewalls for HA in two modes:

- **Active/Passive**— One firewall actively manages traffic while the other is synchronized and ready to transition to the active state, should a failure occur. In this configuration, both firewalls share the same configuration settings, and one actively manages traffic until a path, link, system, or network failure occurs. When the active firewall fails, the passive firewall transitions to the active state and takes over seamlessly and enforces the same policies to maintain network security. Active/passive HA is supported in the virtual wire, Layer 2 and Layer 3 deployments. For information on setting up your firewalls in an active/passive configuration, see Configure Active/Passive HA.

The PA-200 appliance only supports a lite version of active/passive HA. HA lite provides configuration synchronization and some runtime data synchronization such as IPSec security associations. It does not support any session synchronization, and therefore, HA Lite does not offer stateful failover.

- **Active/Active**— Both the firewalls in the pair are active and processing traffic, and work synchronously to handle session setup and session ownership. The active/active deployment is supported in virtual wire and Layer 3 deployments, and is only recommended for networks with asymmetric routing. For information on setting up the firewalls in an active/active configuration, refer to the Active/Active High Availability Tech Note.

## HA Links and Backup Links

The firewalls in an HA pair use HA links to synchronize data and maintain state information. Some models of the firewall have dedicated HA ports—Control link (HA1) and Data link (HA2), while others require you to use the in-band ports as HA links.

On firewalls with dedicated HA ports such as the PA-3000 Series, PA-4000 Series, PA-5000 Series, and PA-7000 Series firewalls (see HA Ports on the PA-7000 Series Firewall), use the dedicated HA ports to manage communication and synchronization between the firewalls. For firewalls without dedicated HA ports such as the PA-200, PA-500, and PA-2000 Series firewalls, as a best practice use the management port for the HA1 link to allow for a direct connection between the management planes on the firewalls, and an in-band port for the HA2 link.

The HA1 and HA2 links provide synchronization for functions that reside on the management plane. Using the dedicated HA interfaces on the management plane is more efficient than using the in-band ports as this eliminates the need to pass the synchronization packets over the dataplane.

- **Control Link**: The HA1 link is used to exchange hellos, heartbeats, and HA state information, and management plane sync for routing, and User-ID information. The firewalls also use this link to synchronize configuration changes with its peer. The HA1 link is a Layer 3 link and requires an IP address.

  **Ports used for HA1**: TCP port 28769 and 28260 for clear text communication; port 28 for encrypted communication (SSH over TCP).

- **Data Link**: The HA2 link is used to synchronize sessions, forwarding tables, IPSec security associations and ARP tables between firewalls in an HA pair. Data flow on the HA2 link is always unidirectional (except for the HA2 keep-alive); it flows from the active or active-primary firewall to the passive or active-secondary firewall. The HA2 link is a Layer 2 link, and it uses ether type 0x7261 by default.

  **Ports used for HA2:** The HA data link can be configured to use either IP (protocol number 99) or UDP (port 29281) as the transport, and thereby allow the HA data link to span subnets.

  Additionally, an HA3 link is used in Active/Active HA deployments. When there is an asymmetric route, the HA3 link is used for forwarding packets to the HA peer that owns the session. The HA3 link is a Layer 2 link and it does not support Layer 3 addressing or encryption.

- **Backup Links**: Provide redundancy for the HA1 and the HA2 links. In-band ports are used as backup links for both HA1 and HA2. Consider the following guidelines when configuring backup HA links:
  - The IP addresses of the primary and backup HA links must not overlap each other.
  - HA backup links must be on a different subnet from the primary HA links.
  - HA1-backup and HA2-backup ports must be configured on separate physical ports. The HA1-backup link uses port 28770 and 28260.

Palo Alto Networks recommends enabling heartbeat backup (uses port 28771 on the MGT interface) if you use an in-band port for the HA1 or the HA1 backup links.

- **Packet-Forwarding Link**: In addition to the HA1 and HA2 links, an active/active deployment also requires a dedicated HA3 link. The firewalls use this link for forwarding packets to the peer during session setup and asymmetric traffic flow. The HA3 link is a Layer 2 link that uses MAC-in-MAC encapsulation; it does not support Layer 3 addressing or encryption. You can configure aggregate interfaces on the PA-3000 Series, PA-4000 Series, PA-5000 Series and PA-7000 Series firewalls as an HA3 link. The aggregate interfaces can also provide redundancy for the HA3 link; you cannot configure backup links for the HA3 link.

## HA Ports on the PA-7000 Series Firewall

HA connectivity on the PA-7000 Series mandates the use of specific ports on the Switch Management Card (SMC) for certain functions; for other functions, you can use the ports on the Network Processing Card (NPC). The PA-7000 Series firewalls synchronize sessions across the NPCs one-for-one.

Use the following table for information on the SMC ports that are designed for HA connectivity:

 © Palo Alto Networks, Inc.

| HA Links and Backup Links | Ports on the SMC | Description |
|---|---|---|
| **Control Link** | HA1-A<br>Speed: Ethernet 10/100/1000 | Used for HA control and synchronization in both HA Modes. Connect this port directly from the HA1-A port on the first firewall to the HA1-A on the second firewall in the pair, or connect them together through a switch or router.<br>HA1 cannot be configured on NPC data ports or the MGT port. |
| **Control Link Backup** | HA1-B<br>Speed: Ethernet 10/100/1000 port | Used for HA control and synchronization as a backup for HA1-A in both HA Modes. Connect this port directly from the HA1-B port on the first firewall to the HA1-B on the second firewall in the pair, or connect them together through a switch or router.<br>HA1 Backup cannot be configured on NPC data ports or the MGT port. |
| **Data Link**<br><br>**Data Link Backup** | HSCI-A<br><br>HSCI-B | The High Speed Chassis Interconnect (HSCI) ports are Quad Port SFP (QSFP) interfaces which are used to connect two PA-7000 Series firewalls in an HA configuration. Each port is comprised of four 10 gigabit links internally for a combined speed of 40 gigabits.<br>The HSCI ports are not routable and must be connected directly to each other. The HSCI-A on the first chassis connects directly to HSCI-A on the second chassis and HSCI-B on the first chassis connects to HSCI-B on the second chassis. This will provide full 80 gigabit transfer rates. In software, both ports (HSCI-A and HSCI-B) are treated as one HA interface.<br>Palo Alto Networks recommends using the dedicated HSCI ports for the HA2 link; the HA3 link must use the HSCI port. If the firewalls are deployed in:<br>• an active/active configuration, the HA3 link must use the HSCI port. The HA2 link and HA2 backup links can use the HSCI port or data ports on the NPC.<br>• an active/passive configuration, you can configure a data port on the NPC for the HA2 link or the HA2 backup link, if needed. |

For an overview of the Modules and Interface cards on the PA-7000 Series firewall, refer to the PA-7000 Series Hardware Reference Guide.

## Device Priority and Preemption

The firewalls in an HA pair can be assigned a *device priority* value to indicate a preference for which firewall should assume the active or active-primary role. If you need to use a specific firewall in the HA pair for actively securing traffic, you must enable the preemptive behavior on both the firewalls and assign a device priority value for each firewall. The firewall with the lower numerical value, and therefore *higher priority*, is designated as active or active-primary. The other firewall is the active-secondary or passive firewall.

By default, preemption is disabled on the firewalls and must be enabled on both firewalls. When enabled, the preemptive behavior allows the firewall with the *higher priority* (lower numerical value) to resume as active or active-primary after it recovers from a failure. When preemption occurs, the event is logged in the system logs.

## Failover Triggers

When a failure occurs on one firewall and the peer takes over the task of securing traffic, the event is called a *failover*. A failover is triggered when a monitored metric on a firewall in the HA pair fails. The metrics that are monitored for detecting a firewall failure are:

- **Heartbeat Polling and Hello messages**

  The firewalls use hello message and heartbeats to verify that the peer firewall is responsive and operational. Hello messages are sent from one peer to the other at the configured *Hello Interval* to verify the state of the firewall. The heartbeat is an ICMP ping to the HA peer over the control link, and the peer responds to the ping to establish that the firewalls are connected and responsive. By default, the interval for the heartbeat is 1000 milliseconds. For details on the HA timers that trigger a failover, see HA Timers.

- **Link Monitoring**

  The physical interfaces to be monitored are grouped into a link group and their state (link up or link down) is monitored. A link group can contain one or more physical interfaces. A firewall failure is triggered when any or all of the interfaces in the group fail. The default behavior is failure of any one link in the link group will cause the firewall to change the HA state to non-functional to indicate a failure of a monitored object.

- **Path Monitoring**

  Monitors the full path through the network to mission-critical IP addresses. ICMP pings are used to verify reachability of the IP address. The default interval for pings is 200ms. An IP address is considered unreachable when 10 consecutive pings (the default value) fail, and a firewall failure is triggered when any or all of the IP addresses monitored become unreachable. The default behavior is any one of the IP addresses becoming unreachable will cause the firewall to change the HA state to non-functional to indicate a failure of a monitored object.

In addition to the failover triggers listed above, a failover also occurs when the administrator places the firewall is a suspended state or if preemption occurs.

On the PA-3000 Series, PA-5000 Series, and PA-7000 Series firewalls, a failover can occur when an internal health check fails. This health check is not configurable and is enabled to verify the operational status for all the components within the firewall.

 © Palo Alto Networks, Inc.

## HA Timers

High availability (HA) timers are used to detect a firewall failure and trigger a failover. To reduce the complexity in configuring HA timers, you can select from three profiles: **Recommended**, **Aggressive** and **Advanced**. These profiles auto-populate the optimum HA timer values for the specific firewall platform to enable a speedier HA deployment.

Use the **Recommended** profile for typical failover timer settings and the **Aggressive** profile for faster failover timer settings. The **Advanced** profile allows you to customize the timer values to suit your network requirements.

The following table describes each timer included in the profiles and the current preset values across the different hardware models; these values are for current reference only and can change in a subsequent release.

**Recommended/Aggressive HA Timer Values by Platform**

| Timers | Description | PA-7000 Series<br>PA-5000 Series<br>PA-4000 Series<br>PA-3000 Series<br>VM-Series | PA-2000 Series<br>PA-500 Series<br>PA-200 Series | Panorama Virtual Appliance<br>Panorama M-Series |
|---|---|---|---|---|
| Monitor fail hold up time | Interval during which the firewall will remain active following a path monitor or link monitor failure. This setting is recommended to avoid an HA failover due to the occasional flapping of neighboring devices. | 0/0 | 0/0 | 0/0 |
| Preemption hold time | Time that a passive or active-secondary firewall will wait before taking over as the active or active-primary firewall. | 1/1 | 1/1 | 1/1 |
| Heartbeat interval | Frequency at which the HA peers exchange heartbeat messages in the form of an ICMP (ping). | 1000/1000<br>2000/1000 (only for VM-Series in AWS) | 2000/1000 | 2000/1000 |

| Timers | Description | PA-7000 Series<br>PA-5000 Series<br>PA-4000 Series<br>PA-3000 Series<br>VM-Series | PA-2000 Series<br>PA-500 Series<br>PA-200 Series | Panorama Virtual Appliance<br>Panorama M-Series |
|---|---|---|---|---|
| Promotion hold time | Time that the passive firewall (in active/passive mode) or the active-secondary firewall (in active/active mode) will wait before taking over as the active or active-primary firewall after communications with the HA peer have been lost. This hold time will begin only after the peer failure declaration has been made. | 2000/500 | 2000/500 | 2000/500 |
| Additional master hold up time | Time interval that is applied to the same event as Monitor Fail Hold Up Time (range 0-60000 ms, default 500 ms). The additional time interval is applied only to the active firewall in active/passive mode and to the active-primary firewall in active/active mode. This timer is recommended to avoid a failover when both firewalls experience the same link/path monitor failure simultaneously. | 500/500 | 500/500 | 7000/5000 |
| Hello interval | Interval in milliseconds between hello packets that are sent to verify that the HA functionality on the other firewall is operational. The range is 8000-60000 ms with a default of 8000 ms for all platforms. | 8000/8000 | 8000/8000 | 8000/8000 |

 © Palo Alto Networks, Inc.

| Timers | Description | PA-7000 Series<br>PA-5000 Series<br>PA-4000 Series<br>PA-3000 Series<br>VM-Series | PA-2000 Series<br>PA-500 Series<br>PA-200 Series | Panorama Virtual Appliance<br>Panorama M-Series |
|---|---|---|---|---|
| Maximum no. of flaps | A flap is counted when the firewall leaves the active state within 15 minutes after it last left the active state. This value indicates the maximum number of flaps that are permitted before the firewall is determined to be suspended and the passive firewall takes over (range 0-16; default 3). | 3/3 | 3/3 | Not Applicable |

# Set Up Active/Passive HA

- Prerequisites for Active/Passive HA
- Configuration Guidelines for Active/Passive HA
- Configure Active/Passive HA
- Define HA Failover Conditions
- Verify Failover

 © Palo Alto Networks, Inc.

## Prerequisites for Active/Passive HA

To set up high availability on your Palo Alto Networks firewalls, you need a pair of firewalls that meet the following requirements:

- **The same model**—Both the firewalls in the pair must be of the same hardware model or virtual machine model.
- **The same PAN-OS version**—Both the firewalls should be running the same PAN-OS version and must each be up-to-date on the application, URL, and threat databases. They must also both have the same multiple virtual systems capability (single or multi vsys).
- **The same type of interfaces**—Dedicated HA links, or a combination of the management port and in-band ports that are set to *interface type* HA.
  - Determine the IP address for the HA1 (control) connection between the HA peers. The HA1 IP address for both peers must be on the same subnet if they are directly connected or are connected to the same switch.

    For firewalls without dedicated HA ports, you can use the management port for the control connection. Using the management port provides a direct communication link between the management planes on both firewalls. However, because the management ports will not be directly cabled between the peers, make sure that you have a route that connects these two interfaces across your network.
  - If you use Layer 3 as the transport method for the HA2 (data) connection, determine the IP address for the HA2 link. Use Layer 3 *only* if the HA2 connection must communicate over a routed network. The IP subnet for the HA2 links must not overlap with that of the HA1 links or with any other subnet assigned to the data ports on the firewall.
- **The same set of licenses**—Licenses are unique to each firewall and cannot be shared between the firewalls. Therefore, you must license both firewalls identically. If both firewalls do not have an identical set of licenses, they cannot synchronize configuration information and maintain parity for a seamless failover.

If you have an existing firewall and you want to add a new firewall for HA purposes and the new firewall has an existing configuration, it is recommended that you Reset the Firewall to Factory Default Settings on the new firewall. This will ensure that the new firewall has a clean configuration. After HA is configured, you will then sync the configuration on the primary firewall to the newly introduced firewall with the clean config.

## Configuration Guidelines for Active/Passive HA

To set up an active (PeerA) passive (PeerB) pair in HA, you must configure some options identically on both firewalls and some independently (non-matching) on each firewall. These HA settings are not synchronized between the firewalls. For details on what is/is not synchronized, refer to HA Synchronization.

To proceed with the instructions on configuring the firewalls in HA, see Configure Active/Passive HA.

The following table lists the settings that you must configure identically on both firewalls:

| Identical Configuration Settings on PeerA and PeerB |
|---|
| • HA must be enabled on both firewalls.<br>• Both firewalls must have the same Group ID value. The Group ID value is used to create a virtual MAC address for all the configured interfaces. The format of the virtual MAC is 00-1B-17:00: xx: yy where<br>00-1B-17: vendor ID; 00: fixed; xx: HA group ID; yy: interface ID.<br>When a new active firewall takes over, Gratuitous ARP messages are sent from each of the connected interfaces of the new active member to inform the connected Layer 2 switches of the virtual MAC address' new location.<br>• If using in-band ports, the interfaces for the HA1 and HA2 links must be set to type HA.<br>• The HA mode must be set to Active Passive.<br>• If required, preemption must be enabled on both firewalls. The device priority value, however, must not be identical.<br>• If required, encryption on the HA1 link (for communication between the HA peers) must be configured on both firewalls.<br>• Based on the combination of HA1 and HA1 Backup ports you are using, use the following recommendations to decide whether you should enable heartbeat backup:<br>• HA1: Dedicated HA1 port<br>HA1 Backup: In-band port<br>Recommendation: Enable Heartbeat Backup<br>• HA1: Dedicated HA1 port<br>HA1 Backup: Management port<br>Recommendation: Do not enable Heartbeat Backup<br>• HA1: In-band port<br>HA1 Backup: In-band port<br>Recommendation: Enable Heartbeat Backup<br>• HA1: Management port<br>HA1 Backup: In-band port<br>Recommendation: Do not enable Heartbeat Backup |

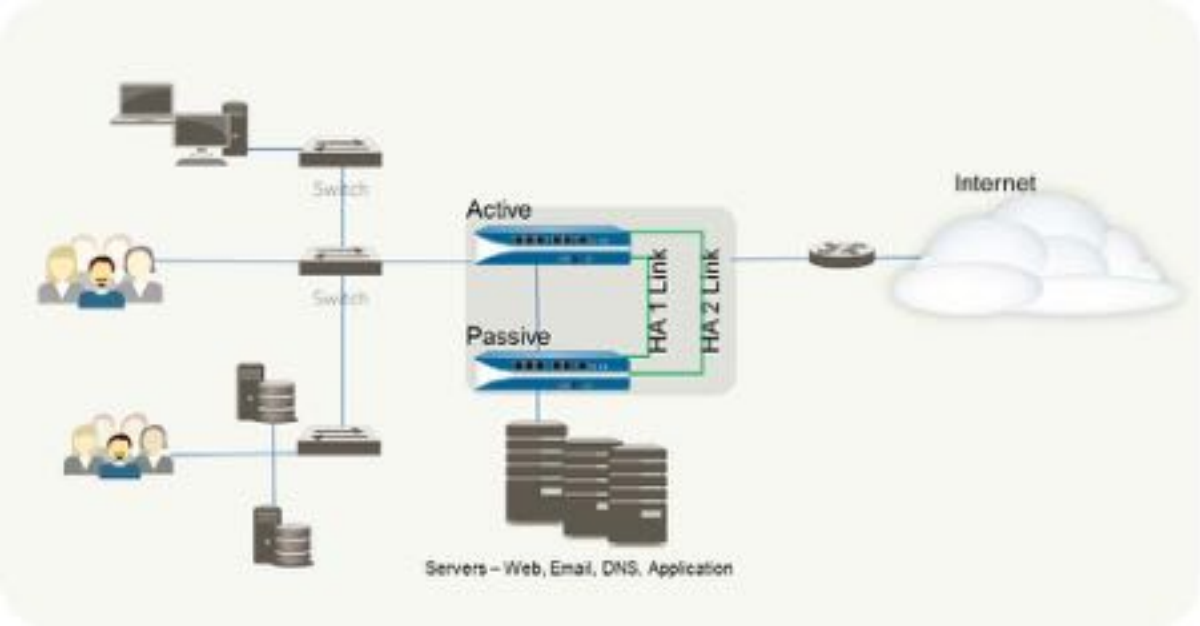
The following table lists the settings that must be configured independently on each firewall:

 © Palo Alto Networks, Inc.

| Independent Configuration Settings | PeerA | PeerB |
|---|---|---|
| Control Link | IP address of the HA1 link configured on this firewall (PeerA). | IP address of the HA1 link configured on this firewall (PeerB). |
| | For firewalls without dedicated HA ports, use the management port IP address for the control link. | |
| Data Link<br>The data link information is synchronized between the firewalls after HA is enabled and the control link is established between the firewalls. | By default, the HA2 link uses Ethernet/Layer 2.<br>If using a Layer 3 connection, configure the IP address for the data link on this firewall (PeerA). | By default, the HA2 link uses Ethernet/Layer 2.<br>If using a Layer 3 connection, configure the IP address for the data link on this firewall (PeerB). |
| Device Priority (required, if preemption is enabled) | The firewall you plan to make active must have a lower numerical value than its peer. So, if Peer A is to function as the active firewall, keep the default value of 100 and increment the value on PeerB. | If PeerB is passive, set the device priority value to a number larger than that on PeerA. For example, set the value to 110. |
| Link Monitoring—Monitor one or more physical interfaces that handle vital traffic on this firewall and define the failure condition. | Select the physical interfaces on the firewall that you would like to monitor and define the failure condition (all or any) to trigger a failover. | Pick a similar set of physical interfaces that you would like to monitor on this firewall and define the failure condition (all or any) to trigger a failover. |
| Path Monitoring—Monitor one or more destination IP addresses that the firewall can use ICMP pings to ascertain responsiveness. | Define the failure condition (all or any), ping interval and the ping count. This is particularly useful for monitoring the availability of other interconnected networking devices. For example, monitor the availability of a router that connects to a server, connectivity to the server itself, or some other vital device that is in the flow of traffic.<br>Make sure that the node/device that you are monitoring is not likely to be unresponsive, especially when it comes under load, as this could cause a a path monitoring failure and trigger a failover. | Pick a similar set of devices or destination IP addresses that can be monitored for determining the failover trigger for PeerB. Define the failure condition (all or any), ping interval and the ping count. |

## Configure Active/Passive HA

The following procedure shows how to configure a pair of firewalls in an active/passive deployment as depicted in the following example topology.



| Connect and Configure the Firewalls | | |
|---|---|---|
| Step 1 | Connect the HA ports to set up a physical connection between the firewalls. | • For firewalls with dedicated HA ports, use an Ethernet cable to connect the dedicated HA1 ports and the HA2 ports on peers. Use a crossover cable if the peers are directly connected to each other.<br>• For firewalls without dedicated HA ports, select two data interfaces for the HA2 link and the backup HA1 link. Then, use an Ethernet cable to connect these in-band HA interfaces across both firewalls.<br>Use the management port for the HA1 link and ensure that the management ports can connect to each other across your network. |
| Pick a firewall in the pair and complete the following steps: | | |
| Step 2 | Enable ping on the management port.<br>Enabling ping allows the management port to exchange heartbeat backup information. | 1. Select **Device > Setup > Management** and then click the Edit icon in the Management Interface Settings section of the screen.<br>2. Select **Ping** as a service that is permitted on the interface. |

 © Palo Alto Networks, Inc.

| Connect and Configure the Firewalls (Continued) | | |
|---|---|---|
| Step 3 | If the firewall does not have dedicated HA ports, set up the data ports to function as HA ports.<br><br>For firewalls with dedicated HA ports continue to the next step. | 1. Select **Network > Interfaces.**<br>2. Confirm that the link is up on the ports that you want to use.<br>3. Select the interface and set **Interface Type** to **HA**.<br> <br>4. Set the **Link Speed** and **Link Duplex** settings, as appropriate. |
| Step 4 | Set the HA mode and group ID. | 1. Select **Device > High Availability > General** and edit the Setup section.<br>2. Set a **Group ID** and optionally a **Description** for the pair. The Group ID uniquely identifies each HA pair on your network. If you have have multiple HA pairs that share the same broadcast domain you must set a unique Group ID for each pair.<br>3. Set the mode to **Active Passive**. |
| Step 5 | Set up the control link connection.<br><br>This example shows an in-band port that is set to interface type HA.<br><br>For firewalls that use the management port as the control link, the IP address information is automatically pre-populated. | 1. In **Device > High Availability > General**, edit the Control Link (HA1) section.<br>2. Select the **Port** that you have cabled for use as the HA1 link.<br>3. Set the **IPv4/IPv6 Address** and **Netmask**.<br>If the HA1 interfaces are on separate subnets, enter the IP address of the **Gateway**. Do not add a gateway address if the firewalls are directly connected<br> |
| Step 6 | (Optional) Enable encryption for the control link connection.<br><br>This is typically used to secure the link if the two firewalls are not directly connected, that is if the ports are connected to a switch or a router. | 1. Export the HA key from one firewall and import it into the peer firewall.<br>a. Select **Device > Certificate Management > Certificates**.<br>b. Select **Export HA key**. Save the HA key to a network location that the peer can access.<br>c. On the peer firewall, select **Device > Certificate Management > Certificates,** and select **Import HA key** to browse to the location that you saved the key and import it in to the peer.<br>2. Select **Device > High Availability > General**, edit the Control Link (HA1) section.<br>3. Select **Encryption Enabled**. |

| Connect and Configure the Firewalls (Continued) | |
|---|---|
| Step 7 Set up the backup control link connection. | 1. In **Device > High Availability > General**, edit the Control Link (HA1 Backup) section.<br>2. Select the HA1 backup interface and set the **IPv4/IPv6 Address** and **Netmask**.<br> |
| Step 8 Set up the data link connection (HA2) and the backup HA2 connection between the firewalls. | 1. In **Device > High Availability > General**, edit the Data Link (HA2) section.<br>2. Select the **Port** to use for the data link connection.<br>3. Select the **Transport** method. The default is **ethernet**, and will work when the HA pair is connected directly or through a switch. If you need to route the data link traffic through the network, select **IP** or **UDP** as the transport mode.<br>4. If you use IP or UDP as the transport method, enter the **IPv4/IPv6 Address** and **Netmask**..<br>  <br>5. Verify that **Enable Session Synchronization** is selected.<br>6. Select **HA2 Keep-alive** to enable monitoring on the HA2 data link between the HA peers. If a failure occurs based on the threshold that is set (default is 10000 ms), the defined action will occur. For active/passive configuration, a critical system log message is generated when an HA2 keep-alive failure occurs.<br>You can configure the HA2 keep-alive option on both firewalls, or just one firewall in the HA pair. If the option is only enabled on one firewall, only that firewall will send the keep-alive messages. The other firewall will be notified if a failure occurs.<br>7. Edit the **Data Link (HA2 Backup)** section, select the interface, and add the **IPv4/IPv6 Address** and **Netmask**. |

 © Palo Alto Networks, Inc.

| Connect and Configure the Firewalls (Continued) | | |
|---|---|---|
| Step 9 | Enable heartbeat backup if your control link uses a dedicated HA port or an in-band port.<br><br>You do not need to enable heartbeat backup if you are using the management port for the control link. | 1. In **Device > High Availability > General**, edit the Election Settings.<br>2. Select **Heartbeat Backup**.<br>To allow the heartbeats to be transmitted between the firewalls, you must verify that the management port across both peers can route to each other.<br><br>Enabling heartbeat backup also allows you to prevent a split-brain situation. Split brain occurs when the HA1 link goes down causing the firewall to miss heartbeats, although the firewall is still functioning. In such a situation, each peer believes that the other is down and attempts to start services that are running, thereby causing a split brain. When the heartbeat backup link is enabled, split brain is prevented because redundant heartbeats and hello messages are transmitted over the management port. |
| Step 10 | Set the device priority and enable preemption.<br><br>This setting is only required if you wish to make sure that a specific firewall is the preferred active firewall. For information, see Device Priority and Preemption. | 1. In **Device > High Availability > General**, edit the Election Settings.<br>2. Set the numerical value in **Device Priority**. Make sure to set a lower numerical value on the firewall that you want to assign a higher priority to.<br><br>If both firewalls have the same device priority value, the firewall with the lowest MAC address on the HA1 control link will become the active firewall.<br>3. Select **Preemptive**.<br>You must enable preemptive on both the active firewall and the passive firewall. |
| Step 11 | (Optional) Modify the failover timers.<br><br>By default, the HA timer profile is set to the **Recommended** profile and is suited for most HA deployments. | 1. In **Device > High Availability > General**, edit the Election Settings.<br>2. Select the **Aggressive** profile for triggering failover faster; select **Advanced** to define custom values for triggering failover in your set up.<br><br>To view the preset value for an individual timer included in a profile, select **Advanced** and click **Load Recommended** or **Load Aggressive**. The preset values for your hardware model will be displayed on screen. |

| Connect and Configure the Firewalls (Continued) | |
|---|---|
| Step 12 (Optional, only configured on the passive firewall) Modify the link status of the HA ports on the passive firewall.<br><br>The passive link state is **shutdown**, by default. After you enable HA, the link state for the HA ports on the active firewall will be green and those on the passive firewall will be down and display as red. | Setting the link state to **Auto** allows for reducing the amount of time it takes for the passive firewall to take over when a failover occurs and it allows you to monitor the link state.<br><br>To enable the link status on the passive firewall to stay up and reflect the cabling status on the physical interface:<br>1. In **Device > High Availability > General**, edit the Active Passive Settings.<br>2. Set the **Passive Link State** to **Auto**.<br>The auto option decreases the amount of time it takes for the passive firewall to take over when a failover occurs.<br><br>Although the interface displays green (as cabled and up) it continues to discard all traffic until a failover is triggered.<br><br>When you modify the passive link state, make sure that the adjacent devices do not forward traffic to the passive firewall based only on the link status of the firewall. |
| Step 13 Enable HA. | 1. Select **Device > High Availability > General** and edit the Setup section.<br>2. Select **Enable HA**.<br>3. Select **Enable Config Sync**. This setting enables the synchronization of the configuration settings between the active and the passive firewall.<br>4. Enter the IP address assigned to the control link of the peer in **Peer HA1 IP Address**.<br>  <br>For firewalls without dedicated HA ports, if the peer uses the management port for the HA1 link, enter the management port IP address of the peer.<br>5. Enter the **Backup HA1 IP Address**. |
| Step 14 Save your configuration changes. | Click **Commit**. |
| Step 15 Complete Step 2 through Step 14 on the other firewall in the HA pair. | |

 © Palo Alto Networks, Inc.

| Connect and Configure the Firewalls (Continued) | |
|---|---|
| Step 16 After you finish configuring both firewalls, verify that the firewalls are paired in active/passive HA. | 1. Access the **Dashboard** on both firewalls, and view the High Availability widget.<br>2. On the active firewall, click the **Sync to peer** link.<br>3. Confirm that the firewalls are paired and synced, as shown below: |
| On the passive firewall: the state of the local firewall should display **passive** and the Running Config should show as **synchronized**.<br> | On the active firewall: The state of the local firewall should display **active** and the Running Config should show as **synchronized**.<br> |

# Define HA Failover Conditions

| Configure the Failover Triggers | | |
|---|---|---|
| Step 1 | To configure link monitoring, define the interfaces that you would like to monitor. A change in the link state of these interface will trigger a failover. | 1. Select **Device > High Availability > Link and Path Monitoring** and **Add** a Link Group.<br>2. Name the **Link Group**, **Add** the interfaces to monitor, and select the **Failure Condition** for the group. The Link group you define is added to the **Link Group** section. |
| | |  |
| Step 2 | (Optional) Modify the failure condition for the Link Groups that you configured (in the preceding step) on the firewall.<br>By default, the firewall will trigger a failover when any monitored link fails. | 1. Select the **Link Monitoring** section.<br>2. Set the **Failure Condition** to **All**.<br>The default setting is **Any**. |
| Step 3 | To configure path monitoring, define the destination IP addresses that the firewall should ping to verify network connectivity. | 1. In the **Path Group** section of the **Device > High Availability > Link and Path Monitoring** tab, pick the **Add option for your set up:** Virtual Wire, VLAN, or Virtual Router.<br>2. Select the appropriate item from the drop-down for the **Name** and **Add** the IP addresses (source and/or destination, as prompted) that you wish to monitor. Then select the **Failure Condition** for the group. The path group you define is added to the **Path Group** section.<br> |
| Step 4 | (Optional) Modify the failure condition for all Path Groups configured on the firewall.<br>By default, the firewall will trigger a failover when any monitored path fails. | Set the **Failure Condition** to **All.**<br>The default setting is **Any**. |
| Step 5 | Save your changes. | Click **Commit**. |

 © Palo Alto Networks, Inc.

If you are using SNMPv3 to monitor the firewalls, note that the SNMPv3 Engine ID is unique to each firewall; the EngineID is not synchronized between the HA pair and, therefore, allows you to independently monitor each firewall in the HA pair. For information on setting up SNMP, see Forward Traps to an SNMP Manager.

Because the EngineID is generated using the firewall serial number, on the VM-Series firewall you must apply a valid license in order to obtain a unique EngineID for each firewall.

## Verify Failover

To test that your HA configuration works properly, trigger a manual failover and verify that the firewalls transition states successfully.

| Verify Failover | | |
|---|---|---|
| Step 1 | Suspend the active firewall. | Select **Device > High Availability > Operational Commands** and click the **Suspend local device** link.<br>  |
| Step 2 | Verify that the passive firewall has taken over as active. | On the **Dashboard**, verify that the state of the passive firewall changes to **active** in the High Availability widget.<br> |
| Step 3 | Restore the suspended firewall to a functional state. Wait for a couple minutes, and then verify that preemption has occurred, if preemptive is enabled. | 1. On the firewall you previously suspended, select **Device > High Availability > Operational Commands** and click the **Make local device functional** link.<br>  <br>2. In the High Availability widget on the **Dashboard,** confirm that the firewall has taken over as the active firewall and that the peer is now in a passive state.<br> |

 © Palo Alto Networks, Inc.

# Reference: HA Synchronization

If you have enabled configuration synchronization on both peers in an HA pair, most of the configuration settings you configure on one peer will automatically sync to the other peer upon commit. To avoid configuration conflicts, always make configuration changes on the active (active/passive) or active-primary (active/active) peer and wait for the changes to sync to the peer before making any additional configuration changes.

The following topics identify what portions of a firewall configuration must be configured on each device independently (rather than synchronized from the HA peer).

- What Settings Don't Sync in Active/Passive HA?
- What Settings Don't Sync in Active/Active HA?
- Synchronization of System Runtime Information

## What Settings Don't Sync in Active/Passive HA?

You must configure the following settings on each firewall in an HA pair in an active/passive deployment. These settings do not sync from one peer to another:

| Configuration Item | What Doesn't Sync in Active/Passive? |
|---|---|
| Management Interface Settings | All management configuration settings must be configured individually on each device, including:<br>• **Device > Setup > Management > General Settings**—Hostname, Domain, Login Banner, Time Zone, Locale, Date, Time, Latitude, Longitude<br>• **Device > Setup > Management > Management Interface Settings**—IP Address, Netmask, Default Gateway, IPv6 Address/Prefix Length, Default IPv6 Gateway, Speed, MTU, and Services (HTTP, HTTP OCSP, HTTPS, Telnet, SSH, Ping, SNMP, User-ID, User-ID Syslog Listener-SSL, User-ID Syslog Listener-UDP) |
| Multi-vsys Capability | To enable multi-vsys you must activate the Virtual Systems license (required to enable support for multiple virtual systems on PA-2000 Series and PA-3000 Series firewalls or to increase the number of virtual systems beyond the base number provided by default on PA-4000 Series, PA-5000 Series, and PA-7000 Series firewalls) on each firewall in the pair.<br>In addition, you must also enable **Multi Virtual System Capability** on each firewall (**Device > Setup > Management > General Settings**). |
| Administrator Authentication Settings | You must define the authentication profile and certificate profile for administrative access to the firewall locally on each firewall (**Device > Setup > Management > Authentication**). |
| Panorama Settings | Set the following Panorama settings on each firewall (**Device > Setup > Management > Panorama Settings**).<br>• **Panorama Servers**<br>• **Disable Panorama Policy and Objects** and **Disable Device and Network Template** |

| Configuration Item | What Doesn't Sync in Active/Passive? |
|---|---|
| SNMP | • **Device > Setup > Operations > SNMP Setup** |
| Statistics Collection | • **Device > Setup > Operations > Statistics Service Setup** |
| Services | • **Device > Setup > Services** |
| Global Service Routes | • **Device > Setup > Services > Service Route Configuration** |
| Data Protection | • **Device > Setup > Content-ID > Manage Data Protection** |
| Jumbo Frames | • **Device > Setup > Session > Session Settings > Enable Jumbo Frame** |
| Forward Proxy Server Certificate Settings | • **Device > Setup > Session > Decryption Settings > SSL Forward Proxy Settings** |
| Master Key Secured by HSM | • **Device > Setup > HSM > Hardware Security Module Provider > Master Key Secured by HSM** |
| Log Export Settings | • **Device > Scheduled Log Export** |
| Software Updates | With software updates, you can either download and install them separately on each device, or download them on one peer and sync the update to the other peer. You must install the update on each peer.<br>• **Device > Software** |
| GlobalProtect Agent Package | With GlobalProtect client updates, you can either download and install them separately on each device, or download them to one peer and sync the update to the other peer. You must activate separately on each peer.<br>• **Device > GlobalProtect Client** |
| Content Updates | With content updates, you can either download and install them separately on each device, or download them on one peer and sync the update to the other peer. You must install the update on each peer.<br>• **Device > Dynamic Updates** |
| Licenses/Subscriptions | • **Device > Licenses** |
| Support Subscription | • **Device > Support** |
| Master Key | The master key must be identical on each firewall in the HA pair, but you must manually enter it on each device (**Device > Master Key and Diagnostics**).<br>Before changing the master key, you must disable config sync on both peers (**Device > High Availability > General > Setup** and clear the **Enable Config Sync** check box) and then re-enable it after you change the keys. |
| Reports, logs, and Dashboard Settings | Log data, reports, and Dashboard data and settings (column display, widgets) are not synced between peers. Report configuration settings, however, are synced. |

 © Palo Alto Networks, Inc.

## What Settings Don't Sync in Active/Active HA?

You must configure the following settings on each firewall in an HA pair in an active/active deployment. These settings do not sync from one peer to another:

| Configuration Item | What Doesn't Sync? |
|---|---|
| Management Interface Settings | All management configuration settings must be configured individually on each device, including:<br>• **Device > Setup > Management > General Settings**—Hostname, Domain, Login Banner, Time Zone, Locale, Date, Time, Latitude, Longitude<br>• **Device > Setup > Management > Management Interface Settings**—IP Address, Netmask, Default Gateway, IPv6 Address/Prefix Length, Default IPv6 Gateway, Speed, MTU, and Services (HTTP, HTTP OCSP, HTTPS, Telnet, SSH, Ping, SNMP, User-ID, User-ID Syslog Listener-SSL, User-ID Syslog Listener-UDP) |
| Multi-vsys Capability | To enable multi-vsys you must activate the Virtual Systems license (required to enable support for multiple virtual systems on PA-2000 Series and PA-3000 Series firewalls or to increase the number of virtual systems beyond the base number provided by default on PA-4000 Series, PA-5000 Series, and PA-7000 Series firewalls) on each firewall in the pair.<br>In addition, you must also enable **Multi Virtual System Capability** on each firewall (**Device > Setup > Management > General Settings**). |
| Administrator Authentication Settings | You must define the authentication profile and certificate profile for administrative access to the firewall locally on each firewall (**Device > Setup > Management > Authentication**). |
| Panorama Settings | Set the following Panorama settings on each firewall (**Device > Setup > Management > Panorama Settings**).<br>• **Panorama Servers**<br>• **Disable Panorama Policy and Objects** and **Disable Device and Network Template** |
| SNMP | • **Device > Setup > Operations > SNMP Setup** |
| Statistics Collection | • **Device > Setup > Operations > Statistics Service Setup** |
| Services | • **Device > Setup > Services** |
| Global Service Routes | • **Device > Setup > Services > Service Route Configuration** |
| Data Protection | • **Device > Setup > Content-ID > Manage Data Protection** |
| Jumbo Frames | • **Device > Setup > Session > Session Settings > Enable Jumbo Frame** |
| Forward Proxy Server Certificate Settings | • **Device > Setup > Session > Decryption Settings > SSL Forward Proxy Settings** |
| HSM Configuration | • **Device > Setup > HSM** |
| Log Export Settings | • **Device > Scheduled Log Export** |

| Configuration Item | What Doesn't Sync? |
|---|---|
| Software Updates | With software updates, you can either download and install them separately on each device, or download them on one peer and sync the update to the other peer. You must install the update on each peer.<br>• **Device > Software** |
| GlobalProtect Agent Package | With GlobalProtect client updates, you can either download and install them separately on each device, or download them to one peer and sync the update to the other peer. You must activate separately on each peer.<br>• **Device > GlobalProtect Client** |
| Content Updates | With content updates, you can either download and install them separately on each device, or download them on one peer and sync the update to the other peer. You must install the update on each peer.<br>• **Device > Dynamic Updates** |
| Licenses/Subscriptions | • **Device > Licenses** |
| Support Subscription | • **Device > Support** |
| Ethernet Interface IP Addresses | All Ethernet interface configuration settings sync except for the IP address (**Network > Interface > Ethernet**). |
| Loopback Interface IP Addresses | All Loopback interface configuration settings sync except for the IP address (**Network > Interface > Loopback**). |
| Tunnel Interface IP Addresses | All Tunnel interface configuration settings sync except for the IP address (**Network > Interface > Tunnel**). |
| LACP System Priority | Each peer must have a unique LACP System ID in an active/active deployment (**Network > Interface > Ethernet > Add Aggregate Group > System Priority**). |
| VLAN Interface IP Address | All VLAN interface configuration settings sync except for the IP address (**Network > Interface > VLAN**). |
| Virtual Routers | Virtual router configuration synchronizes only if you have enabled VR Sync (**Device > High Availability > Active/Active Config > Packet Forwarding**). Whether or not to do this depends on your network design, including whether you have asymmetric routing. |
| IPSec Tunnels | IPSec tunnel configuration synchronization is dependent on whether you have configured the Virtual Addresses to use Floating IP addresses (**Device > High Availability > Active/Active Config > Virtual Address**). If you have configured a floating IP address, these settings sync automatically. Otherwise, you must configure these settings independently on each peer. |
| GlobalProtect Portal Configuration | GlobalProtect portal configuration synchronization is dependent on whether you have configured the Virtual Addresses to use Floating IP addresses (**Network > GlobalProtect > Portals**). If you have configured a floating IP address, the GlobalProtect portal configuration settings sync automatically. Otherwise, you must configure the portal settings independently on each peer. |

 © Palo Alto Networks, Inc.

| Configuration Item | What Doesn't Sync? |
|---|---|
| GlobalProtect Gateway Configuration | GlobalProtect gateway configuration synchronization is dependent on whether you have configured the Virtual Addresses to use Floating IP addresses (**Network > GlobalProtect > Gateways**). If you have configured a floating IP address, the GlobalProtect gateway configuration settings sync automatically. Otherwise, you must configure the gateway settings independently on each peer. |
| QoS | QoS configuration synchronizes only if you have enabled **QoS Sync** (**Device > High Availability > Active/Active Config > Packet Forwarding**). You might choose not to sync QoS setting if, for example, you have different bandwidth on each link or different latency through your service providers. |
| LLDP | No LLDP state or individual firewall data is synchronized in an active/active configuration (**Network > LLDP**). |
| IKE Gateways | IKE gateway configuration synchronization is dependent on whether you have configured the Virtual Addresses to use floating IP addresses (**Network > IKE Gateways**). If you have configured a floating IP address, the IKE gateway configuration settings sync automatically. Otherwise, you must configure the IKE gateway settings independently on each peer. |
| Master Key | The master key must be identical on each firewall in the HA pair, but you must manually enter it on each device (**Device > Master Key and Diagnostics**).<br>Before changing the master key, you must disable config sync on both peers (**Device > High Availability > General > Setup** and clear the **Enable Config Sync** check box) and then re-enable it after you change the keys. |
| Reports, logs, and Dashboard Settings | Log data, reports, and dashboard data and settings (column display, widgets) are not synced between peers. Report configuration settings, however, are synced. |

## Synchronization of System Runtime Information

| Runtime Information | Config Synced? | | HA Link | Details |
|---|---|---|---|---|
| | A/P | A/A | | |
| **Management Plane** | | | | |
| User to Group Mappings | Yes | Yes | HA1 | |
| DHCP Lease (as server) | Yes | Yes | HA1 | |
| DNS Cache | Yes | Yes | HA1 | |
| FQDN Refresh | No | No | HA1 | |
| IKE Keys (phase 2) | Yes | Yes | HA1 | |
| BrightCloud URL Database | No | No | N/A | |

| Runtime Information | Config Synced? | | HA Link | Details |
|---|---|---|---|---|
| | A/P | A/A | | |
| BrightCloud URL Cache | No | No | N/A | This feature is disabled by default and must be enabled separately on each HA peer. |
| BrightCloud Bloom Filter | No | No | N/A | This feature is disabled by default and must be enabled separately on each HA peer. |
| PAN-DB URL Cache | Yes | No | HA1 | This is synchronized upon database backup to disk (every eight hours, when URL database version updates), or when the firewall reboots. |
| Content (manual sync) | Yes | Yes | HA1 | |
| PPPoE, PPPoE Lease | Yes | Yes | HA1 | |
| DHCP Client Settings and Lease | Yes | Yes | HA1 | |
| SSL VPN Logged in User List | Yes | Yes | HA1 | |
| Forward Information Base (FIB) | Yes | Yes | HA1 | |
| **Dataplane** | | | | |
| Session Table | Yes | Yes | HA2 | • Active/passive peers do not sync ICMP or host session information.<br>• Active/active peers do not sync host session or multicast session information. |
| ARP Table | Yes | No | HA2 | |
| Neighbor Discovery (ND) Table | Yes | No | HA2 | |
| MAC Table | Yes | No | HA2 | |
| IPSec Sequence Number (anti-replay) | Yes | Yes | HA2 | |
| DoS Protection | Yes | Yes | HA2 | |
| User to IP Address Mappings | Yes | Yes | HA2 | |
| Virtual MAC | Yes | Yes | HA2 | |

# Monitoring

To forestall potential issues, and accelerate incidence response when needed, the firewall provides intelligence on traffic and user patterns and customizable and informative reports. The dashboard, Application Command Center (ACC), reports, and logs on the firewall allow you to monitor activity on your network. You can monitor the logs and filter the information to generate reports with predefined or customized views. You can, for example, use the predefined templates to generate reports on user activities, or analyze the reports and logs to interpret unusual behavior on your network and generate a custom report on the traffic pattern. For a visually engaging presentation of network activity, the dashboard and the ACC include widgets, charts, and tables that you can interact with to find information that you care about. In addition, you can configure the firewall to forward monitored information as email notifications, syslog messages, SNMP traps, and NetFlow records to external services.

- Use the Dashboard
- Use the Application Command Center
- App Scope
- Use the Automated Correlation Engine
- Take Packet Captures
- Monitor Applications and Threats
- Monitor and Manage Logs
- Manage Reporting
- Use External Services for Monitoring
- Configure Log Forwarding
- Configure Email Alerts
- Use Syslog for Monitoring
- SNMP Monitoring and Traps
- NetFlow Monitoring

© Palo Alto Networks, Inc.

# Use the Dashboard

The **Dashboard** tab widgets show general device information, such as the software version, the operational status of each interface, resource utilization, and up to 10 of the most recent entries in the threat, configuration, and system logs. All of the available widgets are displayed by default, but each administrator can remove and add individual widgets, as needed. Click the refresh icon to update the dashboard or an individual widget. To change the automatic refresh interval, select an interval from the drop-down (**1 min**, **2 mins**, **5 mins**, or **Manual**). To add a widget to the dashboard, click the widget drop-down, select a category and then the widget name. To delete a widget, click in the title bar. The following table describes the dashboard widgets.

| Dashboard Charts | Descriptions |
|---|---|
| Top Applications | Displays the applications with the most sessions. The block size indicates the relative number of sessions (mouse-over the block to view the number), and the color indicates the security risk—from green (lowest) to red (highest). Click an application to view its application profile. |
| Top High Risk Applications | Similar to Top Applications, except that it displays the highest-risk applications with the most sessions. |
| General Information | Displays the device name, model, PAN-OS software version, the application, threat, and URL filtering definition versions, the current date and time, and the length of time since the last restart. |
| Interface Status | Indicates whether each interface is up (green), down (red), or in an unknown state (gray). |
| Threat Logs | Displays the threat ID, application, and date and time for the last 10 entries in the Threat log. The threat ID is a malware description or URL that violates the URL filtering profile. |
| Config Logs | Displays the administrator username, client (Web or CLI), and date and time for the last 10 entries in the Configuration log. |
| Data Filtering Logs | Displays the description and date and time for the last 60 minutes in the Data Filtering log. |
| URL Filtering Logs | Displays the description and date and time for the last 60 minutes in the URL Filtering log. |
| System Logs | Displays the description and date and time for the last 10 entries in the System log.<br>A `Config installed` entry indicates configuration changes were committed successfully. |
| System Resources | Displays the Management CPU usage, Data Plane usage, and the Session Count, which displays the number of sessions established through the firewall. |
| Logged In Admins | Displays the source IP address, session type (Web or CLI), and session start time for each administrator who is currently logged in. |
| ACC Risk Factor | Displays the average risk factor (1 to 5) for the network traffic processed over the past week. Higher values indicate higher risk. |
| High Availability | If high availability (HA) is enabled, indicates the HA status of the local and peer device—green (active), yellow (passive), or black (other). For more information about HA, see High Availability. |
| Locks | Shows configuration locks taken by administrators. |

 © Palo Alto Networks, Inc.

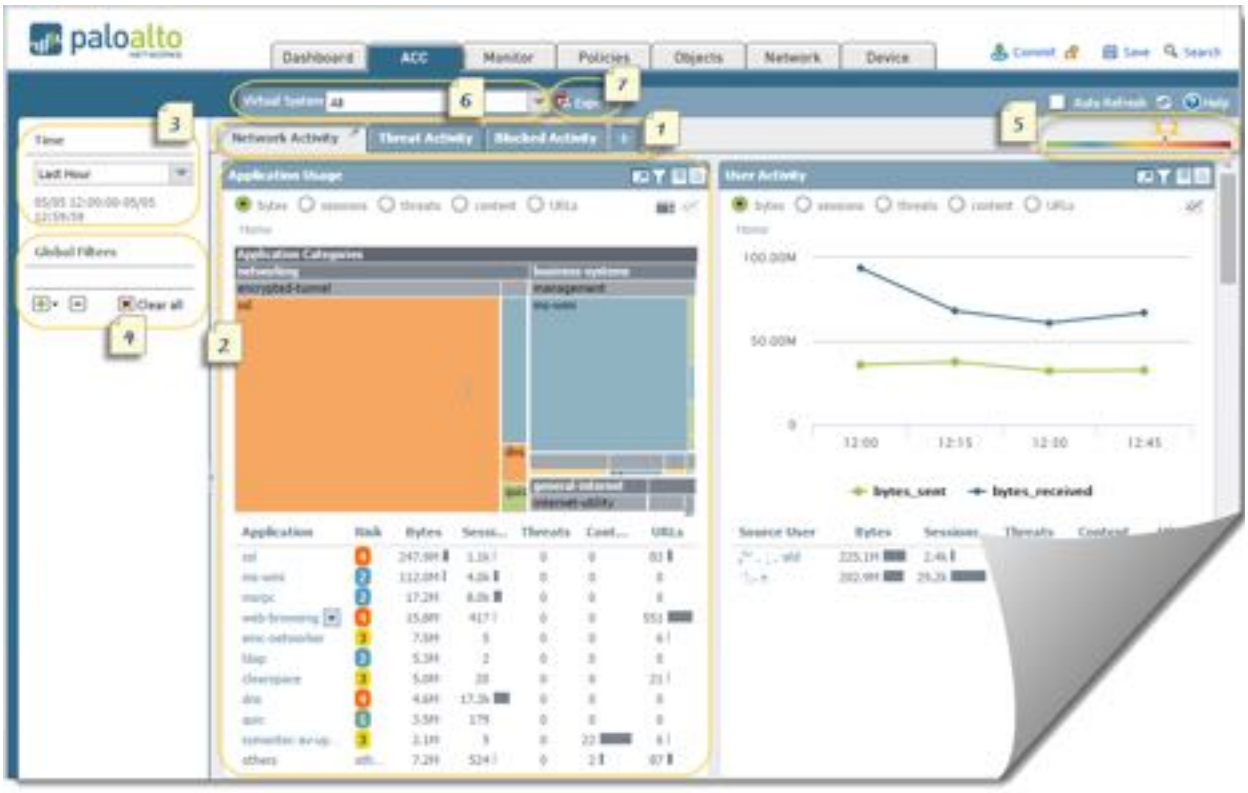
# Use the Application Command Center

The Application Command Center (ACC) is an interactive, graphical summary of the applications, users, URLs, threats, and content traversing your network.The ACC uses the firewall logs to provide visibility into traffic patterns and actionable information on threats. The ACC layout includes a tabbed view of network activity, threat activity, and blocked activity and each tab includes pertinent widgets for better visualization of network traffic. The graphical representation allows you to interact with the data and visualize the relationships between events on the network, so that you can uncover anomalies or find ways to enhance your network security rules. For a personalized view of your network, you can also add a custom tab and include widgets that allow you to drill down into the information that is most important to you.

- ACC—First Look
- ACC Tabs
- ACC Widgets (Widget Descriptions)
- ACC Filters
- Interact with the ACC
- Use Case: ACC—Path of Information Discovery

# ACC—First Look

Take a quick tour of the ACC.



| ACC—First Look | | |
|---|---|---|
| 1 | **Tabs** | The ACC includes three predefined tabs that provide visibility into network traffic, threat activity, and blocked activity. For information on each tab, see ACC Tabs. |
| 2 | **Widgets** | Each tab includes a default set of widgets that best represent the events/trends associated with the tab. The widgets allow you to survey the data using the following filters:<br>• bytes (in and out)<br>• sessions<br>• content (files and data)<br>• URL categories<br>• threats (and count)<br>For information on each widget, see ACC Widgets. |

© Palo Alto Networks, Inc.

| ACC—First Look (Continued) | | |
|---|---|---|
| 3 | **Time** | The charts or graphs in each widget provide a summary and historic view. You can choose a custom range or use the predefined time periods that range from the last 15 minutes up to the last 30 days or last 30 calendar days. The selected time period applies across all tabs in the ACC.<br>The time period used to render data, by default, is the **Last Hour** updated in 15 minute intervals. The date and time interval are displayed onscreen, for example at 11:40, the time range is 01/12 10:30:00-01/12 11:29:59. |
| 4 | **Global Filters** | The Global Filters allow you to set the filter across all widgets and all tabs. The charts/graphs apply the selected filters before rendering the data. For information on using the filters, see ACC Filters. |
| 5 | **Risk Factor** | The risk factor (1=lowest to 5=highest) indicates the relative risk based on the applications used on your network. The risk factor uses a variety of factors to assess the associated risk levels, such as whether the application can share files, is it prone to misuse or does it try to evade firewalls, it also factors in the threat activity and malware as seen through the number of blocked threats, compromised hosts or traffic to malware hosts/domains. |
| 6 | **Source** | The data segment used for the display. The options vary on the firewall and on Panorama.<br>On the firewall, if enabled for multiple virtual systems, you can use the **Virtual System** drop-down to change the ACC display to include all virtual systems or just a selected virtual system.<br>On Panorama, you can select the **Device Group** drop-down to change the ACC display to include all device groups or just a selected device group.<br>Additionally, on Panorama, you can change the **Data Source** as **Panorama** data or **Remote Device Data**. **Remote Device Data** is only available when all the managed firewalls are on PAN-OS 7.0.0 or later. When you filter the display for a specific device group, **Panorama** data is used as the data source**.** |
| 7 | **Export** | You can export the widgets displayed in the currently selected tab as a PDF. The PDF is downloaded and saved to the downloads folder associated with your web browser, on your computer. |

## ACC Tabs

The ACC includes the following predefined tabs for viewing network activity, threat activity, and blocked activity.

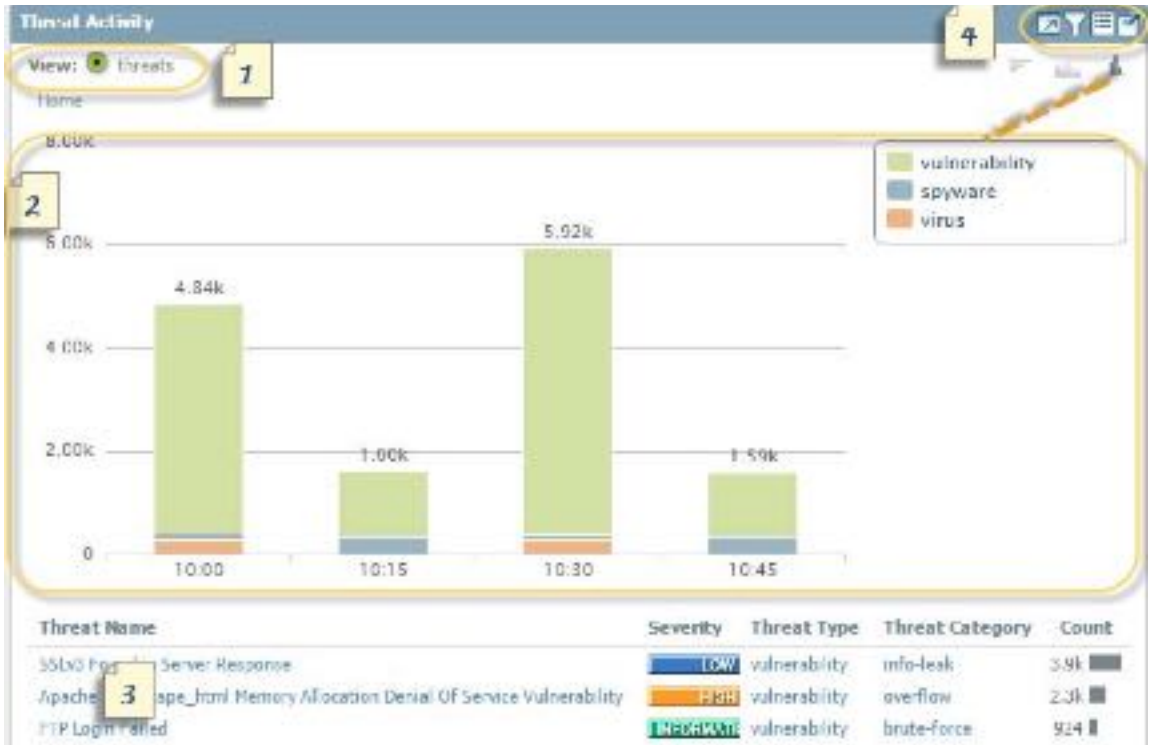
| Tab | Description |
|---|---|
| **Network Activity** | Displays an overview of traffic and user activity on your network including:<br>• Top applications in use<br>• Top users who generate traffic (with a drill down into the bytes, content, threats or URLs accessed by the user)<br>• Most used security rules against which traffic matches occur<br>In addition, you can also view network activity by source or destination zone, region, or IP address, ingress or egress interfaces, and GlobalProtect host information such as the operating systems of the devices most commonly used on the network. |
| **Threat Activity** | Displays an overview of the threats on the network, focusing on the top threats: vulnerabilities, spyware, viruses, hosts visiting malicious domains or URLs, top WildFire submissions by file type and application, and applications that use non-standard ports. The Compromised Hosts widget in this tab (the widget is supported on some platforms only), supplements detection with better visualization techniques; it uses the information from the correlated events tab (**Automated Correlation Engine > Correlated Events**) to present an aggregated view of compromised hosts on your network by source users/IP addresses and sorted by severity. |
| **Blocked Activity** | Focuses on traffic that was prevented from coming into the network. The widgets in this tab allow you to view activity denied by application name, username, threat name, blocked content—files and data that were blocked by a file blocking profile. It also lists the top security rules that were matched on to block threats, content, and URLs. |

You can also Interact with the ACC to create customized tabs with custom layout and widgets that meet your network monitoring needs.

 © Palo Alto Networks, Inc.

## ACC Widgets

The widgets on each tab are interactive; you can set the ACC Filters and drill down into the details for each table or graph, or customize the widgets included in the tab to focus on the information you need. For details on what each widget displays, see Widget Descriptions.



| Widgets | | |
|---|---|---|
| 1 | **View** | You can sort the data by bytes, sessions, threats, count, content, URLs, malicious, benign, files, data, profiles, objects. The available options vary by widget. |
| 2 | **Graph** | The graphical display options are treemap, line graph, horizontal bar graph, stacked area graph, stacked bar graph, and map. The available options vary by widget; the interaction experience also varies with each graph type. For example, the widget for Applications using Non-Standard Ports allows you to choose between a treemap and a line graph.<br>To drill down into the display, click into the graph. The area you click into becomes a filter and allows you to zoom into the selection and view more granular information on the selection. |

| Widgets | | |
|---|---|---|
| 3 | **Table** | The detailed view of the data used to render the graph is provided in a table below the graph. You can interact with the table in several ways:<br>• Click and set a local filter for an attribute in the table. The graph is updated and the table is sorted using the local filter. The information displayed in the graph and the table are always synchronized.<br>• Hover over the attribute in the table and use the options available in the drop-down.<br> |
| 4 | **Actions** | **Maximize view**— Allows you enlarge the widget and view the table in a larger screen space and with more viewable information.<br>**Set up local filters**—Allows you to add ACC Filters to refine the display within the widget. Use these filters to customize the widgets; these customizations are retained between logins.<br>**Jump to logs**—Allows you to directly navigate to the logs (**Monitor > Logs >** *Log type* tab). The logs are filtered using the time period for which the graph is rendered. If you have set local and global filters, the log query concatenates the time period and the filters and only displays logs that match the combined filter set.<br>**Export**—Allows you to export the graph as a PDF. The PDF is downloaded and saved on your computer. It is saved in the Downloads folder associated with your web browser. |

 © Palo Alto Networks, Inc.

## Widget Descriptions

Each tab on the ACC includes a different set of widgets.

| Widget | Description |
|---|---|
| **Network Activity**—Displays an overview of traffic and user activity on your network. | |
| **Application Usage** | The table displays the top ten applications used on your network, all the remaining applications used on the network are aggregated and displayed as other. The graph displays all applications by application category, sub category, and application. Use this widget to scan for applications being used on the network, it informs you about the predominant applications using bandwidth, session count, file transfers, triggering the most threats, and accessing URLs.<br>Sort attributes: bytes, sessions, threats, content, URLs<br>Charts available: treemap, area, column, line (the charts vary by the sort by attribute selected) |
| **User Activity** | Displays the top ten most active users on the network who have generated the largest volume of traffic and consumed network resources to obtain content. Use this widget to monitor top users on usage sorted on bytes, sessions, threats, content (files and patterns), and URLs visited.<br>Sort attributes: bytes, sessions, threats, content, URLs<br>Charts available: area, column, line (the charts vary by the sort by attribute selected) |
| **Source IP Activity** | Displays the top ten IP addresses or hostnames of the devices that have initiated activity on the network. All other devices are aggregated and displayed as other.<br>Sort attributes: bytes, sessions, threats, content, URLs<br>Charts available: area, column, line (the charts vary by the sort by attribute selected) |
| **Destination IP Activity** | Displays the IP addresses or hostnames of the top ten destinations that were accessed by users on the network.<br>Sort attributes: bytes, sessions, threats, content, URLs<br>Charts available: area, column, line (the charts vary by the sort by attribute selected) |
| **Source Regions** | Displays the top ten regions (built-in or custom defined regions) around the world from where users initiated activity on your network.<br>Sort attributes: bytes, sessions, threats, content, URLs<br>Charts available: map, bar |
| **Destination Regions** | Displays the top ten destination regions (built-in or custom defined regions) on the world map from where content is being accessed by users on the network.<br>Sort attributes: bytes, sessions, threats, content, URLs<br>Charts available: map, bar |

| Widget | Description |
|---|---|
| **GlobalProtect Host Information** | Displays information on the state of the hosts on which the GlobalProtect agent is running; the host system is a GlobalProtect client. This information is sourced from entries in the HIP match log that are generated when the data submitted by the GlobalProtect agent matches a HIP object or a HIP profile you have defined on the firewall. If you do not have HIP Match logs, this widget is blank. To learn how to create HIP objects and HIP profiles and use them as policy match criteria, see Configure HIP-Based Policy Enforcement.<br>Sort attributes: profiles, objects, operating systems<br>Charts available: bar |
| **Rule Usage** | Displays the top ten rules that have allowed the most traffic on the network. Use this widget to view the most commonly used rules, monitor the usage patterns, and to assess whether the rules are effective in securing your network.<br>Sort attributes: bytes, sessions, threats, content, URLs<br>Charts available: line |
| **Ingress Interfaces** | Displays the firewall interfaces that are most used for allowing traffic into the network.<br>Sort attributes: bytes, bytes sent, bytes received<br>Charts available: line |
| **Egress Interfaces** | Displays the firewall interfaces that are most used by traffic exiting the network.<br>Sort attributes: bytes, bytes sent, bytes received<br>Charts available: line |
| **Source Zones** | Displays the zones that are most used for allowing traffic into the network.<br>Sort attributes: bytes, sessions, threats, content, URLs<br>Charts available: line |
| **Destination Zones** | Displays the zones that are most used by traffic going outside the network.<br>Sort attributes: bytes, sessions, threats, content, URLs<br>Charts available: line |

**Threat Activity**—Displays an overview of the threats on the network

| | |
|---|---|
| **Compromised Hosts** | Displays the hosts that are likely compromised on your network. This widget summarizes the events from the correlation logs. For each source user/IP address, it includes the correlation object that triggered the match and the match count, which is aggregated from the match evidence collated in the correlated events logs.For details see Use the Automated Correlation Engine.<br>Available on the PA-3000 Series, PA-5000 Series, PA-7000 Series, and Panorama.<br>Sort attributes: severity (by default) |
| **Hosts Visiting Malicious URLs** | Displays the frequency with which hosts (IP address/hostnames) on your network have accessed malicious URLs. These URLs are known to be malware based on categorization in PAN-DB.<br>Sort attributes: count<br>Charts available: line |

 © Palo Alto Networks, Inc.

| Widget | Description |
|---|---|
| **Hosts Resolving Malicious Domains** | Displays the top hosts matching DNS signatures; hosts on the network that are attempting to resolve the hostname or domain of a malicious URL. This information is gathered from an analysis of the DNS activity on your network. It utilizes passive DNS monitoring, DNS traffic generated on the network, activity seen in the sandbox if you have configured DNS sinkhole on the firewall, and DNS reports on malicious DNS sources that are available to Palo Alto Networks customers.<br>Sort attributes: count<br>Charts available: line |
| **Threat Activity** | Displays the threats seen on your network. This information is based on signature matches in Antivirus, Anti-Spyware, and Vulnerability Protection profiles and viruses reported by WildFire.<br>Sort attributes: threats<br>Charts available: bar, area, column |
| **WildFire Activity by Application** | Displays the applications that generated the most WildFire submissions. This widget uses the malicious and benign verdict from the WildFire Submissions log.<br>Sort attributes: malicious, benign<br>Charts available: bar, line |
| **WildFire Activity by File Type** | Displays the threat vector by file type. This widget displays the file types that generated the most WildFire submissions and uses the malicious and benign verdict from the WildFire Submissions log. If this data is unavailable, the widget is empty.<br>Sort attributes: malicious, benign<br>Charts available: bar, line |
| **Applications using Non Standard Ports** | Displays the applications that are entering your network on non-standard ports. If you have migrated your firewall rules from a port-based firewall, use this information to craft policy rules that allow traffic only on the default port for the application. Where needed, make an exception to allow traffic on a non-standard port or create a custom application.<br>Sort attributes: bytes, sessions, threats, content, URLs<br>Charts available: treemap, line |
| **Rules Allowing Applications On Non Standard Ports** | Displays the security policy rules that allow applications on non-default ports. The graph displays all the rules, while the table displays the top ten rules and aggregates the data from the remaining rules as other.<br>This information helps you identify gaps in network security by allowing you to assess whether an application is hopping ports or sneaking into your network. For example, you can validate whether you have a rule that allows traffic on any port except the default port for the application. Say for example, you have a rule that allow DNS traffic on its *application-default* port (port 53 is the standard port for DNS). This widget will display any rule that allows DNS traffic into your network on any port except port 53.<br>Sort attributes: bytes, sessions, threats, content, URLs<br>Charts available: treemap, line |

**Blocked Activity**—Focuses on traffic that was prevented from coming into the network

| Widget | Description |
|---|---|
| **Blocked Application Activity** | Displays the applications that were denied on your network, and allows you to view the threats, content, and URLs that you kept out of your network.<br>Sort attributes: threats, content, URLs<br>Charts available: treemap, area, column |
| **Blocked User Activity** | Displays user requests that were blocked by a match on an antivirus, anti-spyware, file blocking or url filtering profile attached to security policy.<br>Sort attributes: threats, content, URLs<br>Charts available: bar, area, column |
| **Blocked Threats** | Displays the threats that were successfully denied on your network. These threats were matched on antivirus signatures, vulnerability signatures, and DNS signatures available through the dynamic content updates on the firewall.<br>Sort attributes: threats<br>Charts available: bar, area, column |
| **Blocked Content** | Displays the files and data that was blocked from entering the network. The content was blocked because security policy denied access based on criteria defined in a File Blocking security profile or a Data Filtering security profile.<br>Sort attributes: files, data<br>Charts available: bar, area, column |
| **Security Policies Blocking Activity** | Displays the security policy rules that blocked or restricted traffic into your network. Because this widget displays the threats, content, and URLs that were denied access into your network, you can use it to assess the effectiveness of your policy rules. This widget does not display traffic that blocked because of deny rules that you have defined in policy.<br>Sort attributes: threats, content, URLs<br>Charts available: bar, area, column |

 © Palo Alto Networks, Inc.

## ACC Filters

The graphs and tables on the ACC widgets allow you to use filters to narrow the scope of data that is displayed, so that you can isolate specific attributes and analyze information you want to view in greater detail. The ACC supports the simultaneous use of widget and global filters.

- **Widget Filters**—Apply a widget filter, which is a filter that is *local* to a specific widget. A widget filter allows you to interact with the graph and customize the display so that you can drill down in to the details and access the information you want to monitor on a specific widget. To create a widget filter that is persistent across reboots, you must use the **Set Local Filter** option.

- **Global filters**—Apply global filters across all the tabs in the ACC. A global filter allows you to pivot the display around the details you care about right now and exclude the unrelated information from the current display. For example, to view all events relating to a specific user and application, you can apply the username and the application as a global filter and view only information pertaining to the user and the application through all the tabs and widgets on the ACC. Global filters are not persistent.

You can apply global filters in three ways:

- **Set a global filter from a table**—Select an attribute from a table in any widget and apply the attribute as a global filter.
- **Promote a widget filter to be a global filter**—Promote a value in a table or a graph to a global filter by using the dropdown menu next to the value. This option allows you to elevate a local filter used in a widget, and apply the attribute globally to update the display across all the tabs on the ACC.
- **Define a global filter**—Define a filter using the **Global Filters** pane on the ACC.

See Interact with the ACC for details on using these filters.

 © Palo Alto Networks, Inc.

## Interact with the ACC

To customize and refine the ACC display, you can add and delete tabs, add and delete widgets, set local and global filters, and interact with the widgets.

| Work with the Tabs and Widgets | |
|---|---|
| • Add a tab. | 1. Select the + icon along the list of tabs.<br>2. Add a **View Name**. This name will be used as the name for the tab. You can add up to five tabs. |
| • Edit a tab. | Select the tab, and click the pencil icon next to the tab name, to edit the tab. For example .<br>Editing a tab allow you to add or delete or reset the widgets that are displayed in the tab. You can also change the widget layout in the tab. |
| • See what widgets are included in a tab. | 1. Select the tab, and click on the pencil icon to edit it.<br>2. Select the **Add Widgets** drop-down and verify the widgets that have the check boxes selected. |
| • Add a widget or a widget group. | 1. Add a new tab or edit a predefined tab.<br>2. Select **Add Widget**, and then select the check box that corresponds to the widget you want to add. You can select up to a maximum of 12 widgets.<br>3. (Optional) To create a 2-column layout, select **Add Widget Group**. You can drag and drop widgets into the 2-column display. As you drag the widget into the layout, a placeholder will display for you to drop the widget.<br> You cannot name a widget group. |
| • Delete a tab or a widget group/ widget. | 1. To delete a custom tab, select the tab and click the X icon.<br>  <br> You cannot delete a predefined tab.<br>2. To delete a widget group/widget, edit the tab and in the workspace section, click the [X] icon on the right. You cannot undo a deletion. |
| • Reset the default widgets in a tab. | On a predefined tab, such as the **Blocked Activity** tab, you can delete one or more widgets. If you want to reset the layout to include the default set of widgets for the tab, edit the tab and click **Reset View**. |
| • Zoom in on the details in an area, column, or line graph.<br>Watch how the zoom-in capability works. | Click and drag an area in the graph to zoom in. For example, when you zoom into a line graph, it triggers a re-query and the firewall fetches the data for the selected time period. It is not a mere magnification. |

| Work with the Tabs and Widgets (Continued) | |
|---|---|
| • Use the table drop-down to find more information on an attribute.<br> | 1. Hover over an attribute in a table to see the drop-down.<br>2. Click into the drop-down to view the available options.<br>• **Global Find**—Global Find allows you to find references to the attribute (username/IP address, object name, policy rule name, threat ID, or application name) anywhere in the candidate configuration on the firewall.<br>• **Promote Filter**—Sets the attribute as a global filter. This allows you to filter all the views in the ACC based on the filters you have applied.<br>• **Value**—Displays the details of the threat ID, or application name, or address object.<br>• **Who Is**—Performs a domain name (*WHOIS*) lookup for the IP address. The lookup queries databases that store the registered users or assignees of an Internet resource.<br>• **Search HIP Report**—Uses the username or IP address to find matches in a HIP Match report. |
| • Set a widget filter.<br>You can also click an attribute in the table (below the graph) to apply it as a widget filter. | 1. Select a widget and click the icon.<br>2. Click the icon to add the filters you want to apply.<br>3. Click **Apply**. These filters are persistent across reboots.<br>The active widget filters are indicated next to the widget name. |
| • Negate a widget filter | 1. Click the icon to display the Setup Local Filters dialog.<br>2. Add a filter, and then click the negate icon. |
| • Set a global filter from a table. | 1. Hover over an attribute in the table below the chart, and click the drop-down.<br>2. Click **Promote Filter** to add the attribute as a global filter.<br>  |
| • Set a global filter using the Global Filters pane.<br>Watch global filters in action. | 1. Locate the **Global Filters** pane on the left side of the ACC.<br>  <br>2. Click the icon to view the list of filters you can apply. |

 © Palo Alto Networks, Inc.

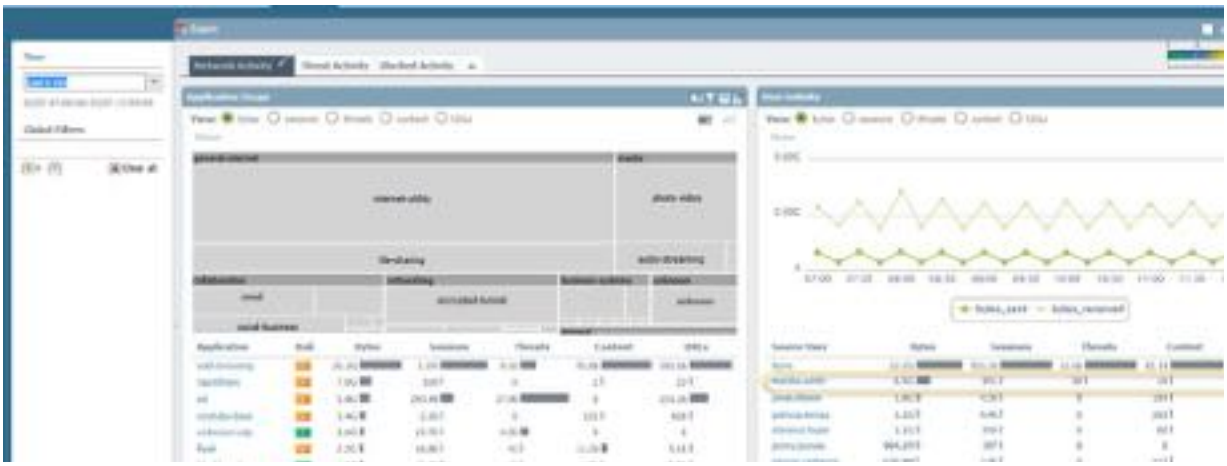
| Work with the Tabs and Widgets (Continued) | |
|---|---|
| • Promote a widget filter to a global filter. | 1. On any table in a widget, click the link for an attribute. This sets the attribute as a widget filter.<br>2. To promote the filter to be a global filter, select the arrow to the right of the filter.<br>  |
| • Remove a filter. | Click the icon to remove a filter.<br>• For global filters: It is located in the Global Filters pane.<br>• For widget filters: Click the icon to display the Setup Local Filters dialog, then select the filter, and click the icon.<br> |
| • Clear all filters. | • For global filters: Click the **Clear All** button under Global Filters.<br>• For widget filters: Select a widget and click the icon. Then click the **Clear All** button in the Setup Local Filters dialog. |
| • See what filters are in use. | • For global filters: The number of global filters applied are displayed on the left pane under Global Filters.<br>• For widget filters: The number of widget filters applied on a widget are displayed next to the widget name. To view the filters, click the icon. |
| • Reset the display on a widget. | • If you set a widget filter or drill into a graph, click the **Home** link to reset the display in the widget.<br> |

## Use Case: ACC—Path of Information Discovery

The ACC has a wealth of information that you can use as a starting point for analyzing network traffic. Let's look at an example on using the ACC to uncover events of interest. This example illustrates how you can use the ACC to ensure that legitimate users can be held accountable for their actions, detect and track unauthorized activity, and detect and diagnose compromised hosts and vulnerable systems on your network.

The widgets and filters in the ACC give you the capability to analyze the data and filter the views based on events of interest or concern. You can trace events that pique your interest, directly export a PDF of a tab, access the raw logs, and save a personalized view of the activity that you want to track. These capabilities make it possible for you to monitor activity and develop policies and countermeasures for fortifying your network against malicious activity. In this section, you will Interact with the ACC widgets across different tabs, drill down using widget filters, and pivot the ACC views using global filters, and export a PDF for sharing with incidence response or IT teams.

At first glance, you see the Application Usage and User Activity widgets in the **ACC > Network Activity** tab. The User Activity widget shows that user Marsha Wirth has transferred 718 Megabytes of data during the last hour. This volume is nearly six times more than any other user on the network. To see the trend over the past few hours, expand the **Time** period to the **Last 6 Hrs**, and now Marsha's activity has been 6.5 Gigabytes over 891 sessions and has triggered 38 threats signatures.



Because Marsha has transferred a large volume of data, apply her username as a global filter (ACC Filters) and pivot all the views in the ACC to Marsha's traffic activity.

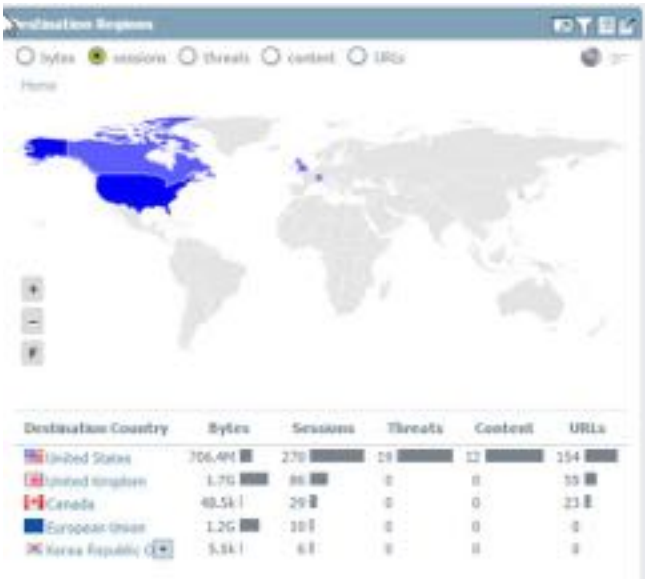
 © Palo Alto Networks, Inc.

The Application Usage tab now shows that the top application that Martha used was rapidshare, a Swiss-owned file-hosting site that belongs to the file-sharing URL category. For further investigation, add rapidshare as a global filter, and view Marsha's activity in the context of rapidshare.

Consider whether you want to sanction rapidshare for company use. Should you allow uploads to this site and do you need a QoS policy to limit bandwidth?

To view which IP addresses Marsha has communicated with, check the **Destination IP Activity** widget, and view the data by bytes and by URLs.

To know which countries Marsha communicated with, sort on **sessions** in the **Destination Regions** widget.



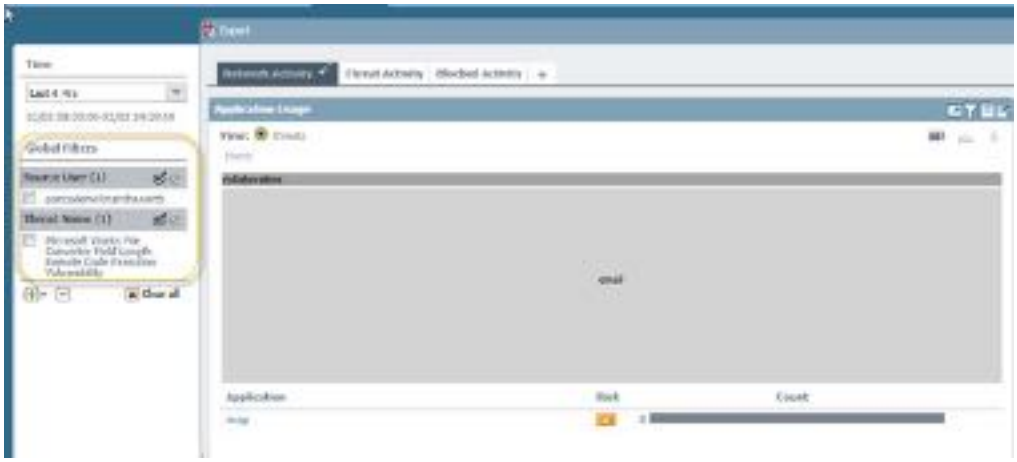
From this data, you can confirm that Marsha, a user on your network, has established sessions in Korea and the European Union, and she logged 19 threats in her sessions within the United States.

To look at Marsha's activity from a threat perspective, remove the global filter for rapidshare. In the **Threat Activity** widget on the **Threat Activity** tab, view the threats. The widget displays that her activity had triggered a match for 26 vulnerabilities in the overflow, DoS and code-execution threat category. Several of these vulnerabilities are of critical severity.

To further drill-down into each vulnerability, click into the graph and narrow the scope of your investigation. Each click automatically applies a local filter on the widget.

 © Palo Alto Networks, Inc.

To investigate each threat by name, you can create a global filter for say, **Microsoft Works File Converter Field Length Remote Code Execution Vulnerability**. Then, view the **User Activity widget** in the **Network Activity** tab. The tab is automatically filtered to display threat activity for Marsha (notice the global filters in the screenshot).



Notice that this Microsoft code-execution vulnerability was triggered over email, by the imap application. You can now establish that Martha has IE vulnerabilities and email attachment vulnerabilities, and perhaps her computer needs to be patched. You can now either navigate to the **Blocked Threats** widget in the **Blocked Activity** tab to check how many of these vulnerabilities were blocked.

Or, you can check the **Rule Usage** widget on the **Network Activity** tab to discover how many vulnerabilities made it into your network and which security rule allowed this traffic, and navigate directly to the security rule using the **Global Find** capability.

Then, drill into why imap used a non-standard port 43206 instead of port 143, which is the default port for the application. Consider modifying the security policy rule to allow applications to only use the default port for the application, or assess whether this port should be an exception on your network.

To review if any threats were logged over imap, check Marsha's activity in the **WildFire Activity by Application** widget in the **Threat Activity** tab. You can confirm that Marsha had no malicious activity, but to verify that other no other user was compromised by the imap application, negate Marsha as a global filter and look for other users who triggered threats over imap.

Click into the bar for imap in the graph and drill into the inbound threats associated with the application. To find out who an IP address is registered to, hover over the attacker IP address and select the **Who Is** link in the drop-down.

Because the session count from this IP address is high, check the **Blocked Content** and **Blocked Threats** widgets in the **Blocked Activity** tab for events related to this IP address. The **Blocked Activity** tab allows you to validate whether or not your policy rules are effective in blocking content or threats when a host on your network is compromised.

 © Palo Alto Networks, Inc.

Use the **Export PDF** capability on the ACC to export the current view (create a snapshot of the data) and send it to an incidence response team. To view the threat logs directly from the widget, you can also click the icon to jump to the logs; the query is generated automatically and only the relevant logs are displayed onscreen (for example in **Monitor > Logs > Threat Logs**).

You have now used the ACC to review network data/trends to find which applications or users are generating the most traffic, and how many application are responsible for the threats seen on the network. You were able to identify which application(s), user(s) generated the traffic, determine whether the application was on the default port, and which policy rule(s) allowed the traffic into the network, and determine whether the threat is spreading laterally on the network. You also identified the destination IP addresses, geo-locations with which hosts on the network are communicating with. Use the conclusions from your investigation to craft goal-oriented policies that can secure users and your network.

# App Scope

The App Scope reports provide visibility and analysis tools to help pinpoint problematic behavior, helping you understand changes in application usage and user activity, users and applications that take up most of the network bandwidth, and identify network threats.

With the App Scope reports, you can quickly see if any behavior is unusual or unexpected. Each report provides a dynamic, user-customizable window into the network; hovering the mouse over and clicking either the lines or bars on the charts opens detailed information about the specific application, application category, user, or source on the ACC. The App Scope charts on **Monitor > App Scope** give you the ability to:

- Toggle the attributes in the legend to only view chart details that you want to review. The ability to include or exclude data from the chart allows you to change the scale and review details more closely.
- Click into an attribute in a bar chart and drill down to the related sessions in the ACC. Click into an Application name, Application Category, Threat Name, Threat Category, Source IP address or Destination IP address on any bar chart to filter on the attribute and view the related sessions in the ACC.
- Export a chart or map to PDF or as an image. For portability and offline viewing, you can Export charts and maps as PDFs or PNG images.

The following App Scope reports are available:

- Summary Report
- Change Monitor Report
- Threat Monitor Report
- Threat Map Report
- Network Monitor Report
- Traffic Map Report

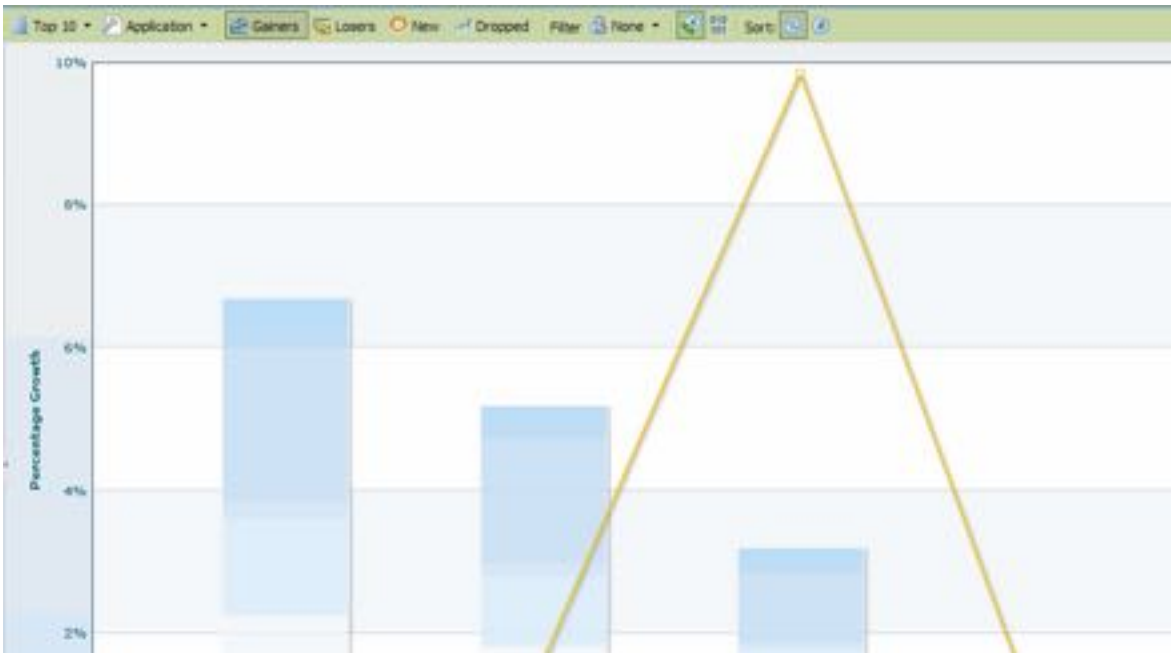
 © Palo Alto Networks, Inc.

## Summary Report

The App Scope Summary report (**Monitor > App Scope > Summary**) displays charts for the top five gainers, losers, and bandwidth consuming applications, application categories, users, and sources.

## Change Monitor Report

The App Scope Change Monitor report (**Monitor > App Scope > Change Monitor**) displays changes over a specified time period. For example, the following chart displays the top applications that gained in use over the last hour as compared with the last 24-hour period. The top applications are determined by session count and sorted by percent.



The Change Monitor Report contains the following buttons and options.

| Button | Description |
|---|---|
| Top 10 | Determines the number of records with the highest measurement included in the chart. |
| Application | Determines the type of item reported: Application, Application Category, Source, or Destination. |
| Gainers | Displays measurements of items that have increased over the measured period. |
| Losers | Displays measurements of items that have decreased over the measured period. |
| New | Displays measurements of items that were added over the measured period. |
| Dropped | Displays measurements of items that were discontinued over the measured period. |

 © Palo Alto Networks, Inc.

| Button | Description |
|---|---|
|  | Applies a filter to display only the selected item. **None** displays all entries. |
| | Determines whether to display session or byte information. |
|  | Determines whether to sort entries by percentage or raw growth. |
|  | Exports the graph as a .png image or as a PDF. |
|  | Specifies the period over which the change measurements are taken. |

## Threat Monitor Report

The App Scope Threat Monitor report (**Monitor > App Scope > Threat Monitor**) displays a count of the top threats over the selected time period. For example, the following figure shows the top 10 threat types over the last 6 hours.

Each threat type is color-coded as indicated in the legend below the chart. The Threat Monitor report contains the following buttons and options.

| Button | Description |
|---|---|
| | Determines the number of records with the highest measurement included in the chart. |
|  | Determines the type of item measured: Threat, Threat Category, Source, or Destination. |
| | Applies a filter to display only the selected type of items. |
| | Determines whether the information is presented in a stacked column chart or a stacked area chart. |
|  | Exports the graph as a .png image or as a PDF. |
| | Specifies the period over which the measurements are taken. |

 © Palo Alto Networks, Inc.

## Threat Map Report

The App Scope Threat Map report (**Monitor > App Scope > Threat Map**) shows a geographical view of threats, including severity. Each threat type is color-coded as indicated in the legend below the chart.

The firewall uses geolocation for creating threat maps. The firewall is placed at the bottom of the threat map screen, if you have not specified the geolocation coordinates (**Device > Setup > Management,** General Settings section) on the firewall.

The Threat Map report contains the following buttons and options.

| Button | Description |
|---|---|
| | Determines the number of records with the highest measurement included in the chart. |
|  | Displays incoming threats. |
|  | Displays outgoing threats. |
| | Applies a filter to display only the selected type of items. |
|  | Zoom in and zoom out of the map. |
|  | Exports the graph as a .png image or as a PDF. |
|  | Indicates the period over which the measurements are taken. |

## Network Monitor Report

The App Scope Network Monitor report (**Monitor > App Scope > Network Monitor**) displays the bandwidth dedicated to different network functions over the specified period of time. Each network function is color-coded as indicated in the legend below the chart. For example, the image below shows application bandwidth for the past 7 days based on session information.

The Network Monitor report contains the following buttons and options.

| Button | Description |
|---|---|
| | Determines the number of records with the highest measurement included in the chart. |
|  | Determines the type of item reported: Application, Application Category, Source, or Destination. |
|  | Applies a filter to display only the selected item. **None** displays all entries. |
| | Determines whether to display session or byte information. |
|  | Exports the graph as a .png image or as a PDF. |
| | Determines whether the information is presented in a stacked column chart or a stacked area chart. |
| | Indicates the period over which the change measurements are taken. |

 © Palo Alto Networks, Inc.

## Traffic Map Report

The App Scope Traffic Map (**Monitor > App Scope > Traffic Map**) report shows a geographical view of traffic flows according to sessions or flows.

The firewall uses geolocation for creating traffic maps. The firewall is placed at the bottom of the traffic map screen, if you have not specified the geolocation coordinates (**Device > Setup > Management,** General Settings section) on the firewall.

Each traffic type is color-coded as indicated in the legend below the chart. The Traffic Map report contains the following buttons and options.

| Buttons | Description |
|---|---|
| Top 10 | Determines the number of records with the highest measurement included in the chart. |
| Incoming threats | Displays incoming threats. |
| Outgoing threats | Displays outgoing threats. |
| 010 101 | Determines whether to display session or byte information. |
| Zoom In Zoom Out | Zoom in and zoom out of the map. |
| Export: | Exports the graph as a .png image or as a PDF. |
| Last 6 hours Last 12 hours Last 24 hours Last 7 days Last 30 days | Indicates the period over which the change measurements are taken. |

# Use the Automated Correlation Engine

The automated correlation engine is an analytics tool that uses the logs on the firewall to detect actionable events on your network. The engine correlates a series of related threat events that, when combined, indicate a likely compromised host on your network or some other higher level conclusion. It pinpoints areas of risk, such as compromised hosts on the network, allows you to assess the risk and take action to prevent exploitation of network resources. The automated correlation engine uses *correlation objects* to analyze the logs for patterns and when a match occurs, it generates a *correlated event*.

The automated correlation engine is supported on the following platforms:

- Panorama—M-Series appliance and the virtual appliance
- PA-7000 Series firewall
- PA-5000 Series firewall
- PA-3000 Series firewall

- Automated Correlation Engine Concepts
- View the Correlated Objects
- Interpret Correlated Events
- Use the Compromised Hosts Widget in the ACC

 © Palo Alto Networks, Inc.

# Automated Correlation Engine Concepts

The automated correlation engine uses *correlation objects* to analyze the logs for patterns and when a match occurs, it generates a *correlated event*.

- Correlation Object
- Correlated Events

## Correlation Object

A correlation object is a definition file that specifies patterns to match against, the data sources to use for the lookups, and time period within which to look for these patterns. A pattern is a boolean structure of conditions that queries the following data sources (or logs) on the firewall: application statistics, traffic, traffic summary, threat summary, threat, data filtering, and URL filtering. Each pattern has a severity rating, and a threshold for the number of times the pattern match must occur within a defined time limit to indicate malicious activity. When the match conditions are met, a correlated event is logged.

A correlation object can connect isolated network events and look for patterns that indicate a more significant event. These objects identify suspicious traffic patterns and network anomalies, including suspicious IP activity, known command-and-control activity, known vulnerability exploits, or botnet activity that, when correlated, indicate with a high probability that a host on the network has been compromised. Correlation objects are defined and developed by the Palo Alto Networks Threat Research team, and are delivered with the weekly dynamic updates to the firewall and Panorama. To obtain new correlation objects, the firewall must have a Threat Prevention license. Panorama requires a support license to get the updates.

The patterns defined in a correlation object can be static or dynamic. Correlated objects that include patterns observed in WildFire are dynamic, and can correlate malware patterns detected by WildFire with command-and-control activity initiated by a host that was targeted with the malware on your network. For example, when a host submits a file to the WildFire cloud and the verdict is malicious, the correlation object looks for other hosts or clients on the network that exhibit the same behavior seen in the cloud. If the malware sample had performed a DNS query and browsed to a malware domain, the correlation object will parse the logs for a similar event. When the activity on a host matches the analysis in the cloud, a high severity correlated event is logged.

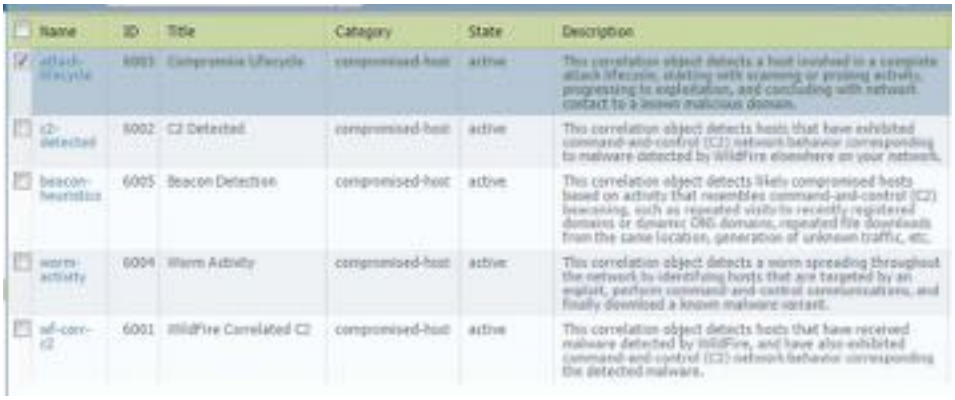
## Correlated Events

A correlated event is logged when the patterns and thresholds defined in a correlation object match the traffic patterns on your network. To Interpret Correlated Events and to view a graphical display of the events, see Use the Compromised Hosts Widget in the ACC.

# View the Correlated Objects

**View the Correlation Objects Available on the Firewall**

Step 1 To view the correlation objects that are currently available, select **Monitor > Automated Correlation Engine > Correlation Objects**. All the objects in the list are enabled by default.



Step 2 View the details on each correlation object. Each object provides the following information:

- **Name** and **Title**—The name and title indicate the type of activity that the correlation object detects. The name column is hidden from view, by default. To view the definition of the object, unhide the column and click the name link.
- **ID**—A unique number that identifies the correlation object; this column is also hidden by default. The IDs are in the 6000 series.
- **Category**—A classification of the kind of threat or harm posed to the network, user, or host. For now, all the objects identify compromised hosts on the network.
- **State**—Indicates whether the correlation object is enabled (active) or disabled (inactive). All the objects in the list are enabled by default, and are hence active. Because these objects are based on threat intelligence data and are defined by the Palo Alto Networks Threat Research team, keep the objects active in order to track and detect malicious activity on your network.
- **Description**—Specifies the match conditions for which the firewall or Panorama will analyze logs. It describes the sequence of conditions that are matched on to identify acceleration or escalation of malicious activity or suspicious host behavior. For example, the **Compromise Lifecycle** object detects a host involved in a complete attack lifecycle in a three-step escalation that starts with scanning or probing activity, progressing to exploitation, and concluding with network contact to a known malicious domain.

For more information, see Automated Correlation Engine Concepts and Use the Automated Correlation Engine.

 © Palo Alto Networks, Inc.

## Interpret Correlated Events

You can view and analyze the logs generated for each correlated event in the **Monitor > Automated Correlation Engine > Correlated Events** tab.

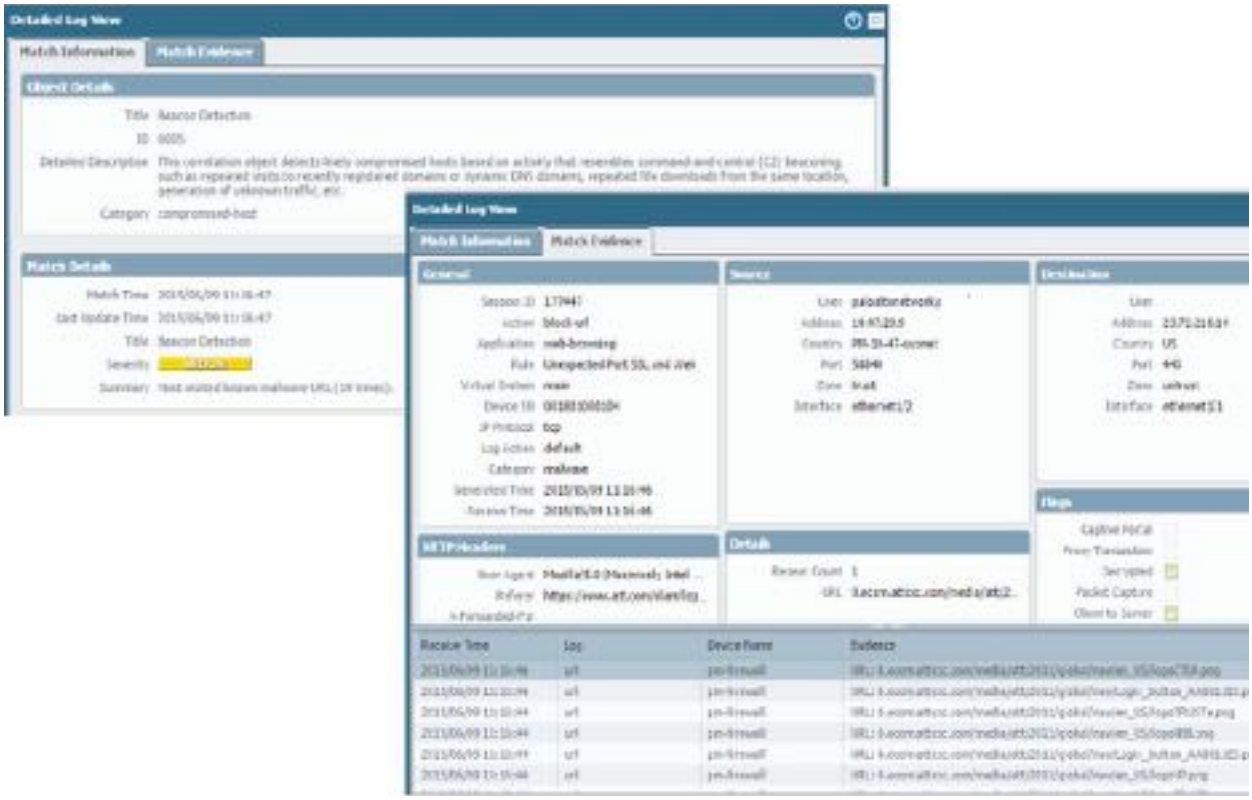
Correlated Events includes the following details:

| Field | Description |
|---|---|
| **Match Time** | The time the correlation object triggered a match. |
| **Update Time** | The time when the event was last updated with evidence on the match. As the firewall collects evidence on pattern or sequence of events defined in a correlation object, the time stamp on the correlated event log is updated. |
| **Object Name** | The name of the correlation object that triggered the match. |
| **Source Address** | The IP address of the user/device on your network from whom.which the traffic originated. |
| **Source User** | The user and user group information from the directory server, if User-ID is enabled. |

| Field | Description |
|---|---|
| **Severity**<br> To configure the firewall or Panorama to send alerts using email, SNMP or syslog messages for a desired severity level, see Use External Services for Monitoring. | A rating that indicates the urgency and impact of the match. The severity level indicates the extent of damage or escalation pattern, and the frequency of occurrence. Because correlation objects are primarily for detecting threats, the correlated events typically relate to identifying compromised hosts on the network and the severity implies the following:<br>• **Critical**—Confirms that a host has been compromised based on correlated events that indicate an escalation pattern. For example, a critical event is logged when a host that received a file with a malicious verdict by WildFire exhibits the same command-and-control activity that was observed in the WildFire sandbox for that malicious file.<br>• **High**—Indicates that a host is very likely compromised based on a correlation between multiple threat events, such as malware detected anywhere on the network that matches the command-and-control activity generated by a particular host.<br>• **Medium**—Indicates that a host is likely compromised based on the detection of one or multiple suspicious events, such as repeated visits to known malicious URLs, which suggests a scripted command-and-control activity.<br>• **Low**—Indicates that a host is possibly compromised based on the detection of one or multiple suspicious events, such as a visit to a malicious URL or a dynamic DNS domain.<br>• **Informational**—Detects an event that may be useful in aggregate for identifying suspicious activity, but the event is not necessarily significant on its own. |
| **Summary** | A description that summarizes the evidence gathered on the correlated event. |

 © Palo Alto Networks, Inc.

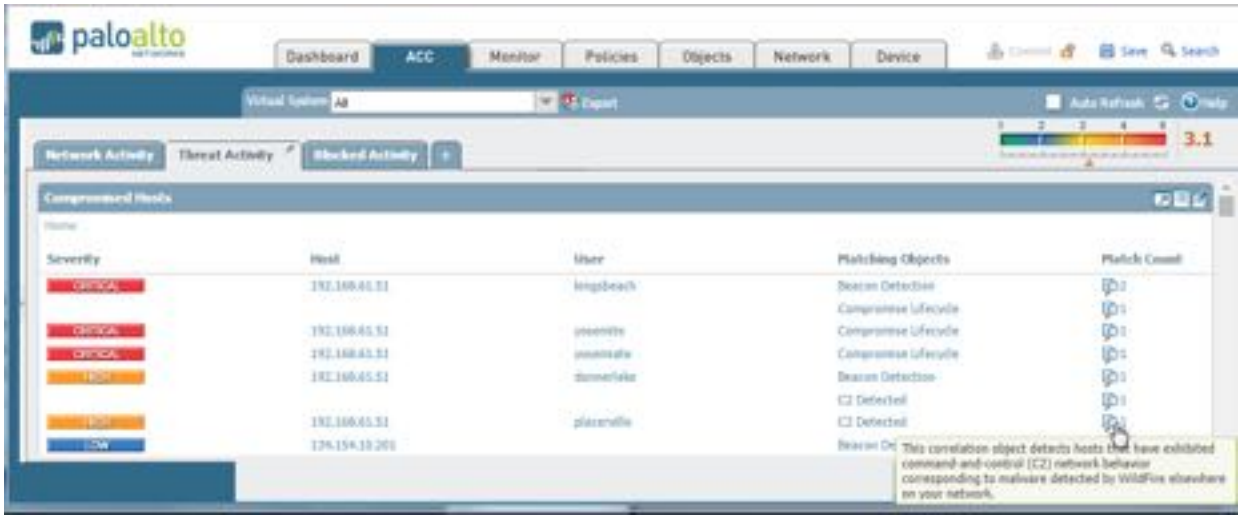
Click the icon to see the detailed log view, which includes all the evidence on a match:



| Tab | Description |
|---|---|
| **Match Information** | Object Details: Presents information on the Correlation Object that triggered the match. |
| | Match Details: A summary of the match details that includes the match time, last update time on the match evidence, severity of the event, and an event summary. |
| **Match Evidence** | Presents all the evidence that corroborates the correlated event. It lists detailed information on the evidence collected for each session. |

## Use the Compromised Hosts Widget in the ACC

The compromised hosts widget on **ACC >Threat Activity**, aggregates the Correlated Events and sorts them by severity. It displays the source IP address/user who triggered the event, the correlation object that was matched and the number of times the object was matched. Use the match count link to jump to the match evidence details.



For more details, see Use the Automated Correlation Engine and Use the Application Command Center.

# Take Packet Captures

All Palo Alto Networks firewalls allow you to take packet captures (pcaps) of traffic that traverses the management interface and network interfaces on the firewall. When taking packet captures on the dataplane, you may need to Disable Hardware Offload to ensure that the firewall captures all traffic.

Packet capture can be very CPU intensive and can degrade firewall performance. Only use this feature when necessary and make sure you turn it off after you have collected the required packets.

There are four different types of packet captures you can enable, depending on what you need to do:

- **Custom Packet Capture**—The firewall captures packets for all traffic or for specific traffic based on filters that you define. For example, you can configure the firewall to only capture packets to and from a specific source and destination IP address or port. You then use the packet captures for troubleshooting network-related issues or for gathering application attributes to enable you to write custom application signatures or to request an application signature from Palo Alto Networks. See Take a Custom Packet Capture.
- **Threat Packet Capture**—The firewall captures packets when it detects a virus, spyware, or vulnerability. You enable this feature in Antivirus, Anti-Spyware, and Vulnerability Protection security profiles. A link to view or export the packet captures will appear in the second column of the Threat log. These packet captures provide context around a threat to help you determine if an attack is successful or to learn more about the methods used by an attacker. You can also submit this type of pcap to Palo Alto Networks to have a threat re-analyzed if you feel its a false-positive or false-negative. See Take a Threat Packet Capture.
- **Application Packet Capture**—The firewall captures packets based on a specific application and filters that you define. A link to view or export the packet captures will appear in the second column of the Traffic logs for traffic that matches the packet capture rule. See Take an Application Packet Capture.
- **Management Interface Packet Capture**—The firewall captures packets on the management interface (MGT) The packet captures are useful when troubleshooting services that traverse the interface, such as device management authentication to external servers (LDAP and RADIUS for example), software and content updates, log forwarding, communication with SNMP servers, and authentication requests for GlobalProtect and Captive Portal. See Take a Packet Capture on the Management Interface.

## Disable Hardware Offload

Packet captures on a Palo Alto Networks firewall are performed in the dataplane CPU, unless you configure the firewall to Take a Packet Capture on the Management Interface, in which case the packet capture is performed on the management plane. When a packet capture is performed on the dataplane, during the ingress stage, the firewall performs packet parsing checks and discards any packets that do not match the packet capture filter. Any traffic that is offloaded to the field-programmable gate array (FPGA) offload processor is also excluded, unless you turn off hardware offload. For example, encrypted traffic (SSL/SSH), network protocols (OSPF, BGP, RIP), application overrides, and terminating applications can be offloaded to the FPGA and therefore are excluded from packet captures by default. Some types of sessions will never be offloaded, such as ARP, all non-IP traffic, IPSec, VPN sessions, SYN, FIN, and RST packets.

Hardware offload is supported on the following firewalls: PA-2000 Series, PA-3050, PA-4000 Series, PA-5000 Series, and PA-7000 Series firewall.

Disabling hardware offload increases the dataplane CPU usage. If dataplane CPU usage is already high, you may want to schedule a maintenance window before disabling hardware offload.

| **Enable/Disable Hardware Offload** | |
|---|---|
| Step 1 | Disable hardware offload by running the following CLI command:<br>`admin@PA-7050> set session offload no` |
| Step 2 | After the firewall captures the required traffic, enable hardware offload by running the following CLI command:<br>`admin@PA-7050> set session offload yes` |

## Take a Custom Packet Capture

Custom packet captures allow you to define the traffic that the firewall will capture. To ensure that you capture all traffic, you may need to Disable Hardware Offload.

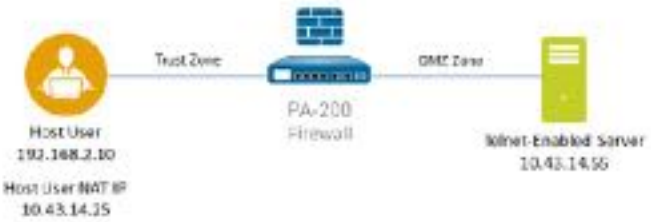
 © Palo Alto Networks, Inc.

### Take a Custom Packet Capture

Step 1 Before you start a packet capture, identify the attributes of the traffic that you want to capture.

For example, to determine the source IP address, source NAT IP address, and the destination IP address for traffic between two systems, perform a ping from the source system to the to the destination system. After the ping is complete, go to **Monitor > Traffic** and locate the traffic log for the two systems. Click the **Detailed Log View** icon located in the first column of the log and note the source address, source NAT IP, and the destination address.

In the example that follows, we will use a packet capture to troubleshoot a Telnet connectivity issue from a user in the Trust zone to a server in the DMZ zone.



**Take a Custom Packet Capture (Continued)**

Step 2 Set packet capture filters, so the firewall only captures traffic you are interested in.

Filters will make it easier for you to locate the information you need in the packet capture and will reduce the processing power required by the firewall to take the packet capture. To capture all traffic, do not define filters and leave the filter option off.

For example, if you configured NAT on the firewall, you will need to apply two filters. The first one filters on the pre-NAT source IP address to the destination IP address and the second one filters traffic from the destination server to the source NAT IP address.

1. Select **Monitor > Packet Capture**.
2. Click **Clear All Settings** at the bottom of the window to clear any existing capture settings.
3. Click **Manage Filters** and click **Add**.
4. Select **Id** 1 and in the **Source** field enter the source IP address you are interested in and in the **Destination** field enter a destination IP address.

   For example, enter the source IP address `192.168.2.10` and the destination IP address `10.43.14.55`. To further filter the capture, set **Non-IP** to **exclude** non-IP traffic, such as broadcast traffic.
5. **Add** the second filter and select **Id** 2.

   For example, in the **Source** field enter `10.43.14.55` and in the **Destination** field enter `10.43.14.25`. In the **Non-IP** drop-down menu select **exclude**.

6. Click **OK**.

Step 3 Set **Filtering** to **On**.

 © Palo Alto Networks, Inc.

**Take a Custom Packet Capture (Continued)**

Step 4 Specify the traffic stage(s) that trigger the packet capture and the filename(s) to use to store the captured content. For a definition of each stage, click the **Help** icon on the packet capture page.

For example, to configure all packet capture stages and define a filename for each stage, perform the following procedure:
