# Table of Contents

Preface . . . . . 13

About This Guide . . . . . 13
Organization. . . . . 13
Typographical Conventions. . . . . 15
Notes and Cautions. . . . . 15
Related Documentation . . . . . 15

Chapter 1
Introduction . . . . . 17

Firewall Overview. . . . . 17
Features and Benefits . . . . . 18
Management Interfaces . . . . . 19

Chapter 2
Getting Started . . . . . 21

Preparing the Firewall . . . . . 21
Setting Up the Firewall . . . . . 22
Using the Firewall Web Interface. . . . . 23
Committing Changes . . . . . 25
Navigating to Configuration Pages . . . . . 26
Using Tables on Configuration Pages . . . . . 26
Required Fields . . . . . 26
Locking Transactions . . . . . 27
Supported Browsers . . . . . 27
Getting Help Configuring the Firewall . . . . . 28
Obtaining More Information . . . . . 28
Technical Support . . . . . 28

Chapter 3
Device Management. . . . . 29

System Setup, Configuration, and License Management . . . . . 30
Defining Management Settings . . . . . 30
Defining Operations Settings . . . . . 37
Defining Services Settings . . . . . 41

Defining Content ID Settings . . . . . 43
Defining Session Settings . . . . . 45
SNMP . . . . . 47
Statistics Service . . . . . 48
Comparing Configuration Files . . . . . 49
Installing a License. . . . . 50
Upgrading/Downgrading the PAN-OS Software . . . . . 50
Upgrading PAN-OS in a High Availability Configuration . . . . . 51
Downgrading PAN-OS Software . . . . . 53
Maintenance Release Downgrade . . . . . 53
Feature release Downgrade . . . . . 54
Updating Threat and Application Definitions . . . . . 55
Administrator Roles, Profiles, and Accounts. . . . . 56
Username and Password Requirements. . . . . 57
Defining Administrator Roles . . . . . 58
Defining Password Profiles . . . . . 59
Creating Administrative Accounts . . . . . 59
Specifying Access Domains for Administrators . . . . . 61
Authentication Profiles. . . . . 62
Setting Up Authentication Profiles . . . . . 62
Creating a Local User Database. . . . . 64
Configuring RADIUS Server Settings . . . . . 65
Configuring LDAP Server Settings . . . . . 66
Configuring Kerberos Settings (Native Active Directory Authentication) . . . . 67
Authentication Sequence . . . . . 67
Setting Up Authentication Sequences . . . . . 68
Firewall Logs . . . . . 68
Logging Configuration . . . . . 70
Scheduling Log Exports . . . . . 71
Defining Configuration Log Settings . . . . . 72
Defining System Log Settings . . . . . 72
Defining HIP Match Log Settings . . . . . 73
Defining Alarm Log Settings . . . . . 73
Managing Log Settings . . . . . 74
Configuring SNMP Trap Destinations . . . . . 75
Configuring Syslog Servers. . . . . 76
Custom Syslog Field Descriptions. . . . . 77
Configuring Email Notification Settings. . . . . 83
Viewing Alarms . . . . . 85
Configuring Netflow Settings . . . . . 85
Importing, Exporting and Generating Security Certificates . . . . . 86
Certificates . . . . . 86
Default Trusted Certificate Authorities . . . . . 88
Certificate Profile . . . . . 89
OCSP Responder . . . . . 90
Encrypting Private Keys and Passwords on the Firewall . . . . . 90
Master Key and Diagnostic Settings . . . . . 91
Updating Master Keys. . . . . 91
High Availability . . . . . 93
Active/Passive HA . . . . . 93
Active/Active HA . . . . . 93

Packet Flow . . . . . 94
Deployment Options . . . . . 95
NAT Considerations . . . . . 96
Setting Up HA . . . . . 99
Enabling HA on the Firewall . . . . . 101
Virtual Systems . . . . . 110
Communications Among Virtual Systems . . . . . 111
Shared Gateways . . . . . 112
Defining Virtual Systems . . . . . 113
Configuring Shared Gateways . . . . . 115
Defining Custom Response Pages . . . . . 115
Viewing Support Information . . . . . 117

Chapter 4
Network Configuration . . . . . 119

Firewall Deployment . . . . . 120
Virtual Wire Deployments . . . . . 120
Layer 2 Deployments . . . . . 124
Layer 3 Deployments . . . . . 124
Tap Mode Deployments . . . . . 125
Defining Virtual Wires . . . . . 125
Packet Content Modification . . . . . 126
Firewall Interfaces . . . . . 127
Viewing the Current Interfaces . . . . . 128
Configuring Layer 2 Interfaces . . . . . 128
Configuring Layer 2 Subinterfaces . . . . . 129
Configuring Layer 3 Interfaces . . . . . 130
Configuring Layer 3 Subinterfaces . . . . . 134
Configuring Virtual Wire Interfaces . . . . . 138
Configuring Virtual Wire Subinterfaces . . . . . 139
Configuring Aggregate Interface Groups . . . . . 141
Configuring Aggregate Ethernet Interfaces . . . . . 142
Configuring VLAN Interfaces . . . . . 143
Configuring Loopback Interfaces . . . . . 146
Configuring Tunnel Interfaces . . . . . 147
Configuring Tap Interfaces . . . . . 149
Configuring HA Interfaces . . . . . 150
Security Zones . . . . . 151
Defining Security Zones . . . . . 151
VLAN Support . . . . . 152
Virtual Routers and Routing Protocols . . . . . 153
Routing Information Protocol . . . . . 153
Open Shortest Path First . . . . . 153
Border Gateway Protocol . . . . . 154
Multicast Routing . . . . . 154
Defining Virtual Routers . . . . . 155
DHCP Server and Relay . . . . . 171
DNS Proxy . . . . . 173

Network Profiles . . . . . 174
Defining Interface Management Profiles. . . . . 175
Defining Monitor Profiles. . . . . 177
Defining Zone Protection Profiles . . . . . 178

Chapter 5
Policies and Security Profiles . . . . . 183

Policies. . . . . 183
Guidelines on Defining Policies . . . . . 184
Specifying Users and Applications for Policies . . . . . 186
Security Policies . . . . . 187
Defining Security Policies. . . . . 187
NAT Policies . . . . . 190
Determining Zone Configuration in NAT and Security Policy . . . . . 193
NAT Rule Options . . . . . 193
Defining Network Address Translation Policies . . . . . 194
NAT Policy Examples. . . . . 195
NAT64 . . . . . 196
Policy-Based Forwarding Policies . . . . . 199
Decryption Policies . . . . . 202
Application Override Policies . . . . . 205
Custom Application Definition with Application Override. . . . . 205
Defining Application Override Policies . . . . . 205
Captive Portal Policies . . . . . 206
Defining Captive Portal Policies . . . . . 207
DoS Protection Policies . . . . . 209
Defining DoS Protection Policies . . . . . 209
Security Profiles . . . . . 211
Antivirus Profiles . . . . . 212
Anti-spyware Profiles . . . . . 213
Vulnerability Protection Profiles . . . . . 215
URL Filtering Profiles . . . . . 217
File Blocking Profiles . . . . . 220
Data Filtering Profiles . . . . . 223
DoS Profiles . . . . . 225
Other Policy Objects. . . . . 226
Addresses and Address Groups . . . . . 227
Defining Address Ranges . . . . . 227
Defining Address Groups . . . . . 230
Defining Regions . . . . . 230
Applications and Application Groups . . . . . 231
Defining Applications. . . . . 233
Custom Applications with Signatures . . . . . 236
Defining Application Groups. . . . . 238
Application Filters . . . . . 238
Services . . . . . 239
Service Groups . . . . . 240
Data Patterns . . . . . 240
Custom URL Categories . . . . . 242
Dynamic Block Lists . . . . . 242

Custom Spyware and Vulnerability Signatures . . . . . 243
Defining Data Patterns . . . . . 243
Defining Spyware and Vulnerability Signatures . . . . . 244
Security Profile Groups . . . . . 246
Log Forwarding . . . . . 247
Decryption Profiles . . . . . 248
Schedules . . . . . 250

Chapter 6
Reports and Logs . . . . . 251

Using the Dashboard . . . . . 252
Using the Application Command Center . . . . . 253
Using App-Scope . . . . . 256
Summary Report . . . . . 257
Change Monitor Report . . . . . 258
Threat Monitor Report . . . . . 259
Threat Map Report . . . . . 260
Network Monitor Report . . . . . 261
Traffic Map Report . . . . . 263
Viewing the Logs . . . . . 264
Viewing Session Information . . . . . 267
Working with Botnet Reports . . . . . 267
Configuring the Botnet Report . . . . . 268
Managing Botnet Reports . . . . . 269
Managing PDF Summary Reports . . . . . 270
Managing User Activity Reports . . . . . 272
Managing Report Groups . . . . . 272
Scheduling Reports for Email Delivery . . . . . 273
Viewing Reports . . . . . 273
Generating Custom Reports . . . . . 274
Identifying Unknown Applications and Taking Action . . . . . 276
Taking Action . . . . . 277
Requesting an App-ID from Palo Alto Networks . . . . . 277
Other Unknown Traffic . . . . . 278
Taking Packet Captures . . . . . 278

Chapter 7
Configuring the Firewall for User Identification . . . . . 281

Overview of User Identification . . . . . 281
How User Identification Works . . . . . 281
Identifying Users and Groups . . . . . 282
How User-ID Components Interact . . . . . 283
User-ID Agent . . . . . 283
PAN-OS User Mapping . . . . . 283
Terminal Services Agent . . . . . 283
PAN-OS LDAP Group Query . . . . . 284

Configuring the Firewall for User Identification . . . . . 286
PAN-OS User Mapping Configuration . . . . . 291
Configuring PAN-OS User Mapping . . . . . 292
Configure a Firewall to Share User Mapping Data . . . . . 295
Setting Up the User-ID Agent . . . . . 296
Installing the User-ID Agent . . . . . 297
Configuring the User-ID Agent . . . . . 298
Discovering Domain Controllers . . . . . 301
Monitoring User-ID Agent Operation . . . . . 301
Uninstalling and Upgrading the User-ID Agent . . . . . 301
Setting Up the Terminal Services Agent . . . . . 301
Installing or Upgrading the Terminal Server Agent on the Terminal Server . 302
Configuring the Terminal Server Agent on the Terminal Server . . . . . 303
Uninstalling the Terminal Server Agent on the Terminal Server . . . . . 307

Chapter 8
Configuring IPSec Tunnels . . . . . 309

Virtual Private Networks . . . . . 310
VPN Tunnels . . . . . 311
IPSec and IKE . . . . . 311
IPSec and IKE Crypto Profiles . . . . . 312
Setting Up IPSec VPNs . . . . . 313
Defining IKE Gateways . . . . . 314
Setting Up IPSec Tunnels . . . . . 315
Defining IKE Crypto Profiles . . . . . 318
Defining IPSec Crypto Profiles . . . . . 319
Viewing IPSec Tunnel Status on the Firewall . . . . . 319
Sample VPN Configuration . . . . . 320
Existing Topology . . . . . 320
New Topology . . . . . 321
Configure the VPN Connection . . . . . 321
VPN Connectivity Troubleshooting . . . . . 322
GlobalProtect Large Scale VPN Deployment . . . . . 323
Overview . . . . . 323
Deploying a Large Scale VPN Network . . . . . 324
Certificates and the OCSP Responder . . . . . 325
Global Protect Gateway Configuration . . . . . 328
GlobalProtect Portal Configuration . . . . . 330
GlobalProtect Satellite Configuration . . . . . 332
Dynamic Routing Protocols and Large Scale VPNs . . . . . 333
Backing up a GlobalProtect Portal . . . . . 334

Chapter 9
Configuring GlobalProtect . . . . . 335
Overview . . . . . 335
GlobalProtect Authentication . . . . . 336
Setting Up GlobalProtect . . . . . 337
Setting Up and Activating the GlobalProtect Agent . . . . . 352
Setting Up the GlobalProtect Agent . . . . . 353

Chapter 10
Configuring Quality of Service. . . . . 355
Firewall Support for QoS . . . . . 355
Configuring QoS for Firewall Interfaces . . . . . 356
Defining QoS Profiles . . . . . 358
Defining QoS Policies . . . . . 359
Displaying QoS Statistics . . . . . 362

Chapter 11
Setting Up a VM-Series Firewall . . . . . 363
Overview . . . . . 363
System Requirements and Limitations . . . . . 364
Requirements . . . . . 364
Limitations . . . . . 364
About Licensing the VM-Series Firewall . . . . . 365
Registering the VM-Series Firewall. . . . . 365
Installing and Licensing the VM-Series Firewall . . . . . 366
Troubleshooting . . . . . 370

Chapter 12
Setting Up Panorama . . . . . 371
Overview . . . . . 371
Setting Up Panorama as a Virtual Appliance . . . . . 372
Installing Panorama . . . . . 372
Configuring the Panorama Network Interface . . . . . 373
Expanding the Log Storage Capacity . . . . . 373
Adding a Virtual Disk . . . . . 374
Setting Up Storage Partitions . . . . . 374
Setting up Panorama on an M-Series Appliance . . . . . 376
Performing Initial Setup . . . . . 376
Logging in to Panorama . . . . . 377
Changing the Default Password . . . . . 377
Configuring High Availability (HA) . . . . . 377
Switching the Logging Priority in an HA Pair . . . . . 379

Chapter 13
Central Device Management Using Panorama . . . . . 381

Accessing the Panorama Web Interface . . . . . 382
Using the Panorama Interface . . . . . 382
Panorama Tab . . . . . 383
Adding Devices . . . . . 385
Defining Device Groups . . . . . 386
Panorama Administrator Roles, Profiles, and Accounts . . . . . 387
Defining Panorama Administrator Roles . . . . . 388
Creating Panorama Administrative Accounts . . . . . 389
Specifying Panorama Access Domains for Administrators . . . . . 392
Device Groups . . . . . 393
Working with Policies . . . . . 393
Working with Objects . . . . . 395
Working with Devices . . . . . 397
Commit Operation in Panorama . . . . . 398
Panorama Backward Compatibility . . . . . 399
Templates . . . . . 399
Configuring Panorama Templates . . . . . 401
Adding a New Template . . . . . 401
Configuring a Template . . . . . 402
Overriding Template Settings . . . . . 402
Removing Templates . . . . . 403
Logging . . . . . 403
Logging and Reporting . . . . . 403
Generating User Activity Reports . . . . . 404
Using Panorama for Log Collection . . . . . 404
Deploying Distributed Log Collection . . . . . 405
Managing Log Collectors . . . . . 407
Defining Log Collector Groups . . . . . 411
Viewing Firewall Deployment Information . . . . . 416
Backing Up Firewall Configurations . . . . . 417
Scheduling Configuration Exports . . . . . 417
Upgrading the Panorama Software . . . . . 419

Chapter 14
Configuring WildFire . . . . . 421

About WildFire . . . . . 421
Setting Up WildFire on the Firewall . . . . . 423
Configuring WildFire Settings on the Firewall . . . . . 423
Configuring WildFire Forwarding . . . . . 424
WildFire Data Filtering Log . . . . . 425
Using the WildFire Portal . . . . . 425
Configuring Settings on the WildFire Portal . . . . . 426
Viewing WildFire Reports . . . . . 427

Appendix A
Custom Pages . . . . . 429

Default Antivirus Response Page . . . . . 429
Default Application Block Page . . . . . 431
Default File Blocking Block Page . . . . . 431
Default URL Filtering Response Page . . . . . 432
Default Anti-spyware Download Response Page . . . . . 433
Default Decryption Opt-out Response Page . . . . . 433
Captive Portal Comfort Page . . . . . 434
URL Filtering Continue and Override Page . . . . . 434
SSL VPN Login Page . . . . . 435
SSL Certificate Revoked Notify Page . . . . . 436

Appendix B
Application Categories, Subcategories, Technologies, and Characteristics 437

Application Categories and Subcategories . . . . . 437
Application Technologies . . . . . 439
Application Characteristics . . . . . 439

Appendix C
Common Criteria/Federal Information Processing Standards Support . 441

Enabling CC/FIPS Mode . . . . . 441
CC/FIPS Security Functions . . . . . 443

Appendix D
Open Source Licenses . . . . . 445

Index. . . . . 465

# Preface

This preface contains the following sections:

- "About This Guide" in the next section
- "Organization" on page 13
- "Typographical Conventions" on page 15
- "Notes and Cautions" on page 15
- "Related Documentation" on page 15

## About This Guide

This guide describes how to administer the Palo Alto Networks firewall using the device's web interface.

This guide is intended for system administrators responsible for deploying, operating, and maintaining the firewall.

## Organization

This guide is organized as follows:

- **Chapter 1, "Introduction"**—Provides an overview of the firewall.
- **Chapter 2, "Getting Started"**—Describes how to install the firewall.
- **Chapter 3, "Device Management"—**Describes how to perform basic system configuration and maintenance for the firewall, including how to configure a pair of firewalls for high availability, define user accounts, update the software, and manage configurations.
- **Chapter 4, "Network Configuration"**—Describes how to configure the firewall for your network, including routing configuration.
- **Chapter 5, "Policies and Security Profiles"**—Describes how to configure security policies and profiles by zone, users, source/destination address, and application.
- **Chapter 6, "Reports and Logs"**—Describes how to view the reports and logs provided with the firewall.

- **Chapter 7, "Configuring the Firewall for User Identification"**—Describes how to configure the firewall to identify the users who attempt to access the network.
- **Chapter 8, "Configuring IPSec Tunnels"**—Describes how to configure IP Security (IPSec) tunnels on the firewall.
- **Chapter 9, "Configuring GlobalProtect"**—Describes GlobalProtect, which allows secure login from client systems located anywhere in the world.
- **Chapter 10, "Configuring Quality of Service"**—Describes how to configure quality of service (QoS) on the firewall.
- **Chapter 12, "Setting Up Panorama"**—Describes how to install the centralized management system for the Palo Alto Networks firewall.
- **Chapter 13, "Central Device Management Using Panorama"**—Describes how to use Panorama to manage multiple firewalls.
- **Chapter 14, "Configuring WildFire"**—describes how to use WildFire for analysis and reporting on malware that traverses the firewall.
- **Appendix A, "Custom Pages"**—Provides HTML code for custom response pages to notify end users of policy violations or special access conditions.
- **Appendix B, "Application Categories, Subcategories, Technologies, and Characteristics"**—Contains a list of the application categories defined by Palo Alto Networks.
- **Appendix C, "Common Criteria/Federal Information Processing Standards Support"**—Describes firewall support for the Federal Information Processing Standards 140-2.
- **Appendix D, "Open Source Licenses"**—Includes information on applicable open source licenses.

# Typographical Conventions

This guide uses the following typographical conventions for special terms and instructions.

| Convention | Meaning | Example |
|---|---|---|
| **boldface** | Names of commands, keywords, and selectable items in the web interface | Click **Security** to open the Security Rules page. |
| *italics* | Name of parameters, files, directories, or Uniform Resource Locators (URLs) | The address of the Palo Alto Networks home page is *http://www.paloaltonetworks.com* |
| `courier font` | Coding examples and text that you enter at the command prompt | Enter the following command:<br>`set deviceconfig system dns-settings` |
| Click | Click the left mouse button | Click **Administrators** under the **Devices** tab. |
| Right-click | Click the right mouse button. | Right-click on the number of a rule you want to copy, and select **Clone Rule**. |

# Notes and Cautions

This guide uses the following symbols for notes and cautions.

| Symbol | Description |
|---|---|
| | NOTE<br>Indicates helpful suggestions or supplementary information. |
| | CAUTION<br>Indicates actions that could cause loss of data. |

# Related Documentation

The following additional documentation is provided with the firewall:

- *Getting Started Guide*
- *Quick Start*
- *Palo Alto Networks License Agreement and Warranty*

You can find additional related documentation at https://live.paloaltonetworks.com/community/documentation.

# Chapter 1
# Introduction

This chapter provides an overview of the firewall:

- "Firewall Overview" in the next section
- "Features and Benefits" on page 18
- "Management Interfaces" on page 19

## Firewall Overview

The Palo Alto Networks firewall allows you to specify security policies based on accurate identification of each application seeking access to your network. Unlike traditional firewalls that identify applications only by protocol and port number, the firewall uses packet inspection and a library of application signatures to distinguish between applications that have the same protocol and port, and to identify potentially malicious applications that use non-standard ports.

For example, you can define security policies for specific applications, rather than rely on a single policy for all port 80 connections. For each identified application, you can specify a security policy to block or allow traffic based on the source and destination zones and addresses (IPv4 and IPv6). Each security policy can also specify security profiles to protect against viruses, spyware, and other threats.

# Features and Benefits

The firewall provides granular control over the traffic allowed to access your network. The primary features and benefits include:

- **Application-based policy enforcement**—Access control by application is far more effective when application identification is based on more than just protocol and port number. High risk applications can be blocked, as well as high risk behavior, such as file-sharing. Traffic encrypted with the s Layer (SSL) protocol can be decrypted and inspected.
- **User Identification (User-ID)**—User-ID allows administrators to configure and enforce firewall policies based on users and user groups, instead of or in addition to network zones and addresses. The firewall can communicate with many directory servers, such as Microsoft Active Directory, eDirectory, SunOne, OpenLDAP, and most other LDAP based directory servers to provide user and group information to the firewall. This information can then be used to provide an invaluable method of providing secure application enablement that can be defined per user or group. For example, the administrator could allow one organization to use a web-based application, but no other organizations in the company would be able to use that application. You can also configure granular control of certain components of an application based on users and groups. Refer to "Configuring the Firewall for User Identification" on page 281.
- **Threat prevention**—Threat prevention services that protect the network from viruses, worms, spyware, and other malicious traffic can be varied by application and traffic source (refer to "Security Profiles" on page 211).
- **URL filtering**—Outbound connections can be filtered to prevent access to inappropriate web sites (refer to "URL Filtering Profiles" on page 217).
- **Traffic visibility**—Extensive reports, logs, and notification mechanisms provide detailed visibility into network application traffic and security events. The Application Command Center (ACC) in the web interface identifies the applications with the most traffic and the highest security risk (refer to "Reports and Logs" on page 251).
- **Networking versatility and speed**—The firewall can augment or replace your existing firewall, and can be installed transparently in any network or configured to support a switched or routed environment. Multi-gigabit speeds and a single-pass architecture provide all services with little or no impact on network latency.
- **GlobalProtect**—GlobalProtect provides security for client systems, such as laptops, that are used in the field by allowing easy and secure login from anywhere in the world.
- **Fail-safe operation**—High availability support provides automatic failover in the event of any hardware or software disruption (refer to "Enabling HA on the Firewall" on page 101).
- **Malware analysis and reporting**—WildFire provides detailed analysis and reporting on malware that traverses the firewall.
- **VM-Series Firewall**—Provides a virtual instance of PAN-OS positioned for use in a virtualized data center environment and particularly well suited for private and public cloud deployments. Installs on any x86 device that is capable of running VMware ESXi, without the need to deploy Palo Alto Networks hardware.

- **Management and Panorama—**Each firewall is managed through an intuitive web interface or a command-line interface (CLI), or all devices can be centrally managed through the Panorama centralized management system, which has a web interface very similar to the device web interface.

# Management Interfaces

The firewall supports the following management interfaces. Refer to "Supported Browsers" on page 27 for a list of supported browsers.

- **Web interface**—Configuration and monitoring over HTTP or HTTPS from a web browser.
- **CLI**—Text-based configuration and monitoring over Telnet, Secure Shell (SSH), or the console port (refer to the *PAN-OS Command Line Interface Reference Guide*).
- **Panorama**—Palo Alto Networks product that provides web-based management, reporting, and logging for multiple firewalls. The Panorama interface is similar to the device web interface, with additional management functions included. Refer to "Setting Up Panorama" on page 371 for instructions on installing Panorama and "Central Device Management Using Panorama" on page 381 for information on using Panorama.
- **Simple Network Management Protocol (SNMP)**—Palo Alto Networks products support SNMPv2c and SNMPv3, read-only access over SNMP, and support for TRAPS. Refer to "Configuring SNMP Trap Destinations" on page 75).
- **Syslog**—Provides message generation for one or more remote syslog servers (refer to "Configuring Syslog Servers" on page 76).
- **XML API**—Provides a Representational State Transfer (REST)-based interface to access device configuration, operational status, reports, and packet captures from the firewall. There is an API browser available on the firewall at *https://<firewall>/api*, where *<firewall>* is the host name or IP address of the firewall. This link provides help on the parameters required for each type of API call. An XML API usage guide is available on the DevCenter online community at *http://live.paloaltonetworks.com*.

# Chapter 2
# Getting Started

This chapter describes how to set up and start using the firewall:

- "Preparing the Firewall" in the next section
- "Setting Up the Firewall" on page 22
- "Using the Firewall Web Interface" on page 23
- "Getting Help Configuring the Firewall" on page 28

***Note:*** *Refer to "Setting Up Panorama" on page 371 for instructions on installing the Panorama centralized management system.*

## Preparing the Firewall

Perform the following tasks to prepare the firewall for setup:

1. Mount the firewall in a rack and power it up as described in the *Hardware Reference Guide*.
2. Register your firewall at *https://support.paloaltonetworks.com* to obtain the latest software and App-ID updates, and to activate support or subscriptions with the authorization codes emailed to you.
3. Obtain an IP address from your network administrator for configuring the management port on the firewall.

# Setting Up the Firewall

To perform the initial firewall setup:

1. Connect your computer to the management port (MGT) on the firewall using an RJ-45 Ethernet cable.
2. Start your computer. Assign a static IP address to your computer on the 192.168.1.0 network (for example, 192.168.1.5) with a netmask of 255.255.255.0.
3. Launch a supported web browser and enter **https://192.168.1.1**.

   The browser automatically opens the Palo Alto Networks login page.
4. Enter **admin** in both the **Name** and **Password** fields, and click **Login**. The system presents a warning that the default password should be changed. Click **OK** to continue.
5. On the **Device** tab, choose **Setup** and configure the following (for general instructions on configuring settings in the web interface, refer to "Using the Firewall Web Interface" on page 23):
   - On the **Management** tab under **Management Interface Settings**, enter the firewall's IP address, netmask, and default gateway.
   - On the **Services** tab, enter the IP address of the Domain Name System (DNS) server. Enter the IP address or host and domain name of the Network Time Protocol (NTP) server and select your time zone.
   - Click **Support** on the side menu.
     If this is the first Palo Alto Networks firewall for your company, click **Register Device** to register the firewall. (If you have already registered a firewall, you have received a user name and password.)
     Click the **Activate support using authorization codes** link and enter the authorization codes that have been emailed to you for any optional features. Use a space to separate multiple authorization codes.
6. Click **Administrators** under the **Devices** tab.
7. Click **admin**.
8. In the **New Password** and **Confirm New Password** fields, enter and confirm a case-sensitive password (up to 15 characters).
9. Click **OK** to submit the new password.
10. Commit the configuration to make these settings active. When the changes are committed, the firewall will be reachable through the IP address assigned in Step 5. For information on committing changes, refer to "Committing Changes" on page 25.

***Note:*** *The default configuration of the firewall when delivered from the factory, or after a factory reset is performed, is a virtual wire between Ethernet ports 1 and 2 with a default policy to deny all inbound traffic and allow all outbound traffic.*

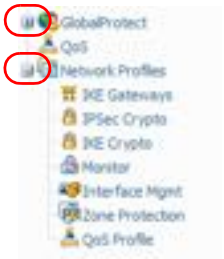
# Using the Firewall Web Interface

The following conventions apply when using the firewall interface.

- To display the menu items for a general functional category, click the tab, such as **Objects** or **Device**, near the top of the browser window.

- Click an item on the side menu to display a panel.

- To display submenu items, click the icon to the left of an item. To hide submenu items, click the icon to the left of the item.

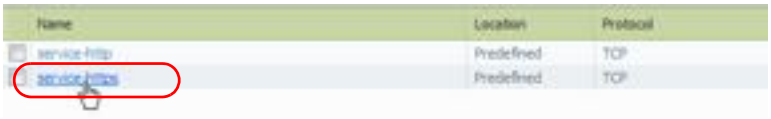


- On most configuration pages, you can click **Add** to create a new item.

- To delete one or more items, select their check boxes and click **Delete**. In most cases, the system prompts you to confirm by clicking **OK** or to cancel the deletion by clicking **Cancel**.

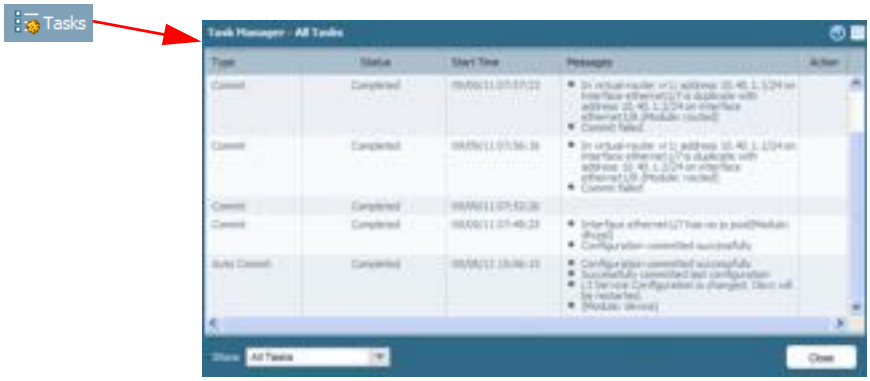
- On some configuration pages, you can select the check box for an item and click **Clone** to create a new item with the same information as the selected item.

- To modify an item, click its underlined link.



- To view help information on a page, click the **Help** icon in upper right area of the page.

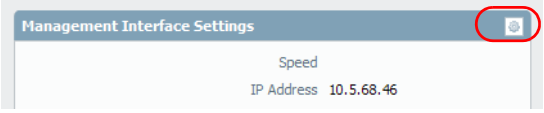
- To view the current list of tasks, click the **Tasks** icon in the lower right corner of the page. The Task Manager window opens to show the list of tasks, along with status, start times, associated messages, and actions. Use the **Show** drop-down list to filter the list of tasks.



- The web interface language is controlled by the current language of the computer that is managing the device if a specific language preference has not been defined. For example, if the computer you use to manage the firewall has a locale of Spanish, when you log in to the firewall, the web interface will be in Spanish.

  To specify a language that will always be used for a given account regardless of the locale of the computer, click the **Language** icon in the lower right corner of the page and the Language Preference window opens. Click the drop-down list to select the desired language and then click **OK** to save your change.

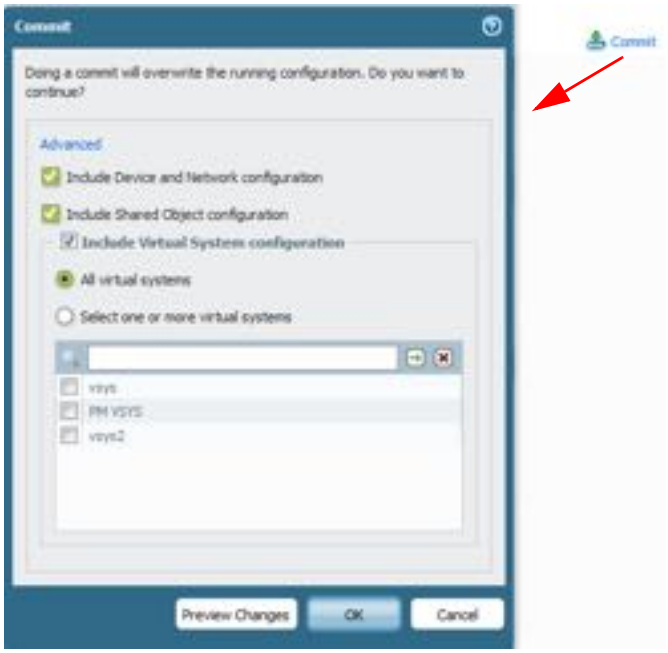
- On pages that list information you can modify (for example, the **Setup** page on the **Devices** tab), click the icon in the upper right corner of a section to edit the settings.



- After you configure settings, you must click **OK** or **Save** to store the changes. When you click **OK**, the current "candidate" configuration is updated.

## Committing Changes

Click **Commit** at the top of the web interface to open the commit dialog box.



The following options are available in the commit dialog box. Click the **Advanced** link, if needed, to display the options:

- **Include Device and Network configuration**—Include the device and network configuration changes in the commit operation.
- **Include Shared Object configuration**—(Multi-virtual system firewalls only) Include the shared object configuration changes in the commit operation.
- **Include Policy and Objects**—(Non-multi-virtual system firewalls only) Include the policy and object configuration changes in the commit operation.
- **Include virtual system configuration**—Include all virtual systems or choose **Select one or more virtual systems**.

  For more information about committing changes, refer to "Defining Operations Settings" on page 37.
- **Preview Changes**—Click this button to bring up a two-pane window that shows proposed changes in the candidate configuration compared to the current running configuration. You can choose the number of lines of context to display, or show all lines. Changes are color coded based on items that have been added, modified, or

deleted.
The **Device > Config Audit** feature performs the same function, refer to "Comparing Configuration Files" on page 49.

***Note:*** *Configuration changes that span multiple configuration areas may require a full commit. For example, if you click* ***Commit*** *and only select the* ***Include Device and Network configuration*** *option, some items that you changed in the Device tab will not commit. This includes certificates and User-ID options as well as Server Profiles used for User-ID, such as an LDAP server profile. This can also occur if you perform a partial commit after importing a configuration. To commit these types of changes, do a full commit and select both* ***Include Device and Network configuration and Include Policy*** *and* ***Object configuration****.*

## Navigating to Configuration Pages

Each configuration section in this guide shows the menu path to the configuration page. For example, to reach the **Vulnerability Protection** page, choose the **Objects** tab and then choose **Vulnerability Protection** under **Security Profiles** in the side menu. This is indicated in this guide by the following path:

▶ ***Objects > Security Profiles > Vulnerability Protection***

## Using Tables on Configuration Pages

The tables on configuration pages include sorting and column chooser options. Click a column header to sort on that column, and click again to change the sort order. Click the arrow to the right of any column and select check boxes to choose the columns to display.

## Required Fields

Required fields are shown with a light yellow background. A message indicating that the field is required appears when you hover over or click in the field entry area.

# Locking Transactions

The web interface provides support for multiple administrators by allowing an administrator to lock a current set of transactions, thereby preventing configuration changes or commit operations by another administrator until the lock is removed. The following types of locks are supported:

- **Config lock**—Blocks other administrators from making changes to the configuration. This type of lock can be set globally or for a virtual system. It can be removed only by the administrator who set it or by a superuser on the system.
- **Commit Lock**—Blocks other administrators from committing changes until all of the locks have been released. This type of lock prevents collisions that can occur when two administrators are making changes at the same time and the first administrator finishes and commits changes before the second administrator has finished. The lock is released when the current changes are committed by the administrator who applied the lock, or it can be released manually.

Any administrator can open the lock window to view the current transactions that are locked, along with a timestamp for each.

To lock a transaction, click the unlocked icon on the top bar to open the Locks dialog box. Click **Take a Lock**, select the scope of the lock from the drop-down list, and click **OK**. Add additional locks as needed, and then click **Close** to close the Lock dialog box.

The transaction is locked, and the icon on the top bar changes to a locked icon that shows the number of locked items in parentheses.

To unlock a transaction, click the locked icon on the top bar to open the Locks window. Click the icon for the lock that you want to remove, and click **Yes** to confirm. Click **Close** to close the Lock dialog box.

You can arrange to automatically acquire a commit lock by selecting the **Automatically acquire commit lock** check box in the Management area of the **Device Setup** page. Refer to "System Setup, Configuration, and License Management" on page 30.

# Supported Browsers

The following web browsers are supported for access to the firewall web interface:

- Internet Explorer 7+
- Firefox 3.6+
- Safari 5+
- Chrome 11+

# Getting Help Configuring the Firewall

Use the information in this section to obtain help on using the firewall.

## Obtaining More Information

To obtain more information about the firewall, refer to the following:

- **General information**—Go to *http://www.paloaltonetworks.com*.
- **Online help**—Click **Help** in the upper-right corner of the web interface to access the online help system.
- **Collaborative area for customer/partner interaction to share tips, scripts, and signatures**—Go to *https://live.paloaltonetworks.com/community/devcenter.*

## Technical Support

For technical support, use the following methods:

- Go to the KnowledgePoint online support community at *http://live.paloaltonetworks.com.*
- Go to *https://support.paloaltonetworks.com*.

## Chapter 3
# Device Management

This chapter describes how to perform basic system configuration and maintenance for the firewall and includes overviews of the virtual systems, high availability, and logging functions:

- "System Setup, Configuration, and License Management" in the next section
- "Comparing Configuration Files" on page 49
- "Installing a License" on page 50
- "Upgrading/Downgrading the PAN-OS Software" on page 50
- "Updating Threat and Application Definitions" on page 55
- "Administrator Roles, Profiles, and Accounts" on page 56
- "Authentication Profiles" on page 62
- "Authentication Sequence" on page 67
- "Certificate Profile" on page 89
- "Firewall Logs" on page 68
- "Configuring SNMP Trap Destinations" on page 75
- "Configuring Syslog Servers" on page 76
- "Configuring Email Notification Settings" on page 83
- "Viewing Alarms" on page 85
- "Configuring Netflow Settings" on page 85
- "Importing, Exporting and Generating Security Certificates" on page 86
- "High Availability" on page 93
- "Virtual Systems" on page 110
- "Defining Custom Response Pages" on page 115
- "Viewing Support Information" on page 117

# System Setup, Configuration, and License Management

The following sections describe how to define the network settings and manage configurations for the firewall:

- "Defining Management Settings" in the next section
- "Defining Operations Settings" on page 37
- "Defining Services Settings" on page 41
- "Defining Content ID Settings" on page 43
- "Defining Session Settings" on page 45
- "SNMP" on page 47
- "Statistics Service" on page 48
- "Installing a License" on page 50

***Note:*** *Refer to "Configuring WildFire" on page 421 for information on configuring the settings on the WildFire tab.*

## Defining Management Settings

▶ ***Device > Setup > Management***

The **Setup** page allows you to configure the firewall for management, operations, services, content identification, WildFire malware analysis and reporting, and session behavior.

If you do not want to use the management port, you can define a loopback interface and manage the firewall through the IP address of the loopback interface (refer to "Configuring Loopback Interfaces" on page 146).

Perform any of the following operations on this page:

- To change the host name or network settings, click **Edit** on the first table on the page, and specify the following information.

**Table 1. Management Settings**

| Item | Description |
|---|---|
| **General Settings** | |
| Hostname | Enter a host name (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Domain | Enter the Fully Qualified Domain Name (FQDN) of the firewall (up to 31 characters). |
| Login Banner | Enter custom text that will be displayed on the firewall login page. The text is displayed below the **Name** and **Password** fields. |

**Table 1. Management Settings (Continued)**

| Item | Description |
|---|---|
| Time Zone | Select the time zone of the firewall. |
| Locale | Select a language for PDF reports from the drop-down list. Refer to "Managing PDF Summary Reports" on page 270.<br>If you have a specific language preference set for the web interface, PDF reports will still use the language specified in this locale setting. Refer to language preference in "Using the Firewall Web Interface" on page 23. |
| Time | To set the date and time on the firewall, click **Set Time**. Enter the current date in (YYYY/MM/DD) or click the calendar icon to select a month and day. Enter the current time in 24-hour format (HH:MM:SS). You can also define an NTP server from Device > Setup > Services. |
| Serial Number | (Panorama only) Enter the serial number of the firewall. |
| Geo Location | Enter the latitude (-90.0 to 90.0) and longitude (-180.0 to 180.0) of the firewall. |
| Automatically acquire commit lock | Automatically apply a commit lock when you change the candidate configuration. For more information, refer to "Locking Transactions" on page 27. |
| Certificate Expiration Check | Instruct the firewall to create warning messages when on-box certificates near their expiration dates. |
| Multi Virtual System Capability | To enable the use of multiple virtual systems (if supported on the firewall model), click **Edit** for Multi Virtual System Capability near the top of the **Setup** page. Select the check box, and click **OK**. For more information about virtual systems, refer to "Virtual Systems" on page 110. |
| **Authentication Settings** | |
| Authentication Profile | Select the authentication profile to use for administrator access to the firewall. For instructions on configuring authentication profiles, refer to "Setting Up Authentication Profiles" on page 62. |
| Certificate Profile | Select the certificate profile to use for administrator access to the firewall. For instructions on configuring certificate profiles, refer to "Certificate Profile" on page 89. |
| Idle Timeout | Enter the timeout interval (1 - 1440 minutes). A value of 0 means that the management, web, or CLI session does not time out. |
| # Failed Attempts | Enter the number of failed login attempts that are allowed for the web interface and CLI before the account is locked. (1-10, default 0). 0 means that there is no limit. |
| Lockout Time | Enter the number of minutes that a user is locked out (0-60 minutes) if the number of failed attempts is reached. The default 0 means that there is no limit to the number of attempts. |

**Table 1. Management Settings (Continued)**

| Item | Description |
|---|---|
| **Panorama Settings** | |
| Panorama Servers | Enter the IP address of Panorama, the Palo Alto Networks centralized management system (if any). The server address is required to manage the device using Panorama. If Panorama is in an HA configuration, enter the secondary Panorama server IP address in the second Panorama Servers field.<br>***Note:*** *To remove any policies that Panorama propagates to managed firewalls, click the* ***Disable Panorama Policy and Objects*** *link. To keep a local copy of the policies and objects to your device before removing them from Panorama, click the* ***Import Panorama Policy and Objects before disabling*** *check box in the dialog box that opens. Click* ***OK****.*<br>***Note:*** *When you select the import check box, the policies and objects will be copied to the current candidate configuration. If you commit this configuration, the policies and objects will become part of your configuration and will no longer be managed by Panorama.*<br>To remove device and network templates, click the **Disable Device and Network Template** link. To keep a local copy of the device and network templates, click the **Import Device and Network Templates before disabling** check box in the dialog box that opens and click **OK**. When you select the import check box, the configuration defined in the device and network templates will be copied to the current candidate configuration. If you commit that configuration, these items will become part of your configuration and will no longer be managed by Panorama. Templates will no longer be accepted on the device until you click **Enable Device and Network Templates**. |
| Receive Timeout for connection to device/ Panorama | • Device—Enter the timeout for receiving TCP messages from all managed devices (1-240 seconds, default 240).<br>• Panorama—Enter the timeout for receiving TCP messages from Panorama (1-240 seconds, default 240). |
| Send Timeout for connection to device/ Panorama | • Device—Enter the timeout for receiving TCP messages from all managed devices (1-240 seconds, default 240).<br>• Panorama—Enter the timeout for receiving TCP messages from Panorama (1-240 seconds, default 240). |
| Retry Count for SSL send to device/ Panorama | • Device—Enter the number of retries for attempts to send Secure Socket Layer (SSL) messages to managed devices (1-64, default 25).<br>• Panorama—Enter the number of retries for attempts to send Secure Socket Layer (SSL) messages to Panorama (1-64, default 25). |
| Share Unused Address and Service Objects with Devices (Panorama only) | Select this check box to share all Panorama shared objects and device group specific objects with managed devices. When unchecked, Panorama policies are checked for references to address, address group, service, and service group objects and any objects that are not referenced will not be shared. This option will ensure that only necessary objects are being sent to managed devices in order to reduce the total object count. |

**Table 1. Management Settings (Continued)**

| Item | Description |
|---|---|
| Shared Objects Take Precedence (Panorama only) | Select the check box to specify that shared objects take precedence over device group objects. This option is a system-wide setting and is off by default. When this option is off, device groups override corresponding objects of the same name. If the option is selected, device group objects cannot override corresponding objects of the same name from a shared location and any device group object with the same name as a shared object will be discarded. |
| **Management Interface Settings** | |
| MGT Interface Speed | Configure a data rate and duplex option for the management interface. The choices include 10Mbps, 100Mbps, and 1Gbps at full or half duplex. Use the default auto-negotiate setting to have the firewall determine the interface speed.<br>This setting should match the port settings on the neighboring network equipment. |
| MGT Interface IP Address | Enter the IP address of the management port. Alternatively, you can use the IP address of a loopback interface for device management. This address is used as the source address for remote logging. |
| Netmask | Enter the network mask for the IP address, such as "255.255.255.0". |
| Default Gateway | Enter the IP address of the default router (must be on the same subnet as the management port). |
| MGT Interface IPv6 Address | (Optional) Enter the IPv6 address of the management port. An IPv6 prefix length is required to indicate the netmask, for example 2001:400:f00::1/64. |
| Default IPv6 Gateway | Enter the IPv6 address of the default router (must be on the same subnet as the management port), if you assigned an IPv6 address to the management port. |
| MGT Interface Services | Select the services enabled on the specified management interface address: HTTP, HTTPS, Telnet, Secure Shell (SSH), and/or ping. |
| Permitted IPs | Enter the list of IP addresses from which firewall management is allowed. When using this option for Panorama, you will need to make sure that each managed device has it's IP address added, otherwise it will not be able to connect send logs to Panorama or receive configuration updates. |

**Table 1. Management Settings (Continued)**

| Item | Description |
|---|---|
| **Logging and Reporting Settings** | |
| Log Storage | Specify the percentage of space allocated to each log type on the hard disk.<br>When you change a percent value, the associated disk allocation changes automatically. If the total of all the values exceeds 100%, a message appears on the page in red, and an error message is presented when you attempt to save the settings. If this occurs, readjust the percentages so the total is within the 100% limit.<br>Click **OK** to save settings and **Restore Defaults** to restore all of the default settings.<br>***Note:*** *When a log reaches its maximum size, it starts to be overwritten beginning with the oldest entries. If you resize an existing log to be smaller than its current size, the firewall starts immediately to cut down the log when you commit the changes, with the oldest logs removed first.* |
| Max Rows in User Activity Report | Enter the maximum number of rows that is supported for the detailed user activity reports (1-1048576, default 65535). |
| Max Rows in CSV Export | Enter the maximum number of rows that will appear in the CSV reports generated from the **Export to CSV** icon in the traffic logs view (range 1-1048576, default 65535). |
| Number of Versions for Config Audit | Enter the number of configuration audit versions to save before discarding the oldest ones (default 100). |
| Number of Versions for Config Backups | (Panorama only) Enter the number of configuration backups to save before discarding the oldest ones (default 100). |
| Average Browse Time (sec) | Configure this variable to adjust how browse time is calculated in the "User Activity Report".<br>The calculation will ignore sites categorized as web advertisements and content delivery networks. The browse time calculation is based on container pages logged in the URL filtering logs. Container pages are used as the basis for this calculation because many sites load content from external sites that should not be considered. For more information on the container page, refer to "Container Pages" on page 45.<br>The average browse time setting is the average time that the admin thinks it should take a user to browse a web page. Any request made after the average browse time has elapsed will be considered a new browsing activity. The calculation will ignore any new web pages that are loaded between the time of the first request (start time) and the average browse time. This behavior was designed to exclude any external sites that are loaded within the web page of interest.<br>Example: If the average browse time setting is 2 minutes and a user opens a web page and views that page for 5 minutes, the browse time for that page will still be 2 minutes. This is done because there is no way to determine how long a user views a given page.<br>(Range 0-300 seconds, default 60 seconds) |

**Table 1. Management Settings (Continued)**

| Item | Description |
|---|---|
| Page Load Threshold (sec) | Configure this variable to adjust how browse time is calculated in the "User Activity Report".<br>This option allows you to adjust the assumed time it takes for page elements to load on the page. Any request that occurs between the first page load and the page load threshold is assumed to be elements of the page. Any requests that occur outside of the page load threshold is assumed to be the user clicking a link within the page.<br>(Range 0-60 seconds, default 20 seconds) |
| Send Hostname In Syslog | Select the check box to send the device hostname field in syslog messages.<br>When this option is set, syslog messages will contain the hostname of the firewall device in their header. |
| Stop Traffic when LogDb full | Select the check box if you want traffic through the firewall to stop when the log database is full (default off). |
| Enable Log on High DP Load | Select this check box if you would like a system log entry generated if the device is under severe load (default off). |
| Buffered log forwarding from device (option in the **Panorama > Set up** tab) | Allows the firewall to buffer log entries on the device's hard disk (local storage) when it loses connectivity to Panorama. When the connection to Panorama is restored, the log entries are forwarded to Panorama; the disk space available for buffering depends on the log storage quota for the platform and the volume of logs that are pending roll over. If the available space is consumed, the oldest entries are deleted to allow logging of new events.<br>Enabled by default. |
| Get Only New Logs on Convert to Primary (option in the **Panorama > Set up** tab) | This option is only applicable when Panorama writes logs to a Network File Share (NFS). With NFS logging, only the *primary* Panorama is mounted to the NFS. Therefore, the devices send logs to the *active primary* Panorama only.<br>This option allows an administrator to configure the managed devices to only send newly generated logs to Panorama when an HA failover occurs and the secondary Panorama resumes logging to the NFS (after it is promoted as primary).<br>This behavior is typically enabled to prevent the devices from sending a large volume of buffered logs when connectivity to Panorama is restored after a significant period of time. |
| Only Active Primary Logs to Local Disk (in Panorama > Set up tab only) | Allows you to configure only the active primary Panorama to save logs to the local disk.<br>This option is valid for a Panorama virtual machine with a virtual disk and to the M-100 appliance in Panorama mode. |
| **Minimum Password Complexity** | |
| Enabled | Enable minimum password requirements for local accounts. With this feature, you can ensure that local administrator accounts on the firewall will adhere to a defined set of password requirements.<br>You can also create a password profile with a subset of these options that will override these settings and can be applied to specific accounts. For more information, refer to "Defining Password Profiles" on page 59 and refer to "Username and Password Requirements" on page 57 for information on valid characters that can be used for accounts. |

**Table 1. Management Settings (Continued)**

| Item | Description |
|---|---|
| | ***Note:*** *The maximum password length that can be entered is 31 characters. When setting requirements, make sure you do not create a combination that will not be accepted. Example, you would not be able to set a requirement of 10 uppercase, 10 lower case, 10 numbers, and 10 special characters since that would exceed the maximum length of 31.*<br><br>**Note:** *If you have High Availability (HA) configured, always use the primary device when configuring password complexity options and commit soon after making changes.* |
| Minimum Length | Require minimum length from 1-15 characters. |
| Minimum Uppercase Letters | Require a minimum number of uppercase letters from 0-15 characters. |
| Minimum Lowercase Letters | Require a minimum number of lowercase letters from 0-15 characters. |
| Minimum Numeric Letters | Require a minimum number of numeric letters from 0-15 numbers. |
| Minimum Special Characters | Require a minimum number of special characters (non-alphanumeric) from 0-15 characters. |
| Block Repeated Characters | Do no allow repeated characters based on the specified value. Example, if the value is set to 4, the password test2222 would not be accepted, but test222 would be accepted (range 2-15). |
| Block Username Inclusion (including reversed) | Select this check box to prevent the account username (or reversed version of the name) from being used in the password. |
| New Password Differs By Characters | When administrators change their passwords, the characters must differ by the specified value. |
| Require Password Change on First Login | Select this check box to prompt the administrators to change their passwords the first time they log in to the device. |
| Prevent Password Reuse Limit | Require that a previous password is not reused based on the specified count. Example, if the value is set to 4, you could not reuse the any of your last 4 passwords (range 0-50). |
| Block Password Change Period (days) | User cannot change their passwords until the specified number of days has been reached (range 0-365 days). |
| Required Password Change Period (days) | Require that administrators change their password on a regular basis specified a by the number of days set, ranging from 0-365 days. Example, if the value is set to 90, administrators will be prompted to change their password every 90 days.<br>You can also set an expiration warning from 0-30 days and specify a grace period. |
| Expiration Warning Period (days) | If a required password change period is set, this setting can be used to prompt the user to change their password at each log in as the forced password change date approaches (range 0-30 days). |

**Table 1. Management Settings (Continued)**

| Item | Description |
|---|---|
| Allowed expired admin login (count) | Allow the administrator to log in the specified number of times after the account has expired. Example, if the value is set to 3 and their account has expired, they can log in 3 more times before their account is locked out (range 0-3 logins). |
| Post Expiration Grace Period (days) | Allow the administrator to log in the specified number of days after the account has expired (range 0-30 days). |

# Defining Operations Settings

▶ *Device > Setup > Operations*

When you change a configuration setting and click **OK**, the current "candidate" configuration is updated, not the active configuration. Clicking **Commit** at the top of the page applies the candidate configuration to the active configuration, which activates all configuration changes since the last commit.

This method allows you to review the configuration before activating it. Activating multiple changes simultaneously helps avoid invalid configuration states that can occur when changes are applied in real-time.

You can save and roll back (restore) the candidate configuration as often as needed and also load, validate, import, and export configurations. Pressing **Save** creates a copy of the current candidate configuration, whereas choosing **Commit** updates the active configuration with the contents of the candidate configuration.

***Note:*** *It is a good idea to periodically save the configuration settings you have entered by clicking the* ***Save*** *link in the upper-right corner of the screen.*

To manage configurations, select the appropriate configuration management functions, as described in the following table.

**Table 2. Configuration Management Functions**

| Function | Description |
|---|---|
| **Configuration Management** | |
| Validate candidate config | Checks the candidate configuration for errors. |
| Revert to last saved config | Restores the last saved candidate configuration from the local drive. The current candidate configuration is overwritten. An error occurs if the candidate configuration has not been saved. |
| Revert to running config | Restores the last running configuration. The current running configuration is overridden. |
| Save named configuration snapshot | Saves the candidate configuration to a file. Enter a file name or select an existing file to be overwritten. Note that the current active configuration file (*running-config.xml*) cannot be overwritten. |

**Table 2. Configuration Management Functions (Continued)**

| Function | Description |
|---|---|
| Save candidate config | Saves the candidate configuration in flash memory (same as clicking **Save** at the top of the page). |
| Load named configuration snapshot | Loads a candidate configuration from the active configuration (*running-config.xml*) or from a previously imported or saved configuration. Select the configuration file to be loaded. The current candidate configuration is overwritten. |
| Load configuration version | Loads a specified version of the configuration. |
| Export named configuration snapshot | Exports the active configuration (*running-config.xml*) or a previously saved or imported configuration. Select the configuration file to be exported. You can open the file and/or save it in any network location. |
| Export configuration version | Exports a specified version of the configuration. |
| Export device state | This feature is used to export the configuration and dynamic information from a firewall that is configured as a GlobalProtect Portal with the large scale VPN feature enabled. If the Portal experiences a failure, the export file can be imported to restore the Portal's configuration and dynamic information.<br>The export contains a list of all satellite devices managed by the Portal, the running configuration at the time of the export, and all certificate information (Root CA, Server, and Satellite certificates).<br>**Important:** You must manually run the device state export or create a scheduled XML API script to export the file to a remote server. This should be done on a regular basis since satellite certificates may change often.<br>To create the device state file from the CLI, from configuration mode run `save device state`.<br>The file will be named device_state_cfg.tgz and is stored in /opt/pancfg/mgmt/device-state. The operational command to export the device state file is `scp export device-state` (you can also use `tftp export device-state`).<br>For information on using the XML API, refer to the document "PAN-OS XML-Based Rest API Usage Guide" at *https://live.paloaltonetworks.com/community/documentation*.<br>Refer to "GlobalProtect Large Scale VPN Deployment" on page 323. |
| Import named config snapshot | Imports a configuration file from any network location. Click **Browse** and select the configuration file to be imported. |
| Import device state | Import the device state information that was exported using the Export device state option. This includes the current running config, Panorama templates, and shared policies. If the device is a Global Protect Portal, the export includes the Certificate Authority (CA) information and the list of satellite devices and their authentication information. |
| **Device Operations** | |

**Table 2. Configuration Management Functions (Continued)**

| Function | Description |
|---|---|
| Reboot Device | To restart the firewall, click **Reboot Device**. You are logged out and the PAN-OS software and active configuration are reloaded. Existing sessions will also be closed and logged and a system log entry will be created that will show the administrator name that initiated the shutdown. Any configuration changes that have not been saved or committed are lost (refer to "Defining Operations Settings" on page 37).<br>***Note:*** *If the web interface is not available, use the CLI command* `request restart system`*. Refer to the PAN-OS Command Line Interface Reference Guide for details.* |
| Shutdown Device | To perform a graceful shutdown of the firewall, click **Shutdown Device** and then click **Yes** on the confirmation prompt. Any configuration changes that have not been saved or committed are lost. All administrators will be logged off and the following processes will occur:<br>• All login sessions will be logged off.<br>• Interfaces will be disabled.<br>• All system processes will be stopped.<br>• Existing sessions will be closed and logged.<br>• System Logs will be created that will show the administrator name who initiated the shutdown. If this log entry cannot be written, a warning will appear and the system will not shutdown.<br>• Disk drives will be cleanly unmounted and the device will powered off.<br>You need to unplug the power source and plug it back in before you can power on the device.<br>***Note:*** *If the web interface is not available, use the CLI command* `request shutdown system`*. Refer to the PAN-OS Command Line Interface Reference Guide for details.* |
| Restart Data Plane | To restart the data functions of the firewall without rebooting, click **Restart Dataplane**. *This option is not available on the PA-200.*<br>***Note:*** *If the web interface is not available, use the CLI command* `request restart dataplane`*. Refer to the PAN-OS Command Line Interface Reference Guide for details.* |

**Table 2. Configuration Management Functions (Continued)**

| Function | Description |
|---|---|
| **Miscellaneous** | |
| Custom Logos | Use this option to customize any of the following:<br>• Login screen background image<br>• Main UI (User Interface) header image<br>• PDF report title page image. Refer to "Managing PDF Summary Reports" on page 270.<br>• PDF report footer image<br>Click to upload an image file, to preview, or to remove a previously-uploaded image.<br>Note the following:<br>• Supported file types are png, gif, and jpg.<br>***Note:*** *Image files that contain an alpha channel are not supported and when used in PDF reports, the reports will not be generated properly. You may need to contact the illustrator who created the image to remove alpha channels in the image or make sure the graphics software you are using does not save files with the alpha channel feature.*<br>• To return to the default logo, remove your entry and commit.<br>• The maximum image size for any logo image is 128 KB.<br>• For the login screen and main user interface options, when you click , the image is shown as it will be displayed. If necessary, the image is cropped to fit. For the PDF reports, the images are auto-resized to fit without cropping. In all cases, the preview shows the recommended image dimensions.<br>For information on generating PDF reports, refer to "Managing PDF Summary Reports" on page 270. |
| SNMP Setup | Specify SNMP parameters. Refer to "SNMP" on page 47. |
| Statistics Service Setup | Specify settings for the statistics service. Refer to "Statistics Service" on page 48. |

***Note:*** *When you click* ***Commit*** *or enter a* ***commit*** *CLI command, all changes made through the web interface and the CLI since the last commit are activated. To avoid possible conflicts, use the transaction locking functions as described in "Locking Transactions" on page 27.*

# Defining Services Settings

▶ *Device > Setup > Services*

Use the **Services** tab to define settings for Domain Name System (DNS), Network Time Protocol (NTP), update servers, proxy servers, and service route configuration.

**Table 3. Services Settings**

| Function | Description |
|---|---|
| DNS | Select the type of DNS service. This setting is used for all DNS queries initiated by the firewall in support of FQDN address objects, logging, and device management. Options include:<br>• Primary and secondary DNS servers for domain name resolution<br>• DNS proxy that has been configured on the firewall |
| Primary DNS Server | Enter the IP address of the primary DNS server. The server is used for DNS queries from the firewall, for example, to find the update server, to resolve DNS entries in logs, or for FDQN-based address objects. |
| Secondary DNS Server | Enter the IP address of a secondary DNS server to use if the primary server is unavailable (optional). |
| Primary NTP Server | Enter the IP address or host name of the primary NTP server, if any. If you do not use NTP servers, you can set the device time manually. |
| Secondary NTP Server | Enter the IP address or host name of secondary NTP servers to use if the primary server is unavailable (optional). |
| Update Server | This setting represents the IP address or host name of the server used to download updates from Palo Alto Networks. The current value is **updates.paloaltonetworks.com**. Do not change the server name unless instructed by technical support. |
| **Proxy Server** | |
| Server | If the device needs to use a proxy server to reach Palo Alto Networks update services, enter the IP address or host name of the server. |
| Port | Enter the port for the proxy server. |
| User | Enter the user name to access the server. |
| Password/Confirm Password | Enter and confirm the password for the user to access the proxy server. |

**Table 3. Services Settings (Continued)**

| Function | Description |
|---|---|
| Service Route Configuration | Specify how the firewall will communicate with other servers/devices for services communication, such as DNS, Email, Palo Alto Updates, and NTP.<br>You can select "Use Management Interface for all" to use the built-in management port (MGT) for all communications, or you can define a specific source IP address to use different interfaces for granular control of each service. For example, you could configure a specific source IP of an interface for all email communication between the firewall and an email server and use a different source IP/interface for Palo Alto Updates.<br>Click **Service Route Configuration** and configure the following:<br>• **Use Management Interface for all**—This option will force all firewall service communications with external servers through the management interface (MGT). If this option is selected, you will need to configure the MGT interface to allow communications between the firewall and the servers/devices that provide services. To configure the MGT interface, navigate to Device > Setup > Management tab and edit "Management Interface Settings".<br>• **Select**—Choose this option to configure granular control for service communication. A table will appear that shows a list of available services and a drop-down to select a source address. Select the desired service and then select the source from the **Source Address** drop-down list. The "Source Address" is the IP address assigned to an interface that will be the source for the service traffic. You do not have to define the destination address since the destination is configured when configuring the given service. For example, when you define your DNS servers from the Device > Setup > Services tab and **Services**, that will set the destination for DNS queries. |

**Table 3. Services Settings (Continued)**

| Function | Description |
|---|---|
| Service Route Configuration *(Continued)* | • **Destination** and **Source Address** fields—If a service that you want to route is not listed in the **Service** column, you can use the Destination and Source Address fields to define routes that will be used by other services. Services not listed include items such as Kerberos, LDAP, and Panorama log collector communications. You do not need to enter the subnet for the destination address.<br>In multi-tenant environments, destination IP-based service routes will be required where common services require different source address. For example, if two tenants need to use RADIUS.<br>It is important that routing and policies are setup properly for the interface that will be used to route the service. For example, if you want to route Kerberos authentication requests on an interface other than the MGT port, you need to configure the Destination and Source Address in the right section of the Service Route Configuration window since Kerberos is not listed in the default Service column. As an example, you could have a source IP address 192.168.2.1 on Ethernet1/3 and then a destination for a Kerberos server of 10.0.0.240. You will need to add Ethernet1/3 to an existing virtual router with a default route, or you can create a new virtual router from Network > Virtual Routers and add static routes as needed. This will ensure that all traffic on the interface will be routed through the virtual router to reach the appropriate destinations. In this case, the destination address is 10.0.0.240 and Ethernet1/3 interface has the source IP 192.168.2.1/24.<br>The CLI output for the Destination and Source Address would look like the following:<br>`PA-200-Test# show route`<br>`destination {`<br>`10.0.0.240 {`<br>`source address 192.168.2.1/24`<br>`}`<br>With this configuration, all traffic on interface Ethernet1/3 will use the default route defined in the virtual router and will be sent to 10.0.0.240. |

# Defining Content ID Settings

▶ ***Device > Setup > Content-ID***

Use the **Content-ID** tab to define settings for URL filtering, data protection, and container pages.

**Table 4. Content ID Settings**

| Function | Description |
|---|---|
| **URL Filtering** | |

**Table 4. Content ID Settings (Continued)**

| Function | Description |
|---|---|
| Dynamic URL Cache Timeout | Click **Edit** and enter the timeout (in hours). This value is used in dynamic URL filtering to determine the length of time an entry remains in the cache after it is returned from the URL filtering service. This option is applicable to URL filtering using the BrightCloud database only. For information on URL filtering, refer to "URL Filtering Profiles" on page 217. |
| URL Continue Timeout | Specify the interval following a user's "continue" action before the user must press continue again for URLs in the same category (range 1 - 86400 minutes, default 15 minutes). |
| URL Admin Override Timeout | Specify the interval after the user enters the admin override password before the user must re-enter the admin override password for URLs in the same category (range 1 - 86400 minutes, default 900 minutes). |
| URL Admin Lockout Timeout | Specify the period of time that a user is locked out from attempting to use the URL Admin Override password following three unsuccessful attempts (1 - 86400 minutes, default 1800 minutes). |
| x-forwarded-for | Include the X-Forwarded-For header that includes the source IP address. When this option is selected, the firewall examines the HTTP headers for the X-Forwarded-For header, which a proxy can use to store the original user's source IP address.<br>The system takes the value and places **Src: x.x.x.x** into the Source User field of the URL logs (where *x.x.x.x* is the IP address that is read from the header). |
| Strip-x-forwarded-for | Remove the X-Forwarded-For header that includes the source IP address. When this option is selected, the firewall zeros out the header value before forwarding the request, and the forwarded packets do not contain internal source IP information. |
| Allow Forwarding of Decrypted Content | Select the check box to allows the firewall to forward decrypted content to an outside service. For example, when this option is set the firewall can send decrypted content to WildFire for analysis. For multi-VSYS configurations, this option is per VSYS. |
| **URL Admin Override** | |
| Settings for URL Admin Override | Specify the settings that are used when a page is blocked by the URL filtering profile and the **Override** action is specified. Refer to "URL Filtering Profiles" on page 217.<br>Click **Add** and configure the following settings for each virtual system that you want to configure for URL admin override.<br>• **Location**—Select the virtual system from the drop-down list (multi-VSYS devices only).<br>• **Password/Confirm Password**—Enter the password that the user must enter to override the block page.<br>• **Server Certificate**—Select the server certificate to be used with SSL communications when redirecting through the specified server.<br>• **Mode**—Determines whether the block page is delivered transparently (it appears to originate at the blocked website) or redirected to the user to the specified server. If you choose **Redirect**, enter the IP address for redirection.<br>Click ☒ to delete an entry. |

**Table 4. Content ID Settings (Continued)**

| Function | Description |
|---|---|
| Manage Data Protection | Add additional protection for access to logs that may contain sensitive information, such as credit card numbers or social security numbers.<br>Click **Manage Data Protection** and configure the following:<br>• To set a new password if one has not already been set, click **Set Password**. Enter and confirm the password.<br>• To change the password, click **Change Password**. Enter the old password, and enter and confirm the new password.<br>• To delete the password and the data that has been protected, click **Delete Password**. |
| Container Pages | Use these settings to specify the types of URLs that the firewall will track or log based on content type, such as application/pdf, application/soap+xml, application/xhtml+, text/html, text/plain, and text/xml. Container pages are set per virtual system, which you select from the **Location** drop-down list. If a virtual system does not have an explicit container page defined, the default content types are used.<br>Click **Add** and enter or select a content type.<br>Adding new content types for a virtual system overrides the default list of content types. If there are no content types associated with a virtual system, the default list of content types is used. |

# Defining Session Settings

▶ *Device > Setup > Session*

The **Session** tab allows you to configure session age-out times and global session-related settings such as firewalling IPv6 traffic and rematching security policy to existing sessions when the policy changes.

**Table 5. Session Settings**

| Field | Description |
|---|---|
| **Session Settings** | |
| Rematch Sessions | Click **Edit** and select the check box **Rematch all sessions on config policy change**.<br>For example, assume that Telnet was previously allowed and then changed to **Deny** in the last commit. The default behavior is for any Telnet sessions that were started before the commit to be rematched and blocked. |
| ICMPv6 Token Bucket Size | Enter the bucket size for rate limiting of ICMPv6 error messages. The token bucket size is a parameter of the token bucket algorithm that controls how bursty the ICMPv6 error packets can be (range 10-65535 packets, default 100). |
| ICMPv6 Error Packet Rate | Enter the average number of ICMPv6 error packets per second allowed globally (range 10-65535 packets/sec, default 100). This value applies to all interfaces. |
| Jumbo Frame<br>Jumbo Frame MTU | Select to enable jumbo frame support. The Default value for Jumbo frames is 9192. (range 512 - 9216 bytes). Refer to the spec sheet for your firewall model, available at *http://www.paloaltonetworks.com*. |

**Table 5. Session Settings (Continued)**

| Field | Description |
|---|---|
| Enable IPv6 Firewalling | To enable firewall capabilities for IPv6, click **Edit** and select the **IPv6 Firewalling** check box.<br>All IPv6-based configurations are ignored if IPv6 is not enabled. |
| NAT64 IPv6 Minimum Network MTU | Allows you to change the global MTU setting for IPv6 translated traffic (default 1280). The default is based on the standard minimum MTU for IPv6 traffic. |
| Accelerated Aging | Allows for the accelerated aging-out of idle sessions.<br>Select the check box to enable accelerated aging and specify the threshold (%) and scaling factor.<br>When the session table reaches the **Accelerated Aging Threshold** (% full), the **Accelerated Aging Scaling Factor** is applied to the aging calculations for all sessions. The session's idle time is calculated as the actual idle time multiplied by the scaling factor. For example, if a scaling factor of 10 is used, a session that would normally time out after 3600 seconds would instead time out 10 times faster, so it would time out in 360 seconds. |
| **Session Timeouts** | |
| Timeouts | Specify timeouts in seconds for each of the categories. Ranges and defaults are listed. |
| **Session Features** | |
| Decryption Certificate Revocation Settings | Select to configure the certificate management options for the firewall. |
| Enable | Select the check box to use Certificate Revocation Lists (CRL) to check the validity of SSL certificates.<br>Each trusted certificate authority (CA) maintains CRL to determine if an SSL certificate is valid (not revoked) for SSL decryption. The Online Certificate Status Protocol (OCSP) can also be used to dynamically check the revocation status of a certificate. For more information on SSL decryption, refer to "Decryption Policies" on page 202. |
| Receive Timeout | Specify the interval after which the CRL request times out and the status is determined to be unknown (1-60 seconds). |
| Enable OCSP | Select the check box to use OCSP to check the validity of SSL certificates. |
| Receive Timeout | Specify the interval after which the OCSP requests times out and the status is determined to be unknown (1-60 seconds). |
| Block Session With Unknown Certificate Status | Select the check box if you want to block certificates that cannot be validated. |
| Block Session On Certificate Status Check Timeout | Select the check box if you want to block certificates when the request for certificate information times out. |
| Certificate Status Timeout | Specify the interval after which certificate status requests time out (1-60 seconds). |

# SNMP

▶ *Device > Setup > Operations*

Use this page to define access to SNMP Management Information Bases (MIBs) for SNMPv2c and SNMPv3. Click **SNMP Setup** on the **Setup** page, and specify the following settings.

A MIB module defines all SNMP traps generated by the system. Each event log in the system is defined as an independent SNMP trap with an Object ID (OID) of its own, and individual fields in an event log are defined as a variable binding (varbind) list.

**Table 6. SNMP Setup**

| Field | Description |
|---|---|
| Physical Location | Specify the physical location of the firewall. |
| Contact | Enter the name or email address of the person responsible for maintaining the firewall. This setting is reported in the standard system information MIB. |
| Use Specific Trap Definitions | Select the check box to use a unique OID for each SNMP trap based on the event type (default is selected). |
| Version | Select the SNMP version (V2c or V3). This setting controls access to the MIB information. By default, V2c is selected with the "public" community string.<br>For V2c, configure the following setting:<br>• **SNMP Community String**—Enter the SNMP community string for firewall access (default **public**).<br><br>For V3, configure the following settings:<br>• **Views**—Click **Add** and configure the following settings:<br>– **Name**—Specify a name for a group of views.<br>– **View**—Specify a name for a view.<br>– **OID**—Specify the object identifier (OID) (for example, 1.2.3.4).<br>– **Option**—Choose whether the OID is to be included or excluded from the view.<br>– **Mask**—Specify a mask value for a filter on the OID in hexadecimal format (for example, 0xf0).<br>• **Users**—Click **Add** and configure the following settings:<br>– **Users**—Specify a user name.<br>– **View**—Specify the group of views for the user.<br>– **Auth Password**—Specify the user's authentication password (minimum 8 characters, maximum of 256 characters, and no character restrictions). All characters allowed). Only Secure Hash Algorithm (SHA) is supported.<br>– **Priv Password**—Specify the user's encryption password (minimum 8 characters, maximum of 256 characters, and no character restrictions). Only Advanced Encryption Standard (AES) is supported. |

# Statistics Service

▶ *Device > Setup > Operations*

The **Statistics Service** feature allows the firewall to send anonymous application, threat, and crash information to the Palo Alto Networks research team. The information collected enables the research team to continually improve the effectiveness of Palo Alto Networks products based on real-world information. This service is disabled by default and once enabled, information will be uploaded every 4 hours.

You can allow the firewall to send any of the following types of information:

- Application and Threat Reports
- Unknown Application Reports
- URL Reports
- Device traces for crashes

To view a sample of the content for a statistical report to be sent, click the report icon . The **Report Sample** tab opens to display the report code. To view a report, click the check box next to the desired report, then click the **Report Sample** tab.

# Comparing Configuration Files

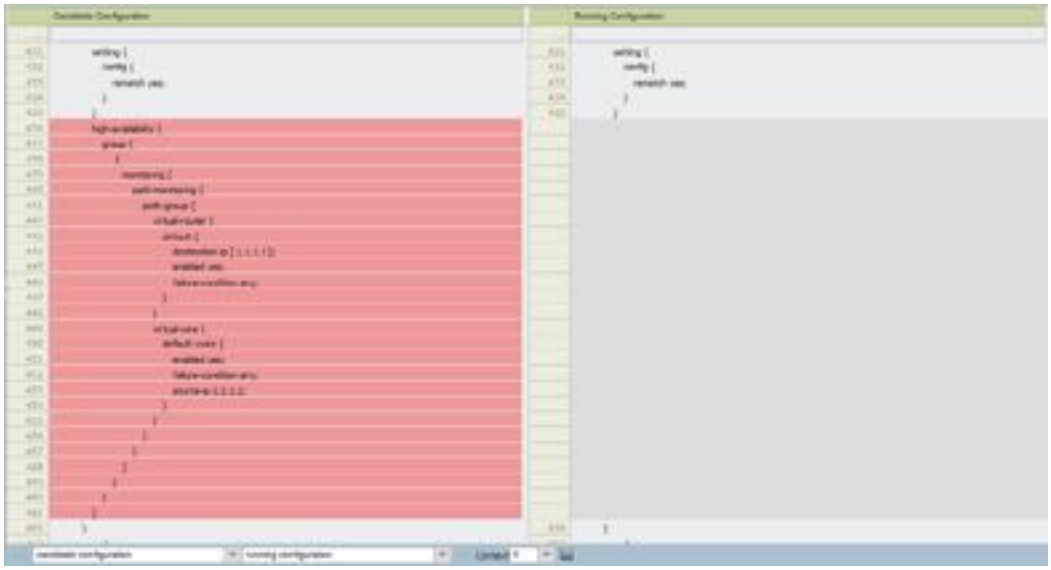
▶*Device > Config Audit*

You can view and compare configuration files by using the **Config Audit** page. From the drop-down lists, select the configurations to compare. Select the number of lines that you want to include for context, and click **Go**.

The system presents the configurations and highlights the differences, as in the following figure.

The page also includes << and >> buttons adjacent to the drop-down lists, which are enabled when comparing two consecutive configuration versions. Click << to change the configurations being compared to the previous set of stored configurations, and click to >> to change the configurations being compared to the next set of stored configurations.

**Figure 1. Configuration Comparison**



Panorama automatically saves all of the configuration files that are committed on each managed firewall, whether the changes are made through the Panorama interface or locally on the firewall.

# Installing a License

▶ *Device > Licenses*

When you purchase a subscription from Palo Alto Networks, you receive an authorization code to activate one or more license keys.

To activate a URL filtering license, you must install the license, download the database, and click **Activate**.

The following functions are available on the **Licenses** page:

- To enable licenses for URL filtering, click **Activate**. If you are using PAN-DB for URL Filtering, you will need to click **Download** to retrieve the initial seed database first and then click Activate. You can also run the CLI request url-filtering download paloaltonetworks region <region name>.
- To enable purchased subscriptions that require an authorization code and have been activated on the support portal, click **Retrieve license keys from license server**.
- To enable purchased subscriptions that require an authorization code and have not been previously activated on the support portal, click **Activate feature using authorization code**. Enter your authorization code, and click **OK**.
- If the firewall does not have connectivity to the license server and you want to upload license keys manually, follow these steps:
  a. Obtain a file of license keys from *http://support.paloaltonetworks.com*.
  b. Save the license key file locally.
  c. Click **Manually upload license key**, click **Browse** and select the file, and click **OK**.

### Important items to consider when installing a license

If you are unable to activate the URL filter using the web interface, CLI commands are available. Refer to the *PAN-OS Command Line Interface Reference Guide* for more information.

# Upgrading/Downgrading the PAN-OS Software

▶ *Device > Software*

To upgrade to a new release of the PAN-OS software, you can view the latest versions of the PAN-OS software available from Palo Alto Networks, read the release notes for each version, and then select the release you want to download and install (a support license is required).

Perform any of the following functions on the **Software** page:

- Click **Check Now** to retrieve the latest software releases available from Palo Alto Networks.
- Click **Release Notes** to view a description of the changes in a release and to view the migration path to install the software.
  You cannot skip a feature release and must have a base image downloaded before upgrading from one feature release to a maintenance release in a higher feature release. This is due to the fact that the maintenance release does not contain the full software

build, only changes made since the base image release, so the base image is needed for the upgrade. For example, if you upgrade from 4.0.12 to 4.1.7, you need to download the 4.1.0 base image (not install), so the 4.1.7 maintenance release upgrade can access the 4.1.0 base image files. If you want to upgrade to from one release to two higher feature releases, you need to upgrade to each feature release. For example, if you want to upgrade from 4.0 to 5.0, you have to upgrade from 4.0 to 4.1, then 4.1 to 5.0.
You can delete the base image files when you complete the upgrade, but that is not recommended since the base image would be needed when you upgrade to the next maintenance release. You would only want to delete the base image for older releases that will not need upgrading. For example, if you are running 4.1, you probably do not need the base images for 3.1 and 4.0 unless you plan on downgrading to those versions.

- Click **Download** to install a new release from the download site. When the download is complete, a checkmark is displayed in the **Downloaded** column. To install a downloaded release, click **Install** next to the release.

  During installation, you are asked whether to reboot when installation is complete. When the installation is complete, you will be logged out while the firewall is restarted. The firewall will be rebooted, if that option was selected.

  When upgrading to a feature release (where the first or second digit in the PAN-OS version changes, e.g. 4.0 to 4.1. or 4.1 to 5.0), you will see a message when you click install that indicates that you are about to perform a feature release upgrade. You should make sure you back up your current configuration since a feature release may migrate certain configurations to accommodate new features. Refer to "Downgrading PAN-OS Software" on page 53.

- Click **Upload** to install a release that you previously stored on your PC. Browse to select the software package, and click **Install from File**. Choose the file that you just selected from the drop-down list, and click **OK** to install the image.

- Click the Delete icon to delete an outdated release.

### Items to note when upgrading the PAN-OS software

- When upgrading from an earlier PAN-OS version, follow the recommended path to reach the latest release, as described in the release notes.

- When upgrading a High Availability (HA) pair to a new feature release (where the first or second digit in the PAN-OS version changes, e.g. 4.0 to 4.1. or 4.1 to 5.0), the configuration may be migrated to accommodate new features. If session synchronization is enabled, sessions will not be synchronized if one device in the cluster is at a different PAN-OS feature release.

- The date and time settings on the firewall must be current. PAN-OS software is digitally signed and the signature is checked by the device prior to installing a new version. If the date setting on the firewall is not current, the device may perceive the software signature to be erroneously in the future and will display the message
  `Decrypt failed: GnuPG edit non-zero, with code 171072 Failed to load into PAN software manager.`

# Upgrading PAN-OS in a High Availability Configuration

This section provides information on upgrading the PAN-OS software on a high availability (HA) configuration in active/passive and active/active modes.

If session synchronization is enabled, sessions will not be synchronized if one device in the cluster is at a different PAN-OS feature release. If session continuity is required, you must temporarily permit non-syn-tcp while the session table is rebuilt.

For information on High Availability (HA) configurations, refer to "High Availability" on page 93. To view the general status of your HA configuration, go to the **Dashboard** tab and view the **High Availability** widget. If the widget is not displayed, click the Widgets link drop-down and select **System > High Availability**.

The following steps assume that you are performing a new feature release upgrade. The same procedures can be used for a maintenance release, but in that case if session synchronization is enabled, there is no interruption to that process while both devices are functional. Also, the higher revision maintenance release in the pair will not go non-functional as it does with a feature release.

To upgrade an HA pair to a new feature release:

***Note:*** *In the following steps, active/passive and active/active applies, the terminology is just different. In active/passive you have an active and a passive device. In active/active you have an active-primary and active-secondary and both devices are passing traffic when the cluster is functional.*

1. Read "Upgrading/Downgrading the PAN-OS Software" on page 50 for general information and important notes on the upgrade process.
2. Save a backup of the current configuration file on both devices by navigating to **Device > Setup > Operations** tab and select **Export named configuration snapshot**, select **running-config.xml** and then click **OK** to save the configuration file to your computer.
3. Upgrade the passive/active-secondary firewall (device B) to the new PAN-OS feature release and then reboot to complete the installation. After the reboot, the device will not be functional until device A (active/active-primary) is suspended.
   If session synchronization is enabled, you can run the operational command `set session tcp-reject-non-syn no`. This will rebuild the session table and sessions prior to the upgrade will continue. Once both devices are at the same feature release, run `set session tcp-reject-non-syn yes` to enable this option.
   In active/passive mode, if the preemptive option is configured, the current passive device will revert to active when state synchronization is complete.
4. Suspend the active/active-primary firewall (device A), which will force the passive/active-secondary (device B) firewall to become functional. At this point, session synchronization will stop due to the fact that both devices are not on the same PAN-OS feature release. Make sure device B is functional and passing traffic before continuing the upgrade on device A.
5. Upgrade "device A" to the new PAN-OS release and then reboot the device to complete the installation. When device A comes back up, all HA functions should resume, including session synchronization.
   If you are allowing non-syn-tcp as indicated in Step 3, you can revert back by running `set session tcp-reject-non-syn yes`.
6. Verify that the active device is passing traffic by viewing the **Monitor > Session Browser**, or by running `show session all` from the CLI.
   You can also check the state of HA on the device by running `show high-availability all | match reason`. If this is an active/active configuration, check that both devices are passing traffic.
   To check session synchronization run `show high-availability interface ha2`. In the

"Hardware Interface counters read from CPU" table check that counters are increasing. In an active/passive configuration, only the active device will show packets transmitted and the passive device will only show packets received. In active/active, you will see packets received and packets transmitted on both devices.

# Downgrading PAN-OS Software

If you need to downgrade the PAN-OS software, you will need to follow different steps based on the PAN-OS release type (feature or maintenance). In a feature release (where the first or second digit in the PAN-OS version changes, e.g. 4.0 to 4.1. or 4.1 to 5.0), the configuration may be migrated to accommodate new features, so you should not downgrade unless you also restore the configuration for the previous release. Maintenance releases can be downgraded without having to worry about restoring the configuration.

- "Maintenance Release Downgrade" in the next section
- "Feature release Downgrade" on page 54

**CAUTION:** It is recommended that you downgrade into a configuration that matches the software version. Unmatched software and configurations can result in failed downgrades or even force the system into maintenance mode. This only applies to a downgrade from one feature release to another, not maintenance releases.

If you have a problem with a downgrade, you may need to enter maintenance mode and reset the device to factory default and then restore the configuration from the original config file that was exported prior to the upgrade.

## Maintenance Release Downgrade

A maintenance release is where the third digit in the release numbers changes (4.1.4 to 4.1.5 or 5.0.0 to 5.0.1). When you upgrade from one maintenance release to another, there are no feature changes, so there is no need to restore the configuration during the downgrade.

To downgrade to an earlier maintenance release:

1. Save a backup of the current configuration file by navigating to the **Device > Setup > Operations** tab and select **Export named configuration snapshot**, select **running-config.xml** and then click **OK** to save the configuration file. This backup can be used to restore the configuration if you have problems with the downgrade and you need to do a factory reset.
2. Navigate to **Device > Software** and you will see the software page that lists all PAN-OS versions that can be downloaded, or that have already been downloaded.
3. To downgrade to an older maintenance release, click **Install** in the **Action** column for the desired release. If the version you want to use shows **Download**, click the **Download** link to retrieve the software package and then click **Install**.
4. After PAN-OS has been downgraded, click **OK** to reboot the device to activate the new version.

## Feature release Downgrade

A feature release is where the first or second digit in the release numbers changes (4.0 to 4.1, or 4.1 to 5.0). When you upgrade from one feature release to another, the configuration may be changed to accommodate the new features. Due to this fact, you will need to restore your configuration backup that was created before the device was upgraded to a feature release. As of PAN-OS 4.1, this configuration backup is automatically created when upgrading to a feature release.

To downgrade to an earlier feature release:

**Note:** It is important to note that this procedure will restore your device to the configuration that was in place before the upgrade to a feature release. Any changes made since that time will be lost, so it is important to back up your current configuration in case you want to restore those changes when you return to the newer release.

1. Save a backup of the current configuration file by navigating to the **Device > Setup > Operations** tab and select **Export named configuration snapshot**, select **running-config.xml** and then click **OK** to save the configuration file. This backup can be used to restore the configuration if you have problems with the downgrade and you need to do a factory reset.
2. To downgrade to an older feature release, you must locate the previous feature release by navigating to **Device > Software** and browsing to the page that contains the release. See Figure 2.
3. Click **Install** in the **Action** column for the feature release. If the version you want to use shows **Download**, click the **Download** link to retrieve the software package and then click **Install**.
4. You will see a prompt that allows you to select a configuration that will be used after the device reboots. In most cases, since this is a feature release downgrade, you want to select the auto saved configuration that was created when the device was upgraded to the next feature release. For example, if you are running PAN-OS 5.0 and want to downgrade to

PAN-OS 4.1, click **Install** in the **Action** column, then in the **Select a Config File for Downgrading** drop-down, select *autosave-4.1.0* as shown in Figure 2.

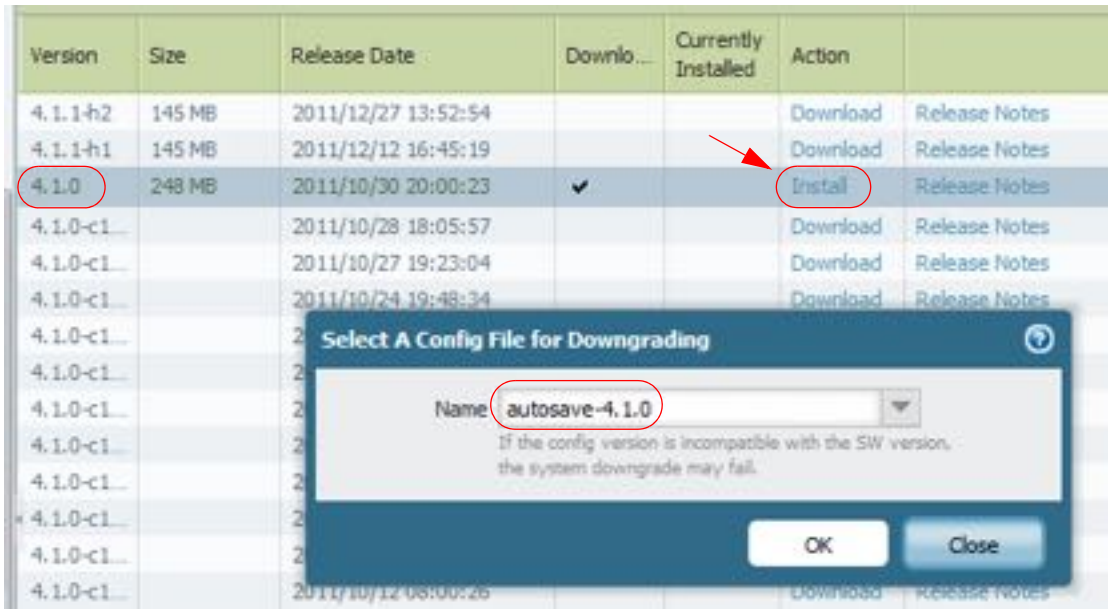


**Figure 2. Downgrade to an older feature release**

5. After PAN-OS has been installed, click **OK** to reboot the device to activate the new version. The selected feature release of PAN-OS and the configuration will then be activated.

***Note:*** *For releases prior to 4.1, you may need to do a factory reset and restore the device. For example, downgrading from 4.0 to 3.1.*

# Updating Threat and Application Definitions

▶ *Device > Dynamic Updates*

Palo Alto Networks periodically posts updates with new or revised application definitions, information on new security threats, such as antivirus signatures (threat prevention license required), URL filtering criteria, updates to GlobalProtect data, and WildFire signatures (WildFire subscription required). You can view the latest updates, read the release notes for each update, and then select the update you want to download and install. You can also revert to a previously installed version of an update.

Perform any of the following functions on this page:

- Click **Check Now** to obtain the latest information from Palo Alto Networks.
- Click **Install** in the **Action** column to update to that version.
- Click **Revert** for a version to return to that version.

- Click **Release Notes** to view a description of an update.
- Click **Upload** to install a file that you previously stored on your PC. Browse to select the file, and click **Install from File**. Choose the file that you just selected from the drop-down list, and click **OK** to install.
- Click the **Schedule** link to schedule automatic updates. Specify the frequency and timing for the updates and whether the update will be downloaded and installed or only downloaded. If you select **Download Only**, you can install the downloaded update by clicking the **Install** link in the **Action** column on the **Dynamic Updates** page. When you click **OK**, the update is scheduled. No commit is required. You can also indicate how persistent the content must be (number of hours) for the action to take place and whether the upload should be synchronized to peer firewalls.

# Administrator Roles, Profiles, and Accounts

The firewall supports the following options to authenticate administrative users who attempt to log in to the firewall:

- **Local database**—The user login and password information is entered directly into the firewall database.
- **RADIUS**—Existing Remote Authentication Dial In User Service (RADIUS) servers are used to authenticate users.
- **LDAP**—Existing Lightweight Directory Access Protocol (LDAP) servers are used to authenticate users.
- **Kerberos**—Existing Kerberos servers are used to authenticate users.
- **Client Certificate**—Existing client certificates are used to authenticate users.

When you create an administrative account, you specify local authentication or client certificate (no authentication profile), or an authentication profile (RADIUS, LDAP, Kerberos, or local DB authentication). This setting determines how the administrator's authentication is checked.

Administrator roles determine the functions that the administrator is permitted to perform after logging in. You can assign roles directly to an administrator account, or define role profiles, which specify detailed privileges, and assign those to administrator accounts.

Refer to the following sections for additional information:

- For instructions on setting up authentication profiles, refer to "Setting Up Authentication Profiles" on page 62.
- For instructions on setting up role profiles, refer to "Defining Administrator Roles" on page 58.
- For instructions on setting up administrator accounts, refer to "Creating Administrative Accounts" on page 59.
- For information on SSL virtual private networks (VPNs), refer to "Configuring GlobalProtect" on page 335.
- For instructions on defining virtual system domains for administrators, refer to "Specifying Access Domains for Administrators" on page 61.

- For instructions on defining certificate profiles for administrators, refer to "Certificate Profile" on page 89.

## Username and Password Requirements

The following table lists the valid characters that can be used in usernames and passwords for PAN-OS and Panorama accounts.

**Note:** The following restrictions apply to PAN-OS 3.1 and later.

**Table 7 Valid Characters for Usernames and Passwords**

| Account Type | Restrictions |
|---|---|
| Password Character Set | There are no restrictions on any password field character sets. |
| Remote Admin, SSL-VPN, or Captive Portal | The following characters are not allowed for the username:<br>• Backtick (`)<br>• Angular brackets (< and >)<br>• Ampersand (&)<br>• Asterisk (*)<br>• At sign (@)<br>• Question mark (?)<br>• Pipe (\|)<br>• Single-Quote (')<br>• Semicolon (;)<br>• Double-Quote (")<br>• Dollar ($)<br>• Parentheses ( '(' and ')' )<br>• Colon (':') |
| Local Administrator Accounts | The following are the allowed characters for local usernames:<br>• Lowercase (a-z)<br>• Uppercase (A-Z)<br>• Numeric (0-9)<br>• Underscore (_)<br>• Period (.)<br>• Hyphen (-)<br>***Note:*** *Login names cannot start with a hyphen (-).* |

***Note:*** *The system does not impose restrictions on the response page character set.*

## Defining Administrator Roles

▶ *Device > Admin Roles*

Use the **Admin Roles** page to define role profiles that determine the access and responsibilities available to administrative users. For instructions on adding administrator accounts, refer to "Creating Administrative Accounts" on page 59.

There are also three pre-defined Admin Roles that can be used for common criteria purposes. You first use the Superuser role for the initial configuration of the device and to create the administrator accounts for the Security Administrator, Audit Administrator, and Cryptographic Administrator. Once the accounts are created and the proper common criteria Admin Roles are applied, you then login using those accounts. The default Superuser account in FIPS or CC mode is **admin** and has a default password of **paloalto**. In standard operating mode, the default **admin** password is **admin**. The pre-defined Admin Roles were created where there is no overlap in capabilities, except that all have read-only access to the audit trail (except audit administrator with full read/delete access. These admin roles cannot be modified and are defined as follows:

- auditadmin—The Audit Administrator is responsible for the regular review of the firewall's audit data.
- cryptoadmin—The Cryptographic Administrator is responsible for the configuration and maintenance of cryptographic elements related to the establishment of secure connections to the firewall.
- securityadmin—The Security Administrator is responsible for all other administrative tasks (e.g. creating the firewall's security policy) not addressed by the other two administrative roles.

**Table 8. Administrator Role Settings**

| Field | Description |
|---|---|
| Name | Enter a name to identify this administrator role (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Description | Enter an optional description of the role (up to 255 characters). |
| Role | Select the general scope of administrative responsibility from the drop-down list. |
| WebUI | Click the icons for specified areas to indicate the type of access permitted for the web interface:<br>• Read/write access to the indicated page.<br>• Read only access to the indicated page.<br>• No access to the indicated page. |
| CLI Role | Select the type of role for CLI access:<br>• **disable**—Access to the device CLI not permitted.<br>• **superuser**—Full access to the current device.<br>• **superreader**—Read-only access to the current device.<br>• **deviceadmin**—Full access to a selected device, except for defining new accounts or virtual systems.<br>• **devicereader**—Read-only access to a selected device. |

## Defining Password Profiles

▶ *Device > Password Profiles*

Password profiles allow you to set basic password requirements for an individual local account. If you enable **Minimum Password Complexity**, which provides password requirements for all local accounts, this password profile will override those settings. Refer to "Minimum Password Complexity" on page 35 for more information and refer to "Username and Password Requirements" on page 57 for information on valid characters that can be used for accounts.

To apply a password profile to an account, go to **Device > Administrators**, select an account and then choose the profile from the **Password Profile** drop-down.

**Table 9 Password Profile Settings**

| Field | Description |
|---|---|
| Name | Enter a name to identify the password profile (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Required Password Change Period (days) | Require that administrators change their password on a regular basis specified a by the number of days set, ranging from 0-365 days. Example, if the value is set to 90, administrators will be prompted to change their password every 90 days.<br>You can also set an expiration warning from 0-30 days and specify a grace period. |
| Expiration Warning Period (days) | If a required password change period is set, this setting can be used to prompt the user to change their password at each log in as the forced password change date approaches (range 0-30 days). |
| Post Expiration Admin Login Count | Allow the administrator to log in the specified number of times after their account has expired. Example, if the value is set to 3 and their account has expired, they can log in 3 more times before their account is locked out (range 0-3 logins). |
| Post Expiration Grace Period (days) | Allow the administrator to log in the specified number of days after their account has expired (range is 0-30 days). |

## Creating Administrative Accounts

▶ *Device > Administrators*

Administrator accounts control access to the firewall. Each administrator can have full or read-only access to a single device or to a virtual system on a single device. The predefined **admin** account has full access.

The following authentication options are supported:

- Password authentication—The user enters a user name and password to log in. No certificates are required.
- Client certificate authentication (web)—If you select this check box, a user name and password are not required; the certificate is sufficient to authenticate access to the firewall.

- Public key authentication (SSH)—The user can generate a public/private key pair on the machine that requires access to the firewall, and then upload the public key to the firewall to allow secure access without requiring the user enter a user name and password.

***Note:*** *To ensure that the device management interface remains secure, it is recommended that administrative passwords be changed periodically using a mixture of lower-case letters, upper-case letters, and numbers. You can also enforce "Minimum Password Complexity" from Setup > Management.*

**Table 10. Administrator Account Settings**

| Field | Description |
|---|---|
| Name | Enter a login name for the user (up to 15 characters). The name is case sensitive and must be unique. Use only letters, numbers, hyphens, periods, and underscores.<br>***Note:*** *Login names cannot start with a hyphen (-).* |
| Authentication Profile | Select an authentication profile for administrator authentication according to the settings in the specified authentication profile. This setting can be used for RADIUS, LDAP, Kerberos, or Local DB authentication.<br>For instructions on setting up authentication profiles, refer to "Setting Up Authentication Profiles" on page 62. |
| Use only client certificate authentication (web) | Select the check box to use client certificate authentication for web access. If you select this check box, a user name and password are not required; the certificate is sufficient to authenticate access to the firewall. |
| New Password<br>Confirm New Password | Enter and confirm a case-sensitive password for the user (up to 15 characters). *You can also enforce "Minimum Password" from Setup > Management.* |
| Use Public Key Authentication (SSH) | Select the check box to use SSH public key authentication. Click **Import Key** and browse to select the public key file. The uploaded key is displayed in the read-only text area.<br>Supported key file formats are IETF SECSH and OpenSSH. Supported key algorithms are DSA (1024 bits) and RSA (768-4096 bits).<br>***Note:*** *If the public key authentication fails, a username and password prompt is presented to the user.* |

**Table 10. Administrator Account Settings (Continued)**

| Field | Description |
|---|---|
| Role | Select an option for assigning a role to this user. The role determines what the user can view and modify.<br>If you choose **Dynamic**, you can select any of the following pre-specified roles from the drop-down list:<br>• **Superuser**—Full access to the current device.<br>• **Superuser (read-only)**—Read-only access to the current device.<br>• **Device Admin**—Full access to a selected device, except for defining new accounts or virtual systems.<br>• **Device administrator (read-only)**—Read-only access to a selected device.<br>• **Vsys Admin**—Full access to a selected virtual system on a specific device (if multiple virtual systems are enabled).<br>• **Vsys Admin (read-only)**—Read-only access to a selected virtual system on a specific device.<br>• **Role Based Admin**—Access based on assigned roles, as defined in "Defining Administrator Roles" on page 58.<br>If you choose **Role Based**, select a previously-defined role profile from the drop-down list. For instructions on defining role profiles, refer to "Defining Administrator Roles" on page 58. |
| Virtual System | Select the virtual systems that you want the administrator to have access to, and click **Add** to move them from the **Available** area to the **Selected** area. |

***Note:*** *On the Panorama* ***Administrators*** *page for "superuser," a lock icon is shown in the right column if an account is locked out. The administrator can click the icon to unlock the account.*

## Specifying Access Domains for Administrators

▶ *Device > Access Domain*

Use the **Access Domain** page to specify domains for administrator access to the firewall. The access domain is linked to RADIUS Vendor-specific Attributes (VSAs) and is supported only if a RADIUS server is used for administrator authentication. For information on configuring RADIUS, refer to "Configuring RADIUS Server Settings" on page 65.

When an administrator attempts to log in to the firewall, the firewall queries the RADIUS server for the administrator's access domain. If there is an associated domain on the RADIUS server, it is returned and the administrator is restricted to the defined virtual systems inside

the named access domain on the device. If RADIUS is not used, the access domain settings on this page are ignored. For information on Panorama Access Domains, refer to "Specifying Panorama Access Domains for Administrators" on page 392.

**Table 11. Access Domain Settings**

| Field | Description |
|---|---|
| Name | Enter a name for the access domain (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, hyphens, and underscores. |
| Virtual Systems | Select virtual systems in the Available column and click **Add** to select them.<br>***Note:*** *Access Domains are only supported on devices that support virtual systems.* |

# Authentication Profiles

Authentication profiles specify local database, RADIUS, LDAP, or Kerberos settings and can be assigned to administrator accounts, SSL-VPN access, and captive portal. When an administrator attempts to log in to the firewall directly or through an SSL-VPN or captive portal, the firewall checks the authentication profile that is assigned to the account and authenticates the user based on the authentication settings.

If the user does not have a local administrator account, the authentication profile that is specified on the device **Setup** page determines how the user is authenticated (refer to "Defining Management Settings" on page 30):

- If you specify **RADIUS** authentication settings on the **Setup** page and the user does not have a local account on the firewall, then the firewall requests authentication information for the user (including role) from the RADIUS server. The Palo Alto Networks RADIUS dictionary file containing the attributes for the various roles is available on the support site at *https://live.paloaltonetworks.com/docs/DOC-3189.*
- If **None** is specified as the authentication profile on the **Settings** page, then the user must be authenticated locally by the firewall according to the authentication profile that is specified for the user.

## Setting Up Authentication Profiles

▶ ***Device > Authentication Profile***

Use the **Authentication Profile** page to configure authentication settings that can be applied to accounts to manage access to the firewall.

**Table 12. Authentication Profile Settings**

| Field | Description |
|---|---|
| Name | Enter a name to identify the profile (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow the profile to be shared by all virtual systems. |

**Table 12. Authentication Profile Settings (Continued)**

| Field | Description |
|---|---|
| Lockout Time | Enter the number of minutes that a user is locked out if the number of failed attempts is reached (0-60 minutes, default 0). 0 means that the lockout is in effect until it is manually unlocked. |
| Failed Attempts | Enter the number of failed login attempts that are allowed before the account is locked out (1-10, default 0). 0 means that there is no limit. |
| Allow List | Specify the users and groups that are explicitly allowed to authenticate. Click **Edit Allow List** and do any of the following:<br>• Select the check box next to the appropriate user or user group in the **Available** column, and click **Add** to add your selections to the **Selected** column.<br>• Use the **All** check box to apply to all users.<br>• Enter the first few characters of a name in the **Search** field to list all the users and user groups that start with those characters. Selecting an item in the list sets the check box in the **Available** column. Repeat this process as often as needed, and then click **Add**.<br>• To remove users or user groups, select the appropriate check boxes in the **Selected** column and click **Remove**, or select **any** to clear all users. |
| Authentication | Choose the type of authentication:<br>• **None**—Do not use any authentication on the firewall.<br>• **Local Database**—Use the authentication database on the firewall.<br>• **RADIUS**—Use a RADIUS server for authentication.<br>• **LDAP**—Use LDAP as the authentication method.<br>• **Kerberos**—Use Kerberos as the authentication method. |
| Server Profile | If you select RADIUS, LDAP, or Kerberos as the authentication method, choose the authentication server from the drop-down list. Servers are configured on the **Server** pages. Refer to "Configuring RADIUS Server Settings" on page 65, "Configuring LDAP Server Settings" on page 66, and "Configuring Kerberos Settings (Native Active Directory Authentication)" on page 67. |
| Login Attribute | If you selected LDAP as the authentication method, enter the LDAP directory attribute that uniquely identifies the user. |

**Table 12. Authentication Profile Settings (Continued)**

| Field | Description |
|---|---|
| Password Expiry Warning | If you selected LDAP as the authentication method, enter the number of days prior to password expiration to send an automated message to the user. If the field is left blank, no warning is provided. This is supported for the following databases: Active Directory, eDirectory, and Sun ONE Directory.<br>This setting is used for SSL-VPN. For more information, refer to "Configuring GlobalProtect" on page 335.<br>You can customize the expiration warning message as part of the SSL-VPN login page by editing the script<br>`<SCRIPT>`<br>`function getPassWarnHTML(expdays)`<br>`{`<br>`var str = "Your password will expire in " + expdays + " days";`<br>`return str;`<br>`}`<br>`</SCRIPT>`<br>Changing the value of the str variable changes the displayed message. |

## Creating a Local User Database

You can set up a local database on the firewall to store authentication information for remote access users, device administrators, and captive portal users. No external authentication server is required with this configuration, so all account management is performed on the device or from Panorama.

When configuring Captive Portal, you first create the local account, add it to a User Group and create an Authentication Profile using the new group. You then enable Captive Portal from Device > User Authentication > Captive Portal and select the Authentication Profile. Once this is configured, you can then create a policy from Policies > Captive Portal. For more information, refer to "Captive Portals" on page 285.

### Adding Local Users

▶ *Device > Local User Database > Users*

Use the **Local Users** page to add user information to the local database.

**Table 13. Local User Settings**

| Field | Description |
|---|---|
| Local User Name | Enter a name to identify the user (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Location | Choose a virtual system or choose **Shared** to make the certificate available to all virtual systems. |
| Mode | Use this field to specify the authentication option:<br>• **Password**—Enter and confirm a password for the user.<br>• **Password Hash**—Enter a hashed password string. |
| Enable | Select the check box to activate the user account. |

### Adding Local User Groups

▶ *Device > Local User Database > User Groups*

Use the **Local User Groups** page to add user group information to the local database.

**Table 14. Local User Group Settings**

| Field | Description |
|---|---|
| Local User Group Name | Enter a name to identify the group (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Location | Choose a virtual system or choose **Shared** to make the certificate available to all virtual systems. |
| All Local Users | Click **Add** to select the users you want to add to the group. |

## Configuring RADIUS Server Settings

▶ *Device > Server Profiles > RADIUS*

Use the **RADIUS** page to configure settings for the RADIUS servers that are identified in authentication profiles. Refer to "Authentication Profiles" on page 62.

**Table 15. RADIUS Server Settings**

| Field | Description |
|---|---|
| Name | Enter a name to identify the server (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Location | Choose a virtual system, or choose **Shared** to make the profile available to all virtual systems. |
| Administrator Use Only | Use this server profile for administrator authentication only. |
| Domain | Enter the RADIUS server domain. The domain setting is used if the user does not specify a domain when logging in. |
| Timeout | Enter an interval after which an authentication request times out (1-30 seconds, default 3 seconds). |
| Retries | Enter the number of automatic retries following a timeout before the request fails (1-5, default 3). |
| Retrieve User Group | Select the check box to use RADIUS VSAs to define the group that has access to the firewall. |
| Servers | Configure information for each server in the preferred order.<br>• **Name**—Enter a name to identify the server.<br>• **IP address**—Enter the server IP address.<br>• **Port**—Enter the server port for authentication requests.<br>• **Secret/Confirm Secret**—Enter and confirm a key to verify and encrypt the connection between the firewall and the RADIUS server. |

## Configuring LDAP Server Settings

▶ *Device > Server Profiles > LDAP*

Use the **LDAP** page to configure settings for the LDAP servers to use for authentication by way of authentication profiles. Refer to "Authentication Profiles" on page 62.

**Table 16. LDAP Server Settings**

| Field | Description |
|---|---|
| Name | Enter a name to identify the profile (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Location | Choose a virtual system, or choose **Shared** to make the profile available to all virtual systems. |
| Administrator Use Only | Use this server profile for administrator authentication only. |
| Servers | Specify the host names, IPv4 or IPv6 addresses, and ports of your LDAP servers. |
| Domain | Enter the server domain name. This domain name should be the NetBIOS name of the domain and will be added to the username when authentication is performed. For example, if your domain is paloaltonetworks.com, you only need to enter paloaltonetworks. |
| Type | Choose the server type from the drop-down list. |
| Base | Specify the root context in the directory server to narrow the search for user or group information. |
| Bind DN | Specify the login name (Distinguished Name) for the directory server. |
| Bind Password / Confirm Bind Password | Specify the bind account password. The agent saves the encrypted password in the configuration file. |
| SSL | Select to use secure SSL or Transport Layer Security (TLS) communications between the Palo Alto Networks device and the directory server. |
| Time Limit | Specify the time limit imposed when performing directory searches (1 - 30 seconds, default 30 seconds). |
| Bind Time Limit | Specify the time limit imposed when connecting to the directory server (1 - 30 seconds, default 30 seconds). |
| Retry Interval | Specify the interval after which the system will try to connect to the LDAP server after a previous failed attempt (1-3600 seconds). |

### Configuring Kerberos Settings (Native Active Directory Authentication)

▶ *Device > Server Profiles > Kerberos*

Use the **Kerberos** page to configure Active Directory authentication without requiring customers to start Internet Authentication Service (IAS) for RADIUS support. Configuring a Kerberos server allows users to authenticate natively to a domain controller.

When the Kerberos settings are configured, Kerberos becomes available as an option when defining authentication profiles. Refer to "Authentication Profiles" on page 62.

You can configure the Kerberos settings to recognize a user account in any of the following formats, where domain and realm are specified as part of the Kerberos server configuration:

- domain\username
- username@realm
- username

**Table 17. Kerberos Server Settings**

| Field | Description |
|---|---|
| Name | Enter a name to identify the server (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Location | Choose a virtual system, or choose **Shared** to make the profile available to all virtual systems. |
| Administrator Use Only | Use this server profile for administrator authentication only. |
| Realm | Specify the hostname portion of the user login name (up to 127 characters)<br>Example: The user account name *user@example.local* has realm *example.local*. |
| Domain | Specify the domain for the user account (up to 63 characters). |
| Servers | For each Kerberos server, click **Add** and specify the following settings:<br>• **Server**—Enter the server IP address.<br>• **Host**—Enter the server FQDN.<br>• **Port**—Enter an optional port number for communication with the server. |

# Authentication Sequence

In some environments, user accounts reside in multiple directories. Guest or other accounts may also be stored in different directories. An authentication sequence is a set of authentication profiles that are applied in order when a user attempts to log in to the firewall. The firewall will always try the local database first, and then each profile in sequence until the user is identified. Access to the firewall is denied only if authentication fails for any of the profiles in the authentication sequence.

For example, after the local database is checked, you can configure an authentication sequence to then try RADIUS, followed by LDAP authentication.

## Setting Up Authentication Sequences

▶ *Device > Authentication Sequence*

Use the **Authentication Sequence** page to configure sets of authentication profiles that are tried in order when a user requests access to the firewall. The user is granted access if authentication is successful using any one of the authentication profiles in the sequence. For more information, refer to "Authentication Profiles" on page 62.

**Table 18. Authentication Sequence Settings**

| Field | Description |
|---|---|
| Profile Name | Enter a name to identify the profile (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow sharing by all virtual systems. |
| Lockout Time | Enter the number of minutes that a user is locked out if the number of failed attempts is reached (0-60 minutes, default 0). 0 means that the lockout is in effect until it is manually unlocked. |
| Failed Attempts | Enter the number of failed login attempts that are allowed before the account is locked out (1-10, default 0). 0 means that there is no limit. |
| Profile List | Choose the authentication profiles to include in the authentication sequence. To change the list order, select an entry and click **Move Up** or **Move Down**. |

# Firewall Logs

▶ *Monitor > Logs*

The firewall provides logs that record configuration changes, system events, security threats, and traffic flows. For each log, you can enable remote logging to a Panorama server, and generate SNMP traps, syslog messages, and email notifications.

The following table describes the logs and logging options.

**Table 19 Log Types and Settings**

| Log | Description |
|---|---|
| Alarms | The alarms log records detailed information on alarms that are generated by the system. The information in this log is also reported in the **Alarms** window. Refer to "Viewing Alarms" on page 85. |
| Configuration | The configuration log records each configuration change, including the date and time, the administrator user name, and whether the change succeeded or failed.<br>All configuration log entries can be sent to Panorama, syslog, and email servers, but they cannot generate SNMP traps.<br>To view expanded details about configuration log entries, move your cursor over the **Before Change** of **After Change** column and click the ellipsis symbol ... . A pop-up window opens to show the full details of the entry. |

**Table 19 Log Types and Settings (Continued)**

| Log | Description |
|---|---|
| Data Filtering | The data filtering log records information on the security policies that help prevent sensitive information such as credit card or social security numbers from leaving the area protected by the firewall (refer to "Data Filtering Profiles" on page 223.<br>If you configure a file blocking profile to block specific file types, the file type and file name will appear in the data filtering log, so you can see what was blocked. |
| HIP Match | The HIP match log lists the host information profile (HIP) match requests for GlobalProtect. Refer to "Configuring GlobalProtect" on page 335. |
| System | The system log records each system event, such as HA failures, link status changes, and administrators logging in and out. Each entry includes the date and time, the event severity, and an event description.<br>System log entries can be logged remotely by severity level. For example, you can generate SNMP traps and email notifications for just critical and high-level events. |
| Threat | The threat log records each security alarm generated by the firewall. Each entry includes the date and time, the threat type, such as a virus or spyware/vulnerability filtering violation, the source and destination zones, addresses, and ports, the application name, and the action and severity.<br>Threat log entries can be logged remotely by severity level by defining log forwarding profiles, and then assigning the profiles to security rules (refer to "Security Policies" on page 187). Threats are logged remotely only for the traffic that matches the security rules where the logging profile is assigned.<br>Threat logs are used in generating reports and in the Application Command Center (refer to "Reports and Logs" on page 251). |
| Traffic | The traffic log can record an entry for the start and end of each session. Each entry includes the date and time, the source and destination zones, addresses, and ports, the application name, the security rule applied to the session, the rule action (allow, deny, or drop), the ingress and egress interface, and the number of bytes.<br>Each security rule specifies whether the start and/or end of each session is logged locally for traffic that matches the rule. The log forwarding profile assigned to the rule determines whether the locally logged entries are also logged remotely.<br>Traffic logs are used in generating reports and in the Application Command Center (refer to "Reports and Logs" on page 251). |
| URL Filtering | The URL filtering log records entries for URL filters, which block access to specific web sites and web site categories or generate an alert when a user accesses a proscribed web site.<br>If you are using the PAN-DB and wold like to request a URL category change for a website, open the URL Filtering log details for the desired log entry and click on **Request Categorization Change**. Select the suggested category from the drop-down menu, enter your email address (optional) and comments (optional) and click **Send**.<br>If you are using the BrightCloud DB, click **Request Categorization Change** and you will be directed to the BrightCloud support page where you can submit you request.<br>(refer to "URL Filtering Profiles" on page 217). |

**Table 19 Log Types and Settings (Continued)**

| Log | Description |
|---|---|
| WildFire | The WildFire logs will show the result of files analyzed by WildFire. Some of the fields that will be displayed include: Filename, Source Zone, Destination Zone, Attacker, Victim, and Application.<br>***Note:*** *A WildFire subscription is required for integrated logging. If you do not have a subscription, you can view log information by using the WildFire portal at https://wildfire.paloaltonetworks.com.*<br>(refer to "About WildFire" on page 421 and "Using the WildFire Portal" on page 425) |

# Logging Configuration

You can configure the firewall to send log entries to a Panorama centralized management system, SNMP trap sinks, syslog servers, and email addresses.

The following table describes the remote log destinations.

**Table 20 Remote Log Destinations**

| Destination | Description |
|---|---|
| Panorama | All log entries can be forwarded to a Panorama centralized management system. To specify the address of the Panorama server, refer to "Defining Management Settings" on page 30. |
| SNMP trap | SNMP traps can be generated by severity level for system, threat, and traffic log entries, but not for configuration log entries. To define the SNMP trap destinations, refer to "Configuring SNMP Trap Destinations" on page 75. |
| Syslog | Syslog messages can be generated by severity level for system, threat, and traffic log entries, and for all configuration log entries. To define the syslog destinations, refer to "Configuring Syslog Servers" on page 76. |
| Email | Emails can be generated by severity level for system, threat, and traffic log entries, and for all configuration log entries. To define the email addresses and servers, refer to "You can configure a custom log format in a Syslog Server Profile by selecting the Custom Log Format tab in Device > Server Profiles > Syslog. Click the desired log type (Config, System, Threat, Traffic, or HIP Match) and then click the fields you want to see in the logs. The tables that follow shows the meaning of each field for each log type." on page 77. |

## Scheduling Log Exports

▶ *Device > Scheduled Log Export*

You can schedule exports of logs and save them to a File Transfer Protocol (FTP) server in CSV format or use Secure Copy (SCP) to securely transfer data between the device and a remote host. Log profiles contain the schedule and FTP server information. For example, a profile may specify that the previous day's logs are collected each day at 3AM and stored on a particular FTP server.

When you click **OK** after creating a new entry, the new profile is added to the **Scheduled Log Export** page. You must commit the change for the export to take place. If you are using SCP, you need to click the **Test SCP server connection** button to test connectivity between the firewall and the SCP server and you must verify and accept the host key of the SCP server.

**Table 21. Scheduled Log Export Settings**

| Field | Description |
|---|---|
| Name | Enter a name to identify the profile (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores.<br>You cannot change the name after the profile is created. |
| Description | Enter an optional description (up to 255 characters). |
| Enabled | Select the check box to enable the scheduling of log exports. |
| Log Type | Select the type of log (traffic, threat, url, data, or hipmatch). Default is traffic. |
| Scheduled export start time (daily) | Enter the time of day (hh:mm) to start the export, using a 24-hour clock (00:00 - 23:59). |
| Protocol | Select the protocol to use to export logs from the firewall to a remote host. You can use SCP to export logs securely, or you can use FTP, which is not a secure protocol. |
| Hostname | Enter the host name or IP address of the FTP server that will be used for the export. |
| Port | Enter the port number that the FTP server will use. Default is 21. |
| Path | Specify the path located on the FTP server that will be used to store the exported information. |
| Enable FTP Passive Mode | Select the check box to use passive mode for the export. By default, this option is selected. |
| Username | Enter the user name for access to the FTP server. Default is anonymous. |
| Password | Enter the password for access to the FTP server. A password is not required if the user is "anonymous." |

## Defining Configuration Log Settings

▶ *Device > Log Settings > Config*

The configuration log settings specify the configuration log entries that are logged remotely with Panorama, and sent as syslog messages and/or email notifications.

**Table 22. Configuration Log Settings**

| Field | Description |
|---|---|
| Panorama | Select the check box to enable sending configuration log entries to the Panorama centralized management system. |
| SNMP Trap | To generate SNMP traps for configuration log entries, select trap name. To specify new SNMP trap destinations, refer to "Configuring SNMP Trap Destinations" on page 75. |
| Email | To generate email notifications for configuration log entries, select an email profile from the drop-down menu. To specify a new email profile, refer to "Configuring Email Notification Settings" on page 83. |
| Syslog | To generate syslog messages for configuration log entries, select the name of the syslog server. To specify new syslog servers, refer to "Configuring Syslog Servers" on page 76. |

## Defining System Log Settings

▶ *Device > Log Settings > System*

The system log settings specify the severity levels of the system log entries that are logged remotely with Panorama and sent as SNMP traps, syslog messages, and/or email notifications. The system logs show system events such as HA failures, link status changes, and administrators logging in and out.

**Table 23. System Log Settings**

| Field | Description |
|---|---|
| Panorama | Select the check box for each severity level of the system log entries to be sent to the Panorama centralized management system. To specify the Panorama server address, refer to "Defining Management Settings" on page 30.<br>The severity levels are:<br>• **Critical**—Hardware failures, including HA failover, and link failures.<br>• **High**—Serious issues, including dropped connections with external devices, such as syslog and RADIUS servers.<br>• **Medium**—Mid-level notifications, such as antivirus package upgrades.<br>• **Low**—Minor severity notifications, such as user password changes.<br>• **Informational**—Log in/log off, administrator name or password change, any configuration change, and all other events not covered by the other severity levels. |

**Table 23. System Log Settings (Continued)**

| Field | Description |
|---|---|
| SNMP Trap<br>Email<br>Syslog | Under each severity level, select the SNMP, syslog, and/or email settings that specify additional destinations where the system log entries are sent. To define new destinations, refer to:<br>• "Configuring SNMP Trap Destinations" on page 75.<br>• "Configuring Syslog Servers" on page 76.<br>• "Configuring Email Notification Settings" on page 83. |

## Defining HIP Match Log Settings

▶ *Device > Log Settings > HIP Match*

The Host Information Profile (HIP) match log settings are used to provide information on security policies that apply to GlobalProtect clients. For more information, refer to "Overview" on page 335.

**Table 24. HIP Match Log Settings**

| Field | Description |
|---|---|
| Panorama | Select the check box to enable sending configuration log entries to the Panorama centralized management system. |
| SNMP Trap | To generate SNMP traps for HIP match log entries, select the name of the trap destination. To specify new SNMP trap destinations, refer to "Configuring SNMP Trap Destinations" on page 75. |
| Email | To generate email notifications for configuration log entries, select the name of the email settings that specify the appropriate email addresses. To specify new email settings, refer to "You can configure a custom log format in a Syslog Server Profile by selecting the Custom Log Format tab in Device > Server Profiles > Syslog. Click the desired log type (Config, System, Threat, Traffic, or HIP Match) and then click the fields you want to see in the logs. The tables that follow shows the meaning of each field for each log type." on page 77. |
| Syslog | To generate syslog messages for configuration log entries, select the name of the syslog server. To specify new syslog servers, refer to "Configuring Syslog Servers" on page 76. |

## Defining Alarm Log Settings

▶ *Device > Log Settings > Alarms*

Use the **Alarms** page to configure notifications when a security rule (or group of rules) has been hit repeatedly in a set period of time.

**Table 25. Alarm Log Settings**

| Field | Description |
|---|---|
| Enable Alarms | Enable alarms based on the events listed on this page. |
| Enable CLI Alarm Notifications | Enable CLI alarm notifications whenever alarms occur. |

**Table 25. Alarm Log Settings (Continued)**

| Field | Description |
|---|---|
| Enable Web Alarm Notifications | Open a window to display alarms on user sessions, including when they occur and when they are acknowledged. |
| Enable Audible Alarms | The firewall will continuously play an audible tone when unacknowledged alarms exist in the web interface or CLI. |
| Encryption/Decryption Failure Threshold | Specify the number of encryption/decryption failures after which an alarm is generated. |
| Log DB Alarm Threshold (% Full) | Generate an alarm when a log database reaches the indicated percentage of the maximum size. |
| Security Policy Limits | An alarm is generated if a particular IP address or port hits a deny rule the number of times specified in the **Security Violations Threshold** setting within the period (seconds) specified in the **Security Violations Time Period** setting. |
| Security Policy Group Limits | An alarm is generated if the collection of rules reaches the number of rule limit violations specified in the **Violations Threshold** field during the period specified in the **Violations Time Period** field. Violations are counted when a session matches an explicit deny policy.<br>Use **Security Policy Tags** to specify the tags for which the rule limit thresholds will generate alarms. These tags become available to be specified when defining security policies. |
| Selective Audit | ***Note:*** *These settings appear on the* ***Alarms*** *page only in Common Criteria mode.*<br>Specify the following settings:<br>• **CC Specific Logging**—Enables verbose logging required for Common Criteria (CC) compliance.<br>• **Login Success Logging**—Logs the success of administrator logins to the firewall.<br>• **Login Failure Logging**—Logs the failure of administrator logins to the firewall.<br>• **Suppressed Administrators**—Does not generate logs for changes that the listed administrators make to the firewall configuration. |

## Managing Log Settings

▶ ***Device > Log Settings > Manage Logs***

Click the links on this page to clear the indicated logs.

# Configuring SNMP Trap Destinations

▶ *Device > Server Profiles > SNMP Trap*

To generate SNMP traps for system, traffic, or threat logs, you must specify one or more SNMP trap destinations. After you define the trap destinations, you can use them for system log entries (refer to "Defining System Log Settings" on page 72).

**Table 26. SNMP Trap Destination Settings**

| Field | Description |
|---|---|
| Name | Enter a name for the SNMP profile (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow sharing by all virtual systems. |
| Version | Choose the SNMP version (V2c or V3). |
| V2c settings | If you choose V2c, configure the following settings:<br>• **Server**—Specify a name for the SNMP trap destination name (up to 31 characters).<br>• **Manager**—Specify the IP address of the trap destination.<br>• **Community**—Specify the community string required to send traps to the specified destination (default public). |
| V3 settings | If you choose V3, configure the following settings:<br>• **Server**—Specify the SNMP trap destination name (up to 31 characters).<br>• **Manager**—Specify the IP address of the trap destination.<br>• **User**—Specify the SNMP user.<br>• **EngineID**—Specify the engine ID of the firewall. The input is a string in hexadecimal representation. The engine ID is any number between 5 to 64 bytes. When represented as a hexadecimal string this is between 10 to 128 characters (2 characters for each byte) with two additional characters for 0x that you need to use as a prefix in the input string.<br>Each firewall has a unique engine ID, which you can get by using a MIB browser to run a GET for OID 1.3.6.1.6.3.10.2.1.1.0.<br>• **Auth Password**—Specify the user's authentication password (minimum 8 characters, maximum of 256 characters, and no character restrictions). All characters allowed). Only Secure Hash Algorithm (SHA) is supported.<br>• **Priv Password**—Specify the user's encryption password (minimum 8 characters, maximum of 256 characters, and no character restrictions). Only Advanced Encryption Standard (AES) is supported. |

***Note:*** *Do not delete a destination that is used in any system log settings or logging profile.*

### SNMP MIBs

The firewall supports the following SNMP MIBs:

- "RFC 1213: MIB-II - Support for The System Group, The Interfaces Group.
- "RFC 2863: IF-MIB - The Interfaces Group MIB
- "RFC 2790: HOST-RESOURCES-MIB - Support for hrDeviceTable and hrProcessorTable.
- "RFC 3433: ENTITY-SENSOR-MIB - Support for entPhySensorTable.
- PAN-PRODUCT-MIB
- PAN-COMMON-MIB
- PAN-TRAPS-MIB
- PAN-LC-MIB

The full set of Enterprise MIBs is available in the Technical Documentation section on the Palo Alto Networks site at *https://live.paloaltonetworks.com/community/documentation*.

# Configuring Syslog Servers

▶ ***Device > Server Profiles > Syslog***

To generate syslog messages for system, configuration, traffic, threat, or HIP match logs, you must specify one or more syslog servers. After you define the syslog servers, you can use them for system and configuration log entries (refer to "Defining System Log Settings" on page 72).

**Table 27. New Syslog Server**

| Field | Description |
|---|---|
| Name | Enter a name for the syslog profile (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow sharing by all virtual systems. |
| **Servers Tab** | |
| Name | Click **Add** and enter a name for the syslog server (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Server | Enter the IP address of the syslog server. |
| Port | Enter the port number of the syslog server (the standard port is 514). |
| Facility | Choose a level from the drop-down list. |

**Table 27. New Syslog Server (Continued)**

| Field | Description |
|---|---|
| **Custom Log Format Tab** | |
| Log Type | Click the log type to open a dialog box that allows you to specify a custom log format. In the dialog box, click a field to add it to the Log Format area. Other text strings can be edited directly in the Log Format area. Click **OK** to save the settings.<br>For details on the fields that can be used for custom logs, refer to "Custom Syslog Field Descriptions" on page 77. |
| Escaping | Specify escape sequences. Use the **Escaped characters** box to list all the characters to be escaped without spaces. |

***Note:*** *You cannot delete a server that is used in any system or configuration log settings or logging profiles.*

## Custom Syslog Field Descriptions

You can configure a custom log format in a Syslog Server Profile by selecting the Custom Log Format tab in **Device > Server Profiles > Syslog.** Click the desired log type (Config, System, Threat, Traffic, or HIP Match) and then click the fields you want to see in the logs. The tables that follow shows the meaning of each field for each log type.

**Table 28 Config Fields**

| Field | Meaning |
|---|---|
| actionflags | A bit field indicating if the log was forwarded to Panorama. Available in PAN-OS 4.0.0 and above. |
| admin | User name of the Administrator performing the configuration. |
| after-change-detail | Details of the configuration after a change is made. |
| before-change-detail | Details of the configuration before a change is made. |
| formtted-receive_time | Time the log was received at the management plane, shown in CEF compliant time format. |
| cef-formatted-time_generated | Time the log was generated, shown in CEF compliant time format. |
| client | Client used by the Admin; Values are Web and CLI. |
| cmd | Command performed by the Admin; Values are add, clone, commit, delete, edit, move, rename, set, validate. |
| host | Host name or IP address of the client machine |
| path | The path of the configuration command issued. Up to 512 bytes in length. |
| receive_time | Time the log was received at the management plane. |
| result | Result of the configuration action. Values are Submitted, Succeeded, Failed, and Unauthorized. |

**Table 28 Config Fields**

| Field | Meaning |
|---|---|
| seqno | A 64bit log entry identifier incriminated sequentially. Each log type has a unique number space. Available in PAN-OS 4.0.0 and above. |
| serial | Serial number of the device that generated the log |
| subtype | Subtype of the Config log; Unused. |
| time_generated | Time the log was received on the data plane. |
| type | Specifies type of log; Values are traffic, threat, config, system and hip-match. |
| vsys | Virtual System associated with the configuration log. |

**Table 29 System Fields**

| Field | Meaning |
|---|---|
| actionflags | A bit field indicating if the log was forwarded to Panorama. Available in PAN-OS 4.0.0 and above. |
| cef-formatted-receive_time | Time the log was received at the management plane, shown in CEF compliant time format. |
| cef-formatted-time_generated | Time the log was generated, shown in CEF compliant time format. |
| eventid | String showing the name of the event |
| fmt | Detailed description of the event. Length is up to 512 bytes. |
| module | This field is valid only when the value of the Subtype field is general; It provides additional information about the sub-system generating the log. Values are general, management, auth, ha, upgrade, chassis. |
| number-of-severity | Severity level as an integer - informational-1, low-2, medium-3, high-4, critical-5. |
| object | Name of the object associated with the system log. |
| opaque | Detailed description of the event. Length is up to 512 bytes. |
| receive_time | Time the log was received at the management plane |
| seqno | A 64bit log entry identifier that increments sequentially. Each log type has a unique number space. Available in PAN-OS 4.0.0 and above. |
| serial | Serial number of the device that generated the log |
| severity | Severity associated with the event; Values are informational, low, medium, high, critical |
| subtype | Subtype of the system log. Refers to the system daemon generating the log; Values are crypto, dhcp, dnsproxy, dos, general, global-protect, ha, hw, nat, ntpd, pbf, port, pppoe, ras, routing, satd, sslmgr, sslvpn, userid, url-filtering, vpn. |
| time_generated | Time the log was received on the data plane. |

**Table 29 System Fields**

| Field | Meaning |
|---|---|
| type | Specifies type of log; Values are traffic, threat, config, system and hip-match. |
| vsys | Virtual System associated with the system event |

**Table 30 Threat Fields**

| Field | Meaning |
|---|---|
| action | Action taken for the session; Values are alert, allow, deny, drop, drop-all-packets, reset-client, reset-server, reset-both, block-url. See Action Field table below for meaning of each value. |
| actionflags | A bit field indicating if the log was forwarded to Panorama. Available in PAN-OS 4.0.0 and above. |
| app | Application associated with the session. |
| category | For URL Subtype, it is the URL category; for WildFire subtype, it is the verdict on the file and is either “malicious” or “benign”; for other subtypes, the value is “any”. |
| cef-formatted-receive_time | Time the log was received at the management plane, shown in CEF compliant time format. |
| cef-formatted-time_generated | Time the log was generated, shown in CEF compliant time format. |
| contenttype | Content type of the HTTP response data. Maximum length 32 bytes. Applicable only when Subtype is URL. Available in PAN-OS 4.0.0 and above. |
| direction | Indicates the direction of the attack, 'client-to-server' or 'server-to-client'. |
| dport | Destination port utilized by the session. |
| dst | Original session destination IP address. |
| dstloc | Destination country or Internal region for private addresses. Maximum length is 32 bytes. Available in PAN-OS 4.0.0 and above. |
| dstuser | User name of the user to which the session was destined. |
| flags | 32 bit field that provides details on the session; See Flags Field table for meaning of each value. |
| from | Zone the session was sourced from. |
| inbound_if | Interface that the session was sourced form. |
| logset | Log Forwarding Profile that was applied to the session. |
| misc | The actual URI when the subtype is URL; File name or file type when the subtype is file; and File name when the subtype is virus; File name when the subtype is wildfire. Length is 63 characters in PAN-OS versions before 4.0. From version 4.0, it is variable length with a maximum of 1023 characters. |
| natdport | Post-NAT destination port. |

**Table 30 Threat Fields**

| Field | Meaning |
|---|---|
| natdst | If Destination NAT performed, the post-NAT Destination IP address. |
| natsport | Post-NAT source port. |
| natsrc | If Source NAT performed, the post-NAT Source IP address. |
| number-of-severity | Severity level as an integer - informational-1, low-2, medium-3, high-4, critical-5. |
| outbound_if | Interface that the session was destined to. |
| proto | IP protocol associated with the session. |
| receive_time | Time the log was received at the management plane. |
| repeatcnt | Number of logs with same Source IP, Destination IP, and Threat ID seen within 5 seconds; Applies to all Subtypes except URL. |
| rule | Name of the rule that the session matched. |
| seqno | A 64bit log entry identifier that increments sequentially. Each log type has a unique number space. Available in PAN-OS 4.0.0 and above. |
| serial | Serial number of the device that generated the log. |
| sessionid | An internal numerical identifier applied to each session. |
| severity | Severity associated with the threat; Values are informational, low, medium, high, critical. |
| sport | Source port utilized by the session. |
| src | Original session source IP address. |
| srcloc | Source country or Internal region for private addresses. Maximum length is 32 bytes. Available in PAN-OS 4.0.0 and above. |
| srcuser | User name of the user that initiated the session. |
| subtype | Subtype of threat log; Values are URL, virus, spyware, vulnerability, file, scan, flood, data, and wildfire. |
| threatid | Palo Alto Networks identifier for the threat. It is a description string followed by a numerical identifier in parenthesis for some Subtypes. The numerical identifier is a 64-bit number from PAN-OS 5.0 and later. |
| time_generated | Time the log was generated on the data plane. |
| time_received | Time the log was received on the data plane. |
| to | Zone the session was destined to. |
| type | Specifies type of log; Values are traffic, threat, config, system and hip-match. |
| vsys | Virtual System associated with the session. |
| wildfire | Logs generated by WildFire. |

**Table 31 Traffic Fields**

| Field | Meaning |
|---|---|
| action | Action taken for the session; Values are allow or deny. See Action Field table. |
| actionflags | A bit field indicating if the log was forwarded to Panorama. Available from PAN-OS 4.0.0. |
| app | Application associated with the session. |
| bytes | Number of total bytes (transmit and receive) for the session. |
| bytes_received | Number of bytes in the server-to-client direction of the session. Available from PAN-OS 4.1.0 on all models except the PA-4000 series. |
| bytes_sent | Number of bytes in the client-to-server direction of the session. Available from PAN-OS 4.1.0 on all models except the PA-4000 series. |
| category | URL category associated with the session (if applicable). |
| cef-formatted-receive_time | Time the log was received at the management plane, shown in CEF compliant time format. |
| cef-formatted-time_generated | Time the log was generated, shown in CEF compliant time format. |
| dport | Destination port utilized by the session. |
| dst | Original session destination IP address. |
| dstloc | Destination country or Internal region for private addresses. Maximum length is 32 bytes. Available in PAN-OS 4.0.0 and above. |
| dstuser | User name of the user to which the session was destined. |
| elapsed | Elapsed time of the session. |
| flags | 32 bit field that provides details on session; See Flags Field table for meaning of each value. This field can be decoded by AND-ing the values with the logged value. |
| from | Zone the session was sourced from. |
| inbound_if | Interface that the session was sourced form. |
| logset | Log Forwarding Profile that was applied to the session. |
| natdport | Post-NAT destination port. |
| natdst | If Destination NAT performed, the post-NAT Destination IP address. |
| natsport | Post-NAT source port. |
| natsrc | If Source NAT performed, the post-NAT Source IP address. |
| outbound_if | Interface that the session was destined to. |
| packets | Number of total packets (transmit and receive) for the session. |
| pkts_received | Number of server-to-client packets for the session. Available from PAN-OS 4.1.0 on all models except the PA-4000 series. |
| pkts_sent | Number of client-to-server packets for the session. Available from PAN-OS 4.1.0 on all models except the PA-4000 series. |

**Table 31 Traffic Fields**

| Field | Meaning |
|---|---|
| proto | IP protocol associated with the session. |
| receive_time | Time the log was received at the management plane. |
| repeatcnt | Number of sessions with same Source IP, Destination IP, Application, and Subtype seen within 5 seconds; Used for ICMP only. |
| rule | Name of the rule that the session matched. |
| seqno | A 64bit log entry identifier incremented sequentially. Each log type has a unique number space. Available in PAN-OS 4.0.0 and above. |
| serial | Serial number of the device that generated the log. |
| sessionid | An internal numerical identifier applied to each session. |
| sport | Source port utilized by the session. |
| src | Original session source IP address. |
| srcloc | Source country or Internal region for private addresses. Maximum length is 32 bytes. Available in PAN-OS 4.0.0 and above. |
| srcuser | User name of the user that initiated the session. |
| start | Time of session start. |
| subtype | Subtype of traffic log; Values are start, end, drop, and deny. See Subtype Field table for meaning of each value. |
| time_generated | Time the log was generated on the data plane. |
| time_received | Time the log was received on the data plane. |
| to | Zone the session was destined to. |
| type | Specifies type of log; Values are traffic, threat, config, system and hip-match. |
| vsys | Virtual System associated with the session. |

**Table 32 HIP Match Fields**

| Field | Meaning |
|---|---|
| actionflags | A bit field indicating if the log was forwarded to Panorama. Available in PAN-OS 4.0.0 and above. |
| cef-formatted-receive_time | Time the log was received at the management plane, shown in CEF compliant time format. |
| cef-formatted-time_generated | Time the log was generated, shown in CEF compliant time format. |
| machinename | Name of the Users machine. |
| matchname | Name of the HIP Object or Profile. |
| matchtype | Specifies whether the HIP field represents a HIP Object or a HIP Profile. |
| receive_time | Time the log was received at the management plane. |

**Table 32 HIP Match Fields**

| Field | Meaning |
|---|---|
| repeatcnt | Number of times the HIP profile matched. |
| seqno | A 64bit log entry identifier incremented sequentially. Each log type has a unique number space. Available in PAN-OS 4.0.0 and above. |
| serial | Serial number of the device that generated the log. |
| src | IP address of the source user. |
| srcuser | User name of the Source user. |
| subtype | Subtype of hip-match log; Unused. |
| time_generated | Time the log was generated on the data plane. |
| type | Specifies type of log; Values are traffic, threat, config, system and hip-match. |
| vsys | Virtual System associated with the HIP Match log. |

# Configuring Email Notification Settings

▶ *Device > Server Profiles > Email*

To generate email messages for logs, you must configure an email profile. After you define the email settings, you can enable email notification for system and configuration log entries (refer to "Defining System Log Settings" on page 72). For information on scheduling email report delivery, refer to "Scheduling Reports for Email Delivery" on page 273.

**Table 33. Email Notification Settings**

| Field | Description |
|---|---|
| Name | Enter a name for the email settings (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow the profile to be shared by all virtual systems. |
| **Servers Tab** | |
| Server | Enter a name to identify the server (1-31 characters). This field is just a label and does not have to be the host name of an existing SMTP server. |
| Display Name | Enter the name shown in the From field of the email. |
| From | Enter the From email address, such as "security_alert@company.com". |
| To | Enter the email address of the recipient. |
| Additional Recipient | Optionally, enter the email address of another recipient. You can only add one additional recipient. To add multiple recipients, add the email address for a distribution list. |
| Gateway | Enter the IP address or host name of the Simple Mail Transport Protocol (SMTP) server used to send the email. |

**Table 33. Email Notification Settings (Continued)**

| Field | Description |
|---|---|
| **Custom Log Format Tab** | |
| Log Type | Click the log type to open a dialog box that allows you to specify a custom log format. In the dialog box, click a field to add it to the Log Format area. Click **OK** to save the settings. |
| Escaping | Include escaped characters and specify the escape character or characters. |

***Note:*** *You cannot delete an email setting that is used in any system or configuration log settings or logging profiles.*

# Viewing Alarms

You can view the current list of alarms at any time by clicking the **Alarms** icon in the lower right corner of the web interface when the Alarm option is configured. This opens a window that lists the unacknowledged and acknowledged alarms in the current alarms log. To acknowledge alarms, select their check boxes and click **Acknowledge**. This action moves the alarms to the Acknowledged Alarms list. The alarms window also includes paging, column sort, and refresh controls.

The Alarms button is visible only when the **Enable Alarms** check box is selected on the **Device > Log Settings > Alarms > Alarm Settings** page.

# Configuring Netflow Settings

▶ *Device > Server Profiles > Netflow*

The firewall can generate and export NetFlow Version 9 records with unidirectional IP traffic flow information to an outside collector. NetFlow export can be enabled on any ingress interface in the system. Separate template records are defined for IPv4, IPv4 with NAT, and IPv6 traffic, and PAN-OS specific fields for App-ID and User-ID can be optionally exported. This feature is available on all platforms, except for the PA-4000 Series models.

The firewall supports the standard NetFlow templates and selects the correct one based on the data to be exported.

To configure NetFlow data exports, define a NetFlow server profile, which specifies the frequency of the export along with the NetFlow servers that will receive the exported data.

Then when you assign the profile to an existing firewall interface, all traffic flowing over that interface is exported to the specified servers. All interface types support assignment of a NetFlow profile. Refer to "Firewall Interfaces" on page 127 for information on assigning a NetFlow profile to an interface.

**Table 34. Netflow Settings**

| Field | Description |
|---|---|
| Name | Enter a name for the Netflow settings (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Template Refresh Rate | Specify the number of minutes or number of packets after which the Netflow template is refreshed (minutes range 1-3600, default 30 min; packets range 1-600, default 20). |
| Active Timeout | Specify the frequency at which data records are exported for each session (minutes). |
| Export PAN-OS Specific Field Types | Export PAN-OS specific fields such as App-ID and User-ID in Netflow records. |
| **Servers** | |
| Name | Specify a name to identify the server (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |

**Table 34. Netflow Settings (Continued)**

| Field | Description |
|---|---|
| Server | Specify the host name or IP address of the server. You can add a maximum of two servers per profile. |
| Port | Specify the port number for server access (default 2055). |

# Importing, Exporting and Generating Security Certificates

## Certificates

▶ *Device > Certificate Management > Certificates*

The **Certificates** page allows you to generate the following security certificates:

- **Forward Trust**—This certificate is presented to clients during decryption when the server to which they are connecting is signed by a CA in the firewall's trusted CA list. If a self-signed certificate is used for forward proxy decryption, you must click the certificate name in the **Certificates** page and select the **Forward Trust Certificate** check box.
- **Forward Untrust**—This certificate is presented to clients during decryption when the server to which they are connecting is signed by a CA that is not in the firewall's trusted CA list.
- **Trusted Root CA**—The certificate is marked as a trusted CA for forward decryption purposes.

  When the firewall decrypts traffic, it checks the upstream certificate to see if it is issued by a trusted CA. If not, it uses a special untrusted CA certificate to sign the decryption certificate. In this case, the user sees the usual certificate error page when accessing the firewall and must dismiss the login warning.

  The firewall has a large list of existing trusted CAs. The trusted root CA certificate is for additional CAs that are trusted for your enterprise but are not part of the pre-installed trusted list.
- **SSL Exclude**—This certificate excludes connections if they are encountered during SSL forward proxy decryption.
- **Certificate for Secure Web GUI**—This certificate authenticates users for access to the firewall web interface. If this check box is selected for a certificate, the firewall will use this certificate for all future web-based management sessions following the next commit operation.

Perform any of the following functions on the **Certificates** page:

- To revoke a certificate:

  a. Select the certificate that you want to revoke.

b. Click **Revoke** and the certificate will be instantly set to the revoked status. No commit is required.

   You can also click an existing certificate and click the **Revoke** icon.

- To renew a certificate:

  a. Select the certificate that you want to renew.

  b. Click **Renew** and then set the number of days to extend the certificate and click **OK**. A new certificate will be generated with the same attributes, but with a new serial number. The old certificate is then replaced with the new certificate.

- To import a web interface, trusted CA, or SSL forward proxy certificate:

  a. Click **Import**.

  b. Enter a name to identify the certificate.

  c. Select the certificate file. If importing a PKCS #12 certificate and private key, this will be the single file holding both objects. If using PEM, this will be the public certificate only.

  d. Click the **Import Private Key** check box to load the private key and enter the passphrase twice. If using the PKCS #12, the key file was selected above. If using PEM, browse to the encrypted private key file (generally named *.key).

  e. Select the virtual system to which you want to import the certificate from the drop-down list.

- To export a certificate:

  a. Select the certificate you want to export.

  b. Click **Export**.

  c. Choose the file format you would like the exported certificate to use (.pfx for PKCS#12 or .pem).

  d. Select the **Export Private Key** check box and enter a passphrase twice to export the private key in addition to the certificate.

- Click **Save** and choose a location to copy the file to your local computer. To generate a certificate:

  a. Click **Generate** to open the Generate Certificate window and specify the information described in the following table.

  b. After generating the certificate, click the certificate link and specify the certificate type (Forward Trust, Forward Untrust, Trusted Root CA, SSL Exclude, or Certificate for Secure Web GUI).

***Note:*** *If you are using Panorama, you also have the option of generating a self-signed certificate for the Panorama server. Refer to "Central Device Management Using Panorama" on page 381 for information on Panorama.*

- To import keys for high availability (HA), click **Import HA Key** and browse to specify the key file for import. To export keys for HA, click **Export HA Key** and specify a location to save the file. The HA keys must be swapped across the two firewalls. In other words, the Key from firewall 1 must be exported and then imported to firewall 2 and vice versa.

**Table 35. Settings to Generate a Certificate**

| Field | Description |
|---|---|
| Certificate Name | Enter a name (up to 31 characters) to identify the certificate. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. Only the name is required. |
| Common Name | Enter the IP address or FQDN that will appear on the certificate. |
| Location | Choose a virtual system or choose **Shared** to make the certificate available to all virtual systems. |
| Signed By | Choose from a list of the CA certificates that were generated on the firewall. The selected certificate can be used to sign the certificate that is being created. |
| Certificate Authority | Mark this certificate as a CA so that it can be used to sign other certificates on the firewall. |
| OCSP Responder | Select an OSCP responder profile from the drop-down list. The profile is configured in Device > Certificate Management > OCSP Responder. When generating a certificate and entering an OCSP Responder, a look up will be performed for the host name of the IP address to generate a OCSP Responder URL, which will then appear in this drop-down. |
| Number of Bits | Choose the key length for the certificate. |
| Digest | Choose the digest algorithm for the certificate. |
| Expiration (days) | Specify the number of days that the certificate will be valid. The default is 365 days.<br>If you specify a **Validity Period** in a GlobalProtect Portal Satellite configuration, that value will override the value entered in this field. |
| Country<br>State<br>Locality<br>Organization<br>Department<br>Email | Optionally specify additional information to identify the certificate.<br>To view a list of country code definitions, click the **ISO 6366 Country Codes** link. |

# Default Trusted Certificate Authorities

▶ ***Device > Certificate Management > Certificates > Default Trusted Certificate Authorities***

Use this page to control the certificate authorities (CAs) that the firewall will trust. You can disable and enable CAs as needed.

**Table 36 Trusted Certificate Authorities Settings**

| Field | Description |
|---|---|
| Enable | If you have disabled a CA and want to enable it, click the check box next to the CA and then click **Enable**. |
| Disable | Click the check box next to the CA that you want to disable, then click **Disable**. This may be desired if you only want to trust certain CAs, or remove all of them to only trust your local CA. |
| Export | Click the check box next to the CA, then click **Export** to export the CA certificate. You can do this to import into another system, or if you want to view the certificate offline. |

# Certificate Profile

▶ *Device > Certificate Management > Certificate Profile*

You can create certificate profiles and then attach a profile to an administrator login on the **Setup** page or to an SSL-VPN login for use in authentication or with captive portals. You can also create certificate profiles to be used by GlobalProtect Gateways for authentication. Refer to "Defining Management Settings" on page 30 and "Captive Portals" on page 285.

**Table 37. Certificate Profile Settings**

| Page Type | Description |
|---|---|
| Name | Enter a name to identify the profile (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Location | If the device is in Multiple Virtual System Mode, select this check box to allow sharing by all virtual systems. |
| Username Field | Choose a user name option from the drop-down list. |
| Domain | Enter the domain for the profile. |
| CA Certificates | Choose a CA certificate from the drop-down list, specify the default OCSP URL, select an option to verify the CA certificate, and click **Add**. Repeat to add additional certificates.<br>The **OCSP Verify CA Certificate** drop down is used if you have a separate OCSP responder that can verify certificates. |
| Use CRL | Select the check box to use a Certificate Revocation List (CRL). |
| Use OCSP | Select the check box to use Online Certificate Status Protocol (OCSP) server. OCSP takes precedence over CRL. |
| CRL Receive Timeout | Specify an interval after which CRL requests time out (1 - 60 secs). |
| OCSP Receive Timeout | Specify an interval after which OCSP requests time out (1 - 60 secs). |
| Certificate Status Timeout | Specify an interval after which requests for certificate status time out (1 - 60 secs). |

**Table 37. Certificate Profile Settings (Continued)**

| Page Type | Description |
|---|---|
| Block session if certificate status is unknown | Select the check box to block a sessions if the certificate status is unknown. |
| Block sessions if certificate status cannot be retrieved within timeout | Select the check box to block a session if the certificate status cannot be retrieved within the timeout interval. |

# OCSP Responder

▶ *Device > Certificate Management > OCSP Responder*

Use the **OCSP Responder** (Online Certificate Status Protocol Responder) page to define a server that will be used to verify the revocation status of certificates issues by the PAN-OS device. When generating new certificates, you can specify the OCSP Responder that will be used.

To enable OCSP, go to **Device > Setup > Sessions** and under **Sessions Features** click **Decryption Certificate Revocation Settings**.

**Table 38 OCSP Responder Settings**

| Field | Description |
|---|---|
| Name | Enter a name to identify the OCSP responder server (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Host Name | Enter the host name of the OCSP responder server that will be used to check certificate revocation status for your devices. |

# Encrypting Private Keys and Passwords on the Firewall

▶ *Device > Master Key and Diagnostics*

Use the **Master Key and Diagnostics** page to specify a master key to encrypt private keys on the firewall. Private keys are stored in encrypted form by default even if a new master key is not specified. If the firewall is in Common Criteria mode, several crypto diagnostics capabilities are available. These diagnostics allow you to run scheduled crypto self-tests and on-demand self-tests.

To create a new master key, enter a 16 character string in the **New Master Key** field and then confirm the key. Enter a lifetime and reminder value and then click **OK**. You will need to update the master key before the expiration. For information on updating master keys, refer to "Updating Master Keys" on page 91.

- "Master Key and Diagnostic Settings" on page 91
- "Updating Master Keys" on page 91

## Master Key and Diagnostic Settings

**Table 39. Master Key and Diagnostics Settings**

| Field | Description |
|---|---|
| Current Master Key | Specify the key that is currently used to encrypt all of the private keys and passwords on the firewall. |
| New Master Key<br>Confirm Master Key | To change the master key, enter and confirm a new key. |
| Life Time | Specify the number of days and hours after which the master key expires (range 1-730 days). |
| Time for Reminder | Specify the number of days and hours before expiration when the user is notified of the impending expiration (range 1-365 days). |
| Common Criteria | In Common Criteria mode, additional buttons are available to run a cryptographic algorithm self-test and software integrity self-test. A scheduler is also included to specify the times at which the two self-tests will run. |

## Updating Master Keys

When creating a new master keys an expiration period will be defined, so it's important to update the keys before the expiration period is reached. When using a master key in a high availability (HA) configuration, it is also important that the same master key is used on both devices to ensure that private keys and certificates are encrypted with the same master key. If the master keys are different, HA configuration synchronization will not work properly. The following section describes how to update the master key if they working properly and instructions are provided if they have already expired or if the master keys on each device in the HA pair are out of sync.
As of PAN-OS 5.0, if the master keys in an HA pair do not match, a critical system log will be generated.

Reasons for updating the master key:

- You want to change the default master key or change a master key that you created.
- Master keys in an HA configuration are out of sync.
- Master key is going to expire soon.

HA Master key update (keys are in sync and have not reached the expiration date):

1. If you are updating the master keys and they are not expired or out of sync, before you update the keys, you need to commit the configuration and ensure that no pending configuration updates exist on both devices in the HA pair.
   You can view the commit status by clicking the **Tasks** link on the bottom right of the web interface on each device. From the CLI, run `show jobs all` to see all running jobs or `show jobs pending` to view pending jobs. To check that no pending updates are present, from configure mode, run `check pending-changes` and you should see **No**.
2. Disable configuration synchronization by navigating to **Device > High Availability** on both devices and from the **General** tab deselect the **Enable Config Sync** check box. Commit the configuration on both devices.
3. Update the master key on device A using 16 characters and commit the configuration.

4. Update the master key on device B with the same master key and commit the configuration.
5. The master keys should now be in sync. Check the logs to make sure no critical system logs related to the master key are present.
6. Enable configuration synchronize again by selecting the **Enable Config Sync** check box and then commit the configuration.

HA master key update (keys out of sync or expired):

1. If the master keys are out of sync or expired, you will see critical errors in the system log. If this occurs, you should immediately disable HA config sync on both devices in the HA pair. Navigate to **Device > High Availability** on both devices and from the **General** tab deselect the **Enable Config Sync** check box. Commit the configuration on both devices.
2. Ensure that no pending configuration updates exist on both devices in the HA pair. If there are pending changes, commit the configuration on both devices and wait until all configuration updates are complete.
   You can view the commit status by clicking the **Tasks** link on the bottom right of the web interface on each device. From the CLI, run `show jobs all` to see all running jobs or `show jobs pending` to view pending jobs. To check that no pending updates are present, from configure mode, run `check pending-changes` and you should see **No**.
3. Update the master key on device A using 16 characters and commit the configuration.
4. Update the master key on device B with the same master key and commit the configuration.
5. Enable configuration synchronization on both devices and commit the configuration.
6. The master keys should now be in sync. Check the logs to make sure no critical system logs related to the master key are present.
7. Enable configuration synchronize again by selecting the **Enable Config Sync** check box and then commit the configuration. If problems persist, please contact the Technical Support department.

# High Availability

PAN-OS supports active/passive and active/active high availability (HA).

***Note:*** *In an HA pair, both firewalls must be the same model and have the same licenses. If state synchronization is enabled, existing sessions continue after a switchover; however, threat prevention functions do not continue. Threat protection will apply to new sessions.*

## Active/Passive HA

In the active/passive configuration, two devices form an HA group to provide redundancy. The two firewalls mirror each other in configuration. If the active firewall fails for any reason, the passive firewall becomes active automatically with no loss of service. A failover can also occur if selected Ethernet links fail or if the active firewall cannot reach one or more of the specified destinations. From a traffic processing perspective, at most one device receives packets at any one time.

The following rules apply to HA operation and failover:

- The active firewall continuously synchronizes its configuration and session information with the passive firewall over the HA interfaces.
- If the active firewall fails, then the passive firewall detects the loss of heartbeats and automatically becomes active.
- If one HA interface fails, synchronization continues over the remaining interface. If the state synchronization connection is lost, then no state synchronization occurs. If the configuration synchronization is lost, heartbeats are lost. Both devices determine that the other is down, and both become active.
- You can configure the management ports (MGT) on the HA devices to provide a backup path for heartbeat and hello messages. If you configure HA1 or HA1 backup on the management port, you do not have to enable the heartbeat backup option.

## Active/Active HA

Active/active high availability allows both devices in an HA pair to pass traffic concurrently and is deployed primarily in asymmetrically routed environments where App-ID and Content-ID support are required. Layer 7 inspection for App-ID and Content-ID is performed on a single device for each session (that device is known as the session owner). PAN-OS uses packet forwarding (through the HA3 link), where required, to send packets to the designated session owner for processing.

***Note:*** *You must enable jumbo frames on the firewall and on all intermediary networking devices when using the HA3 interface. To enable jumbo frames, select* ***Device > Setup < Session*** *and select the option to* ***Enable Jumbo Frame*** *in the Session Settings section.*

Active/active devices can be deployed with Layer 3 or virtual wire interfaces. In Layer 3 deployments, the scanned packets can be forwarded directly by the session owner after processing. In virtual wire deployments, the scanned packets must be returned to the receiving firewall to preserve the forwarding path. If the session owner receives the packet

initially, the HA3 link is not used. Sessions that do not require App-ID and Content-ID are forwarded directly by the receiving device (even if it is not the session owner) to maximize performance.

To provide flexibility, you can configure Layer 3 interfaces in several ways. Note that it often makes sense to configure Layer 3 interfaces with a static interface IP address in addition to a virtual address (floating IP address or ARP load sharing IP address).

- **Static interface IP**—Layer 3 interfaces should be assigned static IP addresses whenever the firewall will be participating in dynamic routing protocols with neighboring devices. One possible active/active deployment option makes use of dynamic routing protocol cost metrics to force a symmetric path through the HA pair. In this case, all traffic will be symmetric and the efficiency of the active/active pair will be maximized.
- **Floating IP**—This mode is employed when Virtual Router Redundancy Protocol (VRRP)-like functionality is required, such as when an IP address must be available regardless of the state of the HA pair members. It is typical to configure two floating IP addresses on a particular interface such that each firewall owns one. Ownership is assigned to the device ID that has the higher priority. If either firewall fails, the floating IP address will be transitioned to the HA peer.
- **ARP load sharing**—This mode is used to distribute the load of host traffic between the two firewalls using Address Resolution Protocol (ARP).

For a more in-depth discussion of these three options refer to the discussions later in this section.

# Packet Flow

Packet flow works as follows in an active/active configuration:

- The session owner is responsible for all packet processing for App-ID and Content-ID. The session owner can be configured to be (1) the first device that receives a packet for the session or (2) the primary device. If the configuration option is set to “primary device,” all sessions are set up on the primary device.

***Note:*** *Logs passing through an active/active HA pair appear on the device that is designated as the session owner.*

- A single device is selected as the session setup device for all new sessions. This is necessary to avoid possible race conditions that can occur in asymmetrically routed environments. The session setup device is determined by one of the following methods:
  - **IP modulo**—Uses a simple modulus operation on the source IP address to determine which device will set up the session. IP modulo distributes session setup responsibilities to a particular HA device according to the parity of the IP address.
  - **Primary Device**—Session setup always occurs on the primary device.
  - **Hash**—Hashing is used to inject more randomness in the setup device selection process.

- When a new session begins, the receiving firewall either sets up the session or forwards it to the HA peer. The action is determined by the session setup configuration, as described previously. During this time, the session owner (the device responsible for maintaining state for App-ID and Content-ID) is determined according to the configuration.
- If packets arrive at the session owner, the packet is scanned for threats (if configured in security policy) and forwarded according to the device's networking configuration. If packets arrive at the HA peer, a session table lookup identifies that the session is owned by the other device and the packet can be forwarded across HA3 to the session owner. If Layer 7 inspection is not required for the session, the receiving device can simply match the session with an existing session table entry and forward the packet towards its final destination.

# Deployment Options

Active/active HA supports concurrent use of virtual wire and Layer 3 interfaces. All active/active deployment options are supported in IPv6 environments, including IPv6 path monitoring.

### Virtual Wire Deployment

Virtual wire deployments support full asymmetric routing as with other active/active deployments. It is important to note that packets forwarded to the session owner for App-ID and Content-ID inspection must be returned to the receiving firewall to preserve the forwarding path.

### Layer 3-Floating IP Deployment

This deployment option allows for the creation of floating IP addresses that can move between the HA devices when a link failure or device failure occurs. The port that owns the floating IP address responds to ARP requests with a virtual MAC address. Floating IP addresses are recommended when VRRP-like functionality is required. Floating IP addresses can be used in VPN and Network Address Translation (NAT) configurations, allowing for persistent connections when a failure occurs on the device offering those services.

***Note:*** *Floating IP address will utilize a different virtual MAC address when the IP moves between HA devices when a failure occurs.*

### Layer 3-ARP Load-Sharing

ARP load-sharing allows the HA pair to share an IP address and provide gateway services. In this scenario, all hosts are configured with a single gateway IP address. ARP requests for the gateway IP address are responded to by a single device in the pair, according to the source of the ARP request. The device selection algorithm can be tuned to achieve a more even distribution of host traffic between the two firewalls. ARP load-sharing should be used when the firewall and hosts exist on the same broadcast domain. If Layer 3 separation exists, the benefits of ARP load-sharing will be lost.

***Note:*** *You cannot ping or perform any management services on an ARP load-sharing IP address in active/active mode.*

### Layer 3-Route Based Redundancy (Static Interface IPs)

Route based redundancy forces traffic to be symmetric by using routing metrics such as Open Shortest Path First (OSPF) costs on the firewalls and on neighboring devices. Load sharing can be handled by adjusting costs to route traffic through both firewalls. In this case, the IP address assigned to the device interface is pinned down and does not fail over to the HA peer during a failover.

## NAT Considerations

In active/active mode, it is necessary to define an active/active device binding in all NAT rules. Active/active device binding becomes available in the web interface when the HA mode has been changed to active/active. When a new session is created, device binding determines which NAT rules are matched by the firewall (the device binding must include the session owner device to produce a match). Although NAT policy match is performed by the session setup device, NAT rules are evaluated from the perspective of the session owner. The session is translated according to NAT rules that are bound to the session owner device. For device-specific rules, a firewall skips all NAT rules that are not bound to the session owner when the NAT policy match is performed.

For example, suppose device 1 is the session owner and is also responsible for setting up the session. When device 1 attempts to match the session to a NAT rule, it will skip all rules with a device binding of device 0.

NAT device binding options include the following:

- **Device 0 and Device 1**—Translation is performed according to device-specific bindings only if the session owner and the device ID in the NAT rule match. Device-specific NAT rules are commonly used when the two firewalls use unique public IP addresses for translation.
- **Both**—This option allows either device to match new sessions to the NAT rule and is commonly used for destination NAT.
- **Primary**—This option allows only the active-primary device to match new sessions to the NAT rule. This setting is used mainly for inbound static NAT, where only one firewall should respond to ARP requests. Unlike device 0/1 bindings, a primary device binding can move between devices when the primary role is transferred.

The following scenarios apply to active/active NAT deployments.

### Source Translation to Dynamic IP or IP/Port Pool

When source translating to a dynamic IP or dynamic IP/port pool, it is necessary to tie NAT rules to a specific device (Device ID 0 or 1). The IP pools to which the HA devices are translating must not overlap. When a session is established, either device can translate return packets.

In the following example, the sessions owned by device 0 are translated to 1.1.1.1 and the sessions owned by device 1 are translated to 1.1.1.2. In the event of a device failure, sessions from device 0 will continue to be translated to 1.1.1.1 until they have ceased. In this example, it is valid to use floating IP addresses on each of the firewalls if that functionality is required.

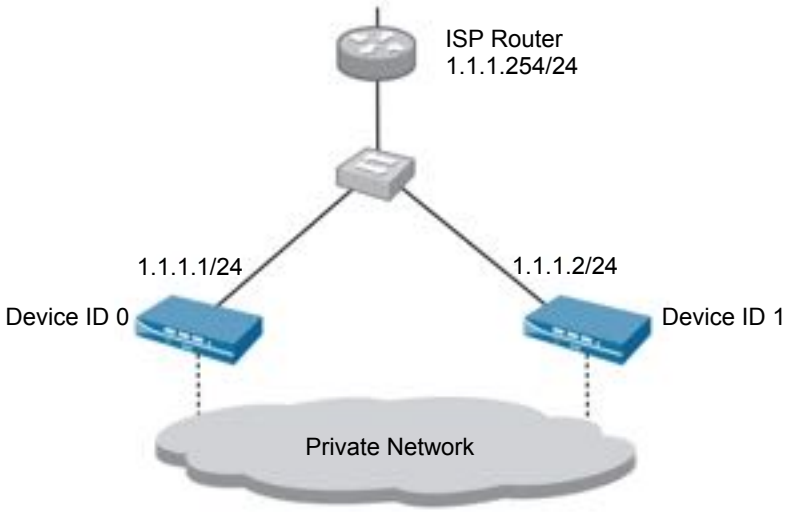

**Figure 3. Source Translation Dynamic IP Configuration**

**Table 40. Source Translation Dynamic IP Rules**

| | Original Packet | | Translated Packet | |
|---|---|---|---|---|
| **Name** | **Source Zone** | **Destination Zone** | **Source Translation** | **Active/Active HA Binding** |
| Src NAT Device 0 | L3Trust | L3Untrust | dynamic-ip-and-port 1.1.1.1 | 0 |
| Src NAT Device 1 | L3Trust | L3Untrust | dynamic-ip-and-port 1.1.1.2 | 1 |

### Dynamic Source Translation to Public IP Addresses for Different Internet Service Providers (ISPs)

In this scenario, NAT rules are tied to specific devices (Device ID 0 or 1). All sessions owned by device 0 are translated to 1.1.1.1 and all sessions owned by device 1 are translated to 2.2.2.1. If device 0 fails, device 1 will attempt to translate existing sessions according to the original IP address of 1.1.1.1. If the second ISP cannot route to these addresses, the sessions will fail. In this example, the ISP-specific interface IP addresses are pinned down to a particular device. A floating IP address should not be used in this configuration.

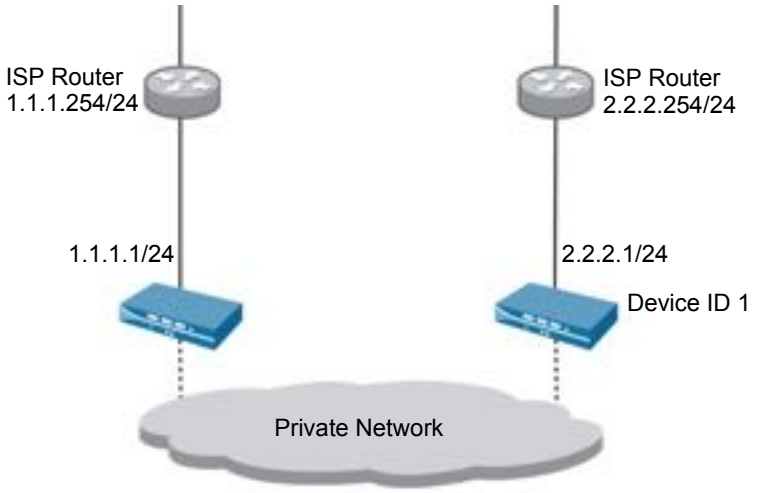

**Figure 4. Dynamic Source Translation to Public IP Address Configuration**

**Table 41. Dynamic Source Translation to Public IP Address Rules**

| | Original Packet | | Translated Packet | |
|---|---|---|---|---|
| **Name** | **Source Zone** | **Destination Zone** | **Source Translation** | **Active/Active HA Binding** |
| Src NAT Device 0 | L3Trust | L3Untrust | dynamic-ip-and-port 1.1.1.1 | 0 |
| Src NAT Device 1 | L3Trust | L3Untrust | dynamic-ip-and-port 2.2.2.1 | 1 |

### Destination Translation to Provider-Independent IP Address

In this scenario, NAT rules are tied to both devices. Translation is the same regardless of which device receives the first incoming packet. A packet destined to 3.3.3.30 will be translated to 10.0.0.200 regardless of which device receives the packet.

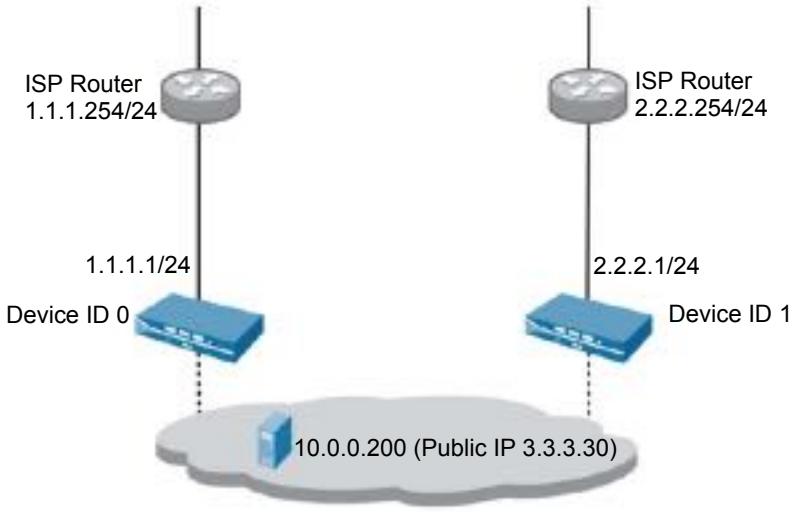

**Figure 5. Destination Translation to Provider-Independent IP Address**

**Table 42. Dynamic Source Translation to Public IP Address Rules**

| | | Original Packet | | Translated Packet | |
|---|---|---|---|---|---|
| **Name** | **Source Zone** | **Destination Zone** | **Destination Address** | **Destination Translation** | **Active/Active HA Binding** |
| DNAT Prov Indep | L3Untrust | L3Untrust | 3.3.3.30 | address: 10.0.0.200 | both |

# Setting Up HA

To set up HA, follow these steps:

1. Use two firewalls with the same model number.
2. Mount both firewalls in a rack near each other, and power them up as described in the *Hardware Reference Guide*. If you are enabling HA on an existing production device, backup the configuration and you may also want to perform a factory reset on the new device that will be introduced. This will ensure that the configuration is clean on the new device. After HA is configured, you would then push the configuration from the existing primary device to the new secondary device. Make sure that you do not push the factory config from the new device to the existing device. For information on performing a factory reset, refer to the *PAN-OS Command Line Interface Reference Guide*.
3. Connect each firewall to your network and the Internet using the same physical ports.

4. Using two crossover RJ-45 Ethernet cables, connect the HA1 and HA2 ports on each firewall to the same ports on the other firewall, or connect the ports on both firewalls to a switch. HA1 is for the control link, and HA2 is for the data link. For active/active configurations, make an additional physical connection, HA3, between the two firewalls. Link aggregation groups are recommended for link redundancy on HA3 when the firewall supports aggregate Ethernet.

***Note:*** *For devices that do not have dedicated HA interfaces, you must use the traffic interfaces for HA. For example, connect the ethernet 1/15 interfaces to each other and the ethernet1/16 interfaces to each other.*

5. Open the **Network** tab and verify that the HA links are up. Configure each to be of the type HA.

**Figure 6. Verifying HA Interfaces**

6. Configure HA settings on both firewalls. Refer to “Enabling HA on the Firewall” on page 101.

### Item to note when setting up HA

Crossover cables are recommended when HA links are directly connected.

# Enabling HA on the Firewall

▶ *Device > High Availability*

After setting up HA as described in "Setting Up HA" on page 99, you can enable HA on both the active and passive firewall. For each section on the **High Availability** page, click **Edit** in the header, and specify the corresponding information described in the following table.

**Table 43. HA Settings**

| Field | Description |
|---|---|
| **General Tab** | |
| Setup | Specify the following settings:<br>• **Enable HA**—Activate HA functionality.<br>• **Group ID**—Enter a number to identify the active/passive pair (1 to 63). Allows multiple pairs of active/passive firewalls to reside on the same network. The ID must be unique when more than one high availability pair resides on an Layer 2 network.<br>• **Description**—Enter a description of the active/passive pair (optional).<br>• **Mode**—Choose active-active or active-passive.<br>• **Peer HA IP Address**—Enter the IP address of the HA1 interface that is specified in the Control Link section of the other firewall.<br>• **Backup Peer HA IP Address**—Enter the IP address for the peer's backup control link.<br>• **Enable Config Sync**—Synchronize the peer system.<br>• **Link Speed**— Select the speed for the data link between the active and passive firewalls (Firewalls with dedicated HA ports).<br>• **Link Duplex**— Select a duplex option for the data link between the active and passive firewalls (Firewalls with dedicated HA ports). |

**Table 43. HA Settings (Continued)**

| Field | Description |
|---|---|
| Election Settings | Specify the following settings:<br>• **Device Priority**—Enter a priority value to identify the active firewall. The firewall with the lower value (higher priority) becomes the active firewall (range 0-255).<br>• **Heartbeat Backup**—Uses the management ports on the HA devices to provide a backup path for heartbeat and hello messages. The management port IP address will be shared with the HA peer through the HA1 control link. No additional configuration is required.<br>• **Preemptive**—Enable the higher priority firewall to resume active operation after recovering from a failure. If this setting is off, then the lower priority firewall remains active even after the higher priority firewall recovers from a failure.<br>• **Preemption Hold Time**—Enter the time a passive or active-secondary device will wait before taking over as the active or active-primary device (range 1-60 min, default 1 min).<br>• **Promotion Hold Time**—Enter the time that the passive device (in active/passive mode) or the active-secondary device (in active/active mode) will wait before taking over as the active or active-primary device after communications with the HA peer have been lost. This hold time will begin only after the peer failure declaration has been made.<br>• **Hello Interval**—Enter the number of milliseconds between the hello packets sent to verify that the HA program on the other firewall is operational. The range is 8000-60000 ms with a default of 8000 ms for all platforms.<br>• **Heartbeat Interval**—Specify how frequently the HA peers exchange heartbeat messages in the form of an ICMP ping (range 1000-60000 ms, default 1000 ms).<br>• **Maximum No. of Flaps**—A flap is counted when the firewall leaves the active state within 15 minutes after it last left the active state. You can specify the maximum number of flaps that are permitted before the firewall is determined to be suspended and the passive firewall takes over (range 0-16, default 3). The value 0 means there is no maximum (an infinite number of flaps is required before the passive firewall takes over).<br>• **Monitor Fail Hold Up Time (ms)**—Specify the interval during which the firewall will remain active following a path monitor or link monitor failure. This setting is recommended to avoid an HA failover due to the occasional flapping of neighboring devices (range 0-60000 ms, default 0 ms).<br>• **Additional Master Hold Up Time (min)**—This time interval is applied to the same event as Monitor Fail Hold Up Time (range 0-60000 ms, default 500 ms). The additional time interval is applied only to the active device in active/passive mode and to the active-primary device in active/active mode. This timer is recommended to avoid a failover when both devices experience the same link/path monitor failure simultaneously. |

**Table 43. HA Settings (Continued)**

| Field | Description |
|---|---|
| Control Link (HA1)/ Control Link (HA1 Backup) | The recommended configuration for the HA control link connection is to use the dedicated HA1 link between the two devices and use the management port as the Control Link (HA Backup) interface. In this case, you do not need to enable the Heartbeat Backup option in the Elections Settings page. If you are using a physical HA1 port for the Control Link HA link and a data port for Control Link (HA Backup), it is recommended that enable the Heartbeat Backup option.<br>For devices that do not have a dedicated HA port, such as the PA-200, you should configure the management port for the Control Link HA connection and a data port interface configured with type HA for the Control Link HA1 Backup connection. Since the management port is being used in this case, there is no need to enable the Heartbeat Backup option in the Elections Settings page because the heartbeat backups will already occur through the management interface connection.<br>***Note:*** *When using a data port for the HA control link, you should be aware that since the control messages have to communicate from the dataplane to the management plane, if a failure occurs in the dataplane, HA control link information cannot communicate between devices and a failover will occur. It is best to use the dedicated HA ports, or on devices that do not have a dedicated HA port, use the management port.*<br>Specify the following settings for the primary and backup HA control links:<br>• **Port**—Select the HA port for the primary and backup HA1 interfaces. The backup setting is optional.<br>***Note:*** *The management port can also be used as the control link.*<br>• **IPv4/IPv6 Address**—Enter the IPv4 or IPv6 address of the HA1 interface for the primary and backup HA1 interfaces. The backup setting is optional.<br>• **Netmask**—Enter the network mask for the IP address (such as "255.255.255.0") for the primary and backup HA1 interfaces. The backup setting is optional.<br>• **Gateway**—Enter the IP address of the default gateway for the primary and backup HA1 interfaces. The backup setting is optional.<br>• **Link Speed (Models with dedicated HA ports only)**—Select the speed for the control link between the firewalls for the dedicated HA1 port.<br>• **Link Duplex (Models with dedicated HA ports only)**—Select a duplex option for the control link between the firewalls for the dedicated HA1 port.<br>• **Encryption Enabled**—Enable encryption after exporting the HA key from the HA peer and importing it onto this device. The HA key on this device must also be exported from this device and imported on the HA peer. Configure this setting for the primary HA1 interface.<br>The key import/export is done on the Certificates page. Refer to "Importing, Exporting and Generating Security Certificates" on page 60.<br>• **Monitor Hold Time (ms)**—Enter the length of time (milliseconds) that the firewall will wait before declaring a peer failure due to a control link failure (1000-60000 ms, default 3000 ms). This option monitors the physical link status of the HA1 port(s). |

**Table 43. HA Settings (Continued)**

| Field | Description |
|---|---|
| Data Link (HA2) | Specify the following settings for the primary and backup data link:<br>• **Port**—Select the HA port. Configure this setting for the primary and backup HA2 interfaces. The backup setting is optional.<br>• **IP Address**—Specify the IPv4 or IPv6 address of the HA interface for the primary and backup HA2 interfaces. The backup setting is optional.<br>• **Netmask**—Specify the network mask for the HA interface for the primary and backup HA2 interfaces. The backup setting is optional.<br>• **Gateway**—Specify the default gateway for the HA interface for the primary and backup HA2 interfaces. The backup setting is optional. If the HA2 IP addresses of the firewalls in the HA pair are in the same subnet, the Gateway field should be left blank.<br>• **Enable Session Synchronization**—Enable synchronization of the session information with the passive firewall, and choose a transport option.<br>• **Transport**—Choose one of the following transport options:<br>– **Ethernet**—Use when the firewalls are connected back-to-back or through a switch (Ethertype 0x7261).<br>– **IP**—Use when Layer 3 transport is required (IP protocol number 99).<br>– **UDP**—Use to take advantage of the fact that the checksum is calculated on the entire packet rather than just the header, as in the IP option (UDP port 29281).<br>• **Link Speed (Models with dedicated HA ports only)**—Select the speed for the control link between the active and passive firewalls for the dedicated HA2 port.<br>• **Link Duplex (Models with dedicated HA ports only)**—Select a duplex option for the control link between the active and passive firewalls for the dedicated HA2 port.<br>• **HA2 keep-alive**—Select this check box to enable monitoring on the HA2 data link between the HA peers. If a failure occurs based on the threshold that is set, the defined action will occur (log or split data-path). The option is disabled by default.<br>You can configure the HA2 keep-alive option on both devices, or just one device in the HA pair. If the option is only set on one device, only that device will send the keep-alive messages. The other device will be notified though if a failure occurs and will go into split data path mode if that action is selected.<br>– **Action**—Select the action to take if monitoring messages fail based on the threshold setting.<br>› **log-only**—Select to generate a critical level system log message when an HA2 failure occurs based on the threshold setting. If the HA2 path recovers, an informational log will be generated.<br>In an active/passive configuration, you should use this action since there's no need to split the data since only one device is active at a given time.<br>› **split data-path**—This action is designed for an active/active HA configuration. In an ***active/active*** configuration, if session synchronization is disabled by the admin, or by a monitoring failure, session ownership and session setup will both be set to the local device and new sessions will be processed locally for the session lifetime. |

**Table 43. HA Settings (Continued)**

| Field | Description |
|---|---|
| | › **Threshold (ms)**—The duration in which keep-alive messages have failed before one of the above actions will be triggered (range 5000-60000ms, default 10000ms).<br><br>***Note:*** *When an HA2 backup link is configured, failover to the backup link will occur if there is a physical link failure. With the HA2 keep-alive option enabled, the failover will also occur if the HA keep-alive messages fail based on the defined threshold.* |
| **Link and Path Monitoring Tab** | |
| Path Monitoring | Specify the following:<br>• **Enabled**—Enable path monitoring. Path monitoring enables the firewall to monitor specified destination IP addresses by sending ICMP ping messages to make sure that they are responsive. Use path monitoring for virtual wire, Layer 2, or Layer 3 configurations where monitoring of other network devices is required for failover and link monitoring alone is not sufficient.<br>• **Failure Condition**—Select whether a failover occurs when any or all of the monitored path groups fail to respond. |
| Path Group | Define one or more path groups to monitor specific destination addresses. To add a path group, click **Add** for the interface type (Virtual Wire, VLAN, or Virtual Router) and specify the following:<br>• **Name**—Enter a name to identify the group.<br>• **Enabled**—Enable the path group.<br>• **Failure Condition—**Select whether a failure occurs when any or all of the specified destination addresses fails to respond.<br>• **Source IP**—For virtual wire and VLAN interfaces, enter the source IP address used in the probe packets sent to the next-hop router (Destination IP address). The local router must be able to route the address to the firewall. The source IP address for path groups associated with virtual routers will be automatically configured as the interface IP address that is indicated in the route table as the egress interface for the specified destination IP address.<br>• **Destination IPs**—Enter one or more (comma-separated) destination addresses to be monitored.<br>• **Ping Interval**—Specify the interval between pings that are sent to the destination address (range 200-60,000 milliseconds, default 200 milliseconds).<br>• **Ping Count**—Specify the number of failed pings before declaring a failure (range 3-10 pings, default 10 pings). |

**Table 43. HA Settings (Continued)**

| Field | Description |
|---|---|
| Link Monitoring | Specify the following:<br>• **Enabled**—Enable link monitoring. Link monitoring allows failover to be triggered when a physical link or group of physical links fails.<br>• **Failure Condition**—Select whether a failover occurs when any or all of the monitored link groups fail. |
| Link Groups | Define one or more link groups to monitor specific Ethernet links. To add a link group, specify the following and click **Add**:<br>• **Name**—Enter a link group name.<br>• **Enabled**—Enable the link group.<br>• **Failure Condition—**Select whether a failure occurs when any or all of the selected links fail.<br>• **Interfaces**—Select one or more Ethernet interfaces to be monitored. |
| **Active/Passive Tab** | |
| Passive Link State | Choose from the following options:<br>• **auto**—Causes the link status to reflect physical connectivity, but discards all packets received. This option allows the link state of the interface to stay up until a failover occurs, decreasing the amount of time it takes for the passive device to take over.<br>This option is supported in Layer 2, Layer 3, and Virtual Wire mode. The auto option is desirable, if it is feasible for your network.<br>***Note:*** *When set to auto, the link state on the passive peer in a VM-Series firewall configured as an HA pair displays in a down state on* ***Network > Interfaces > Ethernet****. The link state for the interface icon is red.*<br>• **shutdown**—Forces the interface link to the down state. This is the default option, which ensures that loops are not created in the network. |
| Monitor Fail Hold Down Time | Specify the length of time (minutes) that a firewall will spend in the non-functional state before becoming passive. This timer is used only when the failure reason is a link or path monitor failure (range 1 to 60, default 1). |
| **Active/Active Config Tab** | |
| Packet Forwarding | Select the Enable check box to enable forwarding of packets over the HA3 link. This is required for asymmetrically routed sessions that require Layer 7 inspection for App-ID and Content-ID. |
| HA3 Interface | Choose the interface to forward packets between HA peers when configured in active/active mode.<br>***Note:*** *You must enable jumbo frames on the firewall and on all intermediary networking devices when using the HA3 interface. To enable jumbo frames, select* ***Device > Setup < Session*** *and select the option to* ***Enable Jumbo Frame*** *in the Session Settings section.* |
| VR Sync | Force synchronization of all virtual routers configured on the HA devices.<br>Virtual Router synchronization can be used when the virtual router is not employing dynamic routing protocols. Both devices must be connected to the same next-hop router through a switched network and must use only static routing. |

**Table 43. HA Settings (Continued)**

| Field | Description |
|---|---|
| QoS Sync | Synchronize the QoS profile selection on all physical interfaces. Use this option when both devices have similar link speeds and require the same QoS profiles on all physical interfaces. This setting affects the synchronization of QoS settings on the **Network** tab. QoS policy is synchronized regardless of this setting. |
| Tentative Hold Time (sec) | When a firewall in an HA active/active state fails it will go into a tentative state. This timer defines how long it will stay in this state. During the tentative period the firewall will attempt to build routing adjacencies and populate its route table before it will process any packets. Without this timer, the recovering firewall would enter the active-secondary state immediately and would blackhole packets because it would not have the necessary routes (default 60 seconds). |
| Session Owner Selection | Specify one of the following options for selecting the session owner:<br>• **Primary Device**—Select this option to have the active/primary firewall handle Layer 7 inspection for all sessions. This setting is recommended primarily for troubleshooting operations.<br>• **First packet**—Select this option to make the firewall that receives the first packet of the session responsible for Layer 7 inspection in support of App-ID and Content-ID. This is the recommended configuration to minimize utilization of the HA3 packet forwarding link. |
| Session Setup | Choose the method for initial session setup.<br>• **IP Modulo**—Selects a firewall based on the parity of the source IP address.<br>• **Primary Device**—Ensures that all sessions are set up on the primary firewall.<br>• **IP Hash**—Determines the setup firewall using a hash of the source IP address or source and destination IP address, and hash seed value if more randomization is desired. |

**Table 43. HA Settings (Continued)**

| Field | Description |
|---|---|
| Virtual Address | Click **Add**, select the IPv4 or IPv6 tab and then click **Add** again to enter options for an HA virtual Address that will be used by the HA active/active cluster. You can select the type of virtual address to be either Floating or ARP Load Sharing. You can also mix the type of virtual address types in the cluster, for example, you could use ARP load sharing on the LAN interface and a Floating IP on the WAN interface. For more information deployment types, refer to "Deployment Options" on page 95.<br>• **Floating**—Enter an IP address that will move between HA devices in the event of a link or device failure. You should configure two floating IP addresses on the interface, so that each firewall will own one and then set the priority. If either firewall fails, the floating IP address will be transitioned to the HA peer.<br>– Device 0 Priority—Set the priority to determine which device will own the floating IP address. A device with the lowest value will have the highest priority.<br>– Device 1 Priority—Set the priority to determine which device will own the floating IP address. A device with the lowest value will have the highest priority.<br>– Failover address if link state is down—Use the failover address when the link state is down on the interface.<br>• **ARP Load Sharing**—Enter an IP address that will be shared by the HA pair and will provide gateway services for hosts. This option should only be used when the firewall and hosts exist on the same broadcast domain. Select the **Device Selection Algorithm**:<br>– **IP Modulo**—If this option is selected, the firewall that will respond to ARP requests will be selected based on the parity of the ARP requesters IP address.<br>– **IP Hash**—If this option is selected, the firewall that will respond to ARP requests will be selected based on a hash of the ARP requesters IP address. |
| **Operational Commands** | |
| Suspend local device | Put the HA device in suspend mode, which temporarily disables HA functionality on the firewall. If you suspend the current active firewall, the secondary firewall will take over. |

### Important items to consider when configuring HA

- The firewall that is assigned the lower device priority value is the higher priority device and becomes the active firewall in an HA pair when preemption is enabled on both firewalls in the pair.
- The Preemption option must be enabled on both devices for the higher priority firewall to resume active operation upon recovery following a failure.
- The subnet that is used for the local and peer IP should not be used anywhere else on the virtual router.
- The OS and Content versions should be the same on each device. A mismatch can prevent the devices in the cluster from synchronizing.
- The LEDs are green on the HA ports for the active firewall and amber on the passive firewall.

- To test failover, pull a cable on the active device, or put the active device into a suspend state by issuing the CLI command `request high-availability state suspend`. You can also suspend the active device by clicking the **Suspend** link at **Device > High Availability > Operational Commands** tab**.**
- To place a suspended device back into a functional state, use the CLI command `request high-availability state functional`.
- To view detailed HA information about the local firewall, use the CLI command **show high-availability all**.
- To compare the configuration of the local and peer firewalls, use the CLI command **show high-availability state** from either device. You can also compare the configurations on the local and peer firewalls using the **Config Audit** tool on the **Device** tab by selecting the desired local configuration in the left selection box and the peer configuration in the right selection box.
- Synchronize the firewalls from the web interface by pressing the **Push Configuration** button located in the HA widget on the **Dashboard** tab. Note that the configuration on the device from which you push the configuration overwrites the configuration on the peer device. To synchronize the firewalls from the CLI on the active device, use the command `request high-availability sync-to-remote running-config`.
- To follow the status of the load, use the CLI command **show jobs processed**.

***Note:*** *In a High Availability (HA) active/passive configuration with devices that use 10 Gigabit SFP+ ports, when a failover occurs and the active device changes to a passive state, the 10 Gigabit Ethernet port is taken down and then brought back up to refresh the port, but does not enable transmit until the device becomes active again. If you have monitoring software on the neighboring device, it will see the port as flapping because it is going down and then up again. This is different behavior than the action with other ports, such as the 1 Gigabit Ethernet port, which is disabled and still allows transmit, so flapping is not detected by the neighboring device.*

### HA Lite

The PA-200 and VM-Series firewalls supports a “lite” version of active/passive HA that does not include any session synchronization. HA lite does provide configuration synchronization and synchronization of some runtime items. It also supports failover of IPSec tunnels (sessions must be re-established), DHCP server lease information, DHCP client lease information, PPPoE lease information, and the firewall's forwarding table when configured in Layer 3 mode.

# Virtual Systems

A virtual system specifies a collection of physical and logical firewall interfaces (including VLANs, and virtual wires) and security zones. (For more information on security zones, refer to "Defining Security Zones" on page 151.) Virtual systems allow you to segment the administration of all policies (security, NAT, QoS, etc.) as well as all reporting and visibility functions provided by the firewall.

Virtual systems generally operate on the security functionality of the firewall. Networking functions including static and dynamic routing are not controlled by virtual systems. If routing segmentation is desired for each virtual system, you must create an additional virtual router.

***Note:*** *The PA-4000 and PA-5000 Series firewalls support multiple virtual systems. The PA-2000 and PA-3000 Series firewalls can support multiple virtual systems if the appropriate license is installed. The PA-500 and PA-200 firewalls do not support virtual systems.*

For example, if you want to customize the security features for the traffic that is associated with your Finance department, you can define a Finance virtual system and then define security policies to apply only to that department.

Figure 7 illustrates the relationship between policies and virtual systems in the firewall. Policies are associated with individual virtual systems, by contrast with device and network level functions, which apply to the overall firewall.

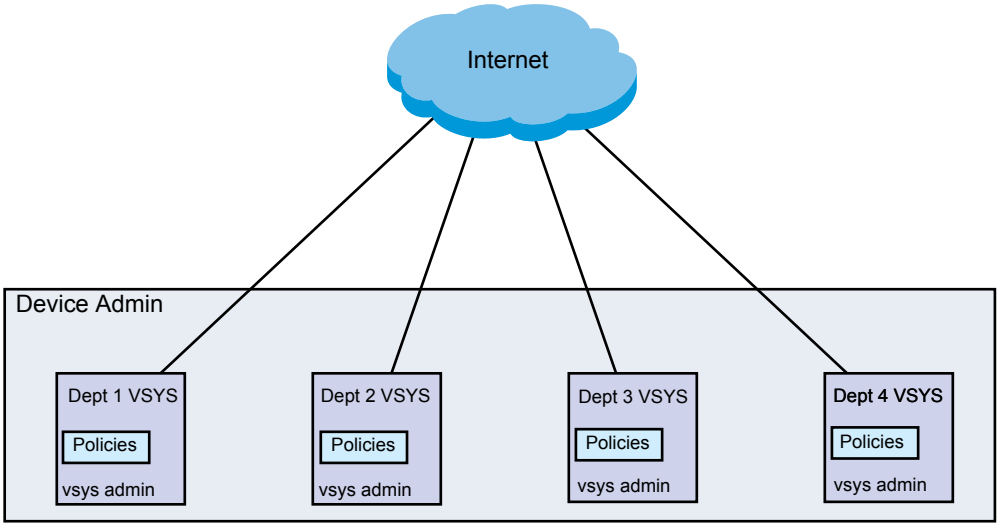

**Figure 7. Virtual Systems and Policies**

To optimize policy administration, you can create virtual system administrator accounts that allow access to individual virtual systems, while maintaining separate administrator accounts for overall device and network functions. For example, a virtual system administrator in the Finance department can be assigned to manage the security policies only for that department.

Initially all interfaces, zones, and policies belong to the default virtual system (vsys1).

When you enable multiple virtual systems, note the following:

- All items needed for policies are created and administered by a virtual systems administrator.
- Zones are objects within virtual systems. Before defining a policy or policy object, select the virtual system from the **Virtual System** drop-down list on the **Policies** or **Objects** tab.
- Interfaces, VLANs, virtual wires, and virtual routers can be assigned to virtual systems. Refer to "Defining Virtual Systems" on page 113.
- Remote logging destinations (SNMP, syslog, and email), as well as applications, services, and profiles, can be shared by all virtual systems or be limited to a selected virtual system.

## Communications Among Virtual Systems

The virtual systems in the firewall are treated as separate entities. To support internal traffic flows between virtual systems, you must indicate which virtual systems are able to communicate with each other. You do so when configuring a virtual system by specifying the other virtual systems that are visible to it. When the virtual systems are made visible to each other, create "external"-type zones and specify which virtual systems will map to each external zone. In the following example, Dept 1 VSYS must have an external zone that refers to Dept 2 VSYS for use in all policies affecting traffic passing between the virtual systems. Traffic log entries are recorded in both virtual systems for inter-VSYS traffic.

Each virtual system must have policies for sending and receiving traffic. For example, allowing Dept 1 VSYS to communicate with Dept 2 VSYS requires a policy in Dept 1 VSYS to allow traffic to go to Dept 2 VSYS and a policy in Dept 2 VSYS to accept incoming traffic from Dept 1 VSYS.

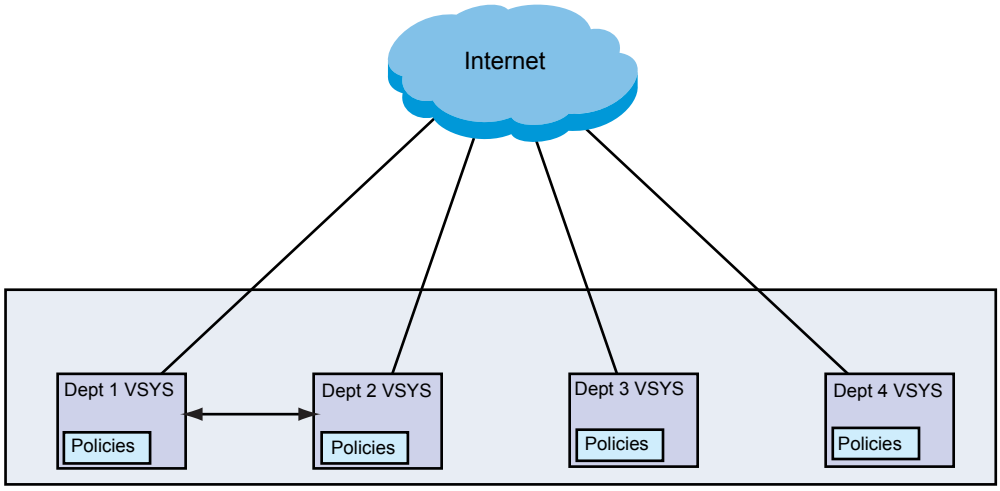

**Figure 8. Communications Among Virtual Systems**

# Shared Gateways

In a standard virtual system interface configuration, each virtual system uses a dedicated interface to the outside world. Each virtual system is autonomous, and there are no direct communication paths among the virtual systems that are internal to the firewall, unless such communications are explicitly configured (refer to "Communications Among Virtual Systems" on page 111). Because each virtual system has its own IP address, multiple addresses are required for external communications.

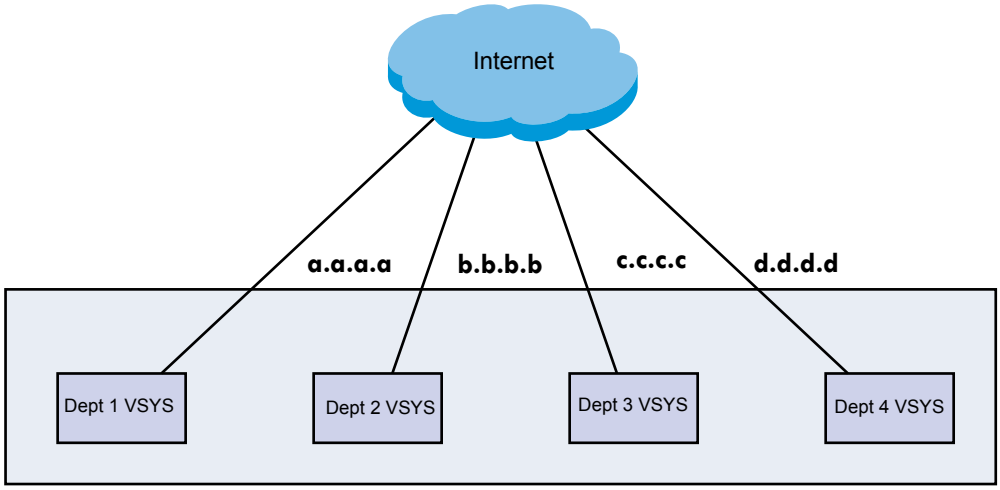

**Figure 9. Virtual Systems Without a Shared Gateway**

Shared gateways allow virtual systems to share a common interface for external communications. This is especially helpful in deployments where the ISP provides only a single IP address. All of the virtual systems communicate with the outside world through the physical interface using a single IP address (see Figure 10). A single virtual router is used to route the traffic for all of the virtual systems through the shared gateway.

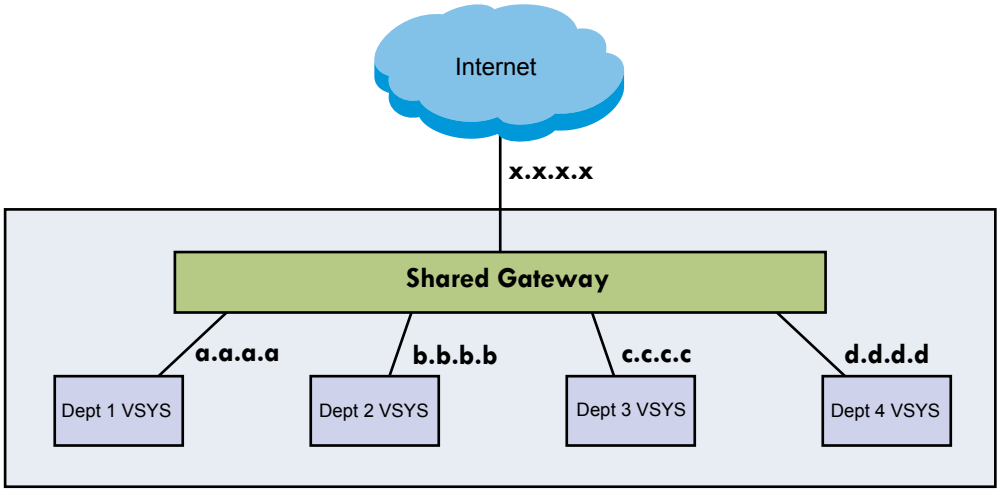

**Figure 10. Virtual Systems with a Shared Gateway**

All policy rules are managed at the virtual system level. You can create NAT and policy-based forwarding rules through the shared gateway, if needed, by selecting the shared gateway from the Virtual System drop-down list on the policy screen.

## Defining Virtual Systems

▶ *Device > Virtual Systems*

To define virtual systems, you must first enable the definition of multiple virtual systems. To do so, open the **Device > Setup** page, click the **Edit** link under **General Settings** in the **Management** tab, and select the **Multi Virtual System Capability** check box. This adds a **Virtual Systems** link to the side menu.

You can now open the **Virtual Systems** page, click **Add**, and specify the following information.

**Table 44. Virtual System Settings**

| Field | Description |
|---|---|
| ID | Enter an integer identifier for the virtual system. Refer to the data sheet for your firewall model for information on the number of supported virtual systems. |
| Name | Enter a name (up to 31 characters) to identify the virtual system. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. Only the name is required. |
| General Tab | Select a DNS proxy profile from the drop-down list if you want to apply DNS proxy rules to this interface. Refer to "DNS Proxy" on page 173.<br>To include objects of a particular type, select the check box for that type (interface, VLAN, virtual wire, virtual router, or visible virtual system). Click **Add** and choose from the drop-down list. You can add one or more objects of any type. To remove an object, select it and click **Delete**. |

**Table 44. Virtual System Settings (Continued)**

| Field | Description |
|---|---|
| Resource Tab | Enter the following settings:<br>• **Sessions Limit**—Maximum number of sessions allowed for this virtual system.<br>• **Security Rules**—Maximum number of security rules allowed for this virtual system.<br>• **NAT Rules**—Maximum number of NAT rules allowed for this virtual system.<br>• **Decryption Rules**—Maximum number decryption rules allowed for this virtual system.<br>• **QoS Rules**—Maximum number of QoS rules allowed for this virtual system.<br>• **Application Override Rules**—Maximum number of application override rules allowed for this virtual system.<br>• **PBF Rules**—Maximum number of policy based forwarding (PBF) rules allowed for this virtual system.<br>• **CP Rules**—Maximum number of captive portal (CP) rules allowed for this virtual system.<br>• **DoS Rules** —Maximum number of denial of service (DoS) rules allowed for this virtual system.<br>• **Site to Site VPN Tunnels**—Maximum number of site-to-site VPN tunnels allowed for this virtual system.<br>• **Concurrent GlobalProtect Tunnel Mode Users**—Maximum number of concurrent remote GlobalProtect users allowed for this virtual system. |

After defining the virtual systems, you can perform any of the following additional tasks:

- To change a virtual system, click the virtual system name or the name of the interface, VLAN, virtual wire, virtual router, or visible virtual systems you want to change, make the appropriate changes, and click **OK**.
- To define security zones for the new virtual system, choose **Network > Zones** and define security zones for each new virtual system (refer to "Defining Security Zones" on page 151). When you define a new zone, you can now select a virtual system.
- Click **Network > Interfaces** and verify that each interface has a virtual system and security zone.

## Configuring Shared Gateways

▶ *Device > Shared Gateways*

Shared gateways use Layer 3 interfaces, and at least one Layer 3 interface must be configured as a shared gateway. Refer to "Configuring Layer 3 Interfaces" on page 130.

**Table 45. Shared Gateway Settings**

| Field | Description |
|---|---|
| ID | Identifier for the gateway (not used by firewall). |
| Name | Enter a name for the shared gateway (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. Only the name is required. |
| Interfaces | Select check boxes for the interfaces that the shared gateway will use. |

# Defining Custom Response Pages

▶ *Device > Response Pages*

Custom response pages are the web pages that are displayed when a user tries to access a URL. You can provide a custom HTML message that is downloaded and displayed instead of the requested web page or file.

Each virtual system can have its own custom response pages.

The following table describes the types of custom response pages that support customer messages.

***Note:*** *Refer to* ***Appendix A, "Custom Pages"*** *for examples of the default response pages.*

**Table 46. Custom Response Page Types**

| Page Type | Description |
|---|---|
| Antivirus Block | Access blocked due to a virus infection. |
| Application Block | Access blocked because the application is blocked by a security policy. |
| Captive Portal Comfort | Page for users to verify their user name and password for machines that are not part of the domain. |
| File Blocking Block | Access blocked because access to the file is blocked. |
| File Blocking Continue | Page for users to confirm that downloading should continue. This option is available only if continue functionality is enabled in the security profile. Refer to "File Blocking Profiles" on page 220. |
| GlobalProtect Portal Help | Custom help page for GlobalProtect users (accessible from the portal). |
| GlobalProtect Portal Login | Page for users who attempt to access the GlobalProtect portal. For information on GlobalProtect, refer to "Overview" on page 335. |

**Table 46. Custom Response Page Types (Continued)**

| Page Type | Description |
|---|---|
| GlobalProtect Welcome Page | Welcome page for users who attempt to log in to the GlobalProtect portal. For information on GlobalProtect, refer to "Overview" on page 335. |
| SSL Certificate Errors Notify Page | Notification that an SSL certificate has been revoked. |
| SSL Decryption Opt-out Page | User warning page indicating that this session will be inspected. |
| URL Filtering Continue and Override Page | Page with initial block policy that allows users to bypass the block. For example, a user who thinks the page was blocked inappropriately can click the **Continue** button to proceed to the page.<br>With the override page, a password is required for the user to override the policy that blocks this URL. See the "URL Admin Override" section of Table 1 for instructions on setting the override password. |
| URL Filtering and Category Match Block Page | Access blocked by a URL filtering profile or because the URL category is blocked by a security policy. |

You can perform any of the following functions under **Response Pages**.

- To import a custom HTML response page, click the link of the page type you would like to change and then click import/export. Browse to locate the page. A message is displayed to indicate whether the import succeeded. For the import to be successful, the file must be in HTML format.
- To export a custom HTML response page, click the **Export** link for the type of page. Select whether to open the file or save it to disk, and select the check box if you want to always use the same option.
- To enable or disable the **Application Block** page or **SSL Decryption Opt-out** pages, click the **Enable** link for the type of page. Select or deselect the **Enable** check box.
- To use the default response page instead of a previously uploaded custom page, delete the custom block page and commit. This will set the default block page as the new active page.

# Viewing Support Information

▶ *Device > Support*

The support page allows you to access support related options. You can view the Palo Alto Networks contact information, view your support expiration date, and view product and security alerts from Palo Alto Networks based on the serial number of your firewall.

Perform any of the following functions on this page:

- **Support**—Use this section to view Palo Alto Networks support contact information, view support status for the device or activate your contract using an authorization code.
- **Production Alerts/Application and Threat Alerts**—These alerts will be retrieved from the Palo Alto Networks update servers when this page is accessed/refreshed. To view the details of production alerts, or application and threat alerts, click the alert name. Production alerts will be posted if there is a large scale recall or urgent issue related to a given release. The application and threat alerts will be posted if significant threats are discovered.
- **Links**—This section provides a link to the Support home page, the site to manage your cases, and a link to register the device using your support login.
- **Tech Support File**—Use the **Generate Tech Support File** link to generate a system file that the Support group can use to help troubleshoot issues that you may be experiencing with the device. After you generate the file, click **Download Tech Support File** to retrieve it and then send it to the Palo Alto Networks Support department.
- **Stats Dump File**—Use the **Generate Stats Dump File** link to generate a set of XML reports that summarizes network traffic over the last 7 days. Once the report is generated, click the **Download Stats Dump File** link to retrieve the report. The files are then used by a Palo Alto Networks or Authorized Partner systems engineer to generate an Application Visibility and Risk Report (AVR Report). The AVR highlights what has been found on the network and the associated business or security risks that may be present and is typically used as part of the evaluation process. For more information on the AVR Report, please contact you Palo Alto Networks or Authorized Partner systems engineer.

## Chapter 4
# Network Configuration

This chapter describes how to configure the firewall to support your network architecture:

- "Firewall Deployment" in the next section
- "Firewall Interfaces" on page 127
- "Security Zones" on page 151
- "VLAN Support" on page 152
- "Virtual Routers and Routing Protocols" on page 153
- "DHCP Server and Relay" on page 171
- "DNS Proxy" on page 173
- "Network Profiles" on page 174

***Note:*** *For information about VPN support on the firewall, refer to "Configuring IPSec Tunnels" on page 309 and "Configuring IPSec Tunnels" on page 309. For information about quality of service (QoS) support, refer to "Configuring Quality of Service" on page 355*

# Firewall Deployment

The firewall can replace your existing firewall when installed between an edge router (or other device that faces the Internet) and a switch or router that connects to your internal network. The firewall supports a wide range of deployment options and interface types that can be used simultaneously on different physical interfaces. They are described in the following sections:

- "Virtual Wire Deployments" in the next section
- "Layer 2 Deployments" on page 124
- "Layer 3 Deployments" on page 124
- "Tap Mode Deployments" on page 125
- "Defining Virtual Wires" on page 125
- "Packet Content Modification" on page 126

## Virtual Wire Deployments

In a virtual wire deployment, the firewall is installed transparently on a network segment by binding two ports together (Figure 11), and should be used only when no switching or routing is needed.

A virtual wire deployment allows the following conveniences:

- Simplifies installation and configuration.
- Does not require any configuration changes to surrounding or adjacent network devices.

The "default-vwire" that is shipped as the factory default configuration, binds together Ethernet ports 1 and 2 and allows all untagged traffic. You can, however, use a virtual wire to connect any two ports and configure it to block or allow traffic based on the virtual LAN (VLAN) tags; the VLAN tag "0" indicates untagged traffic. You can also create multiple subinterfaces, add them into different zones and then classify traffic according to a VLAN tag, or a combination of a VLAN tag with IP classifiers (address, range, or subnet) to apply granular policy control for specific VLAN tags or for VLAN tags from a specific source IP address, range, or subnet.

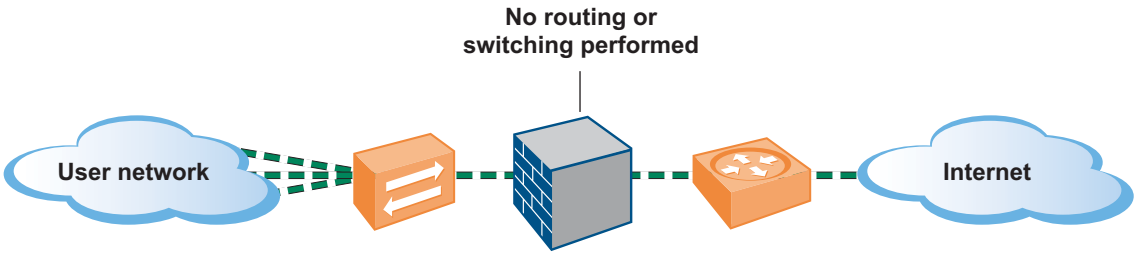

**Figure 11. Virtual Wire Deployment**

### Virtual Wire Subinterfaces

Virtual wire subinterfaces provide flexibility in enforcing distinct policies when you need to manage traffic from multiple customer networks. It allows you to separate and classify traffic into different zones (the zones can belong to separate virtual systems, if required) using the following criteria:

- VLAN tags —The example in Figure 12, shows an Internet Service Provider (ISP) using virtual wire subinterfaces with VLAN tags to separate traffic for two different customers.
- VLAN tags in conjunction with IP classifiers (address, range, or subnet). — The example in Figure 13, shows an Internet Service Provider (ISP) with two separate virtual systems on a firewall that manages traffic from two different customers. On each virtual system, the example illustrates how virtual wire subinterfaces with VLAN tags and IP classifiers are used to classify traffic into separate zones and apply relevant policy for customers from each network.

The general workflow for the configuration is:

1. Configure two Ethernet interfaces as type virtual wire, and assign these interfaces to a virtual wire. To set up virtual wires, see "Configuring Virtual Wire Interfaces" on page 138.
2. Create subinterfaces on the parent Virtual Wire to separate CustomerA and CustomerB traffic. Make sure that the VLAN tags defined on each pair of subinterfaces that are configured as virtual wire(s) are identical. This is essential because a virtual wire does not switch VLAN tags.
   To set up virtual wire subinterfaces, see "Configuring Virtual Wire Subinterfaces" on page 139.
3. Create new subinterface(s) and define IP classifiers. This task is optional and only required if you wish to add additional subinterfaces with IP classifiers for further managing traffic from a customer based on the combination of VLAN tags and a specific source IP address, range or subnet.

   When creating subinterfaces with VLAN tags and IP classifiers you must first create a subinterface with the same VLAN tag but without any IP classifiers and then create subinterfaces with the IP classifiers. Doing so allows traffic that doesn't match the IP classifier to be assigned to the first interface you created.

   You can also use IP classifiers for managing untagged traffic. To do so, you must create a sub-interface with the vlan tag "0", and define sub-interface(s) with IP classifiers for managing untagged traffic using IP classifiers.

***Note:*** *IP classification may only be used on the subinterfaces associated with one side of the virtual wire. The subinterfaces defined on the corresponding side of the virtual wire must use the same VLAN tag, but must not include an IP classifier.*

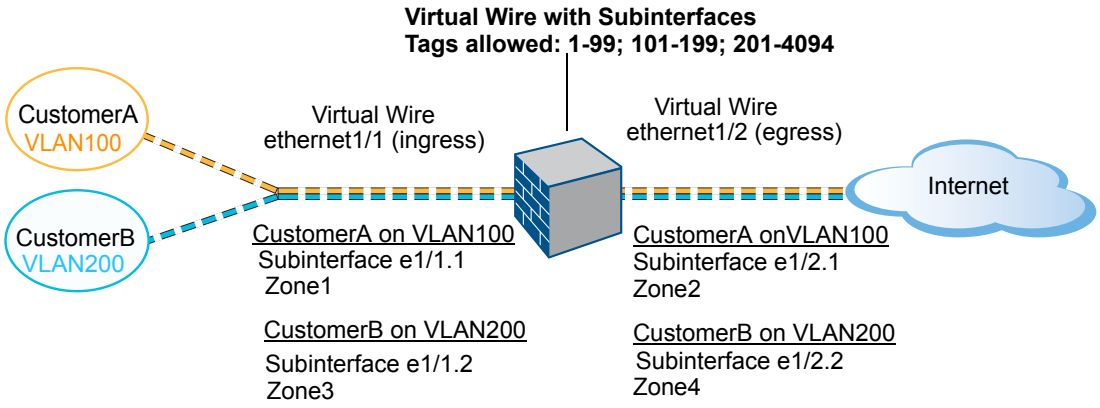

**Figure 12. Virtual Wire Deployment with Subinterfaces (VLAN Tags only)**

The illustration in Figure 12 depicts CustomerA and CustomerB connected to the firewall through one physical interface, ethernet1/1, configured as a Virtual Wire; it is the ingress interface. A second physical interface, ethernet1/2, is also part of the Virtual Wire; it is the egress interface that provides access to the Internet. For CustomerA, you also have subinterfaces ethernet1/1.1 (ingress) and ethernet1/2.1 (egress). For CustomerB, you have the subinterface ethernet1/1.2 (ingress) and ethernet1/2.2 (egress). When configuring the subinterfaces, you must assign the appropriate VLAN tag and zone in order to apply policies for each customer. In this example, the policies for CustomerA are created between Zone1 and Zone2, and policies for CustomerB are created between Zone3 and Zone4.

When traffic enters the firewall from CustomerA or CustomerB, the VLAN tag on the incoming packet is first matched against the VLAN tag defined on the ingress subinterfaces. In this example, a single subinterface matches the VLAN tag on the incoming packet, hence that subinterface is selected. The policies defined for the zone are evaluated and applied before the packet exits from the corresponding subinterface.

***Note:*** *The same VLAN tag must not be defined on the parent virtual wire interface and the subinterface. Verify that the VLAN tags defined on the* ***Tag Allowed*** *list of the parent virtual wire interface (****Network > Virtual Wires****) are not included on a subinterface.*

The illustration in Figure 13 depicts CustomerA and CustomerB connected to one physical firewall that has two virtual systems (vsys), in addition to the default virtual system (vsys1). Each virtual system is an independent virtual firewall that is managed separately for each customer. Each vsys has attached interfaces/subinterfaces and security zones that are managed independently.

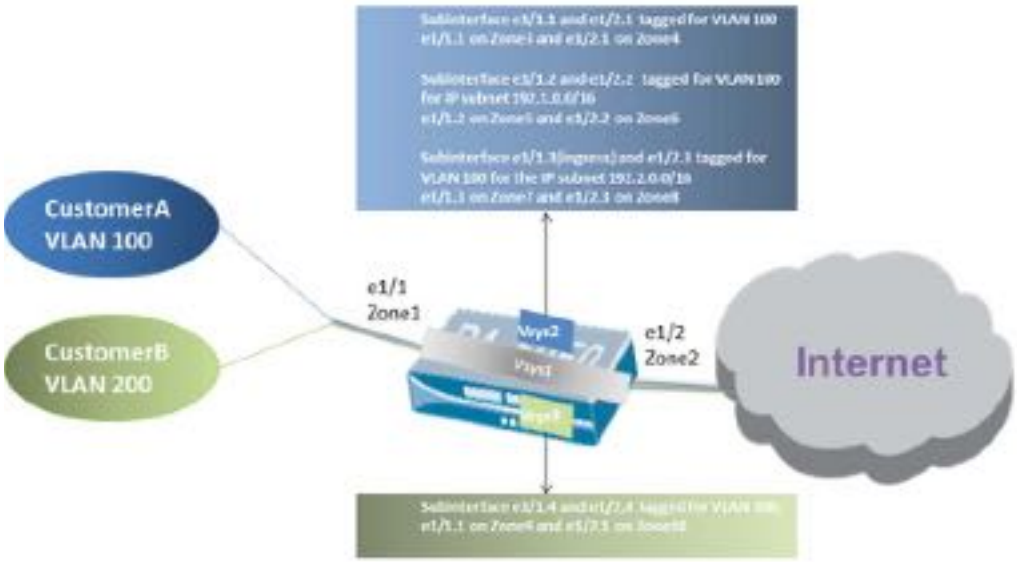

**Figure 13. Virtual Wire Deployment with Subinterfaces (VLAN Tags and IP classifiers)**

Vsys1 is set up to use the physical interfaces ethernet1/1 and ethernet1/2 as a virtual wire; ethernet1/1 is the ingress interface and ethernet1/2 is the egress interface that provides access to the Internet. This virtual wire is configured to accept all tagged and untagged traffic with the exception of VLAN tags 100 and 200 that are assigned to the subinterfaces.

CustomerA is managed on vsys2 and CustomerB is managed on vsys3. On vsys2 and vsys3, the following vwire subinterfaces are created with the appropriate VLAN tags and zones to enforce policy measures:

| Customer | Vsys | Vwire Subinterfaces | Zone | VLAN Tag | IP Classifier |
|---|---|---|---|---|---|
| A | 2 | e1/1.1 (ingress)<br>e1/2.1 (egress) | Zone3<br>Zone4 | 100<br>100 | None |
| | 2 | e1/1.2 (ingress)<br>e1/2.2 (egress) | Zone5<br>Zone6 | 100<br>100 | IP subnet 192.1.0.0/16 |
| | 2 | e1/1.3 (ingress)<br>e1/2.3 (egress) | Zone7<br>Zone8 | 100<br>100 | IP subnet 192.2.0.0/16 |
| B | 3 | e1/1.4 (ingress)<br>e1/2.4 (egress) | Zone9<br>Zone10 | 200<br>200 | None |

When traffic enters the firewall from CustomerA or CustomerB, the VLAN tag on the incoming packet is first matched against the VLAN tag defined on the ingress subinterfaces. In this case, for CustomerA, there are multiple subinterfaces that use the same VLAN tag. Hence, the firewall first narrows the classification to a subinterface based on the source IP address in the packet. The policies defined for the zone are evaluated and applied before the packet exits from the corresponding subinterface.

For return-path traffic, the firewall compares the destination IP address as defined in the IP classifier on the customer-facing subinterface and selects the appropriate virtual wire to route traffic through the accurate subinterface.

***Note:*** *When a session(s) created on a subinterface with VLAN and IP classifiers is offloaded to the hardware for forwarding, the interface counter on the VLAN interface is incremented instead of the subinterface with the IP classifiers. The session counters, however, are accurate for all the interfaces and subinterfaces.*

## Layer 2 Deployments

In a Layer 2 deployment, the firewall provides switching between two or more networks. Each group of interfaces must be assigned to a VLAN object in order for the firewall to switch between them. The firewall will perform VLAN tag switching when layer 2 subinterfaces are attached to a common VLAN object. Choose this option when switching is required (Figure 14).

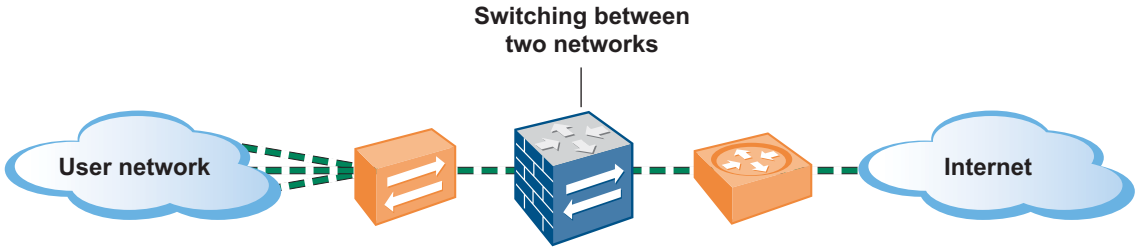

**Figure 14. Layer 2 Deployment**

## Layer 3 Deployments

In a Layer 3 deployment, the firewall routes traffic between multiple ports. An IP address must be assigned to each interface and a virtual router must be defined to route the traffic. Choose this option when routing is required (Figure 15).

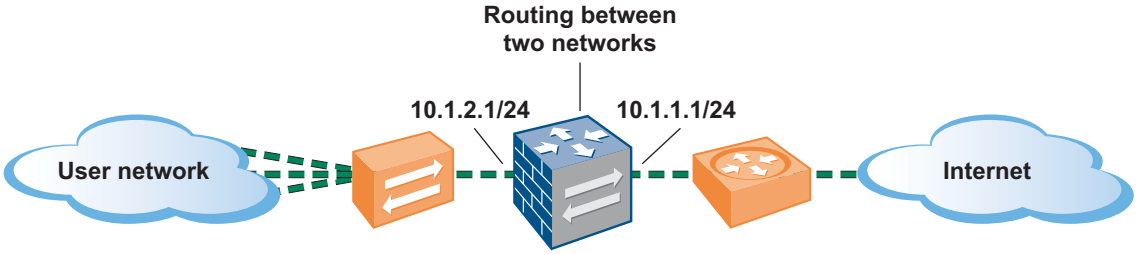

**Figure 15. Layer 3 Deployment**

### Point-to-Point Protocol over Ethernet Support

You can configure the firewall to be a Point-to-Point Protocol over Ethernet (PPPoE) termination point to support connectivity in a Digital Subscriber Line (DSL) environment where there is a DSL modem but no other PPPoE device to terminate the connection.

You can choose the PPPoE option and configure the associated settings when an interface is defined as a Layer 3 interface. For instructions, refer to “Configuring Layer 3 Interfaces” on page 130.

***Note:*** *PPPoE is not supported in HA active/active mode.*

### DHCP Client

You can configure the firewall interface to act as a DHCP client and receive a dynamically assigned IP address. The firewall also provides the capability to propagate settings received by the DHCP client interface into a DHCP server operating on the firewall. This is most commonly used to propagate DNS server settings from an Internet service provider to client machines operating on the network protected by the firewall.

***Note:*** *DHCP client is not supported in HA active/active mode.*

## Tap Mode Deployments

A network tap is a device that provides a way to access data flowing across a computer network. Tap mode deployment allows you to passively monitor traffic flows across a network by way of a switch SPAN or mirror port.

The SPAN or mirror port permits the copying of traffic from other ports on the switch. By dedicating an interface on the firewall as a tap mode interface and connecting it with a switch SPAN port, the switch SPAN port provides the firewall with the mirrored traffic. This provides application visibility within the network without being in the flow of network traffic.

***Note:*** *When deployed in tap mode, the firewall is not able to take action, such as blocking traffic or applying QoS traffic control.*

## Defining Virtual Wires

▶ ***Network > Virtual Wires***

Use this page to define virtual wires after you have specified two virtual wire interfaces on the firewall. For an overview of virtual wire deployments, refer to "Virtual Wire Deployments" on page 120. For instructions on specifying interfaces as virtual wire, refer to "Configuring Virtual Wire Interfaces" on page 138.

**Table 47. Virtual Wire Settings**

| Field | Description |
|---|---|
| Virtual Wire Name | Enter a virtual wire name (up to 31 characters). This name appears in the list of virtual wires when configuring interfaces. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Interfaces | Select two Ethernet interfaces from the displayed list for the virtual wire configuration. Interfaces are listed here only if they have the virtual wire interface type and have not been assigned to another virtual wire. |

**Table 47. Virtual Wire Settings (Continued)**

| Field | Description |
|---|---|
| Tags Allowed | Enter the tag number (0 to 4094) or range of tag numbers (tag1-tag2) for the traffic allowed on the virtual wire. A tag value of zero indicates untagged traffic (the default). Multiple tags or ranges must be separated by commas. Traffic that has an excluded tag value is dropped. Note that tag values are not changed on incoming or outgoing packets.<br>When utilizing virtual wire subinterfaces, the **Tag Allowed** list will cause all traffic with the listed tags to be classified to the parent virtual wire. Virtual wire subinterfaces must utilize tags that do not exist in the parent's **Tag Allowed** list. |
| Multicast Firewalling | Select this option if you want to be able to apply security rules to multicast traffic. If this setting is not enabled, multicast traffic is forwarded across the virtual wire. |
| Link State Pass Through | Select this check box if you want to bring down the other port in a virtual wire when a down link state is detected. If this check box is not selected, link status is not propagated across the virtual wire. |

To change a virtual wire name or the allowed tags, click the virtual wire name on the **Virtual Wires** page, change the settings, and click **OK**. Virtual wires also can be changed from the **Interfaces** page (refer to "Configuring Virtual Wire Interfaces" on page 138).

To delete one or more virtual wires, select the check box next to the virtual wire names and click **Delete**. Note that deleting a virtual wire removes it from the associated virtual wire interfaces shown on the **Interfaces** page.

## Packet Content Modification

Palo Alto Networks firewalls can be configured to perform the following packet content modifications:

- By default, the firewall will clear TCP urgent flags from all packets. This behavior can be changed by disabling this feature in the CLI using the following command: `set deviceconfig setting tcp urgent-data oobinline`.
- Modification of the DiffServ Code Point (DSCP) or IP precedences QoS markings can be configured in the **Actions** section of each security rule.
- VLAN tag translation will be performed whenever the firewall's input and output interfaces are tagged differently.

  ***Note:*** *VLAN tag translation is not available on virtual wire interfaces.*

# Firewall Interfaces

The following table describes the types of interfaces supported on the firewall and how to define them.

**Table 48. Supported Interfaces**

| Interface | Description |
|---|---|
| Layer 2 | One or more Layer 2 interfaces can be configured for untagged VLAN traffic. You can then define Layer 2 subinterfaces for traffic with specific VLAN tags. Refer to "Configuring Layer 2 Interfaces" on page 86 and "Configuring Layer 2 Subinterfaces" on page 87. |
| Layer 3 | One or more Layer 3 interfaces can be configured for untagged routed traffic. You can then define Layer 3 subinterfaces for traffic with specific VLAN tags.<br>Each interface can have multiple IP addresses. Refer to "Configuring Layer 3 Interfaces" on page 88 and "Configuring Layer 3 Subinterfaces" on page 91. |
| Aggregate Ethernet | Two or more Ethernet ports can be combined into a group to increase the throughput and resiliency for a Layer 2, Layer 3, or virtual wire interface and its subinterfaces. Refer to "Configuring Aggregate Ethernet Interfaces" on page 142.<br>***Note:*** *You cannot apply QoS settings to an aggregate Ethernet interface.* |
| VLAN | VLAN interfaces provide Layer 3 routing of VLAN traffic to non-VLAN destinations. Refer to "Configuring VLAN Interfaces" on page 143. |
| Loopback | Loopback interfaces can be used to provide Layer 3 services such as in-band management, GlobalProtect portal or gateway functionality, and IPSec. Each loopback interface behaves as a host interface and is assigned an IP address. Refer to "Configuring Loopback Interfaces" on page 146. |
| Tunnel | Tunnel interfaces can be configured. Refer to "Configuring Tunnel Interfaces" on page 147. |
| Virtual Wire | A virtual wire binds two Ethernet ports together, which allows you to install the firewall transparently in the network with minimum configuration. A virtual wire accepts all traffic or traffic with selected VLAN tags, but provides no switching or routing services. You can also create subinterfaces and classify traffic according to an IP address, IP range, or subnet. Refer to "Configuring Virtual Wire Interfaces" on page 138. |
| Tap | The Tap interface permits connection to a span port on a switch for traffic monitoring only. This mode does not support traffic blocking or URL filtering. Refer to "Configuring Tap Interfaces" on page 149. |
| High Availability | You can configure a data interface to be a high availability (HA) interface on some Palo Alto Networks firewalls. Refer to "Configuring HA Interfaces" on page 150. |

## Viewing the Current Interfaces

▶ *Network > Interfaces*

The **Interfaces** page lists the interface type, link state, and security zone for each configured interface, along with the IP address, virtual router, VLAN tag, and VLAN or virtual wire name (as applicable).

By default, the interfaces are listed by interface name.

The following icon is used on the **Interfaces** page:

Indicates the link is up (green), down (red), or in an unknown state (gray).

## Configuring Layer 2 Interfaces

▶ *Network > Interfaces > Ethernet*

You can configure one or more Ethernet ports as Layer 2 interfaces for untagged VLAN traffic. For each main Layer 2 interface, you can define multiple Layer 2 subinterfaces for traffic with specific VLAN tags (refer to "Configuring Layer 2 Subinterfaces" on page 129). VLAN interfaces can also be used in Layer 2 deployments to provide routing or gateway services to traffic in the Layer 2 domain (refer to "Configuring VLAN Interfaces" on page 143). This can be achieved by creating a VLAN interface and assigning it as the default gateway for hosts connected to the firewall's Layer2 interface.

To configure a Layer 2 Ethernet interface, click the link for the interface on the **Ethernet** tab, and specify the following settings.

**Table 49. Layer 2 Interface Settings**

| Field | Description |
|---|---|
| Interface Name | Choose the interface from the drop-down list. Modify the name if desired. |
| Interface Type | Select **Layer 2** from the drop-down list. |
| Netflow Profile | Select a profile if you want to export all ingress traffic through the interface to a specified NetFlow server. Refer to "Configuring Netflow Settings" on page 85. |
| Comment | Enter an optional description of the interface. |
| **Config Tab** | |
| VLAN | Select a VLAN, or click **New** to define a new VLAN (refer to "VLAN Support" on page 152). **None** removes the configuration from the interface. A VLAN object must be configured to enable switching between Layer 2 interfaces or to enable routing through a VLAN interface. |
| Virtual System | Select the virtual system for the interface. **None** removes the configuration from the interface. |
| Security Zone | Select a security zone for the interface, or click **New** to define a new zone (refer to "Defining Security Zones" on page 151). **None** removes the configuration from the interface. |
| **Advanced Tab** | |
| Link Speed | Select the interface speed in Mbps (10, 100, or 1000) or select auto. |

**Table 49. Layer 2 Interface Settings (Continued)**

| Field | Description |
|---|---|
| Link Duplex | Select whether the interface transmission mode is full-duplex (full), half-duplex (half), or negotiated automatically (auto). |
| Link State | Select whether the interface status is enabled (up), disabled (down), or determined automatically (auto). |

## Configuring Layer 2 Subinterfaces

▶ *Network > Interfaces*

For each Ethernet port configured as a Layer 2 interface, you can define an additional logical Layer 2 interface (subinterface) for each VLAN tag that is used on the traffic received by the port. To configure the main Layer 2 interfaces, refer to "Configuring Layer 2 Interfaces" on page 128. To enable switching between Layer 2 subinterfaces, simply link those subinterfaces to the same VLAN object.

To add a Layer 2 Ethernet subinterface, select the associated physical interface and then click **Add Subinterface** and specify the following information.

**Table 50. Layer 2 Subinterface Settings**

| Field | Description |
|---|---|
| Interface Name | Select the Layer 2 interface where you want to add a subinterface. To configure the Layer 2 interfaces, refer to "Configuring Layer 2 Interfaces" on page 128.<br>Enter the number (1 to 9999) appended to the physical interface name to form the logical interface name. The general name format is:<br>ethernet*x*/*y*.<1-9999> |
| Tag | Enter the tag number (1 to 4094) of the traffic received on this interface. Outgoing traffic on this interface is also set to this tag value. |
| Netflow Profile | Select a profile if you want to export all ingress traffic through the interface to a specified NetFlow server. Refer to "Configuring Netflow Settings" on page 85. |
| Comment | Enter an optional description of the interface. |
| **Assign Interface To** | |
| VLAN | For a Layer 2 interface, select a VLAN, or click **New** to define a new VLAN (refer to "Network Profiles" on page 174). **None** removes the configuration from the interface. A VLAN object must be configured to enable switching between Layer 2 interfaces or to enable routing through a VLAN interface. |
| Security Zone | Select a security zone for the interface, or click **New** to define a new zone (refer to "Defining Security Zones" on page 151). **None** removes the configuration from the interface. |
| Virtual System | Select the virtual system for the interface. **None** removes the configuration from the interface. |

## Configuring Layer 3 Interfaces

▶ *Network > Interfaces > Ethernet*

You can configure one or more Ethernet ports as Layer 3 interfaces for untagged routed traffic. You can then define Layer 3 subinterfaces for traffic with specific VLAN tags (refer to "Configuring Layer 3 Subinterfaces" on page 134) when connecting the firewall to a neighboring device using a trunk link. For information on configuring Layer 3 interfaces for PPPoE, refer to "Point-to-Point Protocol over Ethernet Support" on page 124.
Layer 3 interfaces can also act as a DHCP client to receive its configuration from an external DHCP server.

To configure a Layer 3 Ethernet interface, click the link for the interface on the **Ethernet** tab, and specify the following settings.

**Table 51. Layer 3 Interface Settings**

| Field | Description |
|---|---|
| Interface Name | Choose the interface from the drop-down list. Modify the name if desired. |
| Interface Type | Select **Layer 3** from the drop-down list. |
| Netflow Profile | Select a profile if you want to export all ingress traffic through the interface to a specified NetFlow server. Refer to "Configuring Netflow Settings" on page 85. |
| Comment | Enter an optional description of the interface. |
| **Config Tab** | |
| Virtual Router | Select a virtual router, or click **New** to define a new virtual router (refer to "Virtual Routers and Routing Protocols" on page 153). **None** removes the configuration from the interface. |
| Virtual System | Select the virtual system for the interface. **None** removes the configuration from the interface. |
| Security Zone | Select a security zone for the interface, or click **New** to define a new zone (refer to "Defining Security Zones" on page 151). **None** removes the configuration from the interface. |
| **IPv4 Tab** | |
| Type | Choose how the IP address information will be specified (Static, PPPoE, or DHCP Client), as described below. |
| Static | Enter an IP address and network mask for the interface in the format *ip_address/mask*, and click **Add**. You can enter multiple IP addresses for the interface. To delete an IP address, select the address and click **Delete**. |

**Table 51. Layer 3 Interface Settings (Continued)**

| Field | Description |
|---|---|
| PPPoE | Choose **PPPoE** if the interface will be used for PPPoE and configure the following settings:<br>**General subtab:**<br>• **Enable**—Select the check box to activate the interface for PPPoE termination.<br>• **Username**—Enter the user name for the point-to-point connection.<br>• **Password/Confirm Password**—Enter and then confirm the password for the user name.<br>**Advanced subtab:**<br>• **Authentication**—Choose **CHAP** (Challenge-Handshake Authentication Protocol), **PAP** (Password Authentication Protocol), or the default **Auto** (to have the firewall determine the authentication protocol for PPPoE communications).<br>• **Static Address**—Specify the static IP address that was assigned by the service provider (optional, no default).<br>• **Automatically create default route pointing to peer**—Select the check box to automatically create a default route that points to the PPPoE peer when connected.<br>• **Default Route Metric**—Specify the route metric to be associated with the default route and used for path selection (optional, range 1-65535).<br>• **Access Concentrator**—Specify the name of the access concentrator to which the connection is made (optional, no default).<br>• **Service**—Specify the service string (optional, no default).<br>• **Passive**—Select the check box to use passive mode. In passive mode, a PPPoE end point waits for the access concentrator to send the first frame.<br><br>***Note:*** *PPPoE is not supported in HA active/active mode.* |
| DHCP Client | Choose **DHCP Client** to allow the interface to act as a DHCP client and receive a dynamically assigned IP address. Specify the following:<br>• **Enable**—Select the check box to activate the DHCP client on the interface.<br>• **Automatically create default route point to server**—Select the check box to automatically create a default route that points to the default gateway provided by the DHCP server.<br>• **Default Route Metric**—Specify the route metric to be associated with the default route and used for path selection (optional, range 1-65535).<br>Click **Show DHCP Client Runtime Info** to open a window that displays all settings received from the DHCP server, including DHCP lease status, dynamic IP assignment, subnet mask, gateway, server settings (DNS, NTP, domain, WINS, NIS, POP3, and SMTP).<br><br>***Note:*** *DHCP client is not supported in HA active/active mode.* |
| **IPv6 Tab** | |
| Enable IPv6 on the interface | Select the check box to enable IPv6 addressing on this interface. |

**Table 51. Layer 3 Interface Settings (Continued)**

| Field | Description |
|---|---|
| Interface ID | Enter the 64-bit extended unique identifier in hexadecimal format, for example, 00:26:08:FF:FE:DE:4E:29. If the interface ID is left blank, the firewall will use the EUI-64 generated from the physical interface's MAC address. The interface ID is used as the host portion of an interface address when the **Use interface ID as host portion** option is enabled. |
| Address | Click **Add** and enter an IPv6 address and prefix length, for example 2001:400:f00::1/64. Select **Use interface ID as host portion** to assign an IPv6 address to the interface that will use the interface ID as the host portion of the address. Select **Anycast** to include routing through the nearest node. If the **Prefix** is not entered, the IPv6 address assigned to the interface will be wholly specified in the address text box.<br>Use the **Send Router Advertisement (Send RA)** option to enable router advertisement for this IP address. You can also set the **Autonomous** flag to be sent and you can set the **on-link** option. You must enable the global **Enable Router Advertisement** option on the interface before enabling **Send Router Advertisement** option for a specific IP address. |
| Address Resolution<br>(Duplicate Address Detection) | Select the check box to enable Duplicate Address Detection (DAD) and specify the following information.<br>• **DAD Attempts**—Specify the number of attempts within the neighbor solicitation interval for DAD before the attempt to identify neighbors fails (range 1-10).<br>• **Reachable Time**—Specify the length of time that a neighbor remains reachable after a successful query and response (range 1-36000 seconds).<br>• **Neighbor Solicitation (NS) Interval**—Specify the number of seconds for DAD attempts before failure is indicated (range 1-10 seconds). |

**Table 51. Layer 3 Interface Settings (Continued)**

| Field | Description |
|---|---|
| Enable Router Advertisement | Select the check box to enable Router Advertisement (RA) to provide Stateless Address Autoconfiguration (SLAAC) on IPv6 interfaces. This enables the firewall to act as a default gateway for IPv6 hosts that are not statically configured and will provide the host with an IPv6 prefix that can be used for address configuration. A separate DHCPv6 server can be used in conjunction with this feature to provide DNS and other settings to clients.<br>This option is a global setting for the interface, you can also set router advertisement options per IP address by clicking **Add** and entering in an IP address. You must enable this option on the interface if you are going to specify the **Send Router Advertisement** option per address.<br>Specify the following information that will be used by clients who receive the RA messages.<br>• **Min Interval (sec)**—Specify the minimum interval per second that the firewall will send out router advertisements. Router advertisements will be sent at random intervals between the minimum and maximum values that are configured (range 3-1350 seconds, default 200 seconds).<br>• **Max Interval (sec)**—Specify the maximum interval per second that the firewall will send out router advertisements. Router advertisements will be sent at random intervals between the minimum and maximum values that are configured (range 4-1800 seconds, default 600 seconds).<br>• **Hop Limit**—Specify the hop limit that will be applied to clients for outgoing packets. Enter 0 for no hop limit (range 1-255, default 64).<br>• **Link MTU**—Specify the link MTU that will be applied to clients. Select **unspecified** for no link MTU (range 1280-9192, default unspecified).<br>• **Reachable Time (ms)**—Specify the reachable time that the client will use to assume a neighbor is reachable after having received a reachability confirmation message. Select **unspecified** for no reachable time value (range 0-3600000 milliseconds, default unspecified).<br>• **Retrans Time (ms)**—Specify the retransmission timer that the client will use to determine how long it should wait before retransmitting neighbor solicitation messages. Select **unspecified** for no retrans time (range 0-4294967295 milliseconds, default unspecified).<br>• **Router Lifetime (sec)**—Specify the router lifetime that instructs the client on how long the firewall/router should be used as the default router (range 0-9000 seconds, default 1800).<br>• **Managed Configuration**—Select the check box to indicate to the client that addresses are available via DHCPv6.<br>• **Other Configuration**—Select the check box to indicate to the client that other addresses information is available via DHCPv6, such as DNS-related settings.<br>• **Consistency check**—Select the check box to enable consistency checks that the firewall will use to verify that router advertisement sent from other routers are advertising consistent information on the link. If inconsistencies are detected, a log will be created. |
| **Advanced Tab** | |
| Link Speed | Select the interface speed in Mbps (10, 100, or 1000) or select auto. |
| Link Duplex | Select whether the interface transmission mode is full-duplex (full), half-duplex (half), or negotiated automatically (auto). |

**Table 51. Layer 3 Interface Settings (Continued)**

| Field | Description |
|---|---|
| Link State | Select whether the interface status is enabled (up), disabled (down), or determined automatically (auto). |
| Other Info | Specify the following information on the **Other Info** subtab:<br>• **Management Profile**—Select a profile that specifies which protocols, if any, can be used to manage the firewall over this interface.<br>• **MTU**—Enter the maximum transmission unit (MTU) in bytes for packets sent on this Layer 3 interface (512 to 1500, default 1500). If machines on either side of the firewall perform Path MTU Discovery (PMTUD), the MTU value will be returned in an ICMP fragmentation needed message indicating that the MTU is too large.<br>• **Adjust TCP MSS**—If you select this check box, the maximum segment size (MSS) is adjusted to 40 bytes less than the interface MTU. This setting addresses the situation in which a tunnel through the network requires a smaller MSS. If a packet cannot fit within the MSS without fragmenting, this setting allows an adjustment to be made.<br>• **Untagged Subinterface**—Specifies that all subinterfaces belonging to this Layer 3 interface are untagged.<br>PAN-OS selects an untagged subinterface as the ingress interface based on the destination of the packet. If a packet has an untagged subinterface's IP address as the destination, it will map to the subinterface. This also means that packets going in the reverse direction must have their source address translated to the untagged subinterface's interface IP address. A by product of this classification mechanism is that all multicast and broadcast packets will be assigned to the base interface rather than any of the subinterfaces. Since OSPF uses multicast, it is not supported on untagged subinterfaces. |
| ARP/Interface Entries | To add one or more static ARP entries, click **Add** and enter an IP address and its associated hardware (MAC) address and Layer 3 interface that can access the hardware address. |
| ND Entries | Click **Add** to enter the IPv6 address and MAC address of neighbors to add for discovery. |

## Configuring Layer 3 Subinterfaces

▶ *Network > Interfaces*

For each Ethernet port configured as a Layer 3 interface, you can define an additional logical Layer 3 interface (subinterface) for each VLAN tag that is used on the traffic received by the port. To configure the main Layer 3 interfaces, refer to "Configuring Layer 3 Interfaces" on page 130.

Untagged layer 3 subinterfaces may also be used when the parent Layer 3 interface's "untagged subinterface" option is enabled. Untagged subinterfaces are used in multi-tenant environments where each tenant's traffic must leave the firewall without VLAN tags.

Consider an example where each tenant's traffic egresses the firewall and the next hop is an ISP router. It is not always possible to apply a VLAN tag on the return traffic for proper classification into a virtual system by the firewall. In these cases, you can use an untagged subinterface on the ISP-router facing side. Each untagged subinterface will have an IP address and all outgoing traffic must have its source address translated to that interface IP address. An explicit NAT rule must be created for this feature to function. Source NAT is required on the untagged subinterfaces because the firewall will use the destination IP address on inbound

(return path) packets to select the appropriate virtual system for policy lookup. Any traffic received on the parent interface that is not destined for one of the untagged subinterface IPs will be handled by the virtual system and virtual router assigned to that parent interface.

To add a Layer 3 Ethernet subinterface, select the associated interface and click **Add Subinterface** and specify the following information.

**Table 52. Layer 3 Subinterface Settings**

| Field | Description |
|---|---|
| Interface Name | Select the Layer 3 interface where you want to add a subinterface. To configure the Layer 3 interfaces, refer to "Configuring Layer 3 Interfaces" on page 130.<br>Enter the number (1 to 9999) appended to the physical interface name to form the logical interface name. The general name format is:<br>ethernet*x*/*y*.<1-9999> |
| Tag | Enter the tag number (1 to 4094) of the traffic received on this interface. Outgoing traffic on this interface is also set to this tag value. |
| Netflow Profile | Select a profile if you want to export all ingress traffic through the interface to a specified NetFlow server. Refer to "Configuring Netflow Settings" on page 85. |
| Comment | Enter an optional description of the interface. |
| **Config Tab** | |
| Virtual Router | Select a virtual router, or click **New** to define a new virtual router (refer to "Virtual Routers and Routing Protocols" on page 153). **None** removes the configuration from the interface. |
| Virtual System | Select the virtual system for the interface. **None** removes the configuration from the interface. |
| Security Zone | Select a security zone for the interface, or click **New** to define a new zone (refer to "Defining Security Zones" on page 151). **None** removes the configuration from the interface. |
| **IPv4 Tab** | |
| Type | Choose how the IP address information will be specified (Static, PPPoE, or DHCP Client), as described below. |
| Static | Enter an IP address and network mask for the interface in the format *ip_address/mask*, and click **Add**. You can enter multiple IP addresses for the interface. To delete an IP address, select the address and click **Delete**. |
| DHCP Client | Choose **DHCP Client** to allow the interface to act as a DHCP client and receive a dynamically assigned IP address. Specify the following:<br>• **Enable**—Select the check box to activate the DHCP client on the interface.<br>• **Automatically create default route pointing to default gateway provided by server**—Select the check box to automatically create a default route that points to the DHCP server when connected.<br>• **Default Route Metric**—Specify the route metric to be associated with the default route and used for path selection (optional, range 1-65535).<br>• **Show DHCP Client Runtime Info**—Select to open a window that displays all settings received from the DHCP server, including DHCP lease status, dynamic IP assignment, subnet mask, gateway, server settings (DNS, NTP, domain, WINS, NIS, POP3, and SMTP). |

**Table 52. Layer 3 Subinterface Settings (Continued)**

| Field | Description |
|---|---|
| **IPv6 Tab** | |
| Enable IPv6 on the interface | Select the check box to enable IPv6 addressing on this interface. |
| Interface ID | Enter the 64-bit extended unique identifier in hexadecimal format, for example, 00:26:08:FF:FE:DE:4E:29. If the interface ID is left blank, the firewall will use the EUI-64 generated from the physical interface's MAC address. |
| Address | Click **Add** and enter an IPv6 address and prefix length, for example 2001:400:f00::1/64. Select **Use interface ID as host portion** to assign an IPv6 address to the interface that will use the interface ID as the host portion of the address. Select **Anycast** to include routing through the nearest node. If **Prefix** is not selected, the IPv6 address assigned to the interface will be wholly specified in the address text box.<br>Use the **Send Router Advertisement (Send RA)** option to enable router advertisement for this IP address. You can also set the **Autonomous** flag to be sent and you can set the **on-link** option. You must enable the global **Enable Router Advertisement** option on the interface before enabling **Send RA** option for a specific IP address. |
| Address Resolution<br>(Duplicate Address Detection) | Select the check box to enable Duplicate Address Detection (DAD) and specify the following information.<br>• **DAD Attempts**—Specify the number of attempts within the neighbor solicitation interval for DAD before the attempt to identify neighbors fails (range 1-10).<br>• **Reachable Time**—Specify the length of time that a neighbor remains reachable after a successful query and response (range 1-36000 seconds).<br>• **Neighbor Solicitation (NS) Interval**—Specify the number of seconds for DAD attempts before failure is indicated (range 1-10 seconds). |

**Table 52. Layer 3 Subinterface Settings (Continued)**

| Field | Description |
|---|---|
| Enable Router Advertisement | Select the check box to enable Router Advertisement (RA) to provide Stateless Address Autoconfiguration (SLAAC) on IPv6 interfaces. This enables the firewall to act as a default gateway for IPv6 hosts that are not statically configured and will provide the host with an IPv6 prefix that can be used for address configuration. A separate DHCPv6 server can be used in conjunction with this feature to provide DNS and other settings to clients.<br>This option is a global setting for the interface, you can also set router advertisement options per IP address by clicking **Add** and entering in an IP address. You must enable this option on the interface if you are going to specify the **Send Router Advertisement** option per address.<br>Specify the following information that will be used by clients who receive the RA messages.<br>• **Min Interval (sec)**—Specify the minimum interval per second that the firewall will send out router advertisements. Router Advertisements will be sent at random intervals between the minimum and maximum values that are configured (range 3-1350 seconds, default 200 seconds).<br>• **Max Interval (sec)**—Specify the maximum interval per second that the firewall will send out router advertisements. Router Advertisements will be sent at random intervals between the minimum and maximum values that are configured (range 4-1800 seconds, default 600 seconds).<br>• **Hop Limit**—Specify the hop limit that will be applied to clients for outgoing packets. Enter 0 for no hop limit (range 1-255, default 64).<br>• **Link MTU**—Specify the link MTU that will be applied to clients. Select **unspecified** for no link MTU (range 1280-9192, default unspecified).<br>• **Reachable Time (ms)**—Specify the reachable time that the client will use to assume a neighbor is reachable after having received a reachability confirmation message. Select **unspecified** for no reachable time value (range 0-3600000 milliseconds, default unspecified).<br>• **Retrans Time (ms)**—Specify the retransmission timer that the client will use to determine how long it should wait before retransmitting neighbor solicitation messages. Select **unspecified** for no retrans time (range 0-4294967295 milliseconds, default unspecified).<br>• **Router Lifetime (sec)**—Specify the router lifetime that instructs the client on how long the firewall/router should be used as the default router (range 0-9000 seconds, default 1800).<br>• **Managed Configuration**—Select the check box to indicate to the client that addresses are available via DHCPv6.<br>• **Other Configuration**—Select the check box to indicate to the client that other addresses information is available via DHCPv6, such as DNS-related settings.<br>• **Consistency check**—Select the check box to enable consistency checks that the firewall will use to verify that router advertisement sent from other routers are advertising consistent information on the link. If inconsistencies are detected, a log will be created. |

**Table 52. Layer 3 Subinterface Settings (Continued)**

| Field | Description |
|---|---|
| **Advanced Tab** | |
| Other Info | Specify the following information on the **Other Info** subtab:<br>• **Management Profile**—Select a profile that specifies which protocols, if any, can be used to manage the firewall over this interface.<br>• **MTU**—Enter the maximum transmission unit (MTU) in bytes for packets sent on this Layer 3 interface (512 to 1500, default 1500). If machines on either side of the firewall perform Path MTU Discovery (PMTUD), the MTU value will be returned in an ICMP fragmentation needed message indicating that the MTU is too large.<br>• **Adjust TCP MSS**—If you select this check box, the maximum segment size (MSS) is adjusted to 40 bytes less than the interface MTU. This setting addresses the situation in which a tunnel through the network requires a smaller MSS. If a packet cannot fit within the MSS without fragmenting, this setting allows an adjustment to be made. |
| ARP Entries | To add one or more static Address Resolution Protocol (ARP) entries, enter an IP address and its associated hardware (Media Access Control or MAC) address, and click **Add**. To delete a static entry, select the entry and click **Delete**. Static ARP entries reduce ARP processing and preclude man-in-the-middle attacks for the specified addresses. |
| ND Entries | Click **Add** to enter the IP address and MAC address of neighbors to add for discovery. |

## Configuring Virtual Wire Interfaces

▶ *Network > Interfaces*

To create a virtual wire, you bind two Ethernet ports together, which allows all traffic to pass between the ports, or just traffic with selected VLAN tags (no other switching or routing services are available). You can also create subinterfaces and classify traffic according to an IP address, IP range, or subnet. A virtual wire requires no changes to adjacent network devices. For an overview of virtual wire deployments, refer to "Virtual Wire Deployments" on page 120.

To set up a virtual wire through the firewall, you must first define the virtual wire interfaces, as described in the following procedure. You then create the virtual wire using the interfaces that you created.

To configure each virtual wire interface, follow these steps:

1. Identify the interface you want to use for the virtual wire on the **Ethernet** tab, and remove it from the current security zone, if any.
2. Click the interface name and specify the following information.

**Table 53. Virtual Wire Settings**

| Field | Description |
|---|---|
| Interface Name | The interface name is automatically populated based on the interface that you selected. This field cannot be edited. |
| Interface Type | Select **Virtual Wire** from the drop-down list. |

**Table 53. Virtual Wire Settings (Continued)**

| Field | Description |
|---|---|
| Netflow Profile | Select a profile if you want to export all ingress traffic through the interface to a specified NetFlow server. Refer to "Configuring Netflow Settings" on page 85. |
| Comment | Enter an optional description of the interface. |
| **Config Tab** | |
| Virtual Wire | Select a virtual wire, or click **New** to define a new virtual wire (refer to "Defining Virtual Wires" on page 125). |
| Virtual System (only on systems with multi-virtual system capability) | Select the virtual system for the interface. |
| Security Zone | Select a security zone for the interface, or click **New** to define a new zone (refer to "Defining Security Zones" on page 151). |
| **Advanced Tab** | |
| Link Speed | Specify the interface speed. If the selected interface is a 10 Gbps interface, the only option is **auto**. In other cases, the options are: **10**, **100**, **1000**, or **auto**. |
| Link Duplex | Select whether the interface transmission mode is full-duplex (full), half-duplex (half), or negotiated automatically (auto). |
| Link State | Select whether the interface status is enabled (up), disabled (down), or determined automatically (auto). |

If you want to change a virtual wire to another interface type, click the virtual wire name shown in the **VLAN/Virtual Wire** column, if any, select **None**, and click **OK**.

## Configuring Virtual Wire Subinterfaces

▶ *Network > Interfaces*

Using virtual wire subinterfaces allows you to separate traffic by VLAN tags or a VLAN tag and IP classifier combination, assign the tagged traffic to a different zone and virtual system, and then enforce security policies for the traffic that matches the defined criteria.

For each Ethernet port configured as a virtual wire interface, you can create one or more logical subinterfaces. Each subinterface can segregate traffic using a VLAN tag (with a zero or non-zero value, where the value zero indicates untagged traffic). After you set up a VLAN tagged subinterface, you can then create another subinterface that segregates traffic by combining the VLAN tag with IP classifiers such as a single IP address, a range, or a subnet.

IP classification on subinterfaces can only be used on one side of a virtual wire. Traffic entering the firewall through a virtual wire subinterface where IP classification is defined will be classified by its source IP address. For return path traffic entering through the other end of the virtual wire, classification is based on the destination IP address.

Make sure that the VLAN tags defined on the **Tag Allowed** list of the parent virtual wire interface (Network > Virtual Wires) are not included on the list of tags defined on a virtual wire subinterface.

To configure a parent or main virtual wire interfaces, refer to "Configuring Virtual Wire Interfaces" on page 138.

***Note:*** *The following NAT limitations apply to virtual wires:*

- Source NAT where the ingress interface uses source IP based classification is not supported.
- Destination NAT cannot be used where the egress interface uses source IP based classification.

To add a virtual wire subinterface, select the virtual wire interface where you want to add the subinterface, and click **Add Subinterface** and specify the following information.

**Table 54. Virtual Wire Subinterface Settings**

| Field | Description |
|---|---|
| Interface Name | The main interface name is automatically populated based on the interface that you selected; the label cannot be edited.<br>To define the subinterface, enter a number (1 to 9999) to the physical interface name to form the logical interface name. The general name format is:<br>ethernet*x*/*y*.<1-9999><br>To configure the virtual wire, refer to "Configuring Virtual Wire Interfaces" on page 138. |
| Tag | Enter the tag number (0 to 4094) of the traffic received on this interface.<br>Setting a tag value of 0 will match untagged traffic. |
| Netflow Profile | Select a profile if you want to export all ingress traffic through the interface to a specified NetFlow server. Refer to "Configuring Netflow Settings" on page 85. |
| Comment | Enter an optional description of the interface. |
| IP Classifier | Click **Add** to add an IP address, subnet, or IP range or any combination of the IP classifiers, to classify traffic entering the firewall through this physical port into this subinterface based on its source IP address. Return-path traffic entering the firewall through the other end of the associated virtual wire will be matched according to its destination address.<br>On a virtual wire subinterface, IP classification can only be used in conjunction with VLAN based classification. |
| **Assign Interface To** | |
| Security Zone | Select a security zone for the interface, or click **New** to define a new zone (refer to "Defining Security Zones" on page 151). |
| Virtual System (only on systems with multi-virtual system capability) | Select the virtual system for the interface. |
| Virtual Wire | Select a virtual wire, or click **New** to define a new virtual wire (refer to "Defining Virtual Wires" on page 125). |

## Configuring Aggregate Interface Groups

▶ *Network > Interfaces*

Aggregate interface groups allow you to generate more than 1 Gbps aggregate throughput by using 802.3ad link aggregation of multiple 1 Gbps links. Aggregation of 10Gbps XFP and SFP+ is also supported. The aggregate interface that you create becomes a logical interface. Interface management, zone profiles, VPN interfaces, and VLAN subinterfaces are all properties of the logical aggregate interface, not of the underlying physical interfaces.

Each aggregate group can contain several physical interfaces of the type Aggregate Ethernet. After the group is created, you perform operations such as configuring Layer 2 or Layer 3 parameters on the Aggregate Group object rather than on the Aggregate Ethernet interfaces themselves.

***Note:*** *The algorithm used to evenly distribute traffic on the interfaces in an aggregate group is based on the session ID of the incoming traffic. As traffic enters the aggregate group, the last three unique bits of the session ID are used to determine which interface should be used for a given flow.*

The following rules apply to aggregate interface groups:

- The interfaces are compatible with virtual wire, Layer 2, and Layer 3 interfaces.
- Tap mode is not supported.
- The 1 Gbps links in a group must be of the same type (all copper or all fiber).
- You can include up to eight aggregate interfaces in an aggregate group.
- All of the members of an aggregate group must be of the same type. This is validated during the commit operation.
- Aggregate groups can be used for redundancy and throughput scaling on the HA3 (packet forwarding) link in Active/Active HA deployments.

You can configure one or more interfaces as part of an aggregate Ethernet interface group. First define the group, as described in this section, and then assign interfaces to the group. For instructions on assigning interfaces to the group, refer to "Configuring Layer 3 Subinterfaces" on page 134.

To create and configure aggregate group interfaces, click **Add Aggregate Group** and specify the following information.

**Table 55. Aggregate Group Interface Settings**

| Field | Description |
|---|---|
| Interface Name | Enter a name and numeric suffix to identify the interface. The interface name is listed as *mm.n* where *mm* is the name and *n* is the suffix (1-8). |
| Interface Type | Select the interface type.<br>• **HA**—No additional configuration is required.<br>• **Layer 2**—Configure the settings as described in Table 50.<br>• **Layer 3**—Configure the settings as described in Table 52. |
| Comment | Enter an optional description of the interface. |

**Table 55. Aggregate Group Interface Settings (Continued)**

| Field | Description |
|---|---|
| **Assign Interface To** | |
| Assign Interface To | The interface assignment depends on the interface type, as follows:<br>• **Layer 2**—Specify a VLAN and zone.<br>• **Layer 3**—Specify a virtual router and zone<br>• **Virtual Wire**—Specify a virtual wire and zone.<br>***Note:*** *If the type is HA, there are no options to specify in this section.* |
| Virtual System | Select the virtual system for the interface. **None** removes the configuration from the interface. |

## Configuring Aggregate Ethernet Interfaces

▶ *Network > Interfaces*

Each aggregate Ethernet interface is assigned a name of the form ae.*number* and can be of the type Layer 2, Layer 3, or virtual wire. After the assignment is made, the new interface functions in the same way as any other interface.

To configure aggregate Ethernet interfaces, click the interface name on the **Ethernet** tab and specify the following information.

**Table 56. Aggregate Ethernet Interface Settings**

| Field | Description |
|---|---|
| Interface Name | Choose the interface from the drop-down list. Modify the name if desired. |
| Interface Type | Select **Aggregate Ethernet** from the drop-down list. |
| Netflow Profile | Select a profile if you want to export all ingress traffic through the interface to a specified NetFlow server. Refer to "Configuring Netflow Settings" on page 85. |
| Comment | Enter an optional description of the interface. |
| **Config Tab** | |
| Virtual System | Select the virtual system for the interface. **None** removes the configuration from the interface. |
| Security Zone | Select a security zone for the interface, or click **New** to define a new zone (refer to "Defining Security Zones" on page 151). **None** removes the configuration from the interface. |
| **Advanced Tab** | |
| Link Speed | Select the interface speed in Mbps (10, 100, or 1000) or auto. |
| Link Duplex | Select whether the interface transmission mode is full-duplex (full), half-duplex (half), or negotiated automatically (auto). |
| Link State | Select whether the interface status is enabled (up), disabled (down), or determined automatically (auto). |

## Configuring VLAN Interfaces

▶ *Network > Interfaces*

For each Ethernet port configured as a Layer 2 interface, you can define a VLAN interface to allow routing of the VLAN traffic to Layer 3 destinations outside the VLAN. To configure the main Layer 2 interfaces, refer to "Configuring Layer 2 Interfaces" on page 128.

To define a VLAN interface, open the **VLAN** tab, click **Add**, and specify the following settings.

**Table 57. VLAN Interface Settings**

| Field | Description |
|---|---|
| Interface Name | Specify a numeric suffix for the interface (1-4999). |
| Netflow Profile | Select a profile if you want to export all ingress traffic through the interface to a specified NetFlow server. Refer to "Configuring Netflow Settings" on page 85. |
| Comment | Add an optional description of the interface. |
| **Config Tab** | |
| VLAN | Select a VLAN, or click **New** to define a new VLAN (refer to "Network Profiles" on page 174). **None** removes the configuration from the interface. |
| Virtual Router | Select a virtual router, or click **New** to define a new virtual router (refer to "Virtual Routers and Routing Protocols" on page 153). **None** removes the configuration from the interface. |
| Virtual System | Select the virtual system for the interface. **None** removes the configuration from the interface. |
| Security Zone | Select a security zone for the interface, or click **New** to define a new zone (refer to "Defining Security Zones" on page 151). **None** removes the configuration from the interface. |
| **IPv4 Tab** | |
| Static | Select **Static** to assign static IP addresses. Click **Add** and enter an IP address and network mask for the interface in the format *ip_address/mask*. You can enter multiple IP addresses for the interface. |
| DHCP Client | Select **DHCP** to use DHCP address assignment for the interface, and specify the following:<br>• **Enable**—Select the check box to activate the DHCP client on the interface.<br>• **Automatically create default route point to server**—Select the check box to automatically create a default route that points to the DHCP server when connected.<br>• **Default Route Metric**—Specify the route metric to be associated with the default route and used for path selection (optional, range 1-65535).<br>Click **Show DHCP Client Runtime Info** to open a window that displays all settings received from the DHCP server, including DHCP lease status, dynamic IP assignment, subnet mask, gateway, server settings (DNS, NTP, domain, WINS, NIS, POP3, and SMTP). |

**Table 57. VLAN Interface Settings (Continued)**

| Field | Description |
|---|---|
| ARP Entries | To add one or more static ARP entries, enter an IP address and its associated hardware (MAC) address, and click **Add**. To delete a static entry, select the entry and click **Delete**. |
| **IPv6 Tab** | |
| Enable IPv6 on the interface | Select the check box to enable IPv6 addressing for the subinterface. |
| Interface ID | Enter the 64-bit extended unique identifier in hexadecimal format, for example, 00:26:08:FF:FE:DE:4E:29. If the interface ID is left blank, the firewall will use the EUI-64 generated from the physical interface's MAC address. |
| Address | Click **Add** and enter an IPv6 address and prefix length, for example 2001:400:f00::1/64. Select **Use interface ID as host portion** to assign an IPv6 address to the interface that will use the interface ID as the host portion of the address. Select **Anycast** to include routing through the nearest node. If **Prefix** is not selected, the IPv6 address assigned to the interface will be wholly specified in the address text box.<br>Use the **Send Router Advertisement (Send RA)** option to enable router advertisement for this IP address. You can also set the **Autonomous** flag to be sent and you can set the **on-link** option. You must enable the global **Enable Router Advertisement** option on the interface before enabling **Send Router Advertisement** option for a specific IP address. |
| Address Resolution (Duplicate Address Detection | Select the check box to enable Duplicate Address Detection (DAD) and specify the following information.<br>• **DAD Attempts**—Specify the number of attempts within the neighbor solicitation interval for DAD before the attempt to identify neighbors fails (range 1-10).<br>• **Reachable Time**—Specify the length of time that a neighbor remains reachable after a successful query and response (range 1-36000 seconds).<br>**Neighbor Solicitation (NS) Interval**—Specify the number of seconds for DAD attempts before failure is indicated (range 1-10 seconds). |

**Table 57. VLAN Interface Settings (Continued)**

| Field | Description |
|---|---|
| Enable Router Advertisement | Select the check box to enable Router Advertisement (RA) to provide Stateless Address Autoconfiguration (SLAAC) on IPv6 interfaces. This enables the firewall to act as a default gateway for IPv6 hosts that are not statically configured and will provide the host with an IPv6 prefix that can be used for address configuration. A separate DHCPv6 server can be used in conjunction with this feature to provide DNS and other settings to clients.<br>This option is a global setting for the interface, you can also set router advertisement options per IP address by clicking **Add** and entering in an IP address. You must enable this option on the interface if you are going to specify the **Send Router Advertisement** option per address.<br>Specify the following information that will be used by clients who receive the RA messages.<br>• **Min Interval (sec)**—Specify the minimum interval per second that the firewall will send out router advertisements. Router Advertisements will be sent at random intervals between the minimum and maximum values that are configured (range 3-1350 seconds, default 200 seconds).<br>• **Max Interval (sec)**—Specify the maximum interval per second that the firewall will send out router advertisements. Router Advertisements will be sent at random intervals between the minimum and maximum values that are configured (range 4-1800 seconds, default 600 seconds).<br>• **Hop Limit**—Specify the hop limit that will be applied to clients for outgoing packets. Enter 0 for no hop limit (range 1-255, default 64).<br>• **Link MTU**—Specify the link MTU that will be applied to clients. Select **unspecified** for no link MTU (range 1280-9192, default unspecified).<br>• **Reachable Time (ms)**—Specify the reachable time that the client will use to assume a neighbor is reachable after having received a reachability confirmation message. Select **unspecified** for no reachable time value (range 0-3600000 milliseconds, default unspecified).<br>• **Retrans Time (ms)**—Specify the retransmission timer that the client will use to determine how long it should wait before retransmitting neighbor solicitation messages. Select **unspecified** for no retrans time (range 0-4294967295 milliseconds, default unspecified).<br>• **Router Lifetime (sec)**—Specify the router lifetime that instructs the client on how long the firewall/router should be used as the default router (range 0-9000 seconds, default 1800).<br>• **Managed Configuration**—Select the check box to indicate to the client that addresses are available via DHCPv6.<br>• **Other Configuration**—Select the check box to indicate to the client that other addresses information is available via DHCPv6, such as DNS-related settings.<br>• **Consistency check**—Select the check box to enable consistency checks that the firewall will use to verify that router advertisement sent from other routers are advertising consistent information on the link. If inconsistencies are detected, a log will be created. |

**Table 57. VLAN Interface Settings (Continued)**

| Field | Description |
|---|---|
| **Advanced Tab** | |
| Other Info | Specify the following:<br>• **Management Profile**—Select a profile that specifies which protocols, if any, can be used to manage the firewall over this interface.<br>• **MTU**—Enter the MTU in bytes for packets sent on this interface (512-1500, default 1500). If machines on either side of the firewall perform PMTUD, the MTU value will be returned in an ICMP fragmentation needed message indicating that the MTU is too large.<br>• **Adjust TCP MSS**—if you select this check box, the maximum segment size (MSS) is adjusted to 40 bytes less than the interface MTU. This setting addresses the situation in which a tunnel through the network requires a smaller MSS. If a packet cannot fit within the MSS without fragmenting, this setting allows an adjustment to be made. |
| ARP/Interface Entries | To add one or more static ARP entries, click **Add** and enter an IP address and its associated hardware (MAC) address and Layer 3 interface that can access the hardware address. |
| ND Entries | Click **Add** to enter the IP address and MAC address of neighbors to add for discovery. |

## Configuring Loopback Interfaces

▶ *Network > Interfaces*

You can define one or more Layer 3 loopback interfaces, as needed. For example, you can define a loopback interface to manage the firewall instead of using the management port.

To define a loopback interface, open the **Loopback** tab, click **Add**, and specify the following settings.

**Table 58. Loopback Interface Settings**

| Field | Description |
|---|---|
| Interface Name | Specify a numeric suffix for the interface (1-4999). |
| Netflow Profile | Select a profile if you want to export all ingress traffic through the interface to a specified NetFlow server. Refer to "Configuring Netflow Settings" on page 85. |
| Comment | Add an optional description of the interface. |
| **Config Tab** | |
| Virtual Router | Select a virtual router, or click **New** to define a new virtual router (refer to "Virtual Routers and Routing Protocols" on page 153). **None** removes the configuration from the interface. |
| Virtual System | Select the virtual system for the interface. **None** removes the configuration from the interface. |
| Security Zone | Select a security zone for the interface, or click **New** to define a new zone (refer to "Defining Security Zones" on page 151). **None** removes the configuration from the interface. |

**Table 58. Loopback Interface Settings (Continued)**

| Field | Description |
|---|---|
| **IPv4 Tab** | |
| IP Address | Click **Add** to enter IP addresses and network masks for the interface. |
| **IPv6 Tab** | |
| Enable IPv6 on the interface | Select the check box to enable IPv6 addressing for the subinterface. |
| Interface ID | Specify the unique 64-bit hexadecimal identifier for the subinterface. |
| Address | Enter the IPv6 address. Select **Use interface ID as host portion** to assign an IPv6 address to the interface that will use the interface ID as the host portion of the address. Select **Anycast** to include routing through the nearest node. |
| **Advanced Tab** | |
| Other Info | Specify the following settings:<br>• **Management Profile**—Select a profile that specifies which protocols, if any, can be used to manage the firewall over this interface.<br>• **MTU**—Enter the maximum transmission unit (MTU) in bytes for packets sent on this interface (512 to 1500, default 1500). If machines on either side of the firewall perform Path MTU Discovery (PMTUD), the MTU value will be returned in an ICMP fragmentation needed message indicating that the MTU is too large.<br>• **Adjust TCP MSS**—If you select this check box, the maximum segment size (MSS) is adjusted to 40 bytes less than the interface MTU. This setting addresses the situation in which a tunnel through the network requires a smaller MSS. If a packet cannot fit within the MSS without fragmenting, this setting allows an adjustment to be made. |

## Configuring Tunnel Interfaces

▶ *Network > Interfaces*

To define tunnel interfaces, open the **Tunnel** tab, click **Add**, and specify the following settings.

**Table 59. Tunnel Interface Settings**

| Field | Description |
|---|---|
| Interface Name | Specify a numeric suffix for the interface (1-4999). |
| Netflow Profile | Select a profile if you want to export all ingress traffic through the interface to a specified NetFlow server. Refer to "Configuring Netflow Settings" on page 85. |
| Comment | Add an optional description of the interface. |
| **Config Tab** | |
| Virtual Router | Select a virtual router for this interface, or click **New** to configure a new virtual router. Refer to "Virtual Routers and Routing Protocols" on page 153. **None** removes the configuration from the interface. |
| Virtual System | Select the virtual system for the interface. **None** removes the configuration from the interface. |

**Table 59. Tunnel Interface Settings (Continued)**

| Field | Description |
|---|---|
| Security Zone | Select a security zone for the interface, or click **New** to define a new zone (refer to "Defining Security Zones" on page 151). **None** removes the configuration from the interface. |
| **IPv4 Tab** | |
| IP Address | Click **Add** to enter IP addresses and network masks for the interface. |
| **IPv6 Tab** | |
| Enable IPv6 on the interface | Select the check box to enable IPv6 addressing for the interface.<br>This option allows you to route IPv6 traffic over an IPv4 IPSec tunnel and will provide confidentiality between IPv6 networks. The IPv6 traffic is encapsulated by IPv4 and then ESP.<br>To route IPv6 traffic to the tunnel, you will either use a static route to the tunnel, or use a Policy Based Forwarding (PBF) rule to direct traffic and to provide redundancy by monitoring the other end of the tunnel and failing over when needed. |
| Interface ID | Enter the 64-bit extended unique identifier in hexadecimal format, for example, 00:26:08:FF:FE:DE:4E:29. If the interface ID is left blank, the firewall will use the EUI-64 generated from the physical interface's MAC address. |
| Address | Click **Add** and enter an IPv6 address and prefix length, for example 2001:400:f00::1/64. Select **Use interface ID as host portion** to assign an IPv6 address to the interface that will use the interface ID as the host portion of the address. Select **Anycast** to include routing through the nearest node. If **Prefix** is not selected, the IPv6 address assigned to the interface will be wholly specified in the address text box. |
| **Advanced Tab** | |
| Other Info | Specify the following:<br>• **Management Profile**—Select a profile that specifies which protocols, if any, can be used to manage the firewall over this interface.<br>• **MTU**—Enter the MTU in bytes for packets sent on this interface (512-1500, default 1500). If machines on either side of the firewall perform PMTUD, the MTU value will be returned in an ICMP fragmentation needed message indicating that the MTU is too large.<br>***Note:*** *The firewall automatically considers tunnel overhead when performing IP fragmentation and also adjusts the TCP maximum segment size (MSS) as needed.* |

## Configuring Tap Interfaces

▶ *Network > Interfaces*

You can define tap interfaces as needed to permit connection to a span port on a switch for traffic monitoring only (refer to "Tap Mode Deployments" on page 125).

To define tap interfaces, click an interface name on the **Ethernet** tab, and specify the following information.

**Table 60. Tap Interface Settings**

| Field | Description |
|---|---|
| Interface Name | Specify a name for the interface or keep the default name. |
| Interface Type | Select **Tap** from the drop-down list. |
| Netflow Profile | Select a profile if you want to export all ingress traffic through the interface to a specified NetFlow server. Refer to "Configuring Netflow Settings" on page 85. |
| Comment | Enter an optional description of the interface. |
| **Config Tab** | |
| Virtual System | Select a virtual system. **None** removes the configuration from the interface. |
| Zone | Select a security zone for the interface, or click **New** to define a new zone (refer to "Defining Security Zones" on page 151). **None** removes the configuration from the interface. |
| **Advanced Tab** | |
| Link Speed | Select the interface speed in Mbps (10, 100, or 1000) or auto. |
| Link Duplex | Select whether the interface transmission mode is full-duplex (full), half-duplex (half), or negotiated automatically (auto). |
| Link State | Select whether the interface status is enabled (up), disabled (down), or determined automatically (auto). |

## Configuring HA Interfaces

Each HA interface has a specific function: one interface is for configuration synchronization and heartbeats and the other interface is for state synchronization. If active/active high availability is enabled, a third HA interface can be used to forward packets.

***Note:*** *Some Palo Alto Networks firewalls include dedicated physical ports for use in HA deployments (one for the control link and one for the data link). For firewalls that do not include dedicated ports, you must specify the data ports that will be used for HA. For additional information on HA, refer to "Enabling HA on the Firewall" on page 101.*

To define HA interfaces, click an interface name and specify the following information.

**Table 61. HA Interface Settings**

| Field | Description |
|---|---|
| Interface Name | Choose the interface from the drop-down list. Modify the name if desired. |
| Interface Type | Select **HA** from the drop-down list. |
| Comment | Enter an optional description of the interface. |
| **Advanced Tab** | |
| Link Speed | Select the interface speed in Mbps (10, 100, or 1000) or auto. |
| Link Duplex | Select whether the interface transmission mode is full-duplex (full), half-duplex (half), or negotiated automatically (auto). |
| Link State | Select whether the interface status is enabled (up), disabled (down), or determined automatically (auto). |

# Security Zones

A security zone identifies one or more source or destination interfaces on the firewall. When you define a security policy rule, you must specify the source and destination security zones of the traffic. For example, an interface connected to the Internet is in an "untrusted" security zone, while an interface connected to the internal network is in a "trusted" security zone.

Separate zones must be created for each type of interface (Layer 2, Layer 3, tap, or virtual wire), and each interface must be assigned to a zone before it can process traffic. Security policies can be defined only between zones of the same type. However, if you create a VLAN interface for one or more VLANs, applying security policies between the VLAN interface zone and a Layer 3 interface zone (Figure 16) has the same effect as applying policies between the Layer 2 and Layer 3 interface zones.

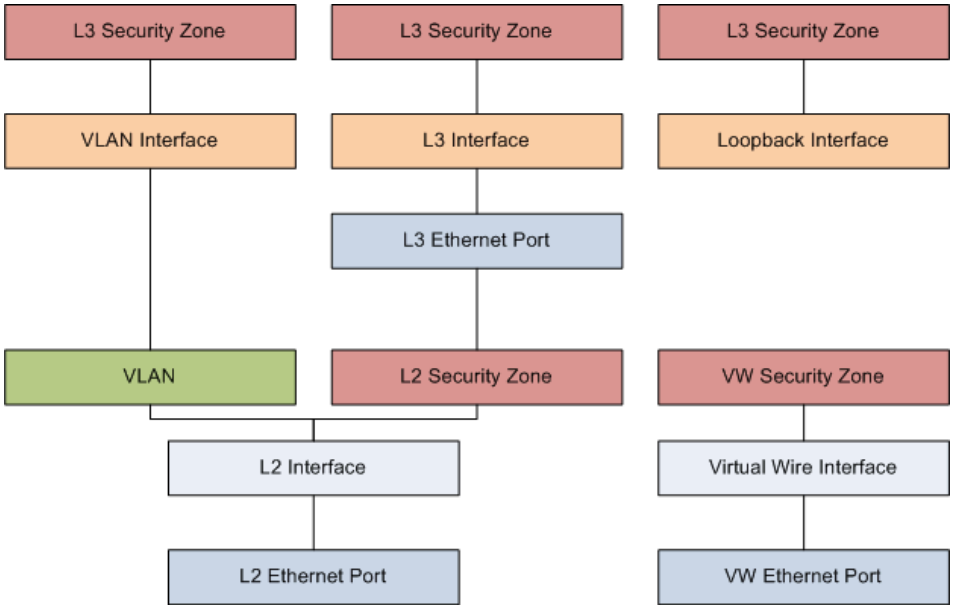

**Figure 16. Zone and Interface Types**

## Defining Security Zones

▶ *Network* > *Zones*

In order for a firewall interface to be able to process traffic, it must be assigned to a security zone. To define security zones, click **New** and specify the following information:

**Table 62. Security Zone Settings**

| Field | Description |
|---|---|
| Name | Enter a zone name (up to 15 characters). This name appears in the list of zones when defining security policies and configuring interfaces. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, periods, and underscores. |
| Location | Select the virtual system that applies to this zone. |

**Table 62. Security Zone Settings (Continued)**

| Field | Description |
|---|---|
| Type | Select a zone type (Layer2, Layer3, Virtual Wire, Tap, or External virtual system) to list all the interfaces of that type that have not been assigned to a zone. The Layer 2 and Layer 3 zone types list all Ethernet interfaces and subinterfaces of that type. The External virtual system type is for communications among virtual systems in the firewall. Refer to "Communications Among Virtual Systems" on page 111.<br>Each interface can belong to one zone in one virtual system. |
| Zone Protection Profiles | Select a profile that specifies how the security gateway responds to attacks from this zone. To add new profiles, refer to "Defining Zone Protection Profiles" on page 178. |
| Log Setting | Select a log forwarding profile for forwarding zone protection logs to an external system. |
| Enable User Identification | Select to enable the user identification function on a per-zone basis. |
| User Identification ACL Include List | Enter the IP address or IP address/mask of a user or group to be identified (format *ip_address/mask*; for example, 10.1.1.1/24). Click **Add**. Repeat as needed. If an include list is not configured, then all IP addresses are allowed. |
| User Identification ACL Exclude List | Enter the IP address or IP address/mask of a user or group that will explicitly not be identified (format *ip_address/mask*; for example, 10.1.1.1/24). Click **Add**. Repeat as needed. If an exclude list is not configured, then all IP addresses are allowed. |

# VLAN Support

▶ ***Network > VLANs***

The firewall supports VLANs that conform to the IEEE 802.1Q standard. Each Layer 2 interface that is defined on the firewall must be associated with a VLAN. The same VLAN can be assigned to multiple Layer 2 interfaces, but each interface can belong to only one VLAN. Optionally, a VLAN can also specify a VLAN interface that can route traffic to Layer 3 destinations outside the VLAN.

**Table 63. VLAN Settings**

| Field | Description |
|---|---|
| Name | Enter a VLAN name (up to 31 characters). This name appears in the list of VLANs when configuring interfaces. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| VLAN Interface | Select a VLAN interface to allow traffic to be routed outside the VLAN. To define a VLAN interface, refer to "Configuring VLAN Interfaces" on page 143. |
| L3 Forwarding Enabled | If you select a VLAN interface, you can select the check box to enable Layer 3 routing over the selected interface. |

**Table 63. VLAN Settings (Continued)**

| Field | Description |
|---|---|
| Interfaces | Specify firewall interfaces for the VLAN. |
| Static MAC Configuration | Specify the interface through which a MAC address is reachable. This will override any learned interface-to-MAC mappings. |

# Virtual Routers and Routing Protocols

You can set up virtual routers to enable the firewall to route packets at Layer 3 by making packet forwarding decisions according to the destination IP address. The Ethernet interfaces and VLAN interfaces defined on the firewall receive and forward the Layer 3 traffic. The destination zone is derived from the outgoing interface based on the forwarding criteria, and policy rules are consulted to identify the security policies to be applied. In addition to routing to other network devices, virtual routers can route to other virtual routers within the same firewall if a next hop is specified to point to another virtual router.

Support is provided for static routing and dynamic routing using the Routing Information Protocol (RIP), Open Shortest Path First (OSPF) protocol, and Border Gateway Protocol (BGP).

***Note:*** *Policy-based forwarding is also supported for traffic on Layer 3 interfaces.*

## Routing Information Protocol

RIP was designed for small IP networks and relies on hop count to determine routes; the best routes have the fewest number of hops. RIP is based on UDP and uses port 520 for route updates. By limiting routes to a maximum of 15 hops, the protocol helps prevent the development of routing loops, but also limits the supported network size. If more than 15 hops are required, traffic is not routed. RIP also can take longer to converge than OSPF and other routing protocols. The firewall supports RIP v2.

## Open Shortest Path First

OSPF determines routes dynamically by obtaining information from other routers and advertising routes to other routers by way of Link State Advertisements (LSAs). The router keeps information about the links between it and the destination and can make highly efficient routing decisions. A cost is assigned to each router interface, and the best routes are determined to be those with the lowest costs, when summed over all the encountered outbound router interfaces and the interface receiving the LSA.

Hierarchical techniques are used to limit the number of routes that must be advertised and the associated LSAs. Because OSPF dynamically processes a considerable amount of route information, it has greater processor and memory requirements than does RIP.

## Border Gateway Protocol

The Border Gateway Protocol (BGP) is the primary Internet routing protocol. BGP determines network reachability based on IP prefixes that are available within autonomous systems (AS), where an AS is a set of IP prefixes that a network provider has designated to be part of a single routing policy.

In the routing process, connections are established between BGP peers (or neighbors). If a route is permitted by the policy, it is stored in the routing information base (RIB). Each time the local firewall RIB is updated, the firewall determines the optimal routes and sends an update to the external RIB, if export is enabled.

Conditional advertisement is used to control how BGP routes are advertised. The BGP routes must satisfy conditional advertisement rules before being advertised to peers.

BGP supports the specification of aggregates, which combine multiple routes into a single route. During the aggregation process, the first step is to find the corresponding aggregation rule by performing a longest match that compares the incoming route with the prefix values for other aggregation rules.

The firewall provides a complete BGP implementation that includes the following features:

- Specification of one BGP routing instance per virtual router.
- Routing policies based on route-map to control import, export and advertisement, prefix-based filtering, and address aggregation.
- Advanced BGP features that include route reflector, AS confederation, route flap dampening, and graceful restart.
- IGP-BGP interaction to inject routes to BGP using redistribution profiles.

BGP configuration consists of the following elements:

- Per-routing-instance settings, which include basic parameters such as local route ID and local AS and advanced options such as path selection, route reflector, AS confederation, route flap, and dampening profiles.
- Authentication profiles, which specify the MD5 authentication key for BGP connections.
- Peer group and neighbor settings, which include neighbor address and remote AS and advanced options such as neighbor attributes and connections.
- Routing policy, which specifies rule sets that peer groups and peers use to implement imports, exports, conditional advertisements, and address aggregation controls.

## Multicast Routing

The multicast routing feature allows the firewall to route multicast streams using Protocol Independent Multicast Sparse Mode (PIM-SM) and PIM Source Specific Multicast (PIM-SSM) for applications such as media broadcasting (radio and video) with PIMv2. The firewall performs Internet Group Management Protocol (IGMP) queries for hosts that are on the same network as the interface on which IGMP is configured. PIM-SM and IGMP can be enabled on Layer 3 interfaces. IGMP v1, v2, and v3 are supported. PIM and IGMP must be enabled on host-facing interfaces.

PAN-OS provides full multicast security while acting as a PIM designated router (DR), PIM rendezvous point (RP), intermediate PIM router, or IGMP querier. The firewall can be deployed in environments in which the RP is statically configured or dynamically elected. The

bootstrap router (BSR) role is not supported. Deployment across IPSec tunnels is fully supported between Palo Alto Networks firewalls. GRE encapsulation within IPSec is not currently supported.

### Security policy

PAN-OS provides two methods to enforce security on multicast feeds. Multicast groups can be filtered in the IGMP and PIM group permission settings specified on an interface level. Multicast traffic must also be explicitly allowed by security policy. A special destination zone known as "Multicast" has been added and must be specified to control multicast traffic in security, QoS, and DoS protection rules. In contrast to unicast security policy, multicast security policies must be explicitly created when the source and destination interfaces are in the same zone. Security profiles are supported in multicast environments that require threat prevention capabilities.

### Logging

Each multicast session passing through the firewall creates only one traffic log entry (even if the firewall is replicating packets for distribution on multiple interfaces). Traffic logs indicate the number of bytes coming into the firewall rather than the number of bytes distributed as part of the multicast feed.

## Defining Virtual Routers

▶ *Network > Virtual Routers*

Defining virtual routers allows you to set up forwarding rules for Layer 3 and enable the use of dynamic routing protocols. Each Layer 3 interface, loopback interface, and VLAN interface defined on the firewall should be associated with a virtual router. Each interface can belong to only one virtual router.

***Note:*** *To configure Ethernet ports as Layer 3 interfaces, refer to "Configuring Layer 3 Interfaces" on page 130. To define Layer 3 subinterfaces, refer to "Configuring Layer 3 Subinterfaces" on page 134. For an overview of virtual routers, refer to "Virtual Routers and Routing Protocols" on page 153.*

Define settings on the specified tabs, as appropriate.

### General Tab

Select the interfaces to include in the virtual router and add any static routes. Refer to the following table.

**Table 64. Virtual Router Settings - General Tab**

| Field | Description |
|---|---|
| Name | Specify a name to describe the virtual router (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Interfaces | Select the interfaces that you want to include in the virtual router. When you select an interface, it is included in the virtual router and can be used as an outgoing interface in the virtual router's routing tab.<br>To specify the interface type, refer to "Firewall Interfaces" on page 127.<br>***Note:*** *When you add an interface, its connected routes are added automatically.* |

**Table 64. Virtual Router Settings - General Tab (Continued)**

| Field | Description |
|---|---|
| Administrative Distances | Specify the following administrative distances:<br>• Static routes (10-240, default 10).<br>• OSPF Int (10-240, default 30).<br>• OSPF Ext (10-240, default 110).<br>• IBGP (10-240, default 200).<br>• EBGP (10-240, default 20).<br>• RIP (10-240, default 120). |

### Static Routes Tab

Optionally enter one or more static routes. Click the IP or IPv6 tab to specify the route using IPv4 or IPv6 addresses. It is usually necessary to configure default routes (0.0.0.0/0) here. Default routes are applied for destinations that are otherwise not found in the virtual router's routing table.

**Table 65. Virtual Router Settings - Static Routes Tab**

| Field | Description |
|---|---|
| Name | Enter a name to identify the static route (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Destination | Enter an IP address and network mask in the format *ip_address/mask*. |
| Interface | Select the interface to forward packets to the destination, or configure the next hop settings, or both. |
| Next Hop | Specify the following next hop settings:<br>• **None**—Select if there is no next hop for the route.<br>• **IP Address**—Specify the IP address of the next hop router.<br>• **Discard**—Select if you want to drop traffic that is addressed to this destination.<br>• **Next VR**—Select a virtual router in the firewall as the next hop. This option allows you to route internally between virtual routers within a single firewall. |
| Admin Distance | Specify the administrative distance for the static route (10-240, default 10). |
| Metric | Specify a valid metric for the static route (1 - 65535). |
| No Install | Select if you do not want to install the route in the forwarding table. The route is retained in the configuration for future reference. |

### Redistribution Profiles Tab

Modify route redistribution filter, priority, and action based on desired network behavior. Route redistribution allows static routes and routes that are acquired by other protocols to be advertised through specified routing protocols. Redistribution profiles must be applied to routing protocols in order to take effect. Without redistribution rules, each protocol runs separately and does not communicate outside its purview. Redistribution profiles can be added or modified after all routing protocols are configured and the resulting network topology is established. Apply redistribution profiles to the RIP and OSPF protocols by defining export rules. Apply redistribution profiles to BGP in the Redistribution Rules tab. Refer to the following table.

**Table 66. Virtual Router Settings - Redistribution Profiles Tab**

| Field | Description |
|---|---|
| Name | Click **Add** to display the **Redistribution Profile** page, and enter the profile name. |
| Priority | Enter a priority (range 1-255) for this profile. Profiles are matched in order (lowest number first). |
| Redistribute | Choose whether to perform route redistribution based on the settings in this window.<br>• **Redist**—Select to redistribute matching candidate routes. If you select this option, enter a new metric value. A lower metric value means a more preferred route.<br>• **No Redist**—Select to not redistribute matching candidate routes. |
| **General Filter Tab** | |
| Type | Select check boxes to specify the route types of the candidate route. |
| Interface | Select the interfaces to specify the forwarding interfaces of the candidate route. |
| Destination | To specify the destination of the candidate route, enter the destination IP address or subnet (format x.x.x.x or x.x.x.x/n) and click **Add**. To remove an entry, click the icon associated with the entry. |
| Next Hop | To specify the gateway of the candidate route, enter the IP address or subnet (format x.x.x.x or x.x.x.x/n) that represents the next hop and click **Add**. To remove an entry, click the icon associated with the entry. |
| **OSPF Filter Tab** | |
| Path Type | Select check boxes to specify the route types of the candidate OSPF route. |
| Area | Specify the area identifier for the candidate OSPF route. Enter the OSPF area ID (format x.x.x.x), and click **Add**. To remove an entry, click the icon associated with the entry. |
| Tag | Specify OSPF tag values. Enter a numeric tag value (1-255), and click Add. To remove an entry, click the icon associated with the entry. |
| **BGP Filter Tab** | |
| Community | Specify a community for BGP routing policy. |
| Extended Community | Specify an extended community for BGP routing policy. |

### RIP Tab

Specify parameters for use of the Routing Information Protocol (RIP) on the selected interfaces. Although it is possible to configure both RIP and OSPF, it is generally recommended to choose only one of these protocols. Refer to the following table.

**Table 67. Virtual Router Settings - RIP Tab**

| Field | Description |
|---|---|
| Enable | Select the check box to enable the RIP protocol. |
| Reject Default Route | Select the check box if you do not want to learn any default routes through RIP. Selecting the check box is highly recommended. |
| Allow Redist Default Route | Select the check box to permit redistribution of default routes through RIP. |
| **Interfaces** | |
| Interface | Select the interface that runs the RIP protocol. |
| Enable | Select to enable these settings. |
| Advertise | Select to advertise a default route to RIP peers with the specified metric value. |
| Metric | Specify a metric value for the router advertisement. This field is visible only if the **Advertise** check box is selected. |
| Auth Profile | Select the profile. |
| Mode | Select **normal**, **passive**, or **send-only**. |
| **Timers** | |
| Interval Seconds (sec) | Define the length of the timer interval in seconds. This duration is used for the remaining RIP timing fields (1 - 60). |
| Update Intervals | Enter the number of intervals between route update announcements (1 - 3600). |
| Expire Intervals | Enter the number of intervals between the time that the route was last updated to its expiration (1- 3600). |
| Delete Intervals | Enter the number of intervals between the time that the route expires to its deletion (1- 3600). |
| **Auth Profiles** | |
| Profile Name | Enter a name for the authentication profile to authenticate RIP messages. To authenticate RIP messages, first define the authentication profiles and then apply them to interfaces on the **RIP** tab. |
| Password Type | Select the type of password (simple or MD5).<br>• If you select **Simple**, enter the simple password and then confirm.<br>• If you select **MD5**, enter one or more password entries, including **Key-ID** (0-255), **Key**, and optional **Preferred** status. Click **Add** for each entry, and then click **OK**. To specify the key to be used to authenticate outgoing message, select the **Preferred** option. |

**Table 67. Virtual Router Settings - RIP Tab (Continued)**

| Field | Description |
|---|---|
| **Export Rules** | |
| Export Rules | (Read-only) Displays the rules that apply to routes sent by the virtual router to a receiving router.<br>• **Allow Redistribute Default Route**—Select the check box to permit the firewall to redistribute its default route to peers.<br>• **Redistribution Profile**—Select a redistribution profile that allows you to modify route redistribution, filter, priority, and action based on the desired network behavior. Refer to "Redistribution Profiles Tab" on page 158. |

## OSPF Tab

Specify parameters for use of the Open Shortest Path First (OSPFv2) protocol on the selected interfaces. Although it is possible to configure both RIP and OSPF, it is generally recommended to choose only one IGP protocol. Refer to the following table.BGP Tab

**Table 68. Virtual Router Settings - OSPF Tab**

| Field | Description |
|---|---|
| Enable | Select the check box to enable the OSPF protocol. |
| Reject Default Route | Select the check box if you do not want to learn any default routes through OSPF. Selecting the check box is recommended, especially for static routes. |
| Router ID | Specify the router ID associated with the OSPF instance in this virtual router. The OSPF protocol uses the router ID to uniquely identify the OSPF instance. |
| **Areas** | |
| Area ID | Configure the area over which the OSPF parameters can be applied.<br>Enter an identifier for the area in x.x.x.x format. This is the identifier that each neighbor must accept to be part of the same area. |

**Table 68. Virtual Router Settings - OSPF Tab (Continued)**

| Field | Description |
|---|---|
| Type | Select one of the following options.<br>• **Normal**—There are no restrictions; the area can carry all types of routes.<br>• **Stub**—There is no outlet from the area. To reach a destination outside of the area, it is necessary to go through the border, which connects to other areas. If you select this option, select **Accept Summary** if you want to accept this type of link state advertisement (LSA) from other areas. Also, specify whether to include a default route LSA in advertisements to the stub area along with the associated metric value (1-255). If the **Accept Summary** option on a stub area Area Border Router (ABR) interface is disabled, the OSPF area will behave as a Totally Stubby Area (TSA) and the ABR will not propagate any summary LSAs.<br>• **NSSA** (Not-So-Stubby Area)—It is possible to leave the area directly, but only by routes other than OSPF routes. If you select this option, select **Accept Summary** if you want to accept this type of LSA. Specify whether to include a default route LSA in advertisements to the stub area along with the associated metric value (1-255). Also, select the route type used to advertise the default LSA. Click **Add** in the **External Ranges** section and enter ranges if you want to enable or suppress advertising external routes that are learned through NSSA to other areas. |
| Range | Click **Add** to aggregate LSA destination addresses in the area into subnets. Enable or suppress advertising LSAs that match the subnet, and click **OK**. Repeat to add additional ranges. |
| Interface | Click **Add** and enter the following information for each interface to be included in the area, and click **OK**.<br>• **Interface**—Choose the interface.<br>• **Enable**—Cause the OSPF interface settings to take effect.<br>• **Passive**—Select the check box to if you do not want the OSPF interface to send or receive OSPF packets. Although OSPF packets are not sent or received if you choose this option, the interface is included in the LSA database.<br>• **Link type**—Choose **Broadcast** if you want all neighbors that are accessible through the interface to be discovered automatically by multicasting OSPF hello messages, such as an Ethernet interface. Choose **p2p** (point-to-point) to automatically discover the neighbor. Choose **p2mp** (point-to-multipoint) when neighbors must be defined manually. Defining neighbors manually is allowed only for p2mp mode.<br>• **Metric**—Enter the OSPF metric for this interface (0-65535).<br>• **Priority**—Enter the OSPF priority for this interface (0-255). It is the priority for the router to be elected as a designated router (DR) or as a backup DR (BDR) according to the OSPF protocol. When the value is zero, the router will not be elected as a DR or BDR.<br>• **Auth Profile**—Select a previously-defined authentication profile.<br>• **Timing**—It is recommended that you keep the default timing settings.<br>• **Neighbors**—For p2pmp interfaces, enter the neighbor IP address for all neighbors that are reachable through this interface. |

**Table 68. Virtual Router Settings - OSPF Tab (Continued)**

| Field | Description |
|---|---|
| Virtual Link | Configure the virtual link settings to maintain or enhance backbone area connectivity. The settings must be defined for area boarder routers, and must be defined within the backbone area (0.0.0.0). Click **Add**, enter the following information for each virtual link to be included in the backbone area, and click **OK**.<br>• **Name**—Enter a name for the virtual link.<br>• **Neighbor ID**—Enter the router ID of the router (neighbor) on the other side of the virtual link.<br>• **Transit Area**—Enter the area ID of the transit area that physically contains the virtual link.<br>• **Enable**—Select to enable the virtual link.<br>• **Timing**—It is recommended that you keep the default timing settings.<br>• **Auth Profile**—Select a previously-defined authentication profile. |
| **Auth Profiles** | |
| Profile Name | Enter a name for the authentication profile. To authenticate the OSPF messages, first define the authentication profiles and then apply them to interfaces on the **OSPF** tab. |
| Password Type | Select the type of password (simple or MD5).<br>• If you select **Simple**, enter the password.<br>• If you select **MD5**, enter one or more password entries, including **Key-ID** (0-255), **Key**, and optional **Preferred** status. Click **Add** for each entry, and then click **OK**. To specify the key to be used to authenticate outgoing message, select the **Preferred** option. |
| **Export Rules** | |
| Allow Redistribute Default Route | Select the check box to permit redistribution of default routes through OSPF. |
| Name | Select the name of a redistribution profile. The value must be an IP subnet or valid redistribution profile name. |
| New Path Type | Choose the metric type to apply. |
| New Tag | Specify a tag for the matched route that has a 32-bit value. |
| **Advanced** | |
| RFC 1583 Compatibility | Select the check box to assure compatibility with RFC 1583. |
| Timers | • **SPF Calculation Delay (sec)**—This option is a delay timer allowing you to tune the delay time between receiving new topology information and performing an SPF calculation. Lower values enable faster OSPF re-convergence. Routers peering with the firewall should be tuned in a similar manner to optimize convergence times.<br>• **LSA Interval (sec)**—The option specifies the minimum time between transmissions of two instances of the same LSA (same router, same type, same LSA ID). This is equivalent to MinLSInterval in RFC 2328. Lower values can be used to reduce re-convergence times when topology changes occur. |

### BGP Tab

Specify parameters for use of Border Gateway Protocol (BGP) on the selected interfaces. Refer to the following table.

**Table 69. Virtual Router Settings - BGP Tab**

| Field | Description |
|---|---|
| Enable | Select the check box to enable BGP. |
| Router ID | Enter the IP address to assign to the virtual router. |
| AS Number | Enter the number of the AS to which the virtual router belongs, based on the router ID (range 1-4294967295). |
| **General Tab** | |
| Reject Default Route | Select the check box to ignore any default routes that are advertised by BGP peers. |
| Install Route | Select the check box to install BGP routes in the global routing table. |
| Aggregate MED | Select to enable route aggregation even when routes have different Multi-Exit Discriminator (MED) values. |
| Default Local Preference | Specifies a value than can be used to determine preferences among different paths. |
| AS Format | Select the 2-byte (default) or 4-byte format. This setting is configurable for interoperability purposes. |
| Always Compare MED | Enable MED comparison for paths from neighbors in different autonomous systems. |
| Deterministic MED Comparison | Enable MED comparison to choose between routes that are advertised by IBGP peers (BGP peers in the same autonomous system). |
| Auth Profiles | Click **Add** to include a new authentication profile and configure the following settings:<br>• **Profile Name**—Enter a name to identify the profile.<br>• **Secret/Confirm Secret**—Enter and confirm a passphrase for BGP peer communications.<br>Click the icon to delete a profile. |
| **Advanced Tab** | |
| Graceful Restart | Activate the graceful restart option.<br>• **Stale Route Time**—Specify the length of time that a route can stay in the stale state (range 1-3600 seconds, default 120 seconds).<br>• **Local Restart Time**—Specify the length of time that the local device takes to restart. This value is advertised to peers (range 1-3600 seconds, default 120 seconds).<br>• **Max Peer Restart Time**—Specify the maximum length of time that the local device accepts as a grace period restart time for peer devices (range 1-3600 seconds, default 120 seconds). |
| Reflector Cluster ID | Specify an IPv4 identifier to represent the reflector cluster. |
| Confederation Member AS | Specify the identifier for the AS confederation to be presented as a single AS to external BGP peers. |

**Table 69. Virtual Router Settings - BGP Tab (Continued)**

| Field | Description |
|---|---|
| Dampening Profiles | Settings include:<br>• **Profile Name**—Enter a name to identify the profile.<br>• **Enable**—Activate the profile.<br>• **Cutoff**—Specify a route withdrawal threshold above which a route advertisement is suppressed (range 0.0-1000.0, default 1.25).<br>• **Reuse**—Specify a route withdrawal threshold below which a suppressed route is used again (range 0.0-1000.0, default 5).<br>• **Max. Hold Time**—Specify the maximum length of time that a route can be suppressed, regardless of how unstable it has been (range 0-3600 seconds, default 900 seconds).<br>• **Decay Half Life Reachable**—Specify the length of time after which a route's stability metric is halved if the route is considered reachable (range 0-3600 seconds, default 300 seconds).<br>• **Decay Half Life Unreachable**—Specify the length of time after which a route's stability metric is halved if the route is considered unreachable (range 0-3600 seconds, default 300 seconds).<br>Click the icon to delete a profile. |
| **Peer Group Tab** | |
| Name | Enter a name to identify the peer. |
| Enable | Select to activate the peer. |
| Aggregated Confed AS Path | Select the check box to include a path to the configured aggregated confederation AS. |
| Soft Reset with Stored Info | Select the check box to perform a soft reset of the firewall after updating the peer settings. |
| Type | Specify the type of peer or group and configure the associated settings (see below in this table for descriptions of Import Next Hop and Export Next Hop).<br>• **IBGP**—Specify the following;<br>– Export Next Hop<br>• **EBGP Confed**—Specify the following;<br>– Export Next Hop<br>• **IBGP Confed**—Specify the following;<br>– Export Next Hop<br>• **EBGP**—Specify the following:<br>– Import Next Hop<br>– Export Next Hop<br>– Remove Private AS (select if you want to force BGP to remove private AS numbers). |
| Import Next Hop | Choose an option for next hop import:<br>• **original**—Use the Next Hop address provided in the original route advertisement.<br>• **use-peer**—Use the peer's IP address as the Next Hop address. |

**Table 69. Virtual Router Settings - BGP Tab (Continued)**

| Field | Description |
|---|---|
| Export Next Hop | Choose an option for next hop export:<br>• **resolve**—Resolve the Next Hop address using the local forwarding table.<br>• **use-self**—Replace the Next Hop address with this router's IP address to ensure that it will be in the forwarding path. |
| Peer | To add a new peer, click **New** and configure the following settings:<br>• **Name**—Enter a name to identify the peer.<br>• **Enable**—Select to activate the peer.<br>• **Peer AS**—Specify the AS of the peer.<br>• **Local Address**—Choose a firewall interface and local IP address.<br>• **Connection Options**—Specify the following options:<br>– **Auth Profile**—Select the profile.<br>– **Keep Alive Interval**—Specify an interval after which routes from a peer are suppressed according to the hold time setting (range 0-1200 seconds, default 30 seconds).<br>– **Multi Hop**—Set the time-to-live (TTL) value in the IP header (range 1-255, default 0). The default value of 0 means 2 for eBGP and 255 for iBGP.<br>– **Open Delay Time**—Specify the delay time between opening the peer TCP connection and sending the first BGP open message (range 0-240 seconds, default 0 seconds).<br>– **Hold Time**—Specify the period of time that may elapse between successive KEEPALIVE or UPDATE messages from a peer before the peer connection is closed. (range 3-3600 seconds, default 90 seconds).<br>– **Idle Hold Time**—Specify the time to wait in the idle state before retrying connection to the peer (range 1-3600 seconds, default 15 seconds).<br>• **Peer Address**—Specify the IP address and port of the peer.<br>• **Advanced Options**—Configure the following settings:<br>– **Reflector Client**—Select the type of reflector client (**Non-Client**, **Client**, or **Meshed Client**). Routes that are received from reflector clients are shared with all internal and external BGP peers.<br>– **Peering Type**—Specify a bilateral peer, or leave unspecified.<br>– **Max. Prefixes**—Specify the maximum number of supported IP prefixes (1 - 100000 or unlimited).<br>• **Incoming Connections/Outgoing Connections**—Specify the incoming and outgoing port numbers and select the Allow check box to allow traffic to or from these ports. |

**Table 69. Virtual Router Settings - BGP Tab (Continued)**

| Field | Description |
|---|---|
| **Import Rules/Export Rules Tabs** | |
| Import Rules/Export Rules | Click the BGP **Import Rules** or **Export Rules** subtab. To add a new rule, click **Add** and configure the following settings.<br>• **General** subtab:<br>– **Name**—Specify a name to identify the rule.<br>– **Enable**—Select to activate the rule.<br>– Used **by**—Select the peer groups that will use this rule.<br>• **Match** subtab:<br>– **AS-Path Regular Expression**—Specify a regular expression for filtering of AS paths.<br>– **Community Regular Expression**—Specify a regular expression for filtering of community strings.<br>– **Extended Community Regular Expression**—Specify a regular expression for filtering of extended community strings.<br>– **Address Prefix**—Specify IP addresses or prefixes for route filtering.<br>– **MED**—Specify a MED value for route filtering.<br>– **Next Hop**—Specify next hop routers or subnets for route filtering.<br>– **From Peer**—Specify peer routers for route filtering.<br>• **Action** subtab:<br>– **Action**—Specify an action (**Allow** or **Deny**) to take when the match conditions are met.<br>– **Local Preference**—Specify a local preference metric, only if the action is **Allow**.<br>– **MED**—Specify a MED value, only if the action is **Allow** (0- 65535).<br>– **Weight**—Specify a weight value, only if the action is **Allow** (0- 65535).<br>– **Next Hop**—Specify a next hop router, only if the action is **Allow**.<br>– **Origin**—Specify the path type of the originating route: IGP, EGP, or incomplete, only if the action is **Allow**.<br>– **AS Path Limit**—Specify an AS path limit, only if the action is **Allow**.<br>– **AS Path**—Specify an AS path: **None**, **Remove**, **Prepend**, **Remove and Prepend**, only if the action is **Allow**.<br>– **Community**—Specify a community option: **None**, **Remove All**, **Remove Regex**, **Append**, or **Overwrite**, only if the action is **Allow**.<br>– **Extended Community**—Specify a community option: **None**, **Remove All**, **Remove Regex**, **Append**, or **Overwrite**, only if the action is **Allow**.<br>– **Dampening**—Specify the dampening parameter, only if the action is **Allow**.<br>Click the icon to delete a group. Click **Clone** to add a new group with the same settings as the selected group. A suffix is added to the new group name to distinguish it from the original group. |

**Table 69. Virtual Router Settings - BGP Tab (Continued)**

| Field | Description |
|---|---|
| **Conditional Adv Tab** | The BGP conditional advertisement feature allows you to control what route to advertise in the event that a different route is not available in the local BGP routing table (LocRIB), indicating a peering or reachability failure. This is useful in cases where you want to try and force routes to one AS over another, for example if you have links to the Internet through multiple ISPs and you want traffic to be routed to one provider instead of the other unless there is a loss of connectivity to the preferred provider. With conditional advertising, you can configure a non-exist filter that matches the prefix of the preferred route. If any route matching the non-exist filter is not found in the local BGP routing table, only then will the device allow advertisement of the alternate route (the route to the other, non-preferred provider) as specified in its advertise filter. To configure conditional advertisement, select the **Conditional Adv** tab and then click **Add**. The following describes how to configure the values in the fields. |
| **Policy** | Specify the policy name for this conditional advertisement rule. |
| **Enable** | Select the check box to enable BGP conditional advertisement. |
| **Used By** | Click **Add** and select the peer groups that will use this conditional advertisement policy. |
| **Non Exist Filters Subtab** | Use this tab to specify the prefix(es) of the preferred route. This specifies the route that you want to advertise, if it is available in the local BGP routing table. If a prefix is going to be advertised and matches a Non Exist filter, the advertisement will be suppressed.<br>Click **Add** to create a non-exist filter.<br>• **Non Exist Filters**—Specify a name to identify this filter.<br>• **Enable**—Select to activate the filter.<br>• **AS-Path Regular Expression**—Specify a regular expression for filtering of AS paths.<br>• **Community Regular Expression**—Specify a regular expression for filtering of community strings.<br>• **Extended Community Regular Expression**—Specify a regular expression for filtering of extended community strings.<br>• **MED**—Specify a MED value for route filtering.<br>• **Address Prefix**—Click **Add** and then specify the exact NLRI prefix for the preferred route.<br>• **Next Hop**—Specify next hop routers or subnets for route filtering.<br>• **From Peer**—Specify peer routers for route filtering. |

**Table 69. Virtual Router Settings - BGP Tab (Continued)**

| Field | Description |
|---|---|
| **Advertise Filters Subtab** | Use this tab to specify the prefix(es) of the route in the Local-RIB routing table that should be advertised in the event that the route in the non-exist filter is not available in the local routing table.<br>If a prefix is going to be advertised and does not match a Non Exist filter, the advertisement will occur.<br>Click **Add** to create an advertise filter.<br>• **Advertise Filters**—Specify a name to identify this filter.<br>• **Enable**—Select to activate the filter.<br>• **AS-Path Regular Expression**—Specify a regular expression for filtering of AS paths.<br>• **Community Regular Expression**—Specify a regular expression for filtering of community strings.<br>• **Extended Community Regular Expression**—Specify a regular expression for filtering of extended community strings.<br>• **MED**—Specify a MED value for route filtering.<br>• **Address Prefix**—Click **Add** and then specify the exact NLRI prefix for the route to be advertised if the preferred route is not available.<br>• **Next Hop**—Specify next hop routers or subnets for route filtering.<br>• **From Peer**—Specify peer routers for route filtering. |
| **Aggregate Tab** | |
| Aggregate Filters | To add a new rule, click **Add** to display the settings. Configure the settings in the **Suppress Filters**, **Advertise Filters**, and **Aggregate Route Attributes** subtabs, and click **Done** to add the rule to the Addresses list. The parameters are described above in this table for the **Import Rules** and **Export Rules** tabs.<br>Click the icon to delete a rule. |
| **Redist Rules Tab** | |
| Name | Select the name of a redistribution profile. The value must be an IP subnet or valid redistribution profile name. |
| Allow Redistribute Default Route | Select the check box to permit the firewall to redistribute its default route to BGP peers. |
| Redist Rules | To add a new rule, click **Add**, configure the settings, and click **Done**. The parameters are described above in this table for the **Import Rules** and **Export Rules** tabs.<br>Click the icon to delete a rule. |

### Multicast Tab

Specify settings for multicast routing in the following table.

**Table 70. Virtual Router Settings - Multicast Tab**

| Field | Description |
|---|---|
| Enable | Select the check box to enable multicast routing. |
| **Rendezvous Point Subtab** | |
| RP Type | Choose the type of Rendezvous Point (RP) that will run on this virtual router. A static RP must be explicitly configured on other PIM routers whereas a candidate RP is elected automatically.<br>• **None**—Choose if there is no RP running on this virtual router.<br>• **Static**—Specify a static IP address for the RP and choose options for **RP Interface** and **RP Address** from the drop-down lists. Select the **Override learned RP for the same group** check box if you want to use the specified RP instead of the RP elected for this group.<br>• **Candidate**—Specify the following information for the candidate RP running on this virtual router:<br>– **RP Interface**—Select an interface for the RP. Valid interface types include loopback, L3, VLAN, aggregate Ethernet, and tunnel.<br>– **RP Address**—Select an IP address for the RP.<br>– **Priority**—Specify a priority for candidate RP messages (default 192).<br>– **Advertisement interval**—Specify an interval between advertisements for candidate RP messages.<br>• **Group list**—If you choose **Static** or **Candidate**, click **Add** to specify a list of groups for which this candidate RP is proposing to be the RP. |
| Remote Rendezvous Point | Click **Add** and specify the following:<br>• **IP address**—Specify the IP address for the RP.<br>• **Override learned RP for the same group**—Select the check box to use the specified RP instead of the RP elected for this group.<br>• **Group**—Specify a list of groups for which the specified address will act as the RP. |
| **Interfaces Subtab** | |
| Name | Enter a name to identify an interface group. |
| Description | Enter an optional description. |
| Interface | Click **Add** to specify one or more firewall interfaces. |
| Group Permissions | Specify general rules for multicast traffic:<br>• **Any Source**—Click **Add** to specify a list of multicast groups for which PIM-SM traffic is permitted.<br>• **Source-Specific**—Click **Add** to specify a list of multicast group and multicast source pairs for which PIM-SSM traffic is permitted. |

**Table 70. Virtual Router Settings - Multicast Tab (Continued)**

| Field | Description |
|---|---|
| IGMP | Specify rules for IGMP traffic. IGMP must be enabled for host facing interfaces (IGMP router) or for IGMP proxy host interfaces.<br>• **Enable**—Select the check box to enable the IGMP configuration.<br>• **IGMP Version**—Choose version 1, 2, or 3 to run on the interface.<br>• **Enforce Router-Alert IP Option**—Select the check box to require the router-alert IP option when speaking IGMPv2 or IGMPv3. This option must be disabled for compatibility with IGMPv1.<br>• **Robustness**—Choose an integer value to account for packet loss on a network (range 1-7, default 2). If packet loss is common, choose a higher value.<br>• **Max Sources**—Specify the maximum number of source-specific memberships allowed on this interface (0 = unlimited).<br>• **Max Groups**—Specify the maximum number of groups allowed on this interface.<br>• **Query Configuration**—Specify the following:<br>– **Query interval**—Specify the interval at which general queries are sent to all hosts.<br>– **Max Query Response Time**—Specify the maximum time between a general query and a response from a host.<br>– **Last Member Query Interval**—Specify the interval between group or source-specific query messages (including those sent in response to leave-group messages).<br>– **Immediate Leave**—Select the check box to leave the group immediately when a leave message is received. |
| PIM configuration | Specify the following Protocol Independent Multicast (PIM) settings:<br>• **Enable**—Select the check box to allow this interface to receive and/or forward PIM messages<br>• **Assert Interval**—Specify the interval between PIM assert messages.<br>• **Hello Interval**—Specify the interval between PIM hello messages.<br>• **Join Prune Interval**—Specify the interval between PIM join and prune messages (seconds). Default is 60.<br>• **DR Priority**—Specify the designated router priority for this interface<br>• **BSR Border**—Select the check box to use the interface as the bootstrap border.<br>• **PIM Neighbors**—Click **Add** to specify the list of neighbors that will communicate with using PIM. |
| **SPT Threshold Subtab** | |
| Name | The Shortest Path Tree (SPT) threshold defines the throughput rate (in kbps) at which multicast routing will switch from shared tree distribution (sourced from the rendezvous point) to source tree distribution.<br>Click **Add** to specify the following SPT settings:<br>• **Multicast Group Prefix**—Specify the multicast IP address/prefix for which the SPT will be switched to source tree distribution when the throughput reaches the desired threshold (kbps).<br>• **Threshold**—Specify the throughput at which we'll switch from shared tree distribution to source tree distribution |

**Table 70. Virtual Router Settings - Multicast Tab (Continued)**

| Field | Description |
|---|---|
| **Source Specific Address Space Subtab** | |
| Name | Defines the multicast groups for which the firewall will provide source-specific multicast (SSM) services.<br>Click **Add** to specify the following settings for source-specific addresses:<br>• **Name**—Enter a name to identify this group of settings.<br>• **Group**—Specify groups for the SSM address space.<br>• **Included**—Select this check box to include the specified groups in the SSM address space. |

### Displaying Runtime Statistics for Virtual Routers

▶ *Network > Virtual Routers*

Detailed runtime statistics are available for the virtual router and dynamic routing protocols from the **Virtual Routers** page. In the **Runtime Stats** column, click the **More Runtime Stats** link to open a new window that contains the routing table as well as routing protocol-specific details. For an overview of virtual routers, refer to "Virtual Routers and Routing Protocols" on page 153.

# DHCP Server and Relay

▶ *Network > DHCP*

The firewall supports the selection of DHCP servers or DHCP relay for IP address assignment on the Layer 3 and VLAN interfaces. Multiple DHCP servers are supported. Client requests can be forwarded to all servers, with the first server response sent back to the client.

The DHCP assignment also works across an IPSec VPN, allowing clients to receive an IP address assignment from a DHCP server on the remote end of an IPSec tunnel. For information on IPSec VPN tunnels, refer to "Configuring IPSec Tunnels" on page 309.

The settings depend on whether you select **DHCP Server** or **DHCP Relay** as the type.

**Table 71. DHCP Settings**

| Field | Description |
|---|---|
| **DHCP Server Tab** | |
| Interface | Select the firewall interface. |
| Mode | Choose whether the settings on this page are enabled, disabled, or are determined automatically. |
| Ping IP when allocating new IP | Select the check box to send a ping message when allocating a new IP address. |

**Table 71. DHCP Settings (Continued)**

| Field | Description |
|---|---|
| Lease | Select **Unlimited**, or select **Timeout** and enter any limitations on the DHCP lease interval. You can enter days, hours, or minutes. For example, if you enter only hours, then the lease is restricted to that number of hours. |
| Inheritance Source | Select a source to propagate various server settings from a DHCP client interface or PPPoE client interface into the DHCP server. Once an inheritance source is specified, select the desired fields in the DHCP server configuration and set to **inherited** to inherit the values from the DHCP server. For example, you can inherit DNS, WINS, NIS, NTP. |
| Primary DNS<br>Secondary DNS | Enter the IP address of the preferred and alternate Domain Name System (DNS) servers. The alternate server address is optional. |
| Primary WINS<br>Secondary WINS | Enter the IP address of the preferred and alternate Windows Internet Naming Service (WINS) servers. The alternate server address is optional. |
| Primary NIS<br>Secondary NIS | Enter the IP address of the preferred and alternate Network Information Service (NIS) servers. The alternate server address is optional. |
| Primary NTP<br>Secondary NTP | Enter the IP address of the preferred and alternate Network Time Protocol server. The alternate server address is optional. |
| Gateway | Enter the IP address of the network gateway that is used to reach the DHCP servers. |
| POP3 Server | Enter the IP address of the Post Office Protocol (POP3) server. |
| SMTP Server | Enter the IP address of the Simple Mail Transfer Protocol (SMTP) server. |
| DNS Suffix | Enter a suffix for the client to use locally when an unqualified hostname is entered that it cannot resolve. |
| IP Pools | Specify the range of IP addresses to which this DHCP configuration applies and click **Add**. You can enter an IP subnet and subnet mask (for example, 192.168.1.0/24) or a range of IP addresses (for example, 192.168.1.10-192.168.1.20). Add multiple entries to specify multiple IP address pools.<br>To edit an existing entry, click **Edit**, make the changes, and click **Done**. To delete an entry, click **Delete**.<br>***Note:*** *If you leave this area blank, there will be no restrictions on the IP ranges.* |
| Reserved Address | Specify the IP address (format *x.x.x.x*) or MAC address (format *xx:xx:xx:xx:xx:xx*) of any devices that you do not want to subject to DHCP address assignment.<br>To edit an existing entry, click **Edit**, make the changes, and click **Done**. To delete an entry, click **Delete**.<br>***Note:*** *If you leave this area blank, then there will be no reserved IP addresses.* |
| **DHCP Relay Tab** | |
| Interface | Select the firewall interface. |
| IPv4 | Select the **IPv4** check box to use IPv4 addresses for DHCP relay and specify IPv4 addresses for up to four DHCP servers. |
| IPv6 | Select the **IPv6** check box to use IPv6 addresses for DHCP relay and specify IPv6 addresses for up to four DHCP servers. Specify an outgoing interface if you are using an IPv6 multicast address for your server. |

# DNS Proxy

▶ *Network > DNS Proxy*

For all DNS queries that are directed to an interface IP address, the firewall supports the selective directing of queries to different DNS servers based on full or partial domain names. TCP or UDP DNS queries are sent through the configured interface. UDP queries switch over to TCP when a DNS query answer is too long for a single UDP packet.

If the domain name is not found in the DNS proxy cache, the domain name is searched for a match based on configuration of the entries in the specific DNS proxy object (on the interface on which the DNS query arrived) and forwarded to a name server based on the match results. If no match is found, the default name servers are used. Static entries and caching are also supported.

**Table 72. DNS Proxy Settings**

| Field | Description |
|---|---|
| Name | Specify a name to identify the DNS proxy (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Enable | Select the check box to enable DNS proxy. |
| Inheritance Source | Select a source to inherit default DNS server settings. This is commonly used in branch office deployments where the firewall's WAN interface is addressed by DHCP or PPPoE. |
| Primary<br>Secondary | Specify the IP addresses of the default primary and secondary DNS servers. If the primary DNS server cannot be found, the secondary will be used. |
| Check inheritance source | Click the link to see the server settings that are currently assigned to the DHCP client and PPPoE client interfaces. These may include DNS, WINS, NTP, POP3, SMTP, or DNS suffix. |
| Interface | Select the **Interface** check box to specify the firewall interfaces to support the DNS proxy rules. Select an interface from the drop-down list and click **Add**. You can add multiple interfaces. To delete an interface, select the interface and click **Delete**. |
| DNS Proxy Rules | Identify DNS proxy server rules. Click **Add** and specify the following information:<br>• **Name**—A name is required so that a static entry can be reference and modified via the CLI.<br>• **Turn on caching of domains resolved by this mapping**—Select the check box to enable caching of domains that are resolved by this mapping.<br>• **Domain Name**—Click **Add** and enter the proxy server domain name. Repeat to add additional names. To delete a name, select the name and click **Delete**. For a DNS proxy rule, the number of tokens in a wildcard string must match the number of tokens in the requested domain. For example, "*.engineering.local" will not match "engineering.local". Both must be specified.<br>• **Primary/Secondary**—Enter the hostname or IP addresses of the primary and secondary DNS servers. |

**Table 72. DNS Proxy Settings (Continued)**

| Field | Description |
|---|---|
| Static Entries | Provide static FQDN to IP address mappings that will be delivered in response to DNS queries made by hosts. Click Add and specify the following information:<br>• **Name**—Enter a name for the Static Entry.<br>• **FQDN**—Enter the Fully Qualified Domain Name (FQDN) that will be mapped to the static IP addresses defined in the Address field.<br>• **Address**—Click Add and enter the IP addresses that map to this domain.<br>Repeat to add additional addresses. To delete an address, select the address and click Delete. |
| Advanced | Specify the following information:<br>• **Cache**—Select the check box to enable DNS caching and specify the following information:<br>– **Size**—Specify the number of entries that the cache will hold (range 1024-10240, default 1024).<br>– **Timeout**—Specify the length of time (hours) after which all cached entries are removed. DNS time-to-live values are used to remove cache entries when they have been stored for less than the configured timeout period. Following a timeout, new requests must be resolved and cached again (range 4 to 24, default 4 hours).<br>• **TCP Queries**—Select the check box to enable DNS queries using TCP and specify the following information:<br>– **Max Pending Requests**—Specify the upper limit on the number of concurrent pending TCP DNS requests that the firewall will support (range 64-256, default 64).<br>• **UDP Queries Retries**—Specify settings for UDP query retries:<br>– **Interval**—Specify the time in seconds after which another request is sent if no response has been received (range 1-30, default 2 seconds).<br>– **Attempts**—Specify the maximum number of attempts (excluding the first attempt) after which the next DNS server is tried (range 1-30, default 5). |

# Network Profiles

Network profiles capture configuration information that the firewall can use to establish network connections and implement policies. The following types of network profiles are supported:

- **IKE gateways**, **IPSec crypto profiles**, and **IKE crypto profiles**—These profiles support configuration and operation of IPSec VPNs. For information on the following profile types, refer to "Configuring IPSec Tunnels" on page 309.
  - IKE gateways include the configuration information that is necessary to perform IKE protocol negotiation with peer gateways when setting up IPSec VPN tunnels.
  - IKE crypto profiles specify the protocols and algorithms for Phase 1 identification, authentication, and encryption in VPN tunnels.
  - IPSec crypto profiles specify the protocols and algorithms for Phase 2 identification, authentication, and encryption in VPN tunnels.
- **Monitor profiles—**These profiles are used to monitor IPSec tunnels and to monitor a next-hop device for policy based forwarding (PBF) rules. In both cases, the monitor profile is used to specify an action to take when a resource (IPSec tunnel or next-hop device) becomes unavailable. Refer to "Monitor Settings" on page 177.
- **Interface management profiles**—These profiles specify the protocols that can be used to manage the firewall for Layer 3 interfaces, including VLAN and loopback interfaces. Refer to "Defining Interface Management Profiles" on page 175.
- **Zone protection profiles**—These profiles determine how the firewall responds to attacks from individual security zones. Refer to "Defining Zone Protection Profiles" on page 178. The following types of protection are supported:
  - **Flood Protection**—Protects against SYN, ICMP, UDP, and other IP-based flooding attacks.
  - **Reconnaissance detection**—Allows you to detect and block commonly used port scans and IP address sweeps that attackers run to find potential attack targets.
  - **Packet-based attack protection**—Protects against large ICMP packets and ICMP fragment attacks as well as a number of IP and TCP level attacks. Per-zone non-syn-tcp behavior can also be specified.
  - **QoS profiles**—These profiles determine how the QoS traffic classes are treated. You can set overall limits on bandwidth regardless of class and also set limits for individual classes. You can also assign priorities to different classes. Priorities determine how traffic is treated in the presence of contention. Refer to "Defining QoS Profiles" on page 358.

## Defining Interface Management Profiles

▶ ***Network > Network Profiles > Interface Mgmt***

Use this page to specify the protocols that are used to manage the firewall. To assign management profiles to each interface, refer to "Configuring Layer 3 Interfaces" on page 130 and "Configuring Layer 3 Subinterfaces" on page 134. For an overview of firewall interfaces, refer to "Firewall Interfaces" on page 127.

***Note:*** *Although the default port used for HTTPS access is 443, if you enable HTTPS access on an in-band port and Global Protect is enabled on the same port, the port used for HTTPS access is automatically set to 4443 instead of 443.*

**Table 73. Interface Management Profile Settings**

| Field | Description |
|---|---|
| Name | Enter a profile name (up to 31 characters). This name appears in the list of interface management profiles when configuring interfaces. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Ping<br>Telnet<br>SSH<br>HTTP<br>HTTPS<br>SNMP<br>Response Pages<br>User-ID Service | Select the check box for each service to be enabled on the interfaces where the profile is applied.<br>The **Response Pages** check box controls whether the ports used to serve captive portal and URL filtering response pages are open on Layer 3 interfaces. Ports 6080 and 6081 are left open if this setting is enabled.<br>The **User-ID Service** option is needed to allow communication between firewalls when a firewall is acting as a redistribution point to provide user mapping information to other PAN-OS firewalls. Refer to "User-ID Agent" on page 283. |
| Permitted IP Addresses | Enter the list of IPv4 or IPv6 addresses from which firewall management is allowed. |

## Defining Monitor Profiles

▶ *Network > Network Profiles > Monitor*

A monitor profile is used to monitor IPSec tunnels and to monitor a next-hop device for policy-based forwarding (PBF) rules. In both cases, the monitor profile is used to specify an action to take when a resource (IPSec tunnel or next-hop device) becomes unavailable. Monitor profiles are optional, but can be very useful for maintaining connectivity between sites and to ensure that PBF rules are maintained.

After creating a monitor profile, you can apply it to an IPSec Tunnel profile from the **General** tab, then selecting the **Show Advanced Options** check box, click the **Tunnel Monitor** check box and then select the desired profile from the drop-down list. In a PBF rule, click the **Forwarding** tab, click the **Monitor** check box and then select the desired profile from the drop down list.

In the example of an IPSec tunnel, the firewall monitors the specified IP address through the tunnel to determine if the tunnel is working properly according to the defined monitor profile. If the tunnel monitor IP address is not reachable, the action will be taken based on the settings you choose that are defined in "Monitor Settings" on page 177.

For a monitor profiles used in PBF rule, a remote IP address is monitored. If the remote IP address becomes unavailable, one of the following actions is taken.

- If the action is "wait-recover," packets continue to be sent according to the PBF rule.
- If the action is "fail-over," the firewall uses routing table lookup to determine routing for the duration of this session.

**Table 74. Monitor Settings**

| Field | Description |
|---|---|
| Name | Enter a name to identify the monitor profile (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Action | Specify an action to take if the tunnel is not available. If the threshold number of heartbeats is lost, the firewall takes the specified action.<br>• **wait-recover**—Wait for the tunnel to recover; do not take additional action. Packets will continue to be sent according to the PBF rule.<br>• **fail-over**—Traffic will fail over to a backup path, if one is available. The firewall uses routing table lookup to determine routing for the duration of this session.<br>In both cases, the firewall tries to negotiate new IPSec keys to accelerate the recovery. |
| Interval | Specify the time between heartbeats (range 2-10, default 3). |
| Threshold | Specify the number of heartbeats to be lost before the firewall takes the specified action (range 2-100, default 5). |

## Defining Zone Protection Profiles

▶ *Network > Network Profiles > Zone Protection*

Use this page to determine how the firewall responds to attacks from specified security zones. The same profile can be assigned to multiple zones. For an overview of security zones, refer to "Security Zones" on page 151. Flood protection applies to those packets that do not belong to an existing session.

***Note:*** *When defining packets per second (pps) thresholds limits for zone protection profiles, the threshold is based on the packets per second that do not match a previously established session.*

**Table 75. Zone Protection Profile Settings**

| Field | Description |
|---|---|
| Name | Enter a profile name (up to 31 characters). This name appears in the list of zone protection profiles when configuring zones. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, and underscores. |
| Description | Enter an optional description for the zone protection profile. |
| **Flood Protection Thresholds - SYN Flood** | |
| Action | Select the action to take in response to a SYN flood attack.<br>• **Random Early Drop**—Causes SYN packets to be dropped to mitigate a flood attack:<br>– When the flow exceeds the **Alert** rate threshold, an alarm is generated.<br>– When the flow exceeds the **Activate** rate threshold, individual SYN packets are dropped randomly to restrict the flow.<br>– When the flow exceeds the **Maximal** rate threshold, all packets are dropped.<br>• **SYN Cookies**—Computes a sequence number for SYN-ACK packets that does not require pending connections to be stored in memory. This is the preferred method. |
| Alert (packets/sec) | Enter the number of SYN packets received by the zone (in a second) that triggers an attack alarm. Alarms can be viewed on the Dashboard (refer to "Using the Dashboard" on page 252) and in the threat log (refer to "Identifying Unknown Applications and Taking Action" on page 276). |
| Activate (packets/sec) | Enter the number of SYN packets received by the zone (in a second) that triggers the action specified. |
| Maximum (packets/sec) | Enter the maximum number of SYN packets able to be received per second. Any number of packets exceeding the maximum will be dropped. |
| **Flood Protection Thresholds - ICMP Flood** | |
| Alert (packets/sec) | Enter the number of ICMP echo requests (pings) received per second that triggers an attack alarm. |
| Activate (packets/sec) | Enter the number of ICMP packets received by the zone (in a second) that causes subsequent ICMP packets to be dropped. |

**Table 75. Zone Protection Profile Settings (Continued)**

| Field | Description |
|---|---|
| Maximum (packets/sec) | Enter the maximum number of ICMP packets able to be received per second. Any number of packets exceeding the maximum will be dropped. |
| **Flood Protection Thresholds - ICMPv6** | |
| Alert (packets/sec) | Enter the number of ICMPv6 echo requests (pings) received per second that triggers an attack alarm. |
| Activate (packets/sec) | Enter the number of ICMPv6 packets received per second for the zone that causes subsequent ICMPv6 packets to be dropped. Metering stops when the number of ICMPv6 packets drops below the threshold |
| Maximum (packets/sec) | Enter the maximum number of ICMPv6 packets able to be received per second. Any number of packets exceeding the maximum will be dropped. |
| **Flood Protection Thresholds - UDP** | |
| Alert (packets/sec) | Enter the number of UDP packets received by the zone (in a second) that triggers an attack alarm. |
| Alert (packets/sec) | Enter the number of UDP packets received by the zone (in a second) that triggers random dropping of UDP packets. The response is disabled when the number of UDP packets drops below the threshold. |
| Maximum (packets/sec) | Enter the maximum number of UDP packets able to be received per second. Any number of packets exceeding the maximum will be dropped. |
| **Flood Protection Thresholds -Other IP** | |
| Alert (packets/sec) | Enter the number of IP packets received by the zone (in a second) that triggers an attack alarm. |
| Activate (packets/sec) | Enter the number of IP packets received by the zone (in a second) that triggers random dropping of IP packets. The response is disabled when the number of IP packets drops below the threshold. Any number of packets exceeding the maximum will be dropped. |
| Maximum (packets/sec) | Enter the maximum number of IP packets able to be received per second. Any number of packets exceeding the maximum will be dropped. |
| **Reconnaissance Protection - TCP Port Scan, UDP Port Scan, Host Sweep** | |
| Interval (sec) | Enter the time interval for port scans and host sweep detection (seconds). |
| Threshold (events) | Enter the number of scanned ports within the specified time interval that will trigger this protection type (events). |
| Action | Enter the action that the system will take in response to this event type:<br>• **Allow**—Permits the port scan of host sweep reconnaissance.<br>• **Alert**—Generates an alert for each scan or sweep that matches the threshold within the specified time interval.<br>• **Block**—Drops all further packets from the source to the destination for the remainder of the specified time interval.<br>• **Block IP**—Drops all further packets for a specified period of time. Choose whether to block source, destination, or source-and-destination traffic and enter a duration (seconds). |

**Table 75. Zone Protection Profile Settings (Continued)**

| Field | Description |
|---|---|
| **IPv6 Drop Packets with** | |
| Type 0 Router Header | Select the check box to drop IPv6 packets that include a Type 0 router header. |
| IPv4 Compatible Address | Select the check box to drop IPv6 packets that include an IPv4-compatible address. |
| Multicast Source Address | Select the check box to drop IPv6 packets that include a multicast source address. |
| Anycast Source Address | Select the check box to drop IPv6 packets that include an anycast source address. |
| **Packet-Based Attack Protection** | |
| **TCP/IP Drop sub tab** | |
| Spoofed IP address | Select the check box to enable protection against IP address spoofing. |
| Fragmented traffic | Discards fragmented IP packets. |
| Mismatched overlapping TCP segment | This setting will cause the firewall to report an overlap mismatch and drop the packet when segment data does not match in these scenarios:<br>• The segment is within another segment.<br>• The segment overlaps with part of another segment.<br>• The segment covers another segment.<br>This protection mechanism uses sequence numbers to determine where packets reside within the TCP data stream. |
| Remove TCP Timestamp | Determines whether the packet has a TCP timestamp in the header and, if it does, strips the timestamp from the header. |
| Reject Non-SYN TCP | Determines whether to reject the packet, if the first packet for the TCP session setup is not a SYN packet:<br>• **global**—Use system-wide setting that is assigned through the CLI.<br>• **yes**—Reject non-SYN TCP.<br>• **no**—Accept non-SYN TCP. Note that allowing non-SYN TCP traffic may prevent file blocking policies from working as expected in cases where the client and/or server connection is not set after the block occurs. |
| Asymmetric Path | Determine whether to drop or bypass packets that contain out of sync ACKs or out of window sequence numbers:<br>• **global**—Use system wide setting that is assigned through the CLI.<br>• **drop**—Drop packets that contain an asymmetric path.<br>• **bypass**—Bypass scanning on packets that contain an asymmetric path. |
| **IP Option Drop** | |
| Strict Source Routing | Discard packets with the Strict Source Routing IP option set. |
| Loose Source Routing | Discard packets with the Loose Source Routing IP option set. |
| Timestamp | Discard packets with the Timestamp IP option set. |
| Record Route | Discard packets with the Record Route IP option set. |
| Security | Discard packets if the security option is defined. |

**Table 75. Zone Protection Profile Settings (Continued)**

| Field | Description |
|---|---|
| Stream ID | Discard packets if the Stream ID option is defined. |
| Unknown | Discard packets if the class and number are unknown. |
| Malformed | Discard packets if they have incorrect combinations of class, number, and length based on RFC 791, 1108, 1393, and 2113. |
| **ICMP Drop sub tab** | |
| ICMP ping ID 0 | Discards packets if the ICMP ping packet has an identifier value of 0. |
| ICMP fragment | Discards packets that consist of ICMP fragments. |
| ICMP large packet (>1024) | Discards ICMP packets that are larger than 1024 bytes. |
| Suppress ICMP TTL expired error | Stop sending ICMP TTL expired messages. |
| Suppress ICMP Frag Needed | Stop sending ICMP fragmentation needed messages in response to packets that exceed the interface MTU and have the do not fragment (DF) bit set. This setting will interfere with the PMTUD process performed by hosts behind the firewall. |
| **IPv6 Drop sub tab** | |
| Type 0 Routing Header | Discard packets with Type 0 Routing header. |
| IPv4 compatible address | Discard packets with IPv4 compatible addresses. |
| Anycast source address | Discard packets with an anycast source address. |
| Needless fragment header | Discard packets with the needless fragment header. |
| MTU in ICMPv6 'Packet Too Big' less than 1280 bytes | Discard packets with MTU in ICMPv6 'Packet Too Big' less than 1280 bytes. |
| Hop-by-Hop extension | Discard packets with the extension header hop-by-hop. |
| Routing extension | Discard packets with the routing extension header. |
| Destination extension | Discard packets with destination extension header. |
| Invalid IPv6 options in extension header | Discard packets with invalid IPv6 option in extension header. |
| Non-zero reserved field | Discard packets if the reserved field has a non-zero value. |
| **ICMPv6 sub tab** | |
| ICMPv6 destination unreachable - require explicit security rule match | Require an explicit security policy match for destination unreachable ICMPv6 errors even when associated with an existing session. |
| ICMPv6 packet too big - require explicit security rule match | Require an explicit security policy match for packet too big ICMPv6 errors even when associated with an existing session. |
| ICMPv6 time exceeded - require explicit security rule match | Require an explicit security policy match for time exceeded ICMPv6 errors even when associated with an existing session. |

**Table 75. Zone Protection Profile Settings (Continued)**

| Field | Description |
|---|---|
| ICMPv6 parameter problem - require explicit security rule match | Require an explicit security policy match for parameter problem ICMPv6 errors even when associated with an existing session. |
| ICMPv6 redirect - require explicit security rule match | Require an explicit security policy match for redirect ICMPv6 messages even when associated with an existing session. |

Chapter 5

# Policies and Security Profiles

This chapter describes how to configure policies and security profiles:

- "Policies" in the next section
- "Security Profiles" on page 211
- "Other Policy Objects" on page 226

## Policies

Policies allow you to control firewall operation by enforcing rules and automatically taking action. The following types of policies are supported:

- Basic security policies to block or allow a network session based on the application, the source and destination zones and addresses, and optionally the service (port and protocol). Zones identify the physical or logical interfaces that send or receive the traffic. Refer to "Security Policies" on page 187.
- Network Address Translation (NAT) policies to translate addresses and ports, as needed. Refer to "NAT Policies" on page 190.
- Policy-based forwarding policies to determine the egress interface used following processing. Refer to "Policy-Based Forwarding Policies" on page 199.
- Decryption policies to specify traffic decryption for security policies. Each policy can specify the categories of URLs for the traffic you want to decrypt. SSH decryption is used to identify and control SSH tunneling in addition to SSH shell access. Refer to "Decryption Policies" on page 202.
- Override policies to override the application definitions provided by the firewall. Refer to "Application Override Policies" on page 205.
- Quality of Service (QoS) policies to determine how traffic is classified for treatment when it passes through an interface with QoS enabled. Refer to "Defining QoS Policies" on page 359.

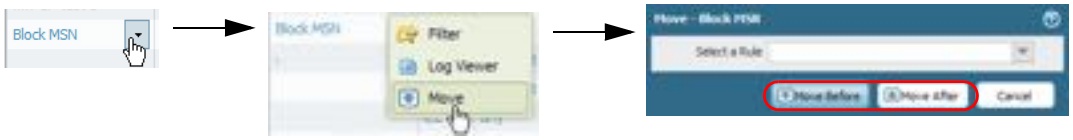
- Captive portal policies to request authentication of unidentified users. Refer to "Captive Portal Policies" on page 206.
- Denial of service (DoS) policies to protect against DoS attacks and take protective action in response to rule matches. Refer to "DoS Protection Policies" on page 209.

***Note:*** *Shared polices pushed from Panorama are shown in green on the firewall web interface pages and cannot be edited at the device level.*

## Guidelines on Defining Policies

For general guidelines on interacting with the firewall interface, refer to "Using the Firewall Web Interface" on page 23. The following specific guidelines apply when interacting with the pages on the **Policies** tab:

- To apply a filter to the list, select from the **Filter Rules** drop-down list. To add a value to define a filter, click the down-facing arrow for the item and choose **Filter**.
- To view application groups, filters, or container information when creating or viewing Security, PBF, or QoS policies, hold your mouse over the object in the **Application** column, click the down arrow and select **Value**. This allows you to easily view application members directly from the policy without having to navigate to the Object tabs.
- To add a new policy rule, do one of the following:
  - Click **Add** at the bottom of the page.
  - Select a rule on which to base the new rule and click **Clone Rule**, or select a rule by clicking the white space of the rule, and select **Clone Rule** at the bottom of the page (a selected rule has a yellow background). The copied rule, "rule*n*" is inserted below the selected rule, where *n* is the next available integer that makes the rule name unique.
- The order in which rules are listed is the order in which the rules are compared against network traffic. Change the ordering of a rule in either of the following ways:
  - Select the rule and click **Move Up**, **Move Down**, **Move Top**, or **Move Bottom.**
  - Click the down-facing arrow for the rule name and choose **Move**. In the pop-up window, choose a rule and choose whether to move the rule you selected for reordering before or after this rule.

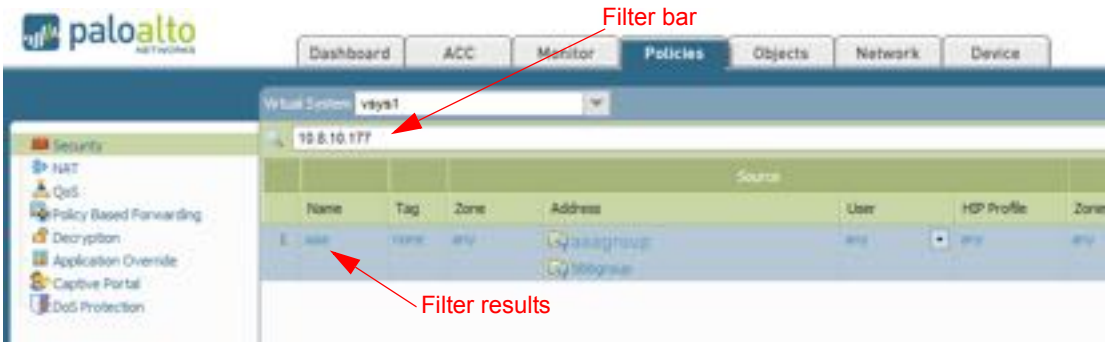


- To enable a rule, select the rule and click **Enable**.

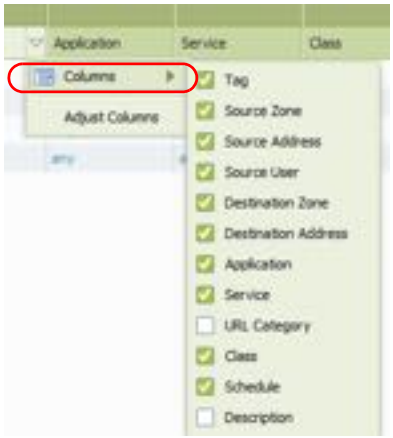
- To show which rules are not currently used, select the **Highlight Unused Rules** check box.

- To display the log for the policy, click the down-facing arrow for the rule name and choose **Log Viewer**.
- For some entries, you can display the current value by clicking the down-facing arrow for the entry and choosing **Value**. You can also edit, filter, or remove certain items directly from the column menu.

- If you have a large number of policies defined, you can use the filter bar to find objects that are used within a policy based on the object name or IP address. The search will also traverse embedded objects to find an address within an address object or address group. In the following screen shot, the IP address 10.8.10.177 was entered in the filter bar and the policy "aaa" is shown. That policy uses an address group object named "aaagroup", which contains the IP address.



- You can show or hide specific columns from view in any of the **Policies** pages.



## Specifying Users and Applications for Policies

▶ *Policies > Security*

▶ *Policies > Decryption*

You can restrict security policies to selected users or applications by clicking the **User** or **Application** link on the **Security** or **Decryption** device rules page. For information on restricting rules by application, refer to "Defining Applications" on page 233.

To restrict a policy to selected users, follow these steps:

1. On the **Security** or **Decryption** device rules page, click the underlined link for the source or destination user to open the selection window.

***Note:*** *If you are using a RADIUS server and not the User-ID Agent, the list of users is not displayed, and you must enter user information manually.*

2. Choose the type of rule to apply:
   - **any**—Includes any user in the rule.
   - **pre-logon**—Include remote users that are connected to the network using GlobalProtect, but are not logged into their system. When the Pre-logon option is configured on the Portal for GlobalProtect clients, any user who is not currently logged into their machine will be identified with the username **pre-logon**. You can then create policies for pre-logon users and the machines can be accessed as if they were logged in and connected to the domain.
   - **known-user**—Includes all authenticated users.
   - **unknown**—Includes all unauthenticated users.
   - **Select**—Includes selected users as determined by the selection in this window.
3. To add groups of users, select from the **Available User Groups** check boxes and click **Add User Group**. Alternatively, you can enter text to match one or more groups and click **Add User Group**.

4. To add individual users, enter a search string in the **User** search field and click **Find**. You can then select users and click **Add User**. Alternatively, you can enter individual user names in the **Additional Users** area.
5. Click **OK** to save the selections and update the security or decryption rule.

# Security Policies

Security policies determine whether to block or allow a new network session based on traffic attributes such as the application, source and destination security zones, the source and destination addresses, and the application service (such as HTTP). Security zones are used to group interfaces according to the relative risk of the traffic they carry. For example, an interface connected to the Internet is in an "untrusted" zone, while an interface connected to the internal network is in a "trusted" zone.

***Note:*** *By default, traffic between each pair of security zones is blocked until at least one rule is added to allow traffic between the two zones.*

*Intra-zone traffic is allowed by default and requires an explicit block rule. If a deny all rule is added as the last rule in the policy, intra-zone traffic will be blocked unless otherwise allowed.*

Security policies can be as general or specific as needed. The policy rules are compared against the incoming traffic in sequence, and because the first rule that matches the traffic is applied, the more specific rules must precede the more general ones. For example, a rule for a single application must precede a rule for all applications if all other traffic-related settings are the same.

## Defining Security Policies

▶ *Policies > Security*

Use the **Security** page to define security policy rules. For configuration guidelines, refer to "Guidelines on Defining Policies" on page 184.

**Table 76. Security Policy Settings**

| Field | Description |
|---|---|
| **General Tab** | |
| Name | Enter a name to identify the rule (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. Only the name is required. |
| Description | Enter a description for the policy (up to 255 characters). |
| Tag | If you need to tag the policy, click **Add** to specify the tag.<br>A policy tag is a keyword or phrase that allows you to sort or filter policies. This is useful when you have defined many policies and want to view those that are tagged with a particular keyword. For example, you may want to tag certain security policies with Inbound to DMZ, decryption policies with the words Decrypt and No-decrypt, or use the name of a specific data center for policies associated with that location. |

**Table 76. Security Policy Settings (Continued)**

| Field | Description |
|---|---|
| **Source Tab** | |
| Source Zone | Click **Add** to choose source zones (default is any). Zones must be of the same type (Layer 2, Layer 3, or virtual wire). To define new zones, refer to "Defining Security Zones" on page 151.<br>Multiple zones can be used to simplify management. For example, if you have three different internal zones (Marketing, Sales, and Public Relations) that are all directed to the untrusted destination zone, you can create one rule that covers all cases. |
| Source Address | Click **Add** to add source addresses, address groups, or regions (default is any). Select from the drop-down list, or click the **Address**, **Address Group**, or **Regions** link at the bottom of the drop-down list, and specify the settings. |
| **User Tab** | |
| Source User | Click **Add** to choose the source users or groups of users subject to the policy. |
| HIP Profiles | Click **Add** to choose Host Information Profiles (HIP) to identify users. For information on HIP, refer to "Overview" on page 335. |
| **Destination Tab** | |
| Destination Zone | Click **Add** to choose destination zones (default is any). Zones must be of the same type (Layer 2, Layer 3, or virtual wire). To define new zones, refer to "Defining Security Zones" on page 151.<br>Multiple zones can be used to simplify management. For example, if you have three different internal zones (Marketing, Sales, and Public Relations) that are all directed to the untrusted destination zone, you can create one rule that covers all cases. |
| Destination Address | Click **Add** to add destination addresses, address groups, or regions (default is any). Select from the drop-down list, or click the **Address** link at the bottom of the drop-down list, and specify address settings. |
| **Application Tab** | |
| Application | Select specific applications for the security rule. To define new applications, refer to "Defining Applications" on page 233. To define application groups, refer to "Defining Application Groups" on page 238.<br>If an application has multiple functions, you can select the overall application or individual functions. If you select the overall application, all functions are included, and the application definition is automatically updated as future functions are added.<br>If you are using application groups, filters, or container in the security rule, you can view details on these objects by holding your mouse over the object in the **Application** column, click the down arrow and select **Value**. This allows you to easily view application members directly from the policy without having to navigate to the Object tabs. |

**Table 76. Security Policy Settings (Continued)**

| Field | Description |
|---|---|
| **Service/ URL Category Tab** | |
| Service | Select services to limit to specific TCP and/or UDP port numbers. Choose one of the following from the drop-down list:<br>• **any**—The selected applications are allowed or denied on any protocol or port.<br>• **application-default**—The selected applications are allowed or denied only on their default ports defined by Palo Alto Networks. This option is recommended for allow policies because it prevents applications from running on unusual ports and protocols, which if not intentional, can be a sign of undesired application behavior and usage. Note that when you use this option, the device still checks for all applications on all ports, but with this configuration, applications are only allowed on their default ports/protocols.<br>• **Select**—Click **Add**. Choose an existing service or choose **Service** or **Service Group** to specify a new entry. Refer to "Services" on page 239 and "Service Groups" on page 240. |
| URL Category | Select URL categories for the security rule.<br>• Choose **any** to allow or deny all sessions regardless of the URL category.<br>• To specify a category, click **Add** and select a specific category (including a custom category) from the drop-down list. You can add multiple categories. Refer to "Custom URL Categories" on page 242 for information on defining custom categories. |
| **Actions Tab** | |
| Action Setting | Click **allow** or **deny** to allow or block a new network session for traffic that matches this rule. |
| Profile Setting | To specify the checking done by the default security profiles, select individual Antivirus, Anti-spyware, Vulnerability Protection, URL Filtering, File Blocking, and/or Data Filtering profiles.<br>To specify a profile group, rather than individual profiles, select **Profile Type Group** and then select a profile group from the **Group Profile** drop-down list.<br>To define new profiles or profile groups, click **New** next to the appropriate profile or group (refer to "Security Profile Groups" on page 246). |

**Table 76. Security Policy Settings (Continued)**

| Field | Description |
|---|---|
| Log Setting | Specify any combination of the following options:<br>Log Setting:<br>• To forward the local traffic log and threat log entries to remote destinations, such as Panorama and syslog servers, select a log profile from the **Log Forwarding Profile** drop-down list. Note that the generation of threat log entries is determined by the security profiles. To define new log profiles, click **New** (refer to "Log Forwarding" on page 247).<br>• To generate entries in the local traffic log for traffic that matches this rule, select the following options:<br>– **Log At Session Start**. Generates a traffic log entry for the start of a session (disabled by default).<br>– **Log At Session End**. Generates a traffic log entry for the end of a session (enabled by default).<br>If the session start or end entries are logged, drop and deny entries are also logged. |
| Other Settings | Specify any combination of the following options:<br>• **Schedule**—To limit the days and times when the rule is in effect, select a schedule from the drop-down list. To define new schedules, click **New** (refer to "Schedules" on page 250).<br>• **QoS Marking**—To change the Quality of Service (QoS) setting on packets matching the rule, select IP DSCP or IP Precedence and enter the QoS value in binary or select a predefined value from the drop-down list. For more information on QoS, refer to "Configuring Quality of Service" on page 355.<br>• **Disable Server Response Inspection—**To disable packet inspection from the server to the client, select this check box. This option may be useful under heavy server load conditions. |

# NAT Policies

If you define Layer 3 interfaces on the firewall, you can use Network Address Translation (NAT) policies to specify whether source or destination IP addresses and ports are converted between public and private addresses and ports. For example, private source addresses can be translated to public addresses on traffic sent from an internal (trusted) zone to a public (untrusted) zone.

NAT is also supported on virtual wire interfaces. When performing NAT on virtual wire interfaces, it is recommended that you translate the source address to a different subnet than the one on which the neighboring devices are communicating. Proxy ARP is not supported on virtual wires and so neighboring devices will only be able to resolve ARP requests for IP addresses that reside on the interface of the device on the other end of the virtual wire.

When configuring NAT on the firewall, it is important to note that a security policy must also be configured to allow the NAT traffic. Security policy will be matched based on the post-NAT zone and the pre-NAT IP address.

The firewall supports the following types of address translation:

- **Dynamic IP/Port**—For outbound traffic. Multiple clients can use the same public IP addresses with different source port numbers. Dynamic IP/Port NAT rules allow translation to a single IP address, a range of IP addresses, a subnet, or a combination of

these. In cases where an egress interface has a dynamically assigned IP address, it can be helpful to specify the interface itself as the translated address. By specifying the interface in the dynamic IP/port rule, NAT policy will update automatically to use any address acquired by the interface for subsequent translations.

***Note:*** *Palo Alto Networks Dynamic IP/port NAT supports more NAT sessions than are supported by the number of available IP addresses and ports. The firewall can use IP address and port combinations up to two times (simultaneously) on the PA-200, PA-500, PA-2000 Series and PA-3000 Series, four times on the PA-4020 and PA-5020, and eight times on the PA-4050, PA-4060, PA-5050, and PA-5060 devices when destination IP addresses are unique.*

- **Dynamic IP**—For outbound traffic. Private source addresses translate to the next available address in the specified address range. Dynamic IP NAT policies allow you to specify a single IP address, multiple IPs, multiple IP ranges, or multiple subnets as the translated address pool. If the source address pool is larger than the translated address pool, new IP addresses seeking translation will be blocked while the translated address pool is fully utilized. To avoid this issue, you can specify a fall back pool that will be used if the primary pool runs out of IP addresses.

- **Static IP**—For inbound or outbound traffic. You can use static IP to change the source or the destination IP address while leaving the source or destination port unchanged. When used to map a single public IP address to multiple private servers and services, destination ports can stay the same or be directed to different destination ports.

***Note:*** *You may need to define static routes on the adjacent router and/or the firewall to ensure that traffic sent to a public IP address is routed to the appropriate private address. If the public address is the same as the firewall interface (or on the same subnet), then a static route is not required on the router for that address. When you specify service (TCP or UDP) ports for NAT, the pre-defined HTTP service (service-http) includes two TCP ports: 80 and 8080. To specify a single port, such as TCP 80, you must define a new service.*

The next table summarizes the NAT types. The two dynamic methods map a range of client addresses (M) to a pool (N) of NAT addresses, where M and N are different numbers. N can also be 1. Dynamic IP/Port NAT differs from Dynamic IP NAT in that the TCP and UDP source ports are not preserved in Dynamic IP/Port, whereas they are unchanged with Dynamic IP NAT. There are also differing limits to the size of the translated IP pool, as noted below.

With Static IP NAT, there is a one-to-one mapping between each original address and its translated address. This can be expressed as 1-to-1 for a single mapped IP address, or M-to-M for a pool of many one-to-one, mapped IP addresses.

**Table 77. NAT Types**

| PAN-OS NAT Type | Source Port Stays the Same | Destination Port Can Change | Mapping Type | Size of Translated Address Pool |
|---|---|---|---|---|
| Dynamic IP/ Port | No | No | Many-to-1<br>M-to-N | Up to 254 consecutive addresses |
| Dynamic IP | Yes | No | M-to-N | Up to 32k consecutive addresses |
| Static IP | Yes | No | 1-to-1<br>M-to-M<br>MIP | Unlimited |
| | Optional | | 1-to-Many VIP PAT | |

## Determining Zone Configuration in NAT and Security Policy

NAT rules must be configured to use the zones associated with pre-NAT IP addresses configured in the policy. For example, if you are translating traffic that is incoming to an internal server (which is reached via a public IP by Internet users), it is necessary to configure the NAT policy using the zone in which the public IP address resides. In this case, the source and destination zones would be the same. As another example, when translating outgoing host traffic to a public IP address, it is necessary to configure NAT policy with a source zone corresponding to the private IP addresses of those hosts. The pre-NAT zone is required because this match occurs before the packet has been modified by NAT.

Security policy differs from NAT policy in that post-NAT zones must be used to control traffic. NAT may influence the source or destination IP addresses and can potentially modify the outgoing interface and zone. When creating security policies with specific IP addresses, it is important to note that pre-NAT IP addresses will be used in the policy match. Traffic subject to NAT must be explicitly permitted by the security policy when that traffic traverses multiple zones.

## NAT Rule Options

The firewall supports no-NAT rules and bi-directional NAT rules.

### No-NAT Rules

No-NAT rules are configured to allow exclusion of IP addresses defined within the range of NAT rules defined later in the NAT policy. To define a no-NAT policy, specify all of the match criteria and select **No Source Translation** in the source translation column.

### Bi-directional NAT Rules

The bi-directional setting in static source NAT rules implicitly creates a destination NAT rule for traffic to the same resources in the reverse direction. In this example, two NAT rules are used to create a source translation for outgoing traffic from IP 10.0.1.10 to public IP 3.3.3.1 and a destination translation for traffic destined for public IP 3.3.3.1 to private IP 10.0.1.10. This pair of rules can be simplified by configuring only the third NAT rule using the bi-directional feature.

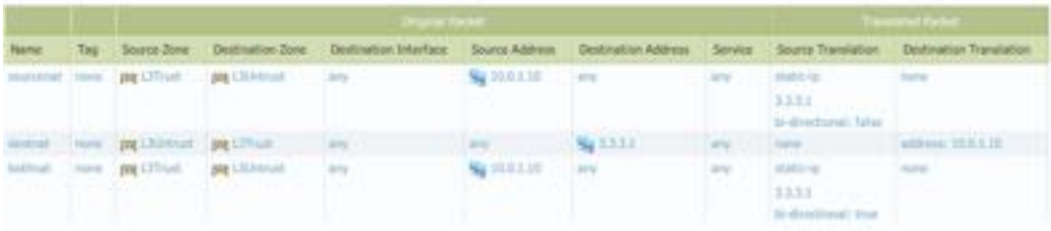


**Figure 17. Bi-Directional NAT Rules**

## Defining Network Address Translation Policies

▶ *Policies > NAT*

NAT address translation rules are based on the source and destination zones, the source and destination addresses, and the application service (such as HTTP). Like security policies, the NAT policy rules are compared against the incoming traffic in sequence, and the first rule that matches the traffic is applied.

As needed, add static routes to the local router so that traffic to all public addresses is routed to the firewall. You may also need to add static routes to the receiving interface on the firewall to route traffic back to the private address (refer to "Firewall Interfaces" on page 127). For configuration guidelines, refer to "Guidelines on Defining Policies" on page 184.

**Table 78. NAT Rule Settings**

| Field | Description |
|---|---|
| Name | Change the default rule name and/or enter a rule description. |
| Description | Enter a description for the policy (up to 255 characters). |
| NAT Type | Specify **ipv4** for NAT between IPv4 addresses, or **nat64** translation between IPv6 and IPv4 addresses.<br>***Note:*** *You cannot combine IPv4 and IPv6 address ranges in a single NAT rule.* |
| Tag | If you need to tag the policy, click **Add** to specify the tag.<br>A policy tag is a keyword or phrase that allows you to sort or filter policies. This is useful when you have defined many policies and want to view those that are tagged with a particular keyword. For example, you may want to tag certain security policies with Inbound to DMZ, decryption policies with the words Decrypt and No-decrypt, or use the name of a specific data center for policies associated with that location. |
| **Original Packet** | |
| Source Zone<br>Destination Zone | Select one or more source and destination zones for the original (non-NAT) packet (default is any). Zones must be of the same type (Layer 2, Layer 3, or virtual wire). To define new zones, refer to "Defining Security Zones" on page 151.<br>Multiple zones can be used to simplify management. For example, you can configure settings so that multiple internal NAT addresses are directed to the same external IP address. |
| Destination Interface | Specify the type of interface for translation. The destination interface can be used to translate IP addresses differently in the case where the network is connected to two ISPs with different IP address pools. |
| Source Address<br>Destination Address | Specify a combination of source and destination addresses for which the source or destination address must be translated. |
| Service | Specify the services for which the source or destination address is translated. To define new service groups, refer to "Service Groups" on page 240. |

**Table 78. NAT Rule Settings (Continued)**

| Field | Description |
|---|---|
| **Translated Packet** | |
| Source Translation | Enter an IP address or address range (address1-address2) that the source address is translated to, and select a dynamic or static address pool. The size of the address range is limited by the type of address pool:<br>• **Dynamic IP And Port**—Address selection is based on a hash of the source IP address. For a given source IP address, the firewall will use the same translated source address for all sessions. Dynamic IP and Port source NAT supports approximately 64k concurrent sessions on each IP address in the NAT pool. On some platforms, over-subscription is supported, which will allow a single IP to host more than 64k concurrent sessions. See the note on page 191 for more details.<br>• **Dynamic IP**—The next available address in the specified range is used, but the port number is unchanged. Up to 32k consecutive IP addresses are supported. A dynamic IP pool can contain multiple subnets, so you can translate your internal network addresses to two or more separate public subnets.<br>– **Advanced (Fall back Dynamic IP Translation)**—Use this option to create a fall back pool that will perform IP and port translation and will be used if the primary pool runs out of addresses. You can define addresses for the pool by using the Translated Address option or the Interface Address option, which is for interfaces that receive an IP address dynamically. When creating a fall back pool, make sure addresses do not overlap with addresses in the primary pool.<br>• **Static IP**—The same address is always used, and the port is unchanged. For example, if the source range is 192.168.0.1-192.168.0.10 and the translation range is 10.0.0.1-10.0.0.10, address 192.168.0.2 is always translated to 10.0.0.2. The address range is virtually unlimited.<br>• **None**—Translation is not performed. |
| Destination Translation | Enter an IP address or range of IP addresses and a translated port number (1 to 65535) that the destination address and port number are translated to. If the **Translated Port** field is blank, the destination port is not changed. Destination translation is typically used to allow an internal server, such as an email server, to be accessed from the public network. |

## NAT Policy Examples

The following NAT policy rule translates a range of private source addresses (10.0.0.1 to 10.0.0.100 in the "L3Trust" zone) to a single public IP address (200.10.2.100 in the "L3Untrust" zone) and a unique source port number (dynamic source translation). The rule applies only to traffic received on a Layer 3 interface in the "L3Trust" zone that is destined for an interface in the "L3Untrust" zone. Because the private addresses are hidden, network sessions cannot be initiated from the public network. If the public address is not a firewall interface address (or on the same subnet), the local router requires a static route to direct return traffic to the firewall.

Security policy must be explicitly configured to permit traffic matching this NAT rule. Create a security policy with source/destination zones and source/destination addresses matching the NAT rule.

**Figure 18. Dynamic Source Address Translation**

In the following example, the first NAT rule translates the private address of an internal mail server to a static public IP address. The rule applies only to outgoing email sent from the "L3Trust" zone to the "L3Untrust" zone. For traffic in the reverse direction (incoming email), the second rule translates the destination address from the server's public address to its private address. Rule2 uses "L3Untrust" for the source and destination zones because NAT policy is based on the pre-NAT address zone. In this case, that pre-NAT address is a public IP address and is therefore in the "L3Untrust" zone.

**Figure 19. Static Source and Destination Address Translation**

In both examples, if the public address is not the address of the firewall's interface (or on the same subnet), you must add a static route to the local router to route traffic to the firewall.

## NAT64

NAT64 is used to translate source and destination IP headers between IPv6 and IPv4 addresses. It allows IPv6 clients to access IPv4 servers and allows IPv4 clients to access IPv6 servers. There are three main transition mechanisms defined by the IETF: dual-stack, tunneling, and translation. When you have IPv4-only and IPv6-only networks and communication is required, you must use translation.

When using NAT64 policies on Palo Alto Networks firewall, it's required that you have a third-party DNS64 solution in place to decouple the DNS query function from the NAT function.

The following NAT64 features are supported:

- Stateful NAT64, which allows preserving of IPv4 addresses so that one IPv4 address can map to multiple IPv6 addresses. An IPv4 address can also be shared with NAT44. In contrast, stateless NAT64 maps one IPv4 address to one IPv6 address.
- IPv4-initiated communication translation. The static binding for IPv4 maps an IPv4 address/port number to an IPv6 IP address. PAN-OS also supports port rewrite that allows you to preserve even more IPv4 addresses.
- Allows translation for /32, /40, /48, /56, /64, and /96 subnets.
- Support for multiple prefixes. You can assign one NAT64 prefix per rule.
- Does not require you to reserve a pool of IPv4 address specifically for NAT64. Therefore, it is possible to use a single IP address to do NAT44 and NAT64.
- Supports hairpinning (NAT U-Turn) and it can prevent hairpinning loop attacks.

- Supports the translation of TCP/UDP/ICMP packets as per RFC, but also other protocols without ALG (best effort). For example, a GRE packet could be translated. This translation has the same limitation as NAT44.
- Supports PMTUD (path MTU discovery) and it updates the MSS (Maximum Segment Size) for TCP.
- Allows configuration of the IPv6 MTU setting. The default value is 1280, which is the minimum MTU for IPv6 traffic. This setting is configured in **Device > Setup > Sessions** tab under **Session Settings**.
- Translates length attribute between IPv4 and IPv6.
- Supported on Layer 3 interfaces and subinterfaces, tunnel, and VLAN interfaces.

## NAT64 Examples

You can configure two types of translation with the firewall: IPv6-initiated communication, which is similar to source NAT in IPv4, and IPv4-initiated communication to an IPv6 server, which is similar to destination NAT in IPv4.

### IPv6-initiated Communication

In this type of translation, the destination IPv6 address in the NAT rule is a prefix following the RFC 6052 format (/32, /40,/48,/56,/64, and /96). The destination IPv6 address netmask in the rule would be used to extract the IPv4 address. The source translation needs to have "Dynamic IP and Port" in order to implement a stateful NAT64. The IPv4 address set as the source is configured the same way as a NAT44 source translation. The destination translation field is not set. However, a destination translation must be done since the address is extracted from the IPv6 address in the packet. It uses prefix defined in the destination IP matching criteria. You should note that in a /96 prefix, it is the last 4 octets, but the location of the IPv4 address would be different if the prefix is not /96.

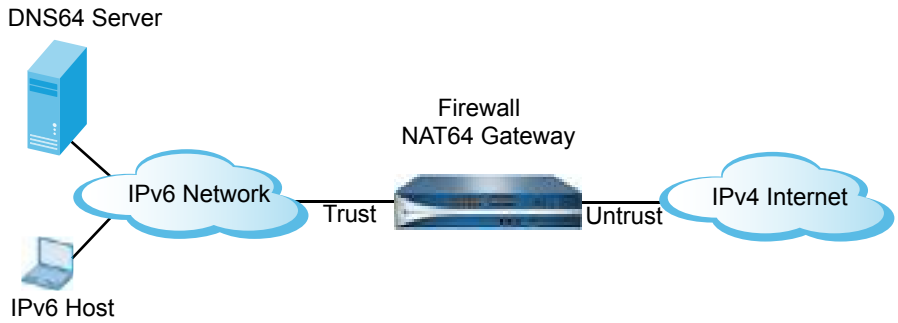

**Figure 20. NAT64 IPv6 Client to IPv4 Network Diagram**

The following table describes the values needed in this NAT64 policy.

**Table 79.**

| Source IP | Destination IP | Source Translation | Destination Translation |
|---|---|---|---|
| Any/IPv6 address | NAT64 IPv6 prefix with RFC6052 compliant netmask | Dynamic IP and port mode (Use IPv4 address) | None<br>(Extracted from the destination IPv6 address) |

### IPv4-initiated Communication

The IPv4 address is the address that maps to the IPv6 address and you use static IP mode in the source translation. The source would be set in an IPv6 prefix as defined in RFC6052 and is appended to the IPv4 source address. The destination address is the IP address set in the destination translation column. It is possible to rewrite the destination port. This method allows a single IP address to share multiple IPv6 servers through the port through a static mapping.

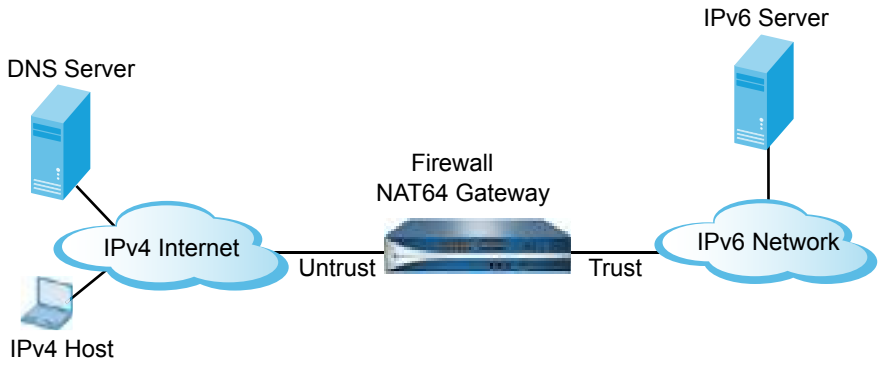

**Figure 21. NAT64 IPv4 Internet to IPv6 Customer Network Diagram**

The following table describes the values needed in this NAT64 policy.

**Table 80. IPv4-initiated Values**

| Source IP | Destination IP | Source Translation | Destination Translation |
|---|---|---|---|
| Any/IPv4 address | IPv4 address | Static IP mode<br>(IPv6 prefix in RFC 6052 format) | Single IPv6 address (actual server IP address)<br>Note: You could specify a server port re-write. |

The packet processing engine of the firewall must do a route lookup to find the destination zone prior to looking at the NAT rule. In NAT64, it is important to address the reachability of the NAT64 prefix for the destination zone assignment since the NAT64 prefix should not be routable by the NAT64 gateway. It is very likely that the NAT64 prefix would hit the default route, or be dropped because there is no route. You can setup a tunnel interface with no termination point since this type of interface will act like a loopback port and accept other netmasks besides /128. You apply the NAT64 prefix to the tunnel and apply the appropriate

zone in order to ensure that IPv6 traffic with NAT64 prefix is assigned to the proper destination zone. It would also have the advantage to drop the IPv6 traffic with NAT64 prefix if the NAT64 rule is not matched.

### IETF Scenarios for IPv4/IPv6 Translation

There are six NAT64 based scenarios defined by the IETF in RFC 6144. The Palo Alto Networks firewall will support all but one of these scenarios, as described in the following table.

**Table 81. Summary of IETF Scenario Implementations for Using PAN-OS**

| Scenario | Source IP | Destination IP | Source Translation | Destination Translation |
|---|---|---|---|---|
| IPv6 Network to the IPv4 Internet | Any/IPv6 address | NAT64 IPv6 prefix with RFC 6052 compliant netmask. | Dynamic IP and port mode.<br>Use *Public* IPv4 address | None<br>(extracted from destination IPv6 address) |
| The IPv4 Internet to an IPv6 Network | Any/IPv4 address | Single IPv4 address | Static IP mode.<br>IPv6 Prefix in RFC 6052 format | Single IPv6 address |
| The IPv6 Internet to an IPv4 Network | Any/IPv6 address | IPV6 globally routable prefix with RFC 6052 compliant netmask. | Dynamic IP and port.<br>Use *Private* IPv4 address | None<br>(extracted from destination IPv6 address) |
| IPv4 network to IPv6 Internet | Not currently supported | | | |
| IPv4 network to IPv6 network | Any/IPv4 address | Single IPv4 address | Static IP mode.<br>IPv6 Prefix in RFC 6052 format | Single IPv6 address |
| IPv6 network to IPv4 network | Any/IPv6 address | NAT64 IPV6 prefix with RFC 6052 compliant netmask. | Dynamic IP and port.<br>Use Private IPv4 address | None<br>(extracted from destination IPv6 address) |

# Policy-Based Forwarding Policies

▶ ***Policies > Policy Based Forwarding***

Normally, when traffic enters the firewall, the ingress interface virtual router dictates the route that determines the outgoing interface and destination security zone based on destination IP address. With policy-based forwarding (PBF), you can specify other information to determine the outgoing interface, including source zone, source address, source user, destination address, destination application, and destination service. The initial session on a given destination IP address and port that is associated with an application will not match an application-specific rule and will be forwarded according to subsequent PBF rules (that do not specify an application) or the virtual router's forwarding table. All subsequent sessions on

that destination IP address and port for the same application will match an application-specific rule. To ensure forwarding through PBF rules, application-specific rules are not recommended.

When necessary, PBF rules can be used to force traffic through an additional virtual system using the Forward-to-VSYS forwarding action. In this case, it is necessary to define an additional PBF rule that will forward the packet from the destination virtual system out through a particular egress interface on the firewall.

For configuration guidelines, refer to "Guidelines on Defining Policies" on page 184.

**Table 82. Policy-Based Forwarding Settings**

| Field | Description |
|---|---|
| **General Tab** | |
| Name | Enter a name to identify the rule (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. Only the name is required. |
| Description | Enter a description for the policy (up to 255 characters). |
| Tag | If you need to tag the policy, click **Add** to specify the tag.<br>A policy tag is a keyword or phrase that allows you to sort or filter policies. This is useful when you have defined many policies and want to view those that are tagged with a particular keyword. For example, you may want to tag certain security policies with Inbound to DMZ, decryption policies with the words Decrypt and No-decrypt, or use the name of a specific data center for policies associated with that location. |
| **Source Tab** | |
| Source Zone | To choose source zones (default is any), click **Add** and select from the drop-down list. To define new zones, refer to "Defining Security Zones" on page 151.<br>Multiple zones can be used to simplify management. For example, if you have three different internal zones (Marketing, Sales, and Public Relations) that are all directed to the untrusted destination zone, you can create one rule that covers all cases.<br>**Note:** Only Layer 3 type zones are supported for policy-based forwarding. |
| Source Address | Click **Add** to add source addresses, address groups, or regions (default is any). Select from the drop-down list, or click the **Address**, **Address Group**, or **Regions** link at the bottom of the drop-down list, and specify the settings. |
| Source User | Click **Add** to choose the source users or groups of users subject to the policy. |
| **Destination/ Application/Service Tab** | |
| Destination Address | Click **Add** to add destination addresses, address groups, or regions (default is any). Select from the drop-down list, or click the **Address**, **Address Group**, or **Regions** link at the bottom of the drop-down list, and specify the settings. |

**Table 82. Policy-Based Forwarding Settings (Continued)**

| Field | Description |
|---|---|
| Application | Select specific applications for the PBF rule. To define new applications, refer to "Defining Applications" on page 233. To define application groups, refer to "Defining Application Groups" on page 238.<br>If you are using application groups, filters, or container in the PBF rule, you can view details on these objects by holding your mouse over the object in the **Application** column, click the down arrow and select **Value**. This enables you to easily view application members directly from the policy without having to go to the Object tabs. |
| Service | Specify the services for which the source or destination address is translated. To define new service groups, refer to "Service Groups" on page 240. |
| **Forwarding Tab** | |
| Action | Select one of the following options:<br>• **Forward**—Specify the next hop IP address and egress interface (the interface that the packet takes to get to the specified next hop).<br>• **Forward To VSYS**—Choose the virtual system to forward to from the drop-down list.<br>• **Discard**—Drop the packet.<br>• **No PBF**—Do not alter the path that the packet will take. |
| Egress Interface | Specify the firewall interface for forwarding traffic from the firewall. |
| Next Hop | Specify the IP address of the next forwarding stop. |
| Monitor | To monitor the forwarding actions, select **Monitor** and specify the following settings:<br>• **Profile**—Choose a profile from the drop-down list.<br>• **Disable if unreachable**—Select this check box if you want to ignore this rule for all new sessions when the next hop router is unreachable.<br>• **IP Address**—Specify the IP address to which ping messages are sent periodically to determine the state of the policy based forwarding rule. |

**Table 82. Policy-Based Forwarding Settings (Continued)**

| Field | Description |
|---|---|
| Enforce Symmetric Return | Select this option to allow virtual routers on the firewall to enforce symmetric return for the PBF rule. Click **Add** if you want to enter the next-hop address(es) that will be used for the forwarding.<br>This option will circumvent the route lookup process for return traffic; the firewall will use the original incoming interface as the egress interface. If the source IP is in the same subnet as the incoming interface on the firewall, symmetric return will not take effect.<br>This feature is useful when you have servers accessible through two ISP connections (on different ingress interfaces) and the return traffic must be routed through the ISP that original routed the sessions.<br>The following should be noted when using this feature:<br>• If an interface has multiple PBF rules, only one rule can enforce symmetric return.<br>• You can use this option for all L3 interfaces, except loopback interfaces. You can also use interfaces that have the IP address assigned dynamically (DHCP and PPoE).<br>• The source must be an interface, not a zone.<br>• Next-hop address list is not supported for tunnel and PPoE interfaces.<br>• Up to 8 next-hop addresses can be defined per PBF rule. |
| Schedule | To limit the days and times when the rule is in effect, select a schedule from the drop-down list. To define new schedules, refer to "Schedules" on page 250. |

# Decryption Policies

▶ *Policies > Decryption*

You can configure the firewall to decrypt traffic for visibility, control, and granular security. Decryption policies can apply to Secure Sockets Layer (SSL) and Secure Shell (SSH) traffic. With the SSH option, you can selectively decrypt outbound and inbound SSH traffic to assure that secure protocols are not being used to tunnel disallowed applications and content. You can also apply decryption profiles to your policies to block and control various aspects of SSL traffic. For more information, refer to "Decryption Profiles" on page 248.

Each decryption policy specifies the categories of URLs to decrypt or not decrypt. App-ID and the Antivirus, Vulnerability, Anti-spyware, URL Filtering, and File-blocking profiles are applied to decrypted traffic before it is re-encrypted as traffic exits the device. End-to-end security between clients and servers is maintained, and the firewall acts as a trusted third party during the connection. No decrypted traffic leaves the device.

The firewall inspects traffic, regardless of the protocols that are encapsulated. Decryption policies can be as general or specific as needed. The policy rules are compared against the traffic in sequence, so more specific rules must precede the more general ones.

***Note:*** *Refer to the Palo Alto Networks tech note, Controlling SSL Decryption, for instructions on managing SSL certificates to avoid certificate mismatch errors, and SSL Decryption Certificates for guidelines on how to develop policies to handle non-standard SSL implementations.*

SSL forward proxy decryption requires the configuration of a trusted certificate that will be presented to the user if the server to which the user is connecting possesses a certificate signed by a CA trusted by the firewall. To configure this certificate, create a certificate on the **Device > Certificate Management > Certificates** page and then click the name of the certificate and check the **Forward Trust Certificate** check box. Refer to "Importing, Exporting and Generating Security Certificates" on page 86.

***Note:*** *Certain applications will not function if they are decrypted by the firewall. To prevent this from occurring, PAN-OS will not decrypt the SSL traffic for these applications and the decryption rule settings will not apply. For a list of these applications, refer to support article located at https://live.paloaltonetworks.com/docs/DOC-1423.*

.

**Table 83. Decryption Rule Settings**

| Field | Description |
|---|---|
| **General Tab** | |
| Name | Enter a name to identify the rule (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. Only the name is required. |
| Description | Enter a description for the rule (up to 255 characters). |
| Tag | If you need to tag the policy, click **Add** to specify the tag.<br>A policy tag is a keyword or phrase that allows you to sort or filter policies. This is useful when you have defined many policies and want to view those that are tagged with a particular keyword. For example, you may want to tag certain security policies with Inbound to DMZ, decryption policies with the words Decrypt and No-decrypt, or use the name of a specific data center for policies associated with that location. |
| **Source Tab** | |
| Source Zone | Click **Add** to choose source zones (default is any). Zones must be of the same type (Layer 2, Layer 3, or virtual wire). To define new zones, refer to "Defining Security Zones" on page 151.<br>Multiple zones can be used to simplify management. For example, if you have three different internal zones (Marketing, Sales, and Public Relations) that are all directed to the untrusted destination zone, you can create one rule that covers all cases. |
| Source Address | Click **Add** to add source addresses, address groups, or regions (default is any). Select from the drop-down list, or click the **Address**, **Address Group**, or **Regions** link at the bottom of the drop-down list, and specify the settings. Select the **Negate** check box to choose any address except the configured ones. |

**Table 83. Decryption Rule Settings (Continued)**

| Field | Description |
|---|---|
| Source User | Click **Add** to choose the source users or groups of users subject to the policy. If you choose the **pre-logon** option, this will include remote users that are connected to the network using GlobalProtect, but are not logged into their system. When the Pre-logon option is configured on the Portal for GlobalProtect clients, any user who is not currently logged into their machine will be identified with the username **pre-logon**. You can then create policies for pre-logon users and the machines can be accessed as if they were logged in and connected to the domain. |
| **Destination Tab** | |
| Destination Zone | Click **Add** to choose destination zones (default is any). Zones must be of the same type (Layer 2, Layer 3, or virtual wire). To define new zones, refer to "Defining Security Zones" on page 151.<br>Multiple zones can be used to simplify management. For example, if you have three different internal zones (Marketing, Sales, and Public Relations) that are all directed to the untrusted destination zone, you can create one rule that covers all cases. |
| Destination Address | Click **Add** to add destination addresses, address groups, or regions (default is any). Select from the drop-down list, or click the **Address**, **Address Group**, or **Regions** link at the bottom of the drop-down list, and specify the settings. Select the **Negate** check box to choose any address except the configured ones. |
| **URL Category Tab** | Select URL categories for the decryption rule.<br>• Choose **any** to match any sessions regardless of the URL category.<br>• To specify a category, click **Add** and select a specific category (including a custom category) from the drop-down list. You can add multiple categories. Refer to "Custom URL Categories" on page 242 for information on defining custom categories. |
| **Options Tab** | |
| Action | Select **decrypt** or **no-decrypt** for the traffic. |
| Type | Select the type of traffic to decrypt from the drop-down list:<br>• **SSL Forward Proxy**—Specifies that the policy will decrypt client traffic destined for an external server.<br>• **SSH Proxy**—Specifies that the policy will decrypt SSH traffic. This option allows you to control SSH tunneling in policies by specifying the ssh-tunnel App-ID.<br>• **SSL Inbound Inspection**—Specifies that the policy will decrypt SSL inbound inspection traffic. |
| Decryption Profile | Select an existing decryption profile, or create a new decryption profile. Refer to "Decryption Profiles" on page 248. |

# Application Override Policies

To change how the firewall classifies network traffic into applications, you can specify application override policies. For example, if you want to control one of your custom applications, an application override policy can be used to identify traffic for that application according to zone, source and destination address, port, and protocol. If you have network applications that are classified as "unknown," you can create new application definitions for them (refer to "Defining Applications" on page 233).

Like security policies, application override policies can be as general or specific as needed. The policy rules are compared against the traffic in sequence, so the more specific rules must precede the more general ones.

## Custom Application Definition with Application Override

Because the App-ID engine in PAN-OS classifies traffic by identifying the application-specific content in network traffic, the custom application definition cannot simply use a port number to identify an application. The application definition must also include traffic (restricted by source zone, source IP address, destination zone, and destination IP address).

To create a custom application with application override:

1. Define the custom application. Refer to "Defining Applications" on page 233. It is not required to specify signatures for the application if the application is used only for application override rules.
2. Define an application override policy that specifies when the custom application should be invoked. A policy typically includes the IP address of the server running the custom application and a restricted set of source IP addresses or a source zone.

## Defining Application Override Policies

▶ ***Policies*** **>** ***Application Override***

After creating a new rule, configure the rule by clicking the current field values and specifying the appropriate information, as described in the following table.

**Table 84. Application Override Rule Settings**

| Field | Description |
|---|---|
| **General Tab** | |
| Name | Enter a name to identify the rule (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. Only the name is required. |
| Description | Enter a description for the rule (up to 255 characters). |
| Tag | If you need to tag the policy, click **Add** to specify the tag.<br>A policy tag is a keyword or phrase that allows you to sort or filter policies. This is useful when you have defined many policies and want to view those that are tagged with a particular keyword. For example, you may want to tag certain security policies with Inbound to DMZ, decryption policies with the words Decrypt and No-decrypt, or use the name of a specific data center for policies associated with that location. |

**Table 84. Application Override Rule Settings (Continued)**

| Field | Description |
|---|---|
| **Source Tab** | |
| Source Zone | Click **Add** to choose source zones (default is any). Zones must be of the same type (Layer 2, Layer 3, or virtual wire). To define new zones, refer to "Defining Security Zones" on page 151.<br>Multiple zones can be used to simplify management. For example, if you have three different internal zones (Marketing, Sales, and Public Relations) that are all directed to the untrusted destination zone, you can create one rule that covers all cases. |
| Source Address | Click **Add** to add source addresses, address groups, or regions (default is any). Select from the drop-down list, or click the **Address**, **Address Group**, or **Regions** link at the bottom of the drop-down list, and specify the settings. Select the **Negate** check box to choose any address except the configured ones. |
| **Destination Tab** | |
| Destination Zone | Click **Add** to choose destination zones (default is any). Zones must be of the same type (Layer 2, Layer 3, or virtual wire). To define new zones, refer to "Defining Security Zones" on page 151.<br>Multiple zones can be used to simplify management. For example, if you have three different internal zones (Marketing, Sales, and Public Relations) that are all directed to the untrusted destination zone, you can create one rule that covers all cases. |
| Destination Address | Click **Add** to add destination addresses, address groups, or regions (default is any). Select from the drop-down list, or click the **Address**, **Address Group**, or **Regions** link at the bottom of the drop-down list, and specify the settings. Select the **Negate** check box to choose any address except the configured ones. |
| **Protocol/Application Tab** | |
| Protocol | Select the protocol for which the application can be overridden. |
| Port | Enter the port number (0 to 65535) or range of port numbers (port1-port2) for the specified destination addresses. Multiple ports or ranges must be separated by commas. |
| Application | Select the override application for traffic flows that match the above rule criteria. When overriding to a custom application, there is no threat inspection that is performed. The exception to this is when you override to a pre-defined application that supports threat inspection.<br>To define new applications, refer to "Defining Applications" on page 233). |

# Captive Portal Policies

You can set up and customize a captive portal to direct user authentication by way of an authentication profile, an authentication sequence, or a certificate profile. Captive portal is used in conjunction with the User-ID Agent to extend user identification functions beyond the Active Directory domain. Users are directed to the portal and authenticated, thereby creating a user-to-IP address mapping.

## Defining Captive Portal Policies

▶ *Policies > Captive Portal*

Before you define captive portal policies, enable captive portal and configure captive portal settings on the **User Identification** page, as described in "Configuring the Firewall for User Identification" on page 286.

After doing so, configure capture portal policies by specifying the following information.

**Table 85. Captive Portal Rule Settings**

| Field | Description |
|---|---|
| Name | Enter a name to identify the rule (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. Only the name is required. |
| Description | Enter a description for the rule (up to 255 characters). |
| Tag | If you need to tag the policy, click **Add** to specify the tag.<br>A policy tag is a keyword or phrase that allows you to sort or filter policies. This is useful when you have defined many policies and want to view those that are tagged with a particular keyword. For example, you may want to tag certain security policies with Inbound to DMZ, decryption policies with the words Decrypt and No-decrypt, or use the name of a specific data center for policies associated with that location. |
| **Source Tab** | |
| Source | Specify the following information:<br>• Choose a source zone if the policy needs to be applied to traffic coming from all interfaces in a given zone. Click **Add** to specify multiple interfaces or zones.<br>• Specify the **Source Address** setting to apply the captive portal policy for traffic coming from specific source addresses. Select the **Negate** check box to choose any address except the configured ones. Click **Add** to specify multiple interfaces or zones. |
| **Destination Tab** | |
| Destination | Specify the following information:<br>• Choose a destination zone if the policy needs to be applied to traffic to all interfaces in a given zone. Click **Add** to specify multiple interfaces or zones.<br>• Specify the **Destination Address** setting to apply the captive portal policy for traffic to specific destination addresses. Select the **Negate** check box to choose any address except the configured ones. Click **Add** to specify multiple interfaces or zones. |

**Table 85. Captive Portal Rule Settings (Continued)**

| Field | Description |
|---|---|
| **Service/ URL Category Tab** | |
| Service | Select services to limit to specific TCP and/or UDP port numbers. Choose one of the following from the drop-down list:<br>• **any**—The selected services are allowed or denied on any protocol or port.<br>• **default**—The selected services are allowed or denied only on the default ports defined by Palo Alto Networks. This option is recommended for allow policies.<br>• **Select**—Click **Add**. Choose an existing service or choose **Service** or **Service Group** to specify a new entry. Refer to "Services" on page 239 and "Service Groups" on page 240. |
| URL Category | Select URL categories for the captive portal rule.<br>• Choose **any** to apply the actions specified on the **Service/Action** tab regardless of the URL category.<br>• To specify a category, click **Add** and select a specific category (including a custom category) from the drop-down list. You can add multiple categories. Refer to "Custom URL Categories" on page 242 for information on defining custom categories. |
| **Service/Action Tab** | |
| Action Setting | Choose an action to take:<br>• **web-form**—Present a captive portal page for the user to explicitly enter authentication credentials.<br>• **no-captive-portal**—Allow traffic to pass without presenting a captive portal page for authentication.<br>• **browser-challenge**—Open an NT LAN Manager (NTLM) authentication request to the user's web browser. The web browser will respond using the user's current login credentials. |

# DoS Protection Policies

DoS protection policies allow you to control the number of sessions between interfaces, zones, addresses, and countries based on aggregate sessions or source and/or destination IP addresses.

## Defining DoS Protection Policies

▶ *Policies > DoS Protection*

Use this page to add, edit, or delete DoS protection policy rules. To add a policy rule, click **Add** and then complete the following fields:

**Table 86. DoS Rule Settings**

| Field | Description |
|---|---|
| **General Tab** | |
| Name | Enter a name to identify the rule (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. Only the name is required. |
| Description | Enter a description for the rule (up to 255 characters). |
| Tag | If you need to tag the policy, click **Add** to specify the tag.<br>A policy tag is a keyword or phrase that allows you to sort or filter policies. This is useful when you have defined many policies and want to view those that are tagged with a particular keyword. For example, you may want to tag certain security policies with Inbound to DMZ, decryption policies with the words Decrypt and No-decrypt, or use the name of a specific data center for policies associated with that location. |
| **Source Tab** | |
| Source | Specify the following information:<br>• Choose **Interface** from the **Type** drop-down list to apply the DoS policy to traffic coming from an interface or a group of interfaces. Choose **Zone** if the DoS policy needs to be applied to traffic coming from all interfaces in a given zone. Click **Add** to specify multiple interfaces or zones.<br>• Specify the **Source Address** setting to apply the DoS policy for traffic coming from specific source addresses. Select the **Negate** check box to choose any address except the configured ones. Click **Add** to specify multiple addresses.<br>• Specify the **Source User** setting to apply the DoS policy for traffic from specific users. Click **Add** to specify multiple users. |

**Table 86. DoS Rule Settings (Continued)**

| Field | Description |
|---|---|
| **Destination Tab** | |
| Destination | Specify the following information:<br>• Choose **Interface** from the **Type** drop-down list to apply the DoS policy to traffic coming from an interface or a group of interfaces. Choose **Zone** if the DoS policy needs to be applied to traffic coming from all interfaces in a given zone. Click **Add** to specify multiple interfaces or zones.<br>• Specify the **Destination Address** setting to apply the DoS policy for traffic to specific destination addresses. Select the **Negate** check box to choose any address except the configured ones. Click **Add** to specify multiple addresses. |
| **Option/Protection Tab** | |
| Service | Select from the drop-down list to apply the DoS policy to only the configured services. |
| Action | Choose the action from the drop-down list:<br>• **Deny**—Drop all traffic.<br>• **Allow**—Permit all traffic.<br>• **Protect**—Enforce protections supplied in the thresholds that are configured as part of the DoS profile applied to this rule. |
| Schedule | Select a pre-configured schedule from the drop-down list to apply the DoS rule to a specific date/time. |
| Log Forwarding | If you want to trigger forwarding of threat log entries to an external service—such as a syslog server or Panorama—select a log forwarding profile from the drop-down or click **Profile** to create a new one. Note that only traffic that matches an action in the rule will be logged and forwarded. |
| Aggregate | Select a DoS protection profile from the drop-down list to determine the rate at which you want to take action in response to DoS threats. The aggregate setting applies to the total of all traffic from the specified source to specified destination. |
| Classified | Select the check box and specify the following:<br>• **Profile**—Select the profile from the drop-down list.<br>• **Address**—Select whether to apply the rule to the source, destination, or source and destination IP addresses.<br>If a classified profile is specified, the profile limitations are applied to a source IP address, destination IP address, or source and destination IP address pair. For example, you could specify a classified profile with a session limit of 100 and specify an **Address** setting of "source" in the rule. The result would be a limit of 100 sessions at any given time for that particular source IP address. |

# Security Profiles

Each security policy can include specification of one or more security profiles, which provide additional protection and control.

You can also add threat exceptions to Anti-spyware and Vulnerability profiles. To make management of threat exceptions easier, you can add threat exceptions directly from the Monitor > Logs > Threat list. To add a threat exception to a profile, locate the threat in the Threat log and then click on the threat name. The Threat Details dialogue will appear, select one or more profiles in the left pane and click OK. This will add a threat exception for that signature in the selected threat profiles with the action of allow. To add a threat exception for specific IP addresses, add the IP addresses in the right pane and click OK. This will add a threat exception with the IP addresses added as a filter on the threat exception.

The following profile types are available:

- Antivirus profiles to protect against worms and viruses or block spyware downloads. Refer to "Antivirus Profiles" in the next section.
- Anti-spyware profiles to block attempts by spyware to access the network. Refer to "Anti-spyware Profiles" on page 213.
- Vulnerability protection profiles to stop attempts to exploit system flaws or gain unauthorized access to systems. Refer to "Vulnerability Protection Profiles" on page 215.
- URL filtering profiles to restrict access to specific web sites and web site categories. Refer to "URL Filtering Profiles" on page 217.
- File blocking profiles to block selected file types. Refer to "File Blocking Profiles" on page 220.
- Data filtering profiles that help prevent sensitive information such as credit card or social security numbers from leaving the area protected by the firewall. Refer to "Data Filtering Profiles" on page 223.

In additional to individual profiles, you can create profile groups to combine profiles that are often applied together.

***Note:*** *You cannot delete a profile that is used in a security policy.*

You can choose from the following actions when defining antivirus and anti-spyware profiles.

- **Default**—Takes the default action that is specified internally in the signature for each threat.
- **Alert**—Generates an alert for each application traffic flow. The alert is saved in the threat log.
- **Block**—Drops the application traffic.
- **Allow**—Permits the application traffic.

The following actions are available when defining custom Spyware and Vulnerability objects:

- **Alert**—Generates an alert for each application traffic flow. The alert is saved in the threat log.

- **Drop Packets**—Keeps all packets from continuing past the firewall.
- **Reset Both**—Resets the client and server.
- **Reset Client**—Resets the client.
- **Reset Server**—Resets the server.
- **Block-IP**—This action blocks traffic from either a source or a source-destination pair (configurable) for a specified period of time.

# Antivirus Profiles

▶ *Objects > Security Profiles > Antivirus*

A security policy can include specification of an antivirus profile to identify which applications are inspected for viruses and the action taken when a virus is detected. The profile can also specify actions to block spyware downloads. The default profile inspects all of the listed protocol decoders for viruses, generates alerts for Simple Mail Transport Protocol (SMTP), Internet Message Access Protocol (IMAP), and Post Office Protocol Version 3 (POP3), and takes the default action for other applications (alert or deny), depending on the type of virus detected.

Customized profiles can be used to minimize antivirus inspection for traffic between trusted security zones, and to maximize the inspection of traffic received from untrusted zones, such as the Internet, as well as the traffic sent to highly sensitive destinations, such as server farms.

For information on action types, refer to "Security Profiles" on page 211.

**Table 87. Antivirus Profile Settings**

| Field | Description |
|---|---|
| Name | Enter a profile name (up to 31 characters). This name appears in the list of antivirus profiles when defining security policies. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, periods, and underscores. |
| Description | Enter a description for the profile (up to 255 characters). |
| **Antivirus Tab** | |
| Packet Capture | Select the check box if you want to capture identified packets. |
| Decoders and Actions | For each type of traffic that you want to inspect for viruses, select an action from the drop-down list. You can also take specific action based on signatures created by WildFire. For more information on WildFire, refer to "About WildFire" on page 421. |

**Table 87. Antivirus Profile Settings (Continued)**

| Field | Description |
|---|---|
| Applications Exceptions and Actions | Identify applications that will be exceptions to the antivirus rule.<br>For example, to block all HTTP traffic except for a specific application, you can define an antivirus profile for which the application is an exception. **Block** is the action for the HTTP decoder, and **Allow** is the exception for the application.<br>To find an application, start typing the application name in the text box. A matching list of applications is displayed, and you can make a selection. The application is added to the table, and you can assign an action.<br>For each application exception, select the action to be taken when the threat is detected. |
| **Virus Exception Tab** | |
| Threat ID | Use this tab if you want the system to ignore specific threats. Exceptions that are already specified are listed. You can add additional threats by entering the threat ID and clicking **Add**. Threat IDs are presented as part of the threat log information. Refer to "Viewing the Logs" on page 264. |

# Anti-spyware Profiles

▶ *Objects > Security Profiles > Anti-spyware*

A security policy can include specification of an anti-spyware profile for "phone home" detection (detection of traffic from installed spyware). The default anti-spyware profile detects phone-home protection for all severity levels except the low and informational levels.

Customized profiles can be used to minimize anti-spyware inspection for traffic between trusted security zones, and to maximize the inspection of traffic received from untrusted zones, such as the Internet, as well as the traffic sent to highly sensitive destinations, such as server farms.

The Exceptions settings allows you to change the response to a specific signature. For example, you can block all packets that match a signature, except for the selected one, which generates an alert.

The **DNS Signatures** settings provides an additional method of identifying infected hosts on a network. These signatures detect specific DNS lookups for host names that have been associated with malware. The DNS signatures can be configured to allow, alert, or (default) block when these queries are observed, just as with regular antivirus signatures. Additionally, hosts that perform DNS queries for malware domains will appear in the botnet report. DNS signatures are downloaded as part of the antivirus updates.

The **Anti-spyware** page presents a default set of columns. Additional columns of information are available by using the column chooser. Click the arrow to the right of a column header and select the columns from the Columns sub-menu. For more information, refer to "Using Tables on Configuration Pages" on page 26.

**Table 88. Anti-spyware Profile Settings**

| Field | Description |
|---|---|
| Name | Enter a profile name (up to 31 characters). This name appears in the list of anti-spyware profiles when defining security policies. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, periods, and underscores. |
| Description | Enter a description for the profile (up to 255 characters). |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow the profile to be shared by all virtual systems. |
| **Rules Tab** | |
| Rule Name | Specify the rule name. |
| Threat Name | Enter **any** to match all signatures, or enter text to match any signature containing the entered text as part of the signature name. |
| Severity | Choose a severity level (**critical**, **high**, **medium**, **low**, or **informational**). |
| Action | Choose an action (**Default**, **Alert**, **Allow**, or **Drop**) for each threat. |
| Packet Capture | Select the check box if you want to capture identified packets. |
| **Exceptions Tab** | |
| Exceptions | Select the **Enable** check box for each threat for which you want to assign an action, or select **All** to respond to all listed threats. The list depends on the selected host, category, and severity. If the list is empty, there are no threats for the current selections.<br>Use the IP Address Exemptions column to add IP address filters to a threat exception. If IP addresses are added to a threat exception, the threat exception action for that signature will only be taken over the rule's action if the signature is triggered by a session having either the source or destination IP matching an IP in the exception. You can add up to 100 IP addresses per signature. With this option, you do not have to create a new policy rule and new vulnerability profile to create an exception for a specific IP address. |
| **DNS Signature Tab** | |
| Infected host DNS Signature | Choose an action to be taken when DNS lookups are made to known malware sites (Alert, Allow, or default (Block)). |
| Packet Capture | Select the check box if you want to capture identified packets. |
| Threat ID | Manually enter DNS signature exceptions (range 4000000-4999999). |

# Vulnerability Protection Profiles

▶ *Objects > Security Profiles > Vulnerability Protection*

A security policy can include specification of a vulnerability protection profile that determines the level of protection against buffer overflows, illegal code execution, and other attempts to exploit system vulnerabilities. The default profile protects clients and servers from all known critical, high, and medium-severity threats.

Customized profiles can be used to minimize vulnerability checking for traffic between trusted security zones, and to maximize protection for traffic received from untrusted zones, such as the Internet, as well as the traffic sent to highly sensitive destinations, such as server farms. To apply vulnerability protection profiles to security policies, refer to "Security Policies" on page 187.

The Rules settings specify collections of signatures to enable, as well as actions to be taken when a signature within a collection is triggered.

The Exceptions settings allows you to change the response to a specific signature. For example, you can block all packets that match a signature, except for the selected one, which generates an alert. The **Exception** tab supports filtering functions.

The **Vulnerability Protection** page presents a default set of columns. Additional columns of information are available by using the column chooser. Click the arrow to the right of a column header and select the columns from the Columns sub-menu. For more information, refer to "Using Tables on Configuration Pages" on page 26.

**Table 89. Vulnerability Protection Profile Settings**

| Field | Description |
|---|---|
| Name | Enter a profile name (up to 31 characters). This name appears in the list of vulnerability protection profiles when defining security policies. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, periods, and underscores. |
| Description | Enter a description for the profile (up to 255 characters). |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow the profile to be shared by all virtual systems. |
| **Rules Tab** | |
| Rule Name | Specify a name to identify the rule. |
| Threat Name | Specify a text string to match. The firewall applies a collection of signatures to the rule by searching signature names for this text string. |
| Action | Choose the action (**Alert**, **Allow**, **Default**, or **Block**) to take when the rule is triggered. The **Default** action is based on the pre-defined action that is part of each signature provided by Palo Alto Networks. To view the default action for a signature, navigate to Objects > Security Profiles > Vulnerability Protection and click **Add** or select an existing profile. Click the **Exceptions** tab and then click **Show all signatures**. A list of all signatures will displayed and you will see an **Action** column. |
| Host | Specify whether to limit the signatures for the rule to those that are client side, server side, or either (**any**). |
| Packet Capture | Select the check box if you want to capture the packet that triggered the rule. |

**Table 89. Vulnerability Protection Profile Settings (Continued)**

| Field | Description |
|---|---|
| Category | Select a vulnerability category if you want to limit the signatures to those that match that category. |
| CVE List | Specify common vulnerabilities and exposures (CVEs) if you want to limit the signatures to those that also match the specified CVEs.<br>Each CVE is in the format CVE-*yyyy*-*xxxx*, where *yyyy* is the year and *xxxx* is the unique identifier. You can perform a string match on this field. For example, to find vulnerabilities for the year 2011, enter "2011". |
| Vendor ID | Specify vendor IDs if you want to limit the signatures to those that also match the specified vendor IDs.<br>For example, the Microsoft vendor IDs are in the form MS*yy*-*xxx*, where *yy* is the two-digit year and *xxx* is the unique identifier. For example, to match Microsoft for the year 2009, enter "MS09". |
| Severity | Select severities to match (**informational**, **low**, **medium**, **high**, or **critical**) if you want to limit the signatures to those that also match the specified severities. |
| **Exceptions Tab** | |
| Threats | Select the **Enable** check box for each threat for which you want to assign an action, or select **All** to respond to all listed threats. The list depends on the selected host, category, and severity. If the list is empty, there are no threats for the current selections.<br>Choose an action from the drop-down list box, or choose from the **Action** drop-down at the top of the list to apply the same action to all threats. If the **Show All** check box is selected, all signatures are listed. If the **Show All** check box is not selected, only the signatures that are exceptions are listed.<br>Select the **Packet Capture** check box if you want to capture identified packets.<br>The vulnerability signature database contains signatures that indicate a brute force attack; for example, Threat ID 40001 triggers on an FTP brute force attack. Brute-force signatures trigger when a condition occurs in a certain time threshold. The thresholds are pre-configured for brute force signatures, and can be changed by clicking the pencil icon next to the threat name on the **Vulnerability** tab (with the **Custom** option selected). You can specify the number of hits per unit of time and whether the threshold applies to source, destination, or source-and-destination.<br>Thresholds can be applied on a source IP, destination IP or a combination of source IP and destination IP.<br>***Note:*** *The default action is shown in parentheses. The* ***CVE*** *column shows identifiers for common vulnerabilities and exposures (CVE). These unique, common identifiers are for publicly known information security vulnerabilities.*<br>Use the IP Address Exemptions column to add IP address filters to a threat exception. If IP addresses are added to a threat exception, the threat exception action for that signature will only be taken over the rule's action if the signature is triggered by a session having either the source or destination IP matching an IP in the exception. You can add up to 100 IP addresses per signature. With this option, you do not have to create a new policy rule and new vulnerability profile to create an exception for a specific IP address. |

# URL Filtering Profiles

▶ *Objects > Security Profiles > URL Filtering*

A security policy can include specification of a URL filtering profile that blocks access to specific web sites and web site categories, or generates an alert when the specified web sites are accessed (a URL filtering license is required). You can also define a "block list" of web sites that are always blocked (or generate alerts) and an "allow list" of web sites that are always allowed. The web categories are predefined by Palo Alto Networks.

To apply URL filtering profiles to security policies, refer to "Security Policies" on page 187. To create custom URL categories with your own lists of URLs, refer to "Custom URL Categories" on page 242.

**Table 90. URL Filtering Profile Settings**

| Field | Description |
|---|---|
| Name | Enter a profile name (up to 31 characters). This name appears in the list of URL filtering profiles when defining security policies. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Description | Enter a description for the profile (up to 255 characters). |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow the profile to be shared by all virtual systems. |
| Action on License Expiration | Select the action to take if the URL filtering license expires:<br>• **Block**—Blocks access to all web sites in the block list or the selected categories.<br>• **Allow**—Allows access to all web sites. |
| Dynamic URL Filtering | Select to enable dynamic URL categorization.<br>URL categorization takes advantage of a URL filtering database on the firewall that lists the most popular URLs and other URLs for malicious categories. The URL filtering database may be able to resolve requests that the local database is unable to categorize. The default is enabled when using the BrightCloud database. When using the PAN-DB, this option is enabled by default and is not configurable.<br>To configure the system response when a URL remains unresolved after a 5 second timeout period, use the Category and Action settings in this window (see Category Action later in this table). Select the action for the category "Not resolved URL." |
| Log Container Page Only | Select the check box to log only the URLs that match the content type that is specified. The default is enabled. |

**Table 90. URL Filtering Profile Settings (Continued)**

| Field | Description |
|---|---|
| Block List | Enter the IP addresses or URL path names of the web sites that you want to block or generate alerts on. Enter each URL one per line.<br><br>**IMPORTANT:** You must omit the "http and https" portion of the URLs when adding web sites to the list.<br>Entries in the block list are an exact match and are case-insensitive. For example, "www.paloaltonetworks.com" is different from "paloaltonetworks.com". If you want to block the entire domain, you should include both "*.paloaltonetworks.com" and "paloaltonetworks.com".<br>Examples:<br>• www.paloaltonetworks.com<br>• 198.133.219.25/en/US<br>Block and allow lists support wildcard patterns. The following characters are considered separators:<br>.<br>/<br>?<br>&<br>=<br>;<br>+<br>Every substring that is separated by the characters listed above is considered a token. A token can be any number of ASCII characters that does not contain any separator character or *. For example, the following patterns are valid:<br>*.yahoo.com (Tokens are: "*", "yahoo" and "com")<br>www.*.com (Tokens are: "www", "*" and "com")<br>www.yahoo.com/search=* (Tokens are: "www", "yahoo", "com", "search", "*")<br>The following patterns are invalid because the character "*" is not the only character in the token.<br>ww*.yahoo.com<br>www.y*.com |
| Action | Select the action to take when a web site in the block list is accessed.<br>• **alert**—Allow the user to access the web site, but add an alert to the URL log.<br>• **block**—Block access to the web site.<br>• **continue**—Allow the user to access the blocked page by clicking **Continue** on the block page.<br>• **override**—Allow the user to access the blocked page after entering a password. The password and other override settings are specified in the URL Admin Override area of the **Settings** page. Refer to Table 1 in the "Defining Management Settings" on page 30. |

**Table 90. URL Filtering Profile Settings (Continued)**

| Field | Description |
|---|---|
| Allow List | Enter the IP addresses or URL path names of the web sites that you want to allow or generate alerts on. Enter each URL one per line.<br><br>**IMPORTANT:** You must omit the "http and https" portion of the URLs when adding web sites to the list.<br>Entries in the allow list are an exact match and are case-insensitive. For example, "www.paloaltonetworks.com" is different from "paloaltonetworks.com". If you want to allow the entire domain, you should include both "*.paloaltonetworks.com" and "paloaltonetworks.com".<br>Examples:<br>• www.paloaltonetworks.com<br>• 198.133.219.25/en/US<br>Block and allow lists support wildcard patterns. The following characters are considered separators:<br>.<br>/<br>?<br>&<br>=<br>;<br>+<br>Every substring that is separated by the characters listed above is considered a token. A token can be any number of ASCII characters that does not contain any separator character or *. For example, the following patterns are valid:<br>*.yahoo.com (Tokens are: "*", "yahoo" and "com")<br>www.*.com (Tokens are: "www", "*" and "com")<br>www.yahoo.com/search=* (Tokens are: "www", "yahoo", "com", "search", "*")<br>The following patterns are invalid because the character "*" is not the only character in the token.<br>ww*.yahoo.com<br>www.y*.com<br>This list takes precedence over the selected web site categories. |
| Category/Action | For each category, select the action to take when a web site of that category is accessed.<br>• **alert**—Allow the user to access the web site, but add an alert to the URL log.<br>• **allow**—Allow the user to access the web site.<br>• **block**—Block access to the web site.<br>• **continue**—Allow the user to access the blocked page by clicking **Continue** on the block page.<br>• **override**—Allow the user to access the blocked page after entering a password. The password and other override settings are specified in the URL Admin Override area of the **Settings** page. Refer to Table 1 in the "Defining Management Settings" on page 30. |
| Check URL Category | Click to access the web site where you can enter a URL or IP address to view categorization information. |

# File Blocking Profiles

▶ *Objects > Security Profiles > File Blocking*

A security policy can include specification of a file blocking profile that blocks selected file types from being uploaded and/or downloaded, or generates an alert when the specified file types are detected. Table 92 lists the supported file formats at the time of this publication. However, because new file type support can be added in a content update, for the most up-to-date list, click **Add** in the **File Types** field of the File Blocking Profile dialog.

To apply file blocking profiles to security policies, refer to "Security Policies" on page 187.

**Table 91. File Blocking Profile Settings**

| Field | Description |
|---|---|
| Name | Enter a profile name (up to 31 characters). This name appears in the list of file blocking profiles when defining security policies. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Description | Enter a description for the profile (up to 255 characters). |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow the profile to be shared by all virtual systems. |
| Rules | Define one or more rules to specify the action taken (if any) for the selected file types. To add a rule, specify the following and click **Add**:<br>• **Name**—Enter a rule name (up to 31 characters).<br>• **Applications**—Select the applications the rule applies to or select **any**.<br>• **File Types**—Select the file types for which you want to block or generate alerts.<br>• **Direction**—Select the direction of the file transfer (Upload, Download, or Both).<br>• **Action**—Select the action taken when the selected file types are detected:<br>– **alert**—An entry is added to the threat log.<br>– **block**—The file is blocked.<br>– **continue**—A message to the user indicates that a download has been requested and asks the user to confirm whether to continue. The purpose is to warn the user of a possible unknown download (also known as a drive-by-download) and to give the user the option of continuing or stopping the download.<br>***Note:*** *When you create a file blocking profile with the action* ***continue*** *or* ***continue-and-forward*** *(used for WildFire forwarding), you can only choose the application* ***web-browsing****. If you choose any other application, traffic that matches the security policy will not flow through the firewall due to the fact that the users will not be prompted with a continue page.*<br>– **forward**—The file is automatically sent to WildFire.<br>– **continue-and-forward**—A continue page is presented, and the file is sent to WildFire (combines the **continue** and **forward** actions). |

**Table 92. Supported File Formats for File Blocking**

| Field | Description |
|---|---|
| apk | Android application package file |
| avi | Video file based on Microsoft AVI (RIFF) file format |
| avi-divx | AVI video file encoded with the DivX codec |
| avi-xvid | AVI video file encoded with the XviD codec |
| bat | MS DOS Batch file |
| bmp-upload | Bitmap image file (upload only) |
| cab | Microsoft Windows Cabinet archive file |
| cdr | Corel Draw file |
| class | Java bytecode file |
| cmd | Microsoft command file |
| dll | Microsoft Windows Dynamic Link Library |
| doc | Microsoft Office Document |
| docx | Microsoft Office 2007 Document |
| dpx | Digital Picture Exchange file |
| dsn | Database Source Name file |
| dwf | Autodesk Design Web Format file |
| dwg | Autodesk AutoCAD file |
| edif | Electronic Design Interchange Format file |
| encrypted-doc | Encrypted Microsoft Office Document |
| encrypted-docx | Encrypted Microsoft Office 2007 Document |
| encrypted-office2007 | Encrypted Microsoft Office 2007 Fil |
| encrypted-pdf | Encrypted Adobe PDF Document |
| encrypted-ppt | Encrypted Microsoft Office PowerPoint |
| encrypted-pptx | Encrypted Microsoft Office 2007 PowerPoint |
| encrypted-rar | Encrypted rar file |
| encrypted-xls | Encrypted Microsoft Office Excel |
| encrypted-xlsx | Encrypted Microsoft Office 2007 Excel |
| encrypted-zip | Encrypted zip file |
| exe | Microsoft Windows Executable |
| flv | Adobe Flash Video file |
| gds | Graphics Data System file |
| gif-upload | GIF image file (upload only) |
| gzip | Files compressed with gzip utility |
| hta | HTML Application file |
| iso | Disc Image file based on ISO-9660 standard |

**Table 92. Supported File Formats for File Blocking (Continued)**

| Field | Description |
|---|---|
| iwork-keynote | Apple iWork Keynote documents |
| iwork-numbers | Apple iWork Numbers documents |
| iwork-pages | Apple iWork Pages documents |
| jar | Java ARchive |
| jpeg-upload | JPG/JPEG image file (upload only) |
| lnk | Microsoft Windows file shortcut |
| lzh | File compressed with lha/lzh utility/algorithm |
| mdb | Microsoft Access Database file |
| mdi | Microsoft Document Imaging file |
| mkv | Matroska Video file |
| mov | Apple Quicktime Movie file |
| mp3 | MP3 audio file |
| mp4 | MP4 audio file |
| mpeg | Movie file using MPEG-1 or MPEG-2 compression |
| msi | Microsoft Windows Installer package file |
| msoffice | Microsoft Office File (doc, xls, ppt, pub, pst) |
| ocx | Microsoft ActiveX file |
| pdf | Adobe Portable Document file |
| PE | Microsoft Windows Portable Executable (exe, dll, com, scr, ocx, cpl, sys, drv, tlb) |
| pgp | Security key or digital signature encrypted with PGP software |
| pif | Windows Program Information File containing executable instructions |
| pl | Perl Script file |
| png-upload | PNG image file (upload only) |
| ppt | Microsoft Office PowerPoint Presentation |
| pptx | Microsoft Office 2007 PowerPoint Presentation |
| psd | Adobe Photoshop Document |
| rar | Compressed file created with winrar |
| reg | Windows Registry file |
| rm | RealNetworks Real Media file |
| rtf | Windows Rich Text Format document file |
| sh | Unix Shell Script file |
| stp | STandard for the Exchange of Product model data 3D graphic file |
| tar | Unix tar archive file |
| tdb | Tanner Database (www.tannereda.com) |
| tif | Windows Tagged Image file |

**Table 92. Supported File Formats for File Blocking (Continued)**

| Field | Description |
|---|---|
| torrent | BitTorrent file |
| wmf | Windows Metafile to store vector images |
| wmv | Windows Media Video file |
| wri | Windows Write document file |
| wsf | Windows Script file |
| xls | Microsoft Office Excel |
| xlsx | Microsoft Office 2007 Excel |
| zcompressed | Compressed Z file in Unix, decompressed with uncompress |
| zip | Winzip/pkzip file |

# Data Filtering Profiles

▶ *Objects > Security Profiles > Data Filtering*

A security policy can include specification of a data filtering profile to help identify sensitive information such as credit card or social security numbers and prevent the sensitive information from leaving the area protected by the firewall.

To apply data filtering profiles to security policies, refer to "Security Policies" on page 187.

**Table 93. Data Filtering Profile Settings**

| Field | Description |
|---|---|
| Name | Enter a profile name (up to 31 characters). This name appears in the list of log forwarding profiles when defining security policies. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Description | Enter a description for the profile (up to 255 characters). |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow the profile to be shared by all virtual systems. |
| Data Capture | Select the check box to automatically collect the data that is blocked by the filter. |

***Note:*** *Specify a password for Manage Data Protection on the* ***Settings*** *page to view your captured data. Refer to "Defining Management Settings" on page 30.*

To add a data pattern, click **Add** and specify the following information.

**Table 94. Data Pattern Settings**

| Field | Description |
|---|---|
| Data Pattern | Choose an existing data pattern from the Data Pattern drop-down list, or configure a new pattern by choosing **Data Pattern** from the list and specifying the following information:<br>• **Name**—Configure a name for the data pattern.<br>• **Description**—Configure a description for the data pattern.<br>• **Shared**—Select this option if the data pattern object will be shared across multiple virtual systems.<br>• **Weight**—Specify unit values for the specified patterns to use in calculating thresholds. For instance, if you designate a weight of 5 for SSN#, every instance of a SSN pattern will increment the threshold by 5. In other words, the detection of ten SSN patterns will result in 10 x 5 (weight) = 50.<br>– **CC#**—Specify a weight for the credit card field (range 0-255).<br>– **SSN#**—Specify a weight for the social security number field, where the field includes dashes, such as 123-45-6789 (range 0-255, 255 is highest weight).<br>– **SSN# (without dash)**—Specify a weight for the social security number field, where the entry is made without dashes, such as 123456789 (range 0-255, 255 is highest weight).<br>• **Custom Patterns**—To match a custom data pattern for the traffic that is subject to this profile, create a custom data pattern by clicking **Add** and specifying the pattern name, regular expression (regex) to match, and weight (0-255, 255 is highest weight). You can add multiple match expressions to the same data pattern profile. |
| Applications | Specify the applications to include in the filtering rule:<br>• Choose **any** to apply the filter to all of the listed applications. This selection does not block all possible applications, just the listed ones.<br>• Click **Add** to specify individual applications. |
| File Types | Specify the file types to include in the filtering rule:<br>• Choose **any** to apply the filter to all of the listed file types. This selection does not block all possible file types, just the listed ones.<br>• Click **Add** to specify individual file types. |
| Direction | Specify whether to apply the filter in the upload direction, download direction, or both. |
| Alert Threshold | Specify the value that will trigger an alert. For example, if you have a threshold of 100 with a SSN weight of 5, the rule will need to detect at least 20 SSN patterns before the rule will be triggered (20 instances x 5 weight = 100). |
| Block Threshold | Specify the value that will trigger a block. For example, if you have a threshold of 100 with a SSN weight of 5, the rule will need to detect at least 20 SSN patterns before the rule will be triggered (20 instances x 5 weight = 100). |

# DoS Profiles

▶ *Objects > Security Profiles > DoS Protection*

A DoS protection policy can include specification of a DoS profile to protect against DoS attacks and take protective action in response to rule matches. The DoS profile specifies the types of actions and the matching criteria.

To apply DoS profiles to DoS policies, refer to "DoS Protection Policies" on page 209.

**Table 95. DoS Profile Settings**

| Field | Description |
|---|---|
| Name | Enter a profile name (up to 31 characters). This name appears in the list of log forwarding profiles when defining security policies. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow the profile to be shared by all virtual systems. |
| Description | Enter a description of the profile (up to 255 characters). |
| Type | Specify one of the following profile types:<br>• **aggregate**—Apply the DoS thresholds configured in the profile to all packets that match the rule criteria on which this profile is applied. For example, an aggregate rule with a SYN flood threshold of 10000 packets per second (pps) counts all packets that hit that particular DoS rule.<br>• **classified**—Apply the DoS thresholds configured in the profile to all packets satisfying the classification criterion (source IP, destination IP or source-and-destination IP). |
| **Flood Protection Tab** | |
| Syn Flood subtab<br>UDP Flood subtab<br>ICMP Flood subtab<br>Other subtab | Select the check box to enable SYN flood protection, and specify the following settings:<br>• **Choice**—(SYN Flood only) Choose from the following options:<br>– **Random early drop**—Drop packets randomly before the overall DoS limit is reached.<br>– **SYN cookies**—Use SYN cookies to generate acknowledgments so that it is not necessary to drop connections in the presence of a SYN flood attack.<br>• **Alarm Rate**—Specify the rate (pps) at which a DoS alarm is generated (range 0-2000000 pps, default 10000 pps).<br>• **Activate Rate**—Specify the rate (pps) at which a DoS response is activated (range 0-2000000 pps, default 10000 pps).<br>• **Maximal Rate**—Specify the rate at which packets will be dropped or blocked.<br>• **Block Duration**—Specify the length of time (seconds) during which the offending packets will be denied. Packets arriving during the block duration do not count towards triggered alerts.<br>***Note:*** *When defining packets per second (pps) thresholds limits for zone protection profiles, the threshold is based on the packets per second that do not match a previously established session.* |

**Table 95. DoS Profile Settings (Continued)**

| Field | Description |
|---|---|
| **Resources Protection Tab** | |
| Sessions | Select the check box to enable resources protection. |
| Max Concurrent Limit | Specify the maximum number of concurrent sessions. If the DoS profile type is aggregate, this limit applies to the entire traffic hitting the DoS rule on which the DoS profile is applied. If the DoS profile type is classified, this limit applies to the entire traffic on a classified basis (source IP, destination IP or source-and-destination IP) hitting the DoS rule on which the DoS profile is applied. |

# Other Policy Objects

Policy objects are the elements that enable you to construct, schedule, and search for policies. The following element types are supported:

- Addresses and address groups to determine the scope of the policy. Refer to "Addresses and Address Groups" in the next section.
- Applications and application groups that allow you to specify how software applications are treated in policies. Refer to "Applications and Application Groups" on page 231.
- Application filters that allow you to simplify searches. Refer to "Application Filters" on page 238.
- Services and service groups to limit the port numbers. Refer to "Services" on page 239.
- Data patterns to define categories of sensitive information for data filtering policies. Refer to "Data Patterns" on page 240.
- Custom URL categories that contain your own lists of URLs to include as a group in URL filtering profiles. Refer to "Custom URL Categories" on page 242.
- Spyware and vulnerability threats to allow for detailed threat responses. Refer to "Security Profile Groups" on page 246.
- Log forwarding to specify log settings. Refer to "Log Forwarding" on page 247.
- Schedules to specify when policies are active. Refer to "Schedules" on page 250.

# Addresses and Address Groups

To define security policies for specific source or destination addresses, you must first define the addresses and address ranges. Addresses requiring the same security settings can be combined into address groups that you can refer to as a unit.

## Defining Address Ranges

▶ *Objects > Addresses*

To define security policies for specific source or destination addresses, you must first define the addresses and address ranges. Addresses requiring the same security settings can be combined into address groups to simplify policy creation (refer to "Defining Address Groups" on page 230).

**Table 96. New Address Settings**

| Field | Description |
|---|---|
| Name | Enter a name that describes the addresses to be defined (up to 63 characters). This name appears in the address list when defining security policies. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow use by all virtual systems. |
| Description | Enter a description for the object (up to 255 characters). |
| Type | Specify an IPv4 or IPv6 address or address range, FQDN, or Dynamic.<br>**IP Netmask:**<br>Enter the IPv4 or IPv6 address or IP address range using the following notation:<br>*ip_address/mask* or *ip_address*<br>where the *mask* is the number of significant binary digits used for the network portion of the address.<br>Example:<br>"192.168.80.150/32" indicates one address, and "192.168.80.0/24" indicates all addresses from 192.168.80.0 through 192.168.80.255.<br>Example:<br>"2001:db8:123:1::1" or "2001:db8:123:1::/64"<br>**IP Range:**<br>To specify an address range, select **IP Range**, and enter a range of addresses. The format is:<br>*ip_address–ip_address*<br>where each address can be IPv4 or IPv6.<br>Example:<br>"2001:db8:123:1::1 - 2001:db8:123:1::22" |

**Table 96. New Address Settings (Continued)**

| Field | Description |
|---|---|
| Type (continued) | **FQDN:**<br>To specify an address using the FQDN, select **FQDN** and enter the domain name.<br>The FQDN initially resolves at commit time. Entries are subsequently refreshed when the firewall performs a check every 30 minutes; all changes in the IP address for the entries are picked up at the refresh cycle.<br>The FQDN is resolved by the system DNS server or a DNS proxy object, if a proxy is configured. For information about DNS proxy, refer to "DNS Proxy" on page 173.<br>**Dynamic:**<br>Specify a name, description, and an identifier that will be used by the XML API to feed in addresses. The identifier can be any string, must be unique and is not limited to a UUID standard. Once you have the name and identifier specified, you will use the "name" of the object in your policies and the identifier (the field located to the right of **"Type:** Dynamic" is used to map the unique IP address to an address object in the XMP API script.<br>  <br>This dynamic address object feature is useful in environments where host IP addresses change frequently; like in virtual environments where hosts are often added and removed and where failovers may occur requiring a change in IP address. By using a name for the dynamic address object for policy matching instead of static IP addresses or networks, the addresses can be dynamically updated without modifying the firewall configuration.<br>Each Dynamic Address Object can contain up to 256 IP addresses. |

## Defining Address Groups

▶ *Objects > Address Groups*

To simplify the creation of security policies, addresses requiring the same security settings can be combined into address groups.

**Table 97. Address Group**

| Field | Description |
|---|---|
| Name | Enter a name that describes the address group (up to 63 characters). This name appears in the address list when defining security policies. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow use by all virtual systems. |
| Addresses | Click Add and select addresses and/or other address groups to be included in this group. |

## Defining Regions

▶ *Objects > Regions*

The firewall supports creation of policy rules that apply to specified countries or other regions. The region is available as an option when specifying source and destination for security policies, decryption policies, and DoS policies. You can choose from a standard list of countries or use the region settings described in this section to define custom regions to include as options for security policy rules.

**Table 98. New Address Settings**

| Field | Description |
|---|---|
| Name | Enter a name that describes the region (up to 31 characters). This name appears in the address list when defining security policies. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Geo Location | To specify latitude and longitude, select the check box and values (*xxx.xxxxxx* format). This information is used in the traffic and threat maps for App-Scope. Refer to "Using App-Scope" on page 256. |
| Addresses | Specify an IP address, range of IP addresses, or subnet to identify the region, using any of the following formats:<br>*x.x.x.x*<br>*x.x.x.x-y.y.y.y*<br>*x.x.x.x/n* |

# Applications and Application Groups

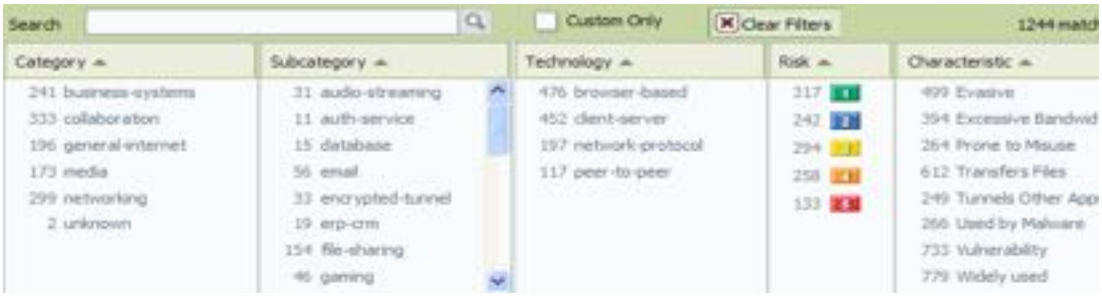
▶ *Objects > Applications*

The **Applications** page lists various attributes of each application definition, such as the application's relative security risk (1 to 5). The risk value is based on criteria such as whether the application can share files, is prone to misuse, or tries to evade firewalls. Higher values indicate higher risk.

The top application browser area of the page lists the attributes that you can use to filter the display. The number to the left of each entry represents the total number of applications with that attribute.

You can perform any of the following functions on this page:

- To apply application filters, click an item that you want to use as a basis for filtering. For example, to restrict the list to the Networking category, click **Networking** and the list will only show networking applications.



- To filter on additional columns, select an entry in the other columns. The filtering is successive: first category filters are applied, then subcategory filters, then technology filters, then risk, and finally characteristic filters.

  For example, the next figure shows the result of applying a category, subcategory, and risk filter. In applying the first two filters, the **Technology** column is automatically restricted to the technologies that are consistent with the selected category and sub category, even though a technology filter has not been explicitly applied.

  Each time a filter is applied, the list of applications in the lower part of the page is automatically updated, as shown in the following figure. Any saved filters can be viewed in **Objects > Application Filters**.

- To search for a specific application, enter the application name or description in the **Search** field, and press **Enter**. The application is listed, and the filter columns are updated to show statistics for the applications that matched the search.

  A search will match partial strings. When you define security policies, you can write rules that apply to all applications that match a saved filter. Such rules are dynamically updated when a new application is added through a content update that matches the filter.

- Click an application name to view additional details about the application, as described in the following table. You can also customize risk and timeout values, as described in the following table.

**Table 99. Application Details**

| Item | Description |
|---|---|
| Name | Name of the application. |
| Description | Description of the application (up to 255 characters). |
| Additional Information | Links to web sources (Wikipedia, Google, and Yahoo!) that contain additional information about the application. |
| Standard Ports | Ports that the application uses to communicate with the network. |
| Capable of File Transfer | Indication of whether the application is able to transfer files. |
| Used by Malware | Indication of whether the application is used by malware. |
| Excessive Bandwidth Use | Indication of whether the application uses too much bandwidth so that network performance may be compromise. |
| Evasive | Indication of whether the application attempts to evade firewalls. |
| Widely used | Indication of whether the effects of the application are wide-ranging. |
| Has Known Vulnerabilities | Indication of whether the application has any currently known vulnerabilities. |
| Tunnels Other Applications | Indication of whether the application can carry other applications within the messages that it sends. |
| Depends on Applications | List of other applications that are required for this application to run. |
| Category | Application category. |
| Subcategory | Application sub category. |
| Technology | Application technology. |
| Risk | Assigned risk of the application.<br>To customize this setting, click the **Customize** link, enter a value (1-5), and click **OK**. |
| Prone to Misuse | Indication of whether the application tends to attract misuse. |
| Session Timeout | Period of time (seconds) required for the application to timeout due to inactivity (1-604800 seconds). This timeout is for protocols other than TCP or UDP. For TCP and UDP, refer to the next rows in this table.<br>To customize this setting, click the **Customize** link, enter a value (seconds), and click **OK**. |

**Table 99. Application Details (Continued)**

| Item | Description |
|---|---|
| TCP Timeout (seconds) | Timeout for terminating a TCP application flow (1-604800 seconds).<br>To customize this setting, click the **Customize** link, enter a value (seconds), and click **OK**. |
| UDP Timeout (seconds): | Timeout for terminating a UDP application flow (1-604800 seconds).<br>To customize this setting, click the **Customize** link, enter a value (seconds), and click **OK**. |

When the firewall is not able to identify an application using the application ID, the traffic is classified as unknown: unknown-tcp or unknown-udp. This behavior applies to all unknown applications except those that fully emulate HTTP. For more information, refer to "Identifying Unknown Applications and Taking Action" on page 276.

You can create new definitions for unknown applications and then define security policies for the new application definitions. In addition, applications that require the same security settings can be combined into application groups to simplify the creation of security policies.

## Defining Applications

▶ *Objects > Applications*

Use the **Applications** page to add new applications for the firewall to evaluate when applying policies.

**Table 100. New Application Settings**

| Field | Description |
|---|---|
| **Configuration Tab** | |
| Name | Enter the application name (up to 31 characters). This name appears in the applications list when defining security policies. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, periods, hyphens, and underscores. The first character must be a letter. |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow the application to be shared by all virtual systems. |
| Description | Enter a description of the application for general reference (up to 255 characters). |
| Category | Select the application category, such as email or database. For a description of each category, refer to "Application Categories and Subcategories" on page 437. The category is used to generate the Top Ten Application Categories chart and is available for filtering (refer to "Using the Application Command Center" on page 253). |
| Subcategory | Select the application subcategory, such as email or database. For a description of each sub category, refer to "Application Categories and Subcategories" on page 437. The sub category is used to generate the Top Ten Application Categories chart and is available for filtering (refer to "Using the Application Command Center" on page 253). |
| Technology | Select the technology for the application. For a description of each technology, refer to "Application Technologies" on page 439. |

**Table 100. New Application Settings (Continued)**

| Field | Description |
|---|---|
| Parent App | Specify a parent application for this application. This setting applies when a session matches both the parent and the custom applications; however, the custom application is reported because it is more specific. |
| Risk | Select the risk level associated with this application (1=lowest to 5=highest). |
| Characteristics | Select the application characteristics that may place the application at risk. For a description of each characteristic, refer to "Application Characteristics" on page 439. |
| **Advanced Tab** | |
| Port | If the protocol used by the application is TCP and/or UDP, select **Port** and enter one or more combinations of the protocol and port number (one entry per line). The general format is:<br><*protocol*>/<*port*><br>where the <*port*> is a single port number, or **dynamic** for dynamic port assignment.<br>Examples: TCP/dynamic or UDP/32.<br>This setting applies when using **app-default** in the **Service** column of a security rule. |
| IP Protocol | To specify an IP protocol other than TCP or UDP, select **IP Protocol**, and enter the protocol number (1 to 255). |
| ICMP Type | To specify an Internet Control Message Protocol version 4 (ICMP) type, select **ICMP Type** and enter the type number (range 0-255). |
| ICMP6 Type | To specify an Internet Control Message Protocol version 6 (ICMPv6) type, select **ICMP6 Type** and enter the type number (range 0-255). |
| None | To specify signatures independent of protocol, select **None**. |
| Timeout | Enter the number of seconds before an idle application flow is terminated (range 0-604800 seconds). A zero indicates that the default timeout of the application will be used. This value is used for protocols other than TCP and UDP in all cases and for TCP and UDP timeouts when the TCP timeout and UDP timeout are not specified. |
| TCP Timeout | Enter the number of seconds before an idle TCP application flow is terminated (range 0-604800 seconds). A zero indicates that the default timeout of the application will be used. |
| UDP Timeout | Enter the number of seconds before an idle UDP application flow is terminated (range 0-604800 seconds). A zero indicates that the default timeout of the application will be used. |
| Scanning | Select check boxes for the scanning types that you want to allow, based on security profiles (file types, data patterns, and viruses). |

**Table 100. New Application Settings (Continued)**

| Field | Description |
|---|---|
| **Signature Tab** | |
| Signatures | Click **Add** to add a new signature, and specify the following information:<br>• **Signature Name**—Enter a name to identify the signature.<br>• **Comment**—Enter an optional description.<br>• **Scope**—Select whether to apply this signature only to the current transaction or to the full user session.<br>• **Ordered Condition Match**—Select if the order in which signature conditions are defined is important.<br>Specify conditions to define signatures:<br>• Add a condition by clicking **Add AND Condition** or **Add OR Condition**. To add a condition within a group, select the group and then click **Add Condition**.<br>• Select an operator from **Pattern Match** and **Equal To**. When choosing a pattern match operator, specify the following:<br>– **Context**—Select from the available contexts.<br>– **Pattern**—Specify a regular expression. See Table 104 for pattern rules for regular expressions.<br>– **Qualifier and Value**—Optionally, add qualifier/value pairs.<br>• When choosing an equal to operator, specify the following,<br>– **Context**—Select from unknown requests and responses for TCP or UDP.<br>– **Position**—Select between the first four or second four bytes in the payload.<br>– **Mask**—Specify a 4-byte hex value, for example, 0xffffff00.<br>– **Value**—Specify a 4-byte hex value, for example, 0xaabbccdd.<br>• To move a condition within a group, select the condition and click the **Move Up** or **Move Down** arrow. To move a group, select the group and click the **Move Up** or **Move Down** arrow. You cannot move conditions from one group to another. |

***Note:*** *It is not required to specify signatures for the application if the application is used only for application override rules.*

To import an application, click **Import**. Browse to select the file, and select the target virtual system from the **Destination** drop-down list.

To export the application, select the check box for the application and click **Export**. Follow the prompts to save the file.

## Custom Applications with Signatures

You can define custom applications with signatures. This section provides examples of how this can be done. Refer to the *PAN-OS Command Line Interface Reference Guide* for information on the show application command.

### Example - Detect web traffic to a specified site

This example shows an application that detects web traffic going to *www.specifiedsite.com*.

Requests to the web site are of the following form:

```
GET /001/guest/
viewprofile.act?fa=25&tg=M&mg=F&searchType=zipcode&type=QUICK&pict=true&cont
ext=adrr&zip=94024&ta=34&sb=&item=0&pn=0 HTTP/1.1

Host: www.specifiedsite.com

User-Agent: Mozilla/5.0 (Windows; U; Windows NT 5.1; en-US; rv:1.9.0.7)
Gecko/2009021910 Firefox/3.0.7 Accept: text/html,application/
xhtml+xml,application/xml;q=0.9,*/*;q=0.8 Accept-Language: en-us,en;q=0.5
Accept-Encoding: gzip,deflate Accept-Charset: ISO-8859-1,utf-8;q=0.7,*;q=0.7
Keep-Alive: 300 Connection: keep-alive Referer: http://www.specifiedsite.com/
001/guest/
search.act?type=QUICK&pict=true&sb=&fa=25&ta=34&mg=F&tg=M&searchType=zipcode
&zip=94024&context=adrr&context=adrr Cookie:
JSESSIONID=A41B41A19B7533589D6E88190B7F0B3D.001; specifiedsite.com/
jumpcookie=445461346*google.com/search?q=lava+life&; locale=en_US;
campaign=1; imageNum=2; cfTag_LogSid=9327803497943a1237780204643;
__utma=69052556.1949878616336713500.1238193797.1238193797.1238193797.1;
__utmb=69052556.2.10.1238193797; __utmc=69052556;
__utmz=69052556.1238193797.1.1.utmcsr=(direct)|utmccn=(direct)|utmcmd=(none)
; __utmv=69052556.gender%3Df; launch=1
```

The following signature can identify *specifiedsite* traffic if the host field is *www.specifiedsite.com*.

```
username@hostname# show application specifiedsite

specifiedsite {
  category collaboration;
  subcategory social-networking;
  technology browser-based;
  decoder http;
  signature {
    s1 {
      and-condition {
        a1 {
          or-condition {
            o1 {
              context http-req-host-header;
              pattern www\.specifiedsite\.com;
            }
          }
        }
      }
    }
  }
}
```

### Example - Detect a post to a specified blog

This example shows an application that detects blog posting activity on *www.specifiedblog.com*. In this example, it is not necessary to detect when somebody tries to read the blog, only to detect when an item is getting posted.

The post traffic request includes the following:

```
POST /wp-admin/post.php HTTP/1.1 Host: panqa100.specifiedblog.com
User-Agent: Mozilla/5.0 (Windows; U; Windows NT 5.1; en-US; rv:1.9.0.7)
```

```
Gecko/2009021910 Firefox/3.0.7 Accept: text/html,application/
xhtml+xml,application/xml;q=0.9,*/*;q=0.8 Accept-Language: en-us,en;q=0.5
Accept-Encoding: gzip,deflate Accept-Charset: ISO-8859-1,utf-8;q=0.7,*;q=0.7
Keep-Alive: 300 Connection: keep-alive Referer: http://
panqa100.specifiedblog.com/wp-admin/post.php?action=edit&post=1

Content-Type: application/x-www-form-urlencoded Content-Length: 462
user_ID=1&action=editpost&post_author=1&post_ID=1&post_title=Hello+world%21&
post_category%5B%5D=1&advanced_view=1&comment_status=open&post_password=&exc
erpt=&content=Hello+world.%3Cbr+%2F%3E&use_instant_preview=1&post_pingback=1
&prev_status=publish&submit=Save&referredby=http%3A%2F%2Fpanqa100.specifiedb
log.com%2Fwp-admin%2F&post_status=publish&trackback_url=&post_name=hello-
world&post_author_override=1&mm=3&jj=27&aa=2009&hh=23&mn=14&ss=42&metakeyinp
ut=&metavalue=HTTP/1.1
```

The host field includes the pattern *specifiedblog.com*. However, if a signature is written with that value in the host, it will match all traffic going to *specifiedblog*.com, including posting and viewing traffic. Therefore, it is necessary to look for more patterns.

One way to do this is to look for *post_title* and *post-author* patterns in the parameters of the post. The resulting signature detects postings to the web site:

```
username@hostname# show application specifiedblog_blog_posting
specifiedblog_blog_posting {
  category collaboration;
  subcategory web-posting;
  technology browser-based;
  decoder http;
  signature {
    s1 {
      and-condition {
        a1 {
          or-condition {
            o1 {
              context http-req-host-header;
              pattern specifiedblog\.com;
              method POST;
            }
          }
        }
        a2 {
          or-condition {
            o2 {
              context http-req-params;
              pattern post_title;
              method POST;
            }
          }
        }
        a3 {
          or-condition {
            o3 {
              context http-req-params;
              pattern post_author;
              method POST;
            }
          }
        }
      }
    }
  }
}
```

## Defining Application Groups

▶ *Objects > Application Groups*

To simplify the creation of security policies, applications requiring the same security settings can be combined into application groups. To define new applications, refer to "Defining Applications" on page 233.

**Table 101. New Application Group**

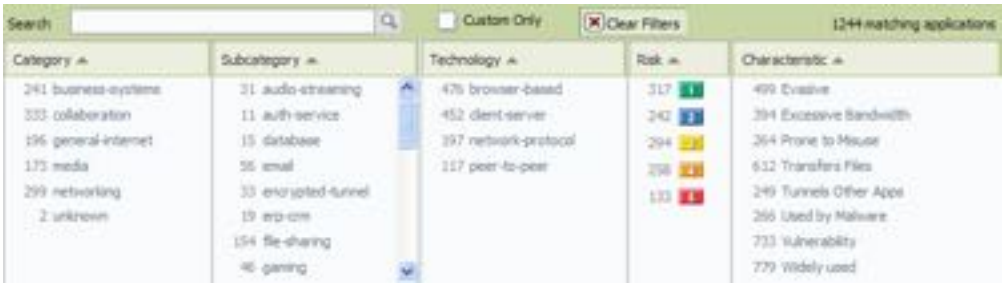
| Field | Description |
|---|---|
| Name | Enter a name that describes the application group (up to 31 characters). This name appears in the application list when defining security policies. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Applications | Click **Add** and select applications, application filters, and/or other application groups to be included in this group. |

# Application Filters

▶ *Objects > Application Filters*

You can define application filters to simplify repeated searches. To define application filters to simplify repeated searches, click **Add** and enter a name for the filter.

In the upper area of the window, click an item that you want to use as a basis for filtering. For example, to restrict the list to the Networking category, click **networking**.



To filter on additional columns, select an entry in the columns to display check boxes. The filtering is successive: first category filters are applied, then sub category filters, then technology filters, then risk, filters, and finally characteristic filters.

For example, the next figure shows the result of choosing a category, sub category, and risk filter. In applying the first two filters, the **Technology** column is automatically restricted to the technologies that are consistent with the selected category and sub category, even though a technology filter has not been explicitly applied.

As you select options, the list of applications in the lower part of the page is automatically updated, as shown in the figure.

# Services

▶ *Objects > Services*

When you define security policies for specific applications, you can select one or more services to limit the port numbers the applications can use. The default service is **any**, which allows all TCP and UDP ports.

The HTTP and HTTPS services are predefined, but you can add additional service definitions. Services that are often assigned together can be combined into service groups to simplify the creation of security policies (refer to "Service Groups" on page 240).

**Table 102. Service Settings**

| Field | Description |
|---|---|
| Name | Enter the service name (up to 63 characters). This name appears in the services list when defining security policies. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Description | Enter a description for the service (up to 255 characters). |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow sharing by all virtual systems. |
| Protocol | Select the protocol used by the service (TCP or UDP). |
| Destination Port | Enter the destination port number (0 to 65535) or range of port numbers (port1-port2) used by the service. Multiple ports or ranges must be separated by commas. The destination port is required. |
| Source Port | Enter the source port number (0 to 65535) or range of port numbers (port1-port2) used by the service. Multiple ports or ranges must be separated by commas. The source port is optional. |

# Service Groups

▶ *Objects > Services Groups*

To simplify the creation of security policies, you can combine services that have the same security settings into service groups. To define new services, refer to "Services" on page 239.

**Table 103. Service Group Settings**

| Field | Description |
|---|---|
| Name | Enter the service group name (up to 63 characters). This name appears in the services list when defining security policies. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Service | Click **Add** to add services to the group. Select from the drop-down list, or click the **Service** button at the bottom of the drop-down list, and specify the settings. Refer to "Services" on page 239 for a description of the settings. |

# Data Patterns

Data pattern support allows you to specify categories of sensitive information that you may want to subject to filtering using data filtering security policies. For instructions on configuring data patterns, refer to "Dynamic Block Lists" on page 242.

When adding a new pattern (regular expression), the following general requirements apply:

- The pattern must have string of at least 7 bytes to match. It can contain more than 7 bytes, but not fewer.
- The string match is case-sensitive, as with most regular expression engines. Looking for "confidential" is different than looking for "Confidential" or "CONFIDENTIAL."

The regular expression syntax in PAN-OS is similar to traditional regular expression engines, but every engine is unique. The following table describes the syntax supported in PAN-OS.

**Table 104. Pattern Rules**

| Syntax | Description |
|---|---|
| . | Match any single character. |
| ? | Match the preceding character or expression 0 or 1 time. The general expression MUST be inside a pair of parentheses.<br>Example: (abc)? |
| * | Match the preceding character or expression 0 or more times. The general expression MUST be inside a pair of parentheses.<br>Example: (abc)* |
| + | Match the preceding character or regular expression 1 or more times. The general expression MUST be inside a pair of parentheses.<br>Example: (abc)+ |

**Table 104. Pattern Rules**

| Syntax | Description |
|---|---|
| \| | Equivalent to "or".<br>Example: ((bif)\|(scr)\|(exe)) matches "bif", "scr" or "exe". Note that the alternative substrings must be in parentheses. |
| - | Used to create range expressions.<br>Example: [c-z] matches any character between c and z, inclusive. |
| [ ] | Match any.<br>Example: [abz]: matches any of the characters a, b, or z. |
| ^ | Match any except.<br>Example: [^abz] matches any character except a, b, or z. |
| { } | Min/Max number of bytes.<br>Example: {10-20} matches any string that is between 10 and 20 bytes. This must be directly in front of a fixed string, and only supports "-". |
| \ | To perform a literal match on any one of the special characters above, it MUST be escaped by preceding them with a '\' (backslash). |
| &amp | & is a special character, so to look for the "&" in a string you must use "&amp" instead. |

### Data Patterns Examples

The following are examples of valid custom patterns:

- .*((Confidential)|(CONFIDENTIAL))
  - Looks for the word "Confidential" or "CONFIDENTIAL" anywhere
  - ".*" at the beginning specifies to look anywhere in the stream
  - Does not match "confidential" (all lower case)
- .*((Proprietary &amp Confidential)|(Proprietary and Confidential))
  - Looks for either "Proprietary & Confidential" or "Proprietary and Confidential"
  - More precise than looking for "Confidential"
- .*(Press Release).*((Draft)|(DRAFT)|(draft))
  - Looks for "Press Release" followed by various forms of the word draft, which may indicate that the press release isn't ready to be sent outside the company
- .*(Trinidad)
  - Looks for a project code name, such as "Trinidad"

# Custom URL Categories

▶ *Objects > Custom URL Categories*

The custom URL categories feature allows you to create your own lists of URLs that can be selected in any URL filtering profile. Each custom category can be controlled independently and will have an action associated with it in each URL filtering profile (allow, block, continue, override, or alert).

URL entries can be added individually, or you can import a list of URLs. To do so, create a text file that contains the URLs to include, with one URL per line. Each URL can be in the format "www.example.com," and can contain * as a wildcard, such as "*.example.com." For additional information on wildcards, refer to the description of Block List in Table 90 on page 217.

***Note:*** *URL entries added to custom categories are case insensitive.*

For instructions on setting up URL filtering profiles, refer to "URL Filtering Profiles" on page 217.

**Table 105. Custom URL Categories**

| Field | Description |
|---|---|
| Name | Enter a name to identify the custom URL category (up to 31 characters). This name appears in the category list when defining URL filtering policies. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Description | Enter a description for the URL category (up to 255 characters). |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow the profile to be shared by all virtual systems. |
| Sites | In the Sites area, click **Add** to enter a URL or click **Import** and browse to select the text file that contains the list of URLs. |

# Dynamic Block Lists

▶ *Objects > Dynamic Block Lists*

Use the **Dynamic Block Lists** page to create an address object based on an imported list of IP addresses. The source of the list must be a text file and must be located on a web server. You can set the **Repeat** option to automatically update the list on the device hourly, daily, weekly, or monthly. After creating a dynamic block list object, you can then use the address object in the source and destination fields for security policies. Each imported list can contain up to 5,000 IP addresses (IPv4 and/or IPv6), IP ranges, or subnets.

The list must contain one IP address, range, or subnet per line, for example:

"192.168.80.150/32" indicates one address, and "192.168.80.0/24" indicates all addresses from 192.168.80.0 through 192.168.80.255.

Example:

"2001:db8:123:1::1" or "2001:db8:123:1::/64"

**IP Range:**

To specify an address range, select **IP Range**, and enter a range of addresses. The format is:
*ip_address–ip_address*
where each address can be IPv4 or IPv6.
Example:
"2001:db8:123:1::1 - 2001:db8:123:1::22"

**Table 106 Dynamic Block Lists**

| Field | Description |
|---|---|
| Name | Enter a name to identify the Dynamic Block List (up to 32 characters). This name will appear when selecting the source or destination in a policy. |
| Description | Enter a description for the block list (up to 255 characters). |
| Source | Enter an HTTP or HTTPS URL path that contains the text file. For example, http://1.1.1.1/myfile.txt. |
| Repeat | Specify the frequency in which the list should be imported. You can choose hourly, daily, weekly, or monthly. At the specified interval, the list will be imported into the configuration. A full commit is not needed for this type of update to occur. |
| Test Source URL | Test that the source URL or server path is available. |

# Custom Spyware and Vulnerability Signatures

This section describes the options available to create custom Spyware and Vulnerability signatures that can be used when creating custom vulnerability profiles.

- ***Objects > Custom Signatures > Data Patterns***
- ***Objects > Custom Signatures > Spyware***
- ***Objects > Custom Signatures > Vulnerability***

## Defining Data Patterns

- ***Objects > Custom Signatures > Data Patterns***

Use the **Data Patterns** page to define the categories of sensitive information that you may want to subject to filtering using data filtering security policies. For information on defining data filtering profiles, refer to "Data Filtering Profiles" on page 223.

**Table 107. Data Pattern Settings**

| Field | Description |
|---|---|
| Name | Enter the data pattern name (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Description | Enter a description for the data pattern (up to 255 characters). |

**Table 107. Data Pattern Settings (Continued)**

| Field | Description |
|---|---|
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow the profile to be shared by all virtual systems. |
| Weight | Enter weights for pre-specified pattern types. The weight is a number between 1 and 255. Alert and Block thresholds specified in the Data Filtering Profile are a function of this weight.<br>• **CC#**—Specify a weight for the credit card field (range 0-255).<br>• **SSN#**—Specify a weight for the social security number field, where the field includes dashes, such as 123-45-6789 (range 0-255, 255 is highest weight).<br>• **SSN# (without dash)**—Specify a weight for the social security number field, where the entry is made without dashes, such as 123456789 (range 0-255, 255 is highest weight). |
| Custom Patterns | The pre-defined patterns include credit card number and social security number (with and without dashes).<br>Click **Add** to add a new pattern. Specify a name for the pattern, enter the regular expression that defines the pattern, and enter a weight to assign to the pattern. Add additional patterns as needed. |

## Defining Spyware and Vulnerability Signatures

▶ *Objects > Custom Signatures > Spyware & Vulnerabilities*

The firewall supports the ability to create custom spyware and vulnerability signatures using the firewall threat engine. You can write custom regular expression patterns to identify spyware phone home communication or vulnerability exploits. The resulting spyware and vulnerability patterns become available for use in any custom vulnerability profiles. The firewall looks for the custom-defined patterns in network traffic and takes the specified action for the vulnerability exploit. Support is provided for creation of custom signatures using HTTP, SMTP, IMAP, FTP, POP3, SMB, MSSQL, MSRPC, RTSP, SSH, SSL, Telnet, Unknown-TCP, and Unknown-UDP.

You can optionally include a time attribute when defining custom signatures by specifying a threshold per interval for triggering possible actions in response to an attack. Action is taken only after the threshold is reached.

Use the **Custom Signatures** page to define signatures for vulnerability profiles.

**Table 108. Custom Signatures - Vulnerability and Spyware**

| Field | Description |
|---|---|
| **Configuration Tab** | |
| Threat ID | Enter a numeric identifier for the configuration. For spyware signatures, the range is 15000-18000; for vulnerability signatures the range is 41000-45000. |
| Name | Specify the threat name. |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow the profile to be shared by all virtual systems. |
| Comment | Enter an optional comment. |

**Table 108. Custom Signatures - Vulnerability and Spyware (Continued)**

| Field | Description |
|---|---|
| Severity | Assign a level that indicates the seriousness of the threat. |
| Default Action | Assign the default action to take if the threat conditions are met:<br>• **Alert**—Generate an alert.<br>• **Drop Packets**—Do not allow packets through.<br>• **Reset Both**—Reset the client and server.<br>• **Reset Client**—Reset the client.<br>• **Reset Server**—Reset the server.<br>• **Block IP**—Block traffic for a specified period of time. Choose whether to block traffic for the source only or source and destination, and enter the duration (seconds). |
| Direction | Indicate whether the threat is assessed from the client to server, server to client, or both. |
| Affected System | Indicate whether the threat involves the client, server, either, or both. Applies to vulnerability signatures, but not spyware signatures. |
| CVE | Specify the common vulnerability enumeration (CVE) as an external reference for additional background and analysis. |
| Vendor | Specify the vendor identifier for the vulnerability as an external reference for additional background and analysis. |
| Bugtraq | Specify the bugtraq (similar to CVE) as an external reference for additional background and analysis. |
| Reference | Add any links to additional analysis or background information. The information is shown when a user clicks on the threat from the ACC, logs, or vulnerability profile. |
| **Signatures Tab** | |
| Standard Signature | Select the **Standard** radio button and then click **Add** to add a new signature. Specify the following information:<br>• **Standard**—Enter a name to identify the signature.<br>• **Comment**—Enter an optional description.<br>• **Ordered Condition Match**—Select if the order in which signature conditions are defined is important.<br>• **Scope**—Select whether to apply this signature only to the current transaction or to the full user session.<br>Specify conditions to define signatures:<br>• Add a condition by clicking **Add AND Condition** or **Add OR Condition**. To add a condition within a group, select the group and then click **Add Condition**. Select from the **Method** and **Context** drop-down lists. Specify a regular expression in the **Pattern** field. Add additional patterns as needed.<br>• To move a condition within a group, select the condition and click the **Move Up** or **Move Down** arrow. To move a group, select the group and click the **Move Up** or **Move Down** arrow. You cannot move conditions from one group to another. |

**Table 108. Custom Signatures - Vulnerability and Spyware (Continued)**

| Field | Description |
|---|---|
| Combination Signature | Select the **Combination** radio button. In the area above the subtabs, specify the following information:<br>On the **Combination Signatures** subtab, specify conditions to define signatures:<br>• Add a condition by clicking **Add AND Condition** or **Add OR Condition**. To add a condition within a group, select the group and then click **Add Condition**. Select from the **Method** and **Context** drop-down lists. Specify a regular expression in the **Pattern** field. Add additional patterns as needed.<br>• To move a condition within a group, select the condition and click the **Move Up** or **Move Down** arrow. To move a group, select the group and click the **Move Up** or **Move Down** arrow. You cannot move conditions from one group to another.<br>On the **Time Attribute** subtab, specify the following information:<br>• **Number of Hits**—Specify the threshold that will trigger any policy-based action as a number of hits (1-1000) in a specified number of seconds (1-3600).<br>• **Aggregation Criteria**—Specify whether the hits are tracked by source IP address, destination IP address, or a combination of source and destination IP addresses. |

# Security Profile Groups

▶ *Objects > Security Profile Groups*

The firewall supports the ability to create security profile groups, which specify sets of security profiles that can be treated as a unit and then added to security policies. For example, you can create a "threats" security profile group that includes profiles for antivirus, anti-spyware, and vulnerability and then create a security policy that includes the "threats" profile.

Antivirus, anti-spyware, vulnerability protection, URL filtering, and file blocking profiles that are often assigned together can be combined into profile groups to simplify the creation of security policies.

To define new security profiles, refer to "Defining Security Policies" on page 187.

**Table 109. Security Profile Group Settings**

| Field | Description |
|---|---|
| Name | Enter the profile group name (up to 31 characters). This name appears in the profiles list when defining security policies. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow the profile to be shared by all virtual systems. |

**Table 109. Security Profile Group Settings (Continued)**

| Field | Description |
|---|---|
| Profiles | Select an antivirus, anti-spyware, vulnerability protection, URL filtering, and/or file blocking profile to be included in this group. Data filtering profiles can also be specified in security profile groups. Refer to "Data Filtering Profiles" on page 223. |

# Log Forwarding

▶ *Objects > Log Forwarding*

Each security policy can specify a log forwarding profile that determines whether traffic and threat log entries are logged remotely with Panorama, and/or sent as SNMP traps, syslog messages, or email notifications. By default, only local logging is performed.

Traffic logs record information about each traffic flow, and threat logs record the threats or problems with the network traffic, such as virus or spyware detection. Note that the antivirus, anti-spyware, and vulnerability protection profiles associated with each rule determine which threats are logged (locally or remotely). To apply logging profiles to security policies, refer to "Security Policies" on page 187.

**Table 110. Log Forwarding Profile Settings**

| Field | Description |
|---|---|
| Name | Enter a profile name (up to 31 characters). This name appears in the list of log forwarding profiles when defining security policies. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow sharing by all virtual systems. |
| **Traffic Settings** | |
| Panorama | Select the check box to enable sending traffic log entries to the Panorama centralized management system. To define the Panorama server address, refer to "Defining Management Settings" on page 30. |
| SNMP Trap<br>Email<br>Syslog | Select the SNMP, syslog, and/or email settings that specify additional destinations where the traffic log entries are sent. To define new destinations, refer to:<br>• "Configuring SNMP Trap Destinations" on page 75.<br>• "You can configure a custom log format in a Syslog Server Profile by selecting the Custom Log Format tab in Device > Server Profiles > Syslog. Click the desired log type (Config, System, Threat, Traffic, or HIP Match) and then click the fields you want to see in the logs. The tables that follow shows the meaning of each field for each log type." on page 77<br>• "Configuring Syslog Servers" on page 76 |

**Table 110. Log Forwarding Profile Settings (Continued)**

| Field | Description |
|---|---|
| **Threat Log Settings** | |
| Panorama | Click the check box for each severity level of the threat log entries to be sent to Panorama. The severity levels are:<br>• **Critical**—Very serious attacks detected by the threat security engine.<br>• **High**—Major attacks detected by the threat security engine.<br>• **Medium**—Minor attacks detected by the threat security engine, including URL blocking.<br>• **Low**—Warning-level attacks detected by the threat security engine.<br>• **Informational**—All other events not covered by the other severity levels, including informational attack object matches. |
| SNMP Trap<br>Email<br>Syslog | Under each severity level, select the SNMP, syslog, and/or email settings that specify additional destinations where the threat log entries are sent. |

# Decryption Profiles

▶ *Objects > Decryption Profiles*

Decryption profiles enable you to block and control specific aspects of the SSL forward proxy, SSL inbound inspection, and SSH traffic. After you create a decryption profile, you can then apply that profile to a decryption policy.
You can also control the trusted CAs that your device trusts, for more information, refer to "Default Trusted Certificate Authorities" on page 88.

**Table 111. Decryption Profile Settings**

| Field | Description |
|---|---|
| **SSL Forward Proxy Tab** | |
| Server Certificate Checks | Select options to control server certificates. |
| Block sessions with expired certificates | Terminate the SSL connection if the server certificate is expired. This will prevent a user from being able to accept an expired certificate and continuing with an SSL session. |
| Block sessions with untrusted issuers | Terminate the SSL session if the server certificate issuer is untrusted. |
| Restrict certificate extensions | Limits the certificate extensions used in the dynamic server certificate to key usage and extended key usage.<br>Details—Displays details on the values used for key usage and extended key usage. |
| Unsupported Mode Checks | Select options to control unsupported SSL applications. |
| Block sessions with unsupported version | Terminate sessions if the "client hello" message is not supported by PAN-OS. The SSL versions supported by PAN-OS are: SSLv3, TLS1.0, and TLS1.1. |

**Table 111. Decryption Profile Settings**

| Field | Description |
|---|---|
| Block sessions with unsupported cipher suites | Terminate the session if the cipher suite specified in the SSL handshake if it is not supported by PAN-OS. |
| Block sessions with client authentication | Terminate sessions with client authentication for SSL forward proxy traffic. |
| Failure Checks | Select the action to take if system resources are not available to process decryption. |
| Block sessions if resources not available | Terminate sessions if system resources are not available to process decryption. |
| | ***Note:*** *For unsupported modes and failure modes, the session information is cached for 12 hours, so future sessions between the same hosts and server pair are not decrypted. Use the check boxes to block those sessions instead.* |
| **SSL Inbound Inspection Tab** | |
| Unsupported Mode Checks | Selection options to control sessions if unsupported modes are detected in SSL traffic. |
| Block sessions with unsupported versions | Terminate sessions if the "client hello" message is not supported by PAN-OS. The SSL versions supported by PAN-OS are: SSLv3, TLS1.0, and TLS1.1. |
| Block sessions with unsupported cipher suites | Terminate the session if the cipher suite used is not supported by PAN-OS. |
| Failure Checks | Select the action to take if system resources are not available. |
| Block sessions if resources not available | Terminate sessions if system resources are not available to process decryption. |
| **SSH Tab** | |
| Unsupported Mode Checks | Selection options to control sessions if unsupported modes are detected in SSH traffic. Supported SSH version is SSH version 2. |
| Block sessions with unsupported versions | Terminate sessions if the "client hello" message is not supported by PAN-OS. |
| Block sessions with unsupported algorithms | Terminate sessions if the algorithm specified by the client or server is not supported by PAN-OS. |
| Failure Checks | Select actions to take if SSH application errors occur and if system resources are not available. |

**Table 111. Decryption Profile Settings**

| Field | Description |
|---|---|
| Block sessions on SSH errors | Terminate sessions if SSH errors occur. |
| Block sessions if resources not available | Terminate sessions if system resources are not available to process decryption. |

# Schedules

▶ *Objects > Schedules*

By default, each security policy applies to all dates and times. To limit a security policy to specific times, you can define schedules, and then apply them to the appropriate policies. For each schedule, you can specify a fixed date and time range or a recurring daily or weekly schedule. To apply schedules to security policies, refer to "Security Policies" on page 187.

***Note:*** *When a security policy is invoked by a defined schedule, only new sessions are affected by the applied security policy. Existing sessions are not affected by the scheduled policy.*

**Table 112. Schedule Settings**

| Field | Description |
|---|---|
| Name | Enter a schedule name (up to 31 characters). This name appears in the schedule list when defining security policies. The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Shared | If the device is in Multiple Virtual System Mode, select this check box to allow sharing by all virtual systems. |
| Recurrence | Select the type of schedule (**Daily**, **Weekly**, or **Non-Recurring**). |
| Daily | Click **Add** and specify a start and end time in 24-hour format (HH:MM). |
| Weekly | Click **Add**, select a day of the week, and specify the start and end time in 24-hour format (HH:MM). |
| Non-recurring | Click **Add** and specify a start and end date and time. |

## Chapter 6
# Reports and Logs

This chapter describes how to view the reports and logs provided with the firewall:

- "Using the Dashboard" in the next section
- "Using the Application Command Center" on page 253
- "Using App-Scope" on page 256
- "Viewing the Logs" on page 264
- "Working with Botnet Reports" on page 267
- "Managing PDF Summary Reports" on page 270
- "Managing User Activity Reports" on page 272
- "Managing Report Groups" on page 272
- "Scheduling Reports for Email Delivery" on page 273
- "Viewing Reports" on page 273
- "Generating Custom Reports" on page 274
- "Identifying Unknown Applications and Taking Action" on page 276
- "Taking Packet Captures" on page 278

***Note:*** *Most of the reports in this section support optional selection of a virtual system from the drop-down list at the top of page.*

# Using the Dashboard

▶ *Dashboard*

The **Dashboard** page displays general device information, such as the software version, the operational status of each interface, resource utilization, and up to 10 of the most recent entries in the threat, configuration, and system logs. All of the available charts are displayed by default, but each user can remove and add individual charts, as needed.

Click **Refresh** to update the Dashboard. To change the automatic refresh interval, select an interval from the drop-down list (1 min, 2 mins, 5 mins, or Manual). To add a Widget to the Dashboard, click the Widget drop-down, select a category and then the widget name. To delete a widget, click in the title bar.

Review the following information in each chart.

**Table 113. Dashboard Charts**

| Chart | Description |
|---|---|
| Top Applications | Displays the applications with the most sessions. The block size indicates the relative number of sessions (mouse-over the block to view the number), and the color indicates the security risk—from green (lowest) to red (highest). Click an application to view its application profile. |
| Top High Risk Applications | Similar to Top Applications, except that it displays the highest-risk applications with the most sessions. |
| General Information | Displays the device name, model, PAN-OS software version, the application, threat, and URL filtering definition versions, the current date and time, and the length of time since the last restart. |
| Interface Status | Indicates whether each interface is up (green), down (red), or in an unknown state (gray). |
| Threat Logs | Displays the threat ID, application, and date and time for the last 10 entries in the Threat log. The threat ID is a malware description or URL that violates the URL filtering profile. |
| Config Logs | Displays the administrator user name, client (Web or CLI), and date and time for the last 10 entries in the Configuration log. |
| Data Filtering Logs | Displays the description and date and time for the last 60 minutes in the Data Filtering log. |
| URL Filtering Logs | Displays the description and date and time for the last 60 minutes in the URL Filtering log. |
| System Logs | Displays the description and date and time for the last 10 entries in the System log. Note that a "Config installed" entry indicates configuration changes were committed successfully. |
| System Resources | Displays the Management CPU usage, Data Plane usage, and the Session Count, which displays the number of sessions established through the firewall. |
| Logged In Admins | Displays the source IP address, session type (Web or CLI), and session start time for each administrator who is currently logged in. |
| ACC Risk Factor | Displays the average risk factor (1 to 5) for the network traffic processed over the past week. Higher values indicate higher risk. |

**Table 113. Dashboard Charts (Continued)**

| Chart | Description |
|---|---|
| High Availability | If high availability (HA) is enabled, indicates the HA status of the local and peer device—green (active), yellow (passive), or black (other). For more information about HA, refer to "Enabling HA on the Firewall" on page 101. |
| Locks | Shows configuration locks taken by administrators. |

# Using the Application Command Center

▶ *ACC*

The **Application Command Center (ACC)** page displays the overall risk level for your network traffic, the risk levels and number of threats detected for the most active and highest-risk applications on your network, and the number of threats detected from the busiest application categories and from all applications at each risk level. The ACC can be viewed for the past hour, day, week, month, or any custom-defined time frame.

Risk levels (1=lowest to 5=highest) indicate the application's relative security risk based on criteria such as whether the application can share files, is prone to misuse, or tries to evade firewalls.

To view the Application Command Center:

1. Under the **ACC** tab, change one or more of the following settings at the top of the page, and click **Go**:
   a. Select a virtual system, if virtual systems are defined.
   b. Select a time period from the **Time** drop-down list. The default is Last Hour.
   c. Select a sorting method from the **Sort By** drop-down list. You can sort the charts in descending order by number of sessions, bytes, or threats. The default is by number of sessions.
   d. For the selected sorting method, select the top number of applications and application categories shown in each chart from the **Top** drop-down list.

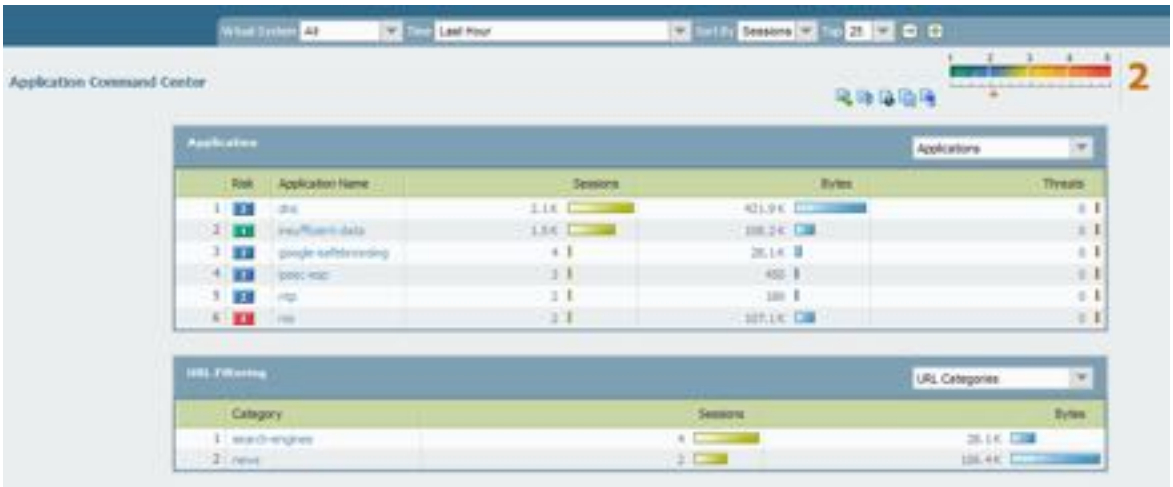


**Figure 22. Application Command Center Page**

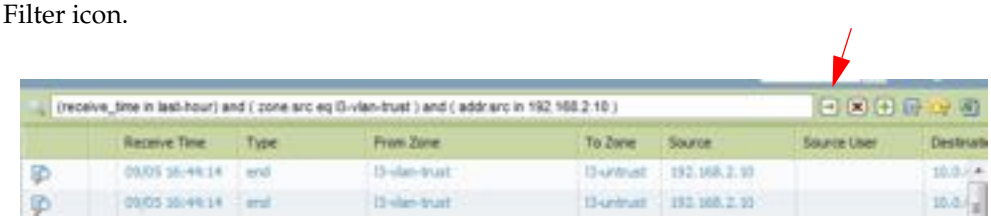
2. To open log pages associated with the information on the page, use the log links in the upper-right corner of the page, as shown here. The context for the logs matches the information on the page.

3. To filter the list, click an item in one of the columns, this will add that item to the filter bar located above the log column names. After adding the desired filters, click the Apply Filter icon.



4. Choose a view from the drop-down list for the area of interest, as described in the following table.

5. Use the drop-down lists for Applications, URL Categories, Threats, Content/File Types, and HIP Objects.

**Table 114. Application Command Center Charts**

| Chart | Description |
|---|---|
| Application | Displays information organized according to the menu selection. Information includes the number of sessions, bytes transmitted and received, number of threats, application category, application subcategories, application technology, and risk level, as applicable.<br>• Applications<br>• High risk applications<br>• Categories<br>• Sub Categories<br>• Technology<br>• Risk |
| URL Filtering | Displays information organized according to the menu selection. Information includes the URL, URL category, repeat count (number of times access was attempted, as applicable).<br>• URL Categories<br>• URLs<br>• Blocked URL Categories<br>• Blocked URLs |

**Table 114. Application Command Center Charts (Continued)**

| Chart | Description |
|---|---|
| Threat Prevention | Displays information organized according to the menu selection. Information includes threat ID, count (number of occurrences), number of sessions, and subtype (such as vulnerability), as applicable.<br>• Threats<br>• Types<br>• Spyware<br>• Spyware Phone Home<br>• Spyware Downloads<br>• Vulnerability<br>• Virus |
| Data Filtering | • Content/File Types<br>• Types<br>• File Names |
| HIP Matches | • HIP Objects<br>• HIP Profiles |

6. To view additional details, click any of the links. A details page opens to show information about the item at the top and additional lists for related items.

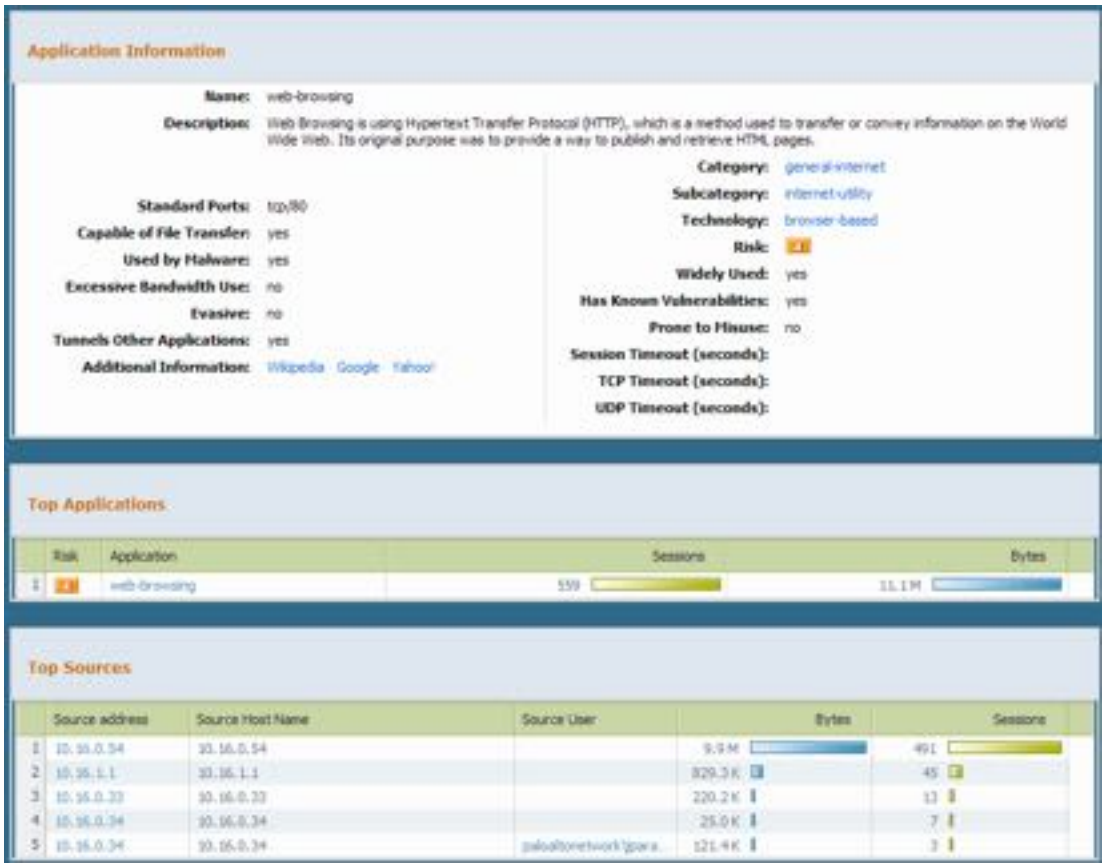


**Figure 23. Application Command Center Drill Down Page**

# Using App-Scope

▶ *Monitor > App Scope*

The App-Scope reports introduce a visibility and analysis tools to help pinpoint problematic behavior, helping you understand the following aspects of your network:

- Changes in application usage and user activity
- Users and applications that take up most of the network bandwidth
- Network threats

With the App-Scope reports, you can quickly see if any behavior is unusual or unexpected. Each report provides a dynamic, user-customizable window into the network. The reports include options to select the data and ranges to display.

To view the reports, click the report name under **App-Scope** on the left side of the page in the **Monitor** tab. Select one of the report types lists below. Report options are available from the drop-down lists at the top and bottom of some of the pages.

**Table 115. Application Command Center Charts**

| Chart | Description |
|---|---|
| Summary | "Summary Report" on page 257 |
| Change Monitor | "Change Monitor Report" on page 258 |
| Threat Monitor | "Threat Monitor Report" on page 259 |
| Threat Map | "Threat Monitor Report" on page 259 |
| Network Monitor | "Network Monitor Report" on page 261 |
| Traffic Map | "Traffic Map Report" on page 263 |

## Summary Report

The Summary report (Figure 24) displays charts for the top five gainers, losers, and bandwidth consuming applications, application categories, users, and sources.

**Figure 24. App-Scope Summary Report**

## Change Monitor Report

The Change Monitor report (Figure 25) displays changes over a specified time period. For example, Figure 25 displays the top applications that gained in use over the last hour as compared with the last 24-hour period. The top applications are determined by session count and sorted by per cent.

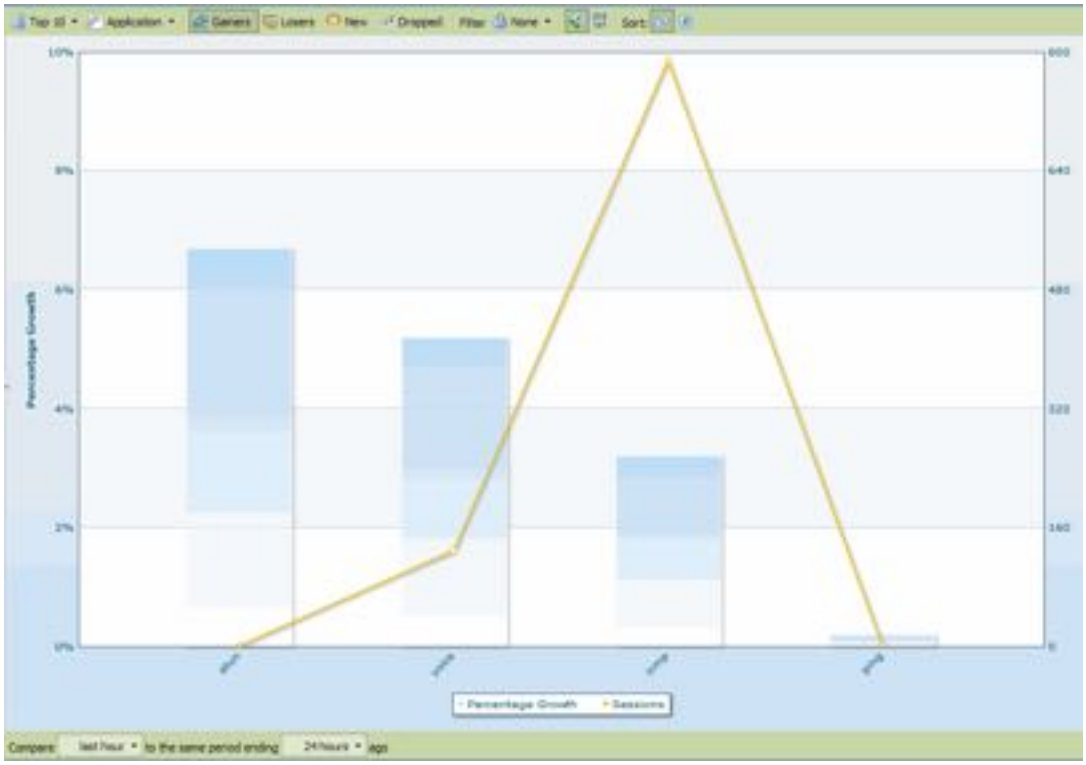

**Figure 25. App-Scope Change Monitor Report**

This report contains the following buttons and options.

**Table 116. Change Monitor Report Options**

| Item | Description |
|---|---|
| **Top Bar** | |
| Top 10 | Determines the number of records with the highest measurement included in the chart. |
| Application | Determines the type of item reported: Application, Application Category, Source, or Destination. |
| Gainers | Displays measurements of items that have increased over the measured period. |
| Losers | Displays measurements of items that have decreased over the measured period. |
| New | Displays measurements of items that were added over the measure period. |

**Table 116. Change Monitor Report Options (Continued)**

| Item | Description |
|---|---|
| zzZ Dropped | Displays measurements of items that were discontinued over the measure period. |
| Filter None | Applies a filter to display only the selected item. **None** displays all entries. |
| 010 101 | Determines whether to display session or byte information. |
| Sort: % # | Determines whether to sort entries by percentage or raw growth. |
| **Bottom Bar** | |
| Compare last hour to the same period ending 24 hours ago | Specifies the period over which the change measurements are taken. |

## Threat Monitor Report

The Threat Monitor report (Figure 26) displays a count of the top threats over the selected time period. For example, Figure 26 shows the top 10 threat types for the past 6 hours.

**Figure 26. App-Scope Threat Monitor Report**

Each threat type is color-coded as indicated in the legend below the chart. This report contains the following buttons and options.

**Table 117. Threat Monitor Report Buttons**

| Button | Description |
|---|---|
| **Top Bar** | |
| | Determines the number of records with the highest measurement included in the chart. |
| | Determines the type of item measured: Threat, Threat Category, Source, or Destination. |
| | Applies a filter to display only the selected type of items. |
| | Determines whether the information is presented in a stacked column chart or a stacked area chart. |
| **Bottom Bar** | |
| | Specifies the period over which the measurements are taken. |

## Threat Map Report

The Threat Map report (Figure 27) shows a geographical view of threats, including severity.

**Figure 27. App-Scope Threat Monitor Report**

Each threat type is color-coded as indicated in the legend below the chart. Click a country on the map to zoom in. Click the **Zoom Out** button in the lower right corner of the screen to zoom out. This report contains the following buttons and options.

**Table 118. Threat Map Report Buttons**

| Button | Description |
|---|---|
| **Top Bar** | |
| | Determines the number of records with the highest measurement included in the chart. |
|  | Displays incoming threats. |
|  | Displays outgoing threats. |
| | Applies a filter to display only the selected type of items. |
| **Bottom Bar** | |
|  | Indicates the period over which the measurements are taken. |

## Network Monitor Report

The Network Monitor report (Figure 28) displays the bandwidth dedicated to different network functions over the specified period of time. Each network function is color-coded as indicated in the legend below the chart. For example, Figure 28 shows application bandwidth for the past 7 days based on session information.

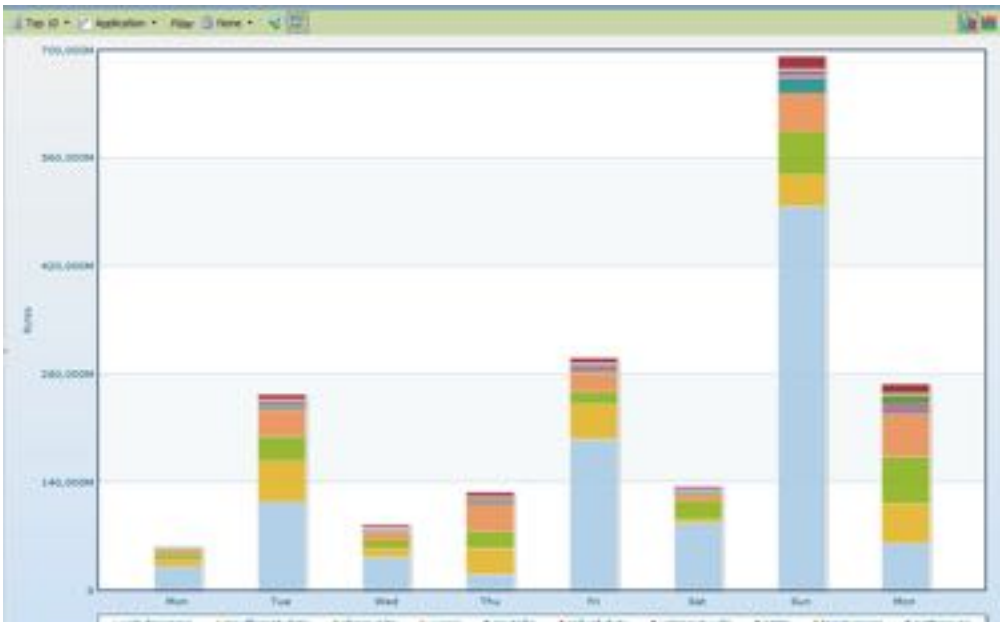

**Figure 28. App-Scope Network Monitor Report**

The report contains the following buttons and options.

**Table 119. Network Monitor Report Buttons**

| Button | Description |
|---|---|
| **Top Bar** | |
| | Determines the number of records with the highest measurement included in the chart. |
|   | Determines the type of item reported: Application, Application Category, Source, or Destination. |
|   | Applies a filter to display only the selected item. **None** displays all entries. |
| | Determines whether to display session or byte information. |
| | Determines whether the information is presented in a stacked column chart or a stacked area chart. |
| **Bottom Bar** | |
| | Indicates the period over which the change measurements are taken. |

## Traffic Map Report

The Traffic Map report (Figure 29) shows a geographical view of traffic flows according to sessions or flows.

**Figure 29. App-Scope Traffic Monitor Report**

Each traffic type is color-coded as indicated in the legend below the chart. This report contains the following buttons and options.

**Table 120. Threat Map Report Buttons**

| Button | Description |
|---|---|
| **Top Bar** | |
| Top 10 | Determines the number of records with the highest measurement included in the chart. |
| Incoming threats | Displays incoming threats. |
| Outgoing threats | Displays outgoing threats. |
| 010 101 | Determines whether to display session or byte information. |

**Table 120. Threat Map Report Buttons (Continued)**

| Button | Description |
|---|---|
| **Bottom Bar** | |
| Last 6 hours Last 12 hours Last 24 hours Last 7 days Last 30 days | Indicates the period over which the change measurements are taken. |

# Viewing the Logs

▶ *Monitor > Logs*

The firewall maintains logs for WildFire, configurations, system, alarms, traffic flows, threats, URL filtering, data filtering, and Host Information Profile (HIP) matches. You can view the current logs at any time. To locate specific entries, you can apply filters to most of the log fields.

***Note:*** *The firewall displays the information in logs so that role-based administration permissions are respected. When you display logs, only the information that you have permission to see is included. For information on administrator permissions, refer to "Defining Administrator Roles" on page 58.*

To view the logs, click the log types on the left side of the page in the **Monitor** tab.

Each log page has a filter area at the top of the page.

Use the filter area as follows:

- Click any of the underlined links in the log listing to add that item as a log filter option. For example, if you click the **Host** link in the log entry for 10.0.0.252 and **Web Browsing** in both items are added, and the search will find entries that match both (AND search).

***Note:*** *To filter information for a user group, add the query (user in 'domain/user-group'). For example, to generate a list of the activities for the marketing group in Company ABC, you would query (user in 'company_abc/marketing').*

- To define other search criteria, click the **Add Log Filter** icon. Select the type of search (and/or), the attribute to include in the search, the matching operator, and the values for the match, if appropriate. Click **Add** to add the criterion to the filter area on the log page, and then click **Close** to close the pop-up window. Click the **Apply Filter** icon to display the filtered list.

***Note:*** *You can combine filter expressions added on the log page with those that you define in the Expression pop-up window. Each is added as an entry on the Filter line on the log page.*

*If you set the "in" Received Time filter to* ***Last 60 seconds****, some of the page links on the log viewer may not show results because the number of pages may grow or shrink due to the dynamic nature of the selected time.*

- To clear filters and redisplay the unfiltered list, click the **Clear Filter** button.
- To save your selections as a new filter, click the **Save Filter** button, enter a name for the filter, and click **OK**.
- To export the current log listing (as shown on the page, including any applied filters) click the **Save Filter** button. Select whether to open the file or save it to disk, and select the check box if you want to always use the same option. Click **OK**.

To change the automatic refresh interval, select an interval from the drop-down list (1 min, 30 seconds, 10 seconds, or Manual). To change the number of log entries per page, select the number of rows from the **Rows** drop-down list.

Log entries are retrieved in blocks of 10 pages. Use the paging controls at the bottom of the page to navigate through the log list. Select the **Resolve Hostname** check box to begin resolving external IP addresses to domain names.

To display additional details, click the spyglass icon for an entry.

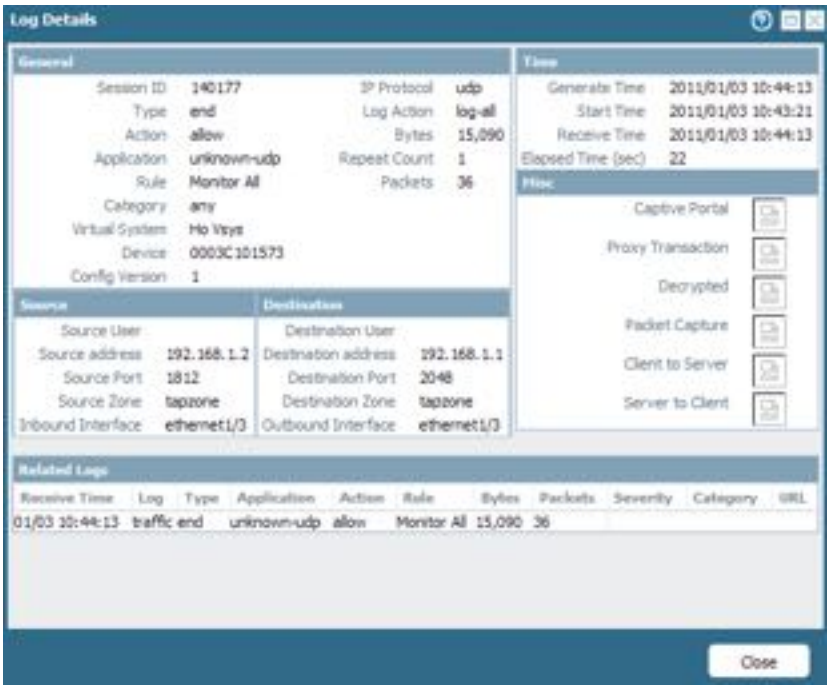

**Figure 30. Log Entry Details**

If the source or destination has an IP address to name mapping defined in the **Addresses** page, the name is presented instead of the IP address. To view the associated IP address, move your cursor over the name.

Review the following information in each log.

**Table 121. Log Descriptions**

| Chart | Description |
|---|---|
| Traffic | Displays an entry for the start and end of each session. Each entry includes the date and time, the source and destination zones, addresses, and ports, the application name, the security rule name applied to the flow, the rule action (allow, deny, or drop), the ingress and egress interface, and the number of bytes.<br>Click next to an entry to view additional details about the session, such as whether an ICMP entry aggregates multiple sessions between the same source and destination (the Count value will be greater than one).<br>Note that the **Type** column indicates whether the entry is for the start or end of the session, or whether the session was denied or dropped. A "drop" indicates that the security rule that blocked the traffic specified "any" application, while a "deny" indicates the rule identified a specific application.<br>If traffic is dropped before the application is identified, such as when a rule drops all traffic for a specific service, the application is shown as "not-applicable". |
| Threat | Displays an entry for each security alarm generated by the firewall. Each entry includes the date and time, a threat name or URL, the source and destination zones, addresses, and ports, the application name, and the alarm action (allow or block) and severity.<br>Click next to an entry to view additional details about the threat, such as whether the entry aggregates multiple threats of the same type between the same source and destination (the Count value will be greater than one).<br>Note that the **Type** column indicates the type of threat, such as "virus" or "spyware." The **Name** column is the threat description or URL, and the **Category** column is the threat category (such as "keylogger") or URL category.<br>If local packet captures are enabled, click next to an entry to access the captured packets, as in the following figure. To enable local packet captures, refer to the subsections under "Security Profiles" on page 211. |
| URL Filtering | Displays logs for URL filters, which block access to specific web sites and web site categories or generate an alert when a proscribed web site is accessed. Refer to "URL Filtering Profiles" on page 217 for information on defining URL filtering profiles. |
| WildFire | Displays logs for files that are uploaded and analyzed by the WildFire server, log data is sent back to the device after analysis, along with the analysis results.<br>A subscription is required for this feature. If you do not have a subscription, you can use the WildFire Portal to view log information. Refer to "Using the WildFire Portal" on page 425. |
| Data Filtering | Displays logs for the security policies that help prevent sensitive information such as credit card or social security numbers from leaving the area protected by the firewall. Refer to "Data Filtering Profiles" on page 223 for information on defining data filtering profiles.<br>To configure password protection for access the details for a log entry, click the icon. Enter the password and click **OK**. Refer to "Defining Custom Response Pages" on page 115 for instructions on changing or deleting the data protection password.<br>***Note:*** *The system prompts you to enter the password only once per session.* |

**Table 121. Log Descriptions (Continued)**

| Chart | Description |
|---|---|
| Configuration | Displays an entry for each configuration change. Each entry includes the date and time, the administrator user name, the IP address from where the change was made, the type of client (Web or CLI), the type of command executed, whether the command succeeded or failed, the configuration path, and the values before and after the change. |
| System | Displays an entry for each system event. Each entry includes the date and time, the event severity, and an event description. |
| HIP Match | Displays information about security policies that apply to GlobalProtect clients. For more information, refer to "Overview" on page 335. |
| Alarms | The alarms log records detailed information on alarms that are generated by the system. The information in this log is also reported in the **Alarms** window. Refer to "Viewing Alarms" on page 85. |

### Viewing Session Information

▶ *Monitor > Session Browser*

Open the **Session Browser** page to browse and filter current running sessions on the firewall. For information on filtering options for this page, refer to "Viewing the Logs" on page 264.

## Working with Botnet Reports

The botnet report feature allows you to use behavior-based mechanisms to identify potential botnet-infected hosts in the network. Using network, threat, URL, and data filtering logs, the firewall evaluates threats based on criteria that include visits to malware sites and dynamic DNS sites, visits to recently registered domains (within the last 30 days), unknown application usage, and the existence of Internet Relay Chat (IRC) traffic.

After correlating and identifying hosts that match infected botnet behavior, the firewall assigns each potentially infected host a confidence score of 1 to 5 to indicate the likelihood of botnet infection (1 indicates the lowest and 5 the highest likelihood of infection). Because behavior-based detection mechanisms require correlating traffic across multiple logs over a period of 24 hours, the firewall generates a report every 24 hours that contains a sorted list of hosts based on confidence level.

## Configuring the Botnet Report

▶ *Monitor > Botnet*

Use these settings to specify types of suspicious traffic (traffic that may indicate botnet activity). To configure the settings, click the **Configuration** button on the right side of the **Botnet** page.

**Table 122. Botnet Configuration Settings**

| Field | Description |
|---|---|
| HTTP Traffic | Select the **Enable** check box for the events that you want to include in the reports:<br>• **Malware URL visit**—Identifies users communicating with known malware URLs based on malware and botnet URL filtering categories.<br>• **Use of dynamic DNS**—Looks for dynamic DNS query traffic that could indicate botnet communication.<br>• **Browsing to IP domains**—Identifies users that browse to IP domains instead of URLs.<br>• **Browsing to recently registered domains**—Looks for traffic to domains that have been registered within the past 30 days.<br>• **Executable files from unknown sites**—Identifies executable files downloaded from unknown URLs. |
| Unknown Applications | Select the check boxes to mark unknown TCP or unknown UDP applications as suspicious, and specify the following information:<br>• **Sessions Per Hour**—Number of application sessions per hour that are associated with the unknown application.<br>• **Destinations Per Hour**—Number of destinations per hour that are associated with the unknown application.<br>• **Minimum Bytes**—Minimum payload size<br>• **Maximum Bytes**—Maximum payload size. |
| IRC | Select the check box to include IRC servers as suspicious. |

## Managing Botnet Reports

▶ *Monitor > Botnet > Report Setting*

You can specify report queries and then generate and view botnet analysis reports. The reports are based on botnet configuration settings (refer to "Configuring the Botnet Report" on page 268). You can include or exclude source or destination IP addresses, users, zones, interfaces, regions, or countries.

Scheduled reports run once per day. You can also generate and display reports on demand by clicking **Run Now** in the window where you define the report queries. The generated report is displayed on the **Botnet** page.

To manage botnet reports, click the **Report Setting** button on the right side of the **Botnet** page.

To export a report, select the report and click **Export to PDF** or **Export to CSV**.

**Table 123. Botnet Report Settings**

| Field | Description |
|---|---|
| Test Run Time Frame | Select the time interval for the report (last 24 hours or last calendar day). |
| # Rows | Specify the number of rows in the report. |
| Scheduled | Select the check box to run the report on a daily basis. To run the report manually, click **Run Now** at the top of the Botnet Report window. |
| Query | Construct the report query by specifying the following, and then clicking **Add** to add the configured expression to the query. Repeat as needed to construct the complete query:<br>• **Connector**—Specify a logical connector (AND/OR).<br>• **Attribute**—Specify the source or destination zone, address, or user.<br>• **Operator**—Specify the operator to relate the attribute to a value.<br>• **Value**—Specify the value to match. |
| Negate | Select the check box to apply the negation of the specified query, meaning that the report will contain all information that is not a result of the defined query. |

# Managing PDF Summary Reports

▶ *Monitor > PDF Reports > Manage PDF Summary*

PDF summary reports contain information compiled from existing reports, based on data for the top 5 in each category (instead of top 50). They also contain trend charts that are not available in other reports.

**Figure 31. PDF Summary Report**

To create PDF summary reports, click **Add**. The **Manage PDF Summary Reports** page opens to show all of the available report elements.

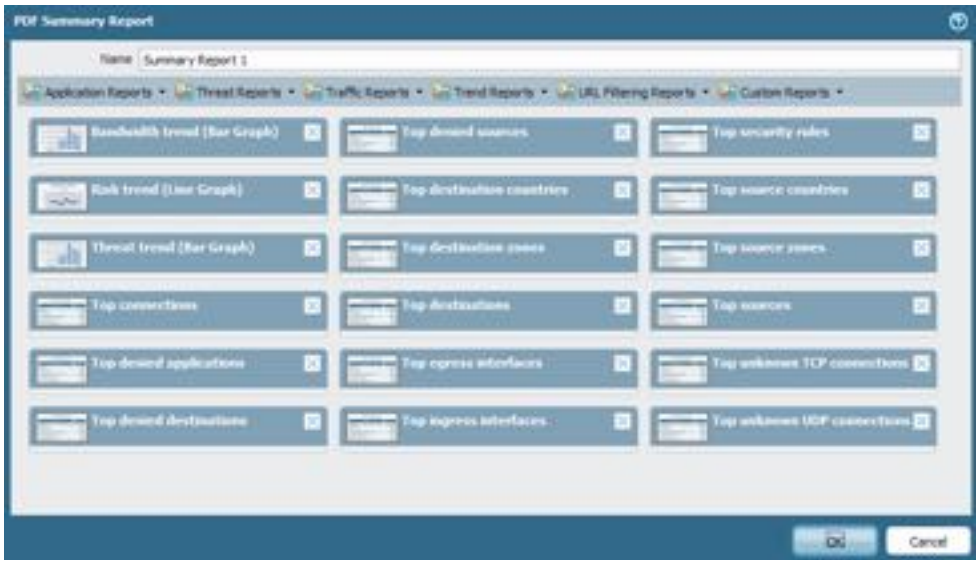

**Figure 32. Managing PDF Reports**

Use one or more of these options to design the report:

- To remove an element from the report, click the icon in the upper-right corner of the element's icon box or remove the check box from the item in the appropriate drop-down list box near the top of the page.
- Select additional elements by choosing from the drop-down list boxes near the top of the page.
- Drag and drop an element's icon box to move it to another area of the report.

***Note:*** *A maximum of 18 report elements is permitted. You may need to delete existing elements to add additional ones.*

Click **Save**, enter a name for the report, as prompted, and click **OK**.

To display PDF reports, choose **PDF Summary Report**, and select a report type from the drop-down list at the bottom of the page to display the generated reports of that type. Click an underlined report link to open or save the report.

# Managing User Activity Reports

▶ *Monitor > PDF Reports > User Activity Report*

Use this page to create reports that summarize the activity of individual users. Click **New** and specify the following information.

**Table 124. User Activity Report Settings**

| Field | Description |
|---|---|
| Name | Enter a name to identify the report (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| User | Enter the user name or IP address (IPv4 or IPv6) of the user who will be the subject of the report. |
| Time frame | Select the time frame for the report from the drop-down list. |

To run the report on demand, select the report and click **Edit**, and then click **Run**.

# Managing Report Groups

▶ *Monitor > PDF Reports > Report Groups*

Report groups allow you to create sets of reports that the system can compile and send as a single aggregate PDF report with an optional title page and all the constituent reports included.

**Table 125. Report Group Settings**

| Field | Description |
|---|---|
| Name | Enter a name to identify the report group (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Title Page | Select the check box to include a title page in the report. |
| Title | Enter the name that will appear as the report title. |
| Report selection | Select reports from the left column and click **Add** to move each report to the report group on the right. You can select Predefined, Custom, PDF Summary, and Log View report types.<br>The **Log View** report is a report type that is automatically created each time you create a custom report and uses the same name as the custom report. This report will show the logs that were used to build the contents of the custom report.<br>To include the log view data, when creating a report group, you add your custom report under the **Custom Reports** list and then add the log view report by selecting the matching report name from the **Log View** list. When you receive the report, you will see your custom report data followed by the log data that was used to create the custom report. |

To use the report group, refer to "Scheduling Reports for Email Delivery" in the next section.

# Scheduling Reports for Email Delivery

▶ *Monitor > PDF Reports > Email Scheduler*

Use the Email scheduler to schedule reports for delivery by email. Before adding a schedule, you must define report groups and an email profile. Refer to "Managing Report Groups" on page 272 and "Configuring Email Notification Settings" on page 83.

Scheduled reports begin running at 2:00 AM, and email forwarding occurs after all scheduled reports have finished running.

**Table 126. Email Scheduler Settings**

| Field | Description |
|---|---|
| Name | Enter a name to identify the schedule (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Report Group | Select the report group (refer to "Managing Report Groups" on page 272). |
| Recurrence | Select the frequency at which to generate and send the report. |
| Email Profile | Select the profile that defines the email settings. Refer to "You can configure a custom log format in a Syslog Server Profile by selecting the Custom Log Format tab in Device > Server Profiles > Syslog. Click the desired log type (Config, System, Threat, Traffic, or HIP Match) and then click the fields you want to see in the logs. The tables that follow shows the meaning of each field for each log type." on page 77 for information on defining email profiles. |
| Override Recipient email(s) | Enter an optional email address to use instead of the recipient specified in the email profile. |

# Viewing Reports

▶ *Monitor > Reports*

The firewall provides various "top 50" reports of the traffic statistics for the previous day or a selected day in the previous week.

To view the reports, click the report names on the right side of the page (Custom Reports, Application Reports, Traffic Reports, Threat Reports, URL Filtering Reports, and PDF Summary Reports).

By default, all reports are displayed for the previous calendar day. To view reports for any of the previous days, select a report generation date from the **Select** drop-down list at the bottom of the page.

The reports are listed in sections. You can view the information in each report for the selected time period. To export the log in CSV format, click **Export to CSV**. To open the log information in PDF format, click **Export to PDF**. The PDF file opens in a new window. Click the icons at the top of the window to print or save the file.

# Generating Custom Reports

▶ *Monitor > Manage Custom Reports*

You can create custom reports that are optionally based on existing report templates. The reports can be run on demand or scheduled to run each night. To view previously defined reports, choose **Reports** on the side menu.

Click **Add** to create a new custom report. To base a report on an existing template, click **Load Template** and choose the template.

Specify the following settings to define the report.

**Table 127. Custom Report Settings**

| Field | Description |
|---|---|
| Name | Enter a name to identify the report (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Database | Choose the database to use as the data source for the report. |
| Time Frame | Choose a fixed time frame or choose **Custom** and specify a date and time range. |
| Sort By | Choose sorting options to organize the report, including the amount of information to include in the report. The available options depend on the choice of database. |
| Group By | Choose grouping options to organize the report, including the amount of information to include in the report. The available options depend on the choice of database. |
| Scheduled | Select the check box to run the report each night. The report then becomes available by choosing **Reports** on the side menu. |
| Columns | Choose columns to include in the report from the **Available** column and use the right-facing arrows to move them to the **Selected** column. Use the up and down arrows to reorder the selected columns, and use the left-facing arrows to remove previously selected columns. |

**Table 127. Custom Report Settings (Continued)**

| Field | Description |
|---|---|
| Query and Query Builder | To build a report query, specify the following and click **Add**. Repeat as needed to construct the full query.<br>• **Connector**—Choose the connector (and/or) to precede the expression you are adding.<br>• **Attribute**—Choose a data element. The available options depend on the choice of database.<br>• **Operator**—Choose the criterion to determine whether the attribute applies (such as =). The available options depend on the choice of database.<br>• **Value**—Specify the attribute value to match.<br>For example, the following figure (based on the Traffic Log database) shows a query that matches if the traffic log entry was received in the past 24 hours and is from the "untrust" zone.<br> |
| Negate | Select the check box to interpret the query as a negation. In the previous example, the negate option causes a match on entries that are not in the past 24 hours or are not from the "untrust" zone. |

# Identifying Unknown Applications and Taking Action

There are several ways to view unknown applications using the web interface of the Palo Alto Networks devices:

- **Application Command Center (ACC)**—Unknown applications are sorted along with other applications in the ACC. Click a link for an unknown application to view the details of the application, including top sources and destinations. For top sources, click the link to look up the owner of the address.

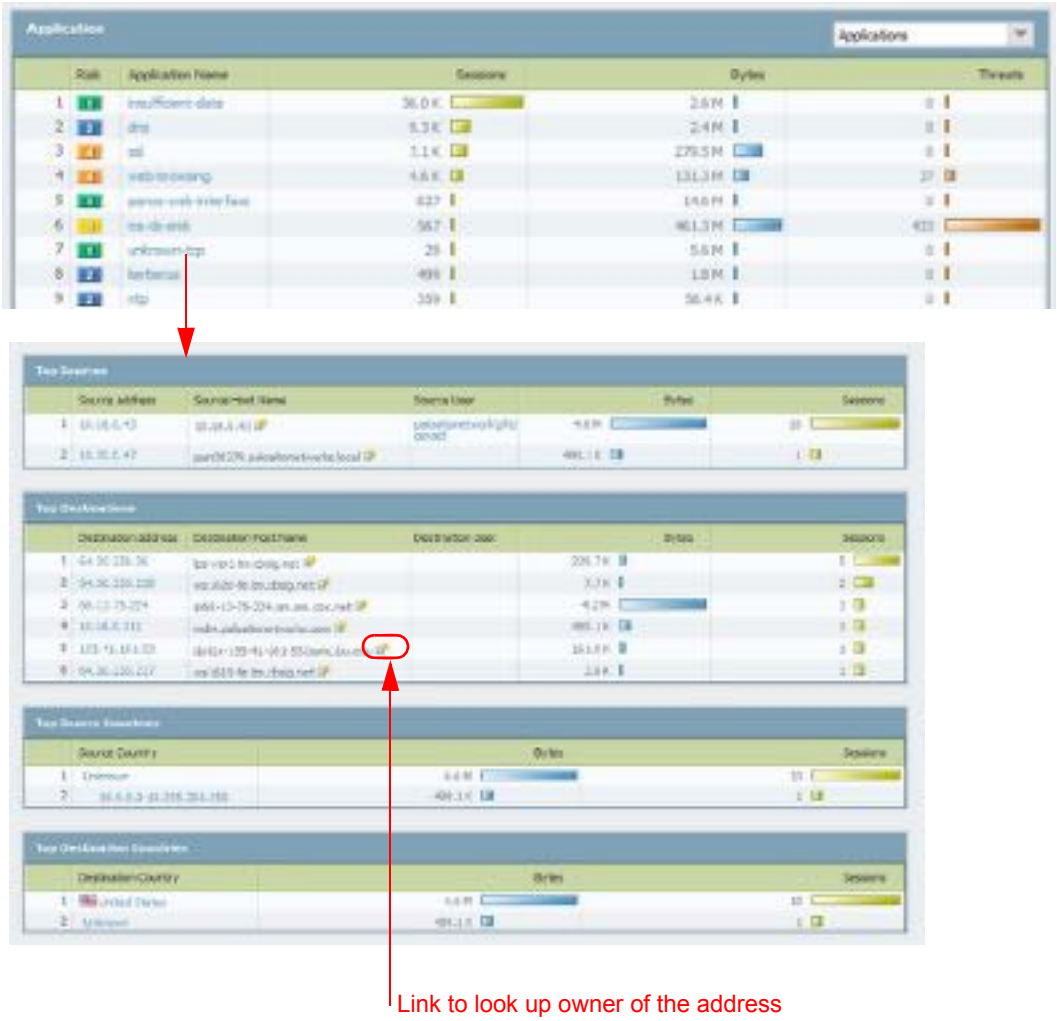

**Figure 33. Unknown Applications in the ACC List**

- **Unknown application reports**—Unknown application reports are automatically run on a daily basis and stored in the Reports section of the **Monitor** tab. These reports can provide useful information to help identify unknown applications.

- **Detailed traffic logs**—You can use the detailed traffic logs to track down unknown applications. If logging is enabled for the start and end of session, the traffic log will provide specific information about the start and end of an unknown session. Use the filter option to restrict the display to entries that match "unknown-tcp," as shown in the next figure.

**Figure 34. Unknown Applications in Traffic Logs**

## Taking Action

You can take the following actions to deal with unknown applications:

- Use custom application definition with application override (refer to "Custom Application Definition with Application Override" on page 205).
- Use custom applications with signatures (refer to "Custom Applications with Signatures" on page 236).
- Request an App-ID from Palo Alto Networks (refer to "Requesting an App-ID from Palo Alto Networks" in the next section).

Policies can also be set to control unknown applications by unknown TCP, unknown UDP or by a combination of source zone, destination zone, and IP addresses. Refer to "Application Override Policies" on page 205.

***Note:*** *You can use custom signatures in App-ID definitions.*

## Requesting an App-ID from Palo Alto Networks

If it is necessary to identify an application using application contents instead of port, protocol, and IP address, you can submit the application to Palo Alto Networks for classification. This is important for applications that run over the Internet and for which custom application does not work. You can submit the application to Palo Alto Networks in either of the following ways:

- If the application is a readily accessible on the Internet (for example, an instant messaging application), then submit the name of the application and the URL to your account team or to this web site: *http://www.paloaltonetworks.com/researchcenter/tools*.

- If the application is not easily accessible (for example, a customer relationship management application) you must submit a packet capture (PCAP) of the running application using the session packet capture function built into the firewall. For assistance, contact technical support at *support@paloaltonetworks.com*.

### Other Unknown Traffic

The firewall may report an application to be "unknown" in the ACC, logs, or reports for either of the following reasons:

- **Incomplete**—A handshake took place, but no data packets were sent prior to the timeout.
- **Insufficient-Data**—A handshake took place followed by one or more data packets; however, not enough data packets were exchanged to identify the application.

## Taking Packet Captures

▶ ***Monitor > Packet Capture***

PAN-OS supports packet capture for troubleshooting or detecting unknown applications. You can define filters such that only the packets that match the filters are captured. The packet captures are locally stored on the device and are available for download to your local computer.

***Note:*** *Packet Capture is for troubleshooting only. This feature can cause the system performance to degrade and should be used only when necessary. After the capture is complete, please remember to disable the feature.*

To specify filtering and capture options, specify the information in the following table.

To clear all filtering and capture settings, click **Clear All Settings.**

To select capture files for download, click the file name in the capture file list on the right side of the page.

**Table 128. Packet Capture Settings**

| Field | Description |
|---|---|
| **Filtering** | |
| Manage Filters | Click **Manage Filters**, click **Add** to add a new filter, and specify the following information:<br>• **Id**—Enter or select an identifier for the filter.<br>• **Ingress Interface**—Select the firewall interface.<br>• **Source**—Specify the source IP address.<br>• **Destination**—Specify the destination IP address.<br>• **Src Port**—Specify the source port.<br>• **Dest Port**—Specify the destination port.<br>• **Proto**—Specify the protocol to filter.<br>• **Non-IP**—Choose how to treat non-IP traffic (exclude all IP traffic, include all IP traffic, include only IP traffic, or do not include an IP filter).<br>• **IPv6**—Select the check box to include IPv6 packets in the filter. |

**Table 128. Packet Capture Settings (Continued)**

| Field | Description |
|---|---|
| Filtering | Click to toggle the filtering selections on or off. |
| Pre-Parse Match | Click to toggle the pre-parse match option on or off.<br>The pre-parse-match option is added for advanced troubleshooting purposes. After a packet enters the ingress port, it proceeds through several processing steps before it is parsed for matches against pre-configured filters.<br>It is possible for a packet, due to a failure, to not reach the filtering stage. This can occur, for example, if a route lookup fails.<br>Set the pre-parse-match setting to **ON** to emulate a positive match for every packet entering the system. This allows the firewall to capture even the packets that do not reach the filtering process. If a packet is able to reach the filtering stage, it is then processed according to the filter configuration and discarded if it fails to meet filtering criteria. |
| **Capture Files** | |
| Capturing | Click to toggle packet capturing on or off. |
| Capture Settings | Click **Add** and specify the following:<br>• **Stage**—Indicate the point at which to capture the packet:<br>– **drop**—When packet processing encounters an error and the packet is to be dropped.<br>– **firewall**—When the packet has a session match or a first packet with a session is successfully created.<br>– **receive**—When the packet is received on the dataplane processor.<br>– **transmit**—When the packet is to be transmitted on the dataplane processor.<br>• **File**—Specify the capture file name. The file name should begin with a letter and can include letters, digits, periods, underscores, or hyphens.<br>• **Packet Count**—Specify the number of packets after which capturing stops.<br>• **Byte Count**—Specify the number of bytes after which capturing stops. |

Chapter 7

# Configuring the Firewall for User Identification

This chapter describes how to configure the firewall to identify the users who attempt to access the network.

- "Overview of User Identification" in the next section
- "User Identification Agents" on page 284
- "PAN-OS User Mapping Configuration" on page 291
- "Setting Up the User-ID Agent" on page 296
- "Setting Up the Terminal Services Agent" on page 301

## Overview of User Identification

User Identification (User-ID) is a feature of Palo Alto Networks firewalls that allows administrators to configure and enforce firewall policies based on users and user groups, instead of or in addition to network zones and addresses.

User-ID identifies the user on the network and the IP addresses of the computers the user is logged into to effectively enforce firewall policies. User-ID can also retrieve user and group information from a connected LDAP directory, allowing administrators to configure policies based on user groups, which are then translated into a list of users.

### How User Identification Works

The functionality provided by User-ID requires the collection of information from the network and directory servers. The following elements are involved in the information collection:

- **Identifying users on the network**
  User-ID provides a variety of mechanisms to reliably identify network users and their associated login session information (computers and network addresses). Some of the mechanisms require the installation of a User-ID Agent on network servers to provide the

most transparent user experience. With PAN-OS 5.0 and greater, you can use the built in PAN-OS User Mapping feature that performs the same function as the User-ID Agent, but does not require an agent installation.

- **Event log monitoring**
  Whenever a user authenticates to the Active Directory (AD) domain, a Microsoft Windows server, or Microsoft Exchange server, an event log is produced. Users can be identified on the network by monitoring those servers for the corresponding login events.
- **Server session monitoring**
  Another method is to continually monitor servers for network sessions established by users on the network. When a user successfully authenticated to a server, the session table of the server provides the user name and network source the user is connecting from.
- **Client Probing**
  In a Microsoft Windows environment, the client system can provide information about logged on users through Windows Management Instrumentation (WMI) for authorized users and services. Probing Microsoft Windows clients on demand provides information on users logged into a client computer.
- **XML API**
  Other identification methods are not directly supported by the User-ID features and options. For these cases, an XML over SSL interface is available, allowing customized solutions to register valid users and their corresponding client address on the network with User-ID.
- **Captive Portal**
  If the user cannot be identified based on login information, an established session or client probe, the firewall can re-direct any outbound HTTP requests and re-direct the user to a web form. The web form can transparently authenticate the user through a NTLM challenge, which is automatically evaluated and answered by the web browser or through an explicit login page.
- **Shared computers**
  Shared computers, such as Microsoft Terminal Servers, are problematic for most implementations, because a number of users share the same system and therefore the same network address. In this case, an Agent can be installed on the Terminal Server, which then associates not just the network address, but also allocated port ranges to the logged in users.

## Identifying Users and Groups

Policy management on the basis of individual users is unmanageable; therefore, users need to be associated and tied to user groups. Every enterprise environment stores user information in a directory service, such as Microsoft Active Directory or Novell eDirectory. All of those directory services are accessible through LDAP or LDAP over SSL (LDAPS).

The directory services provide resolution of user names and the associated user groups, which allows firewall administrators to configure security policies for user groups rather than individual users.

# How User-ID Components Interact

The User-ID Agent, PAN-OS, and the Terminal Services Agent interact with each other to provide complete user identification services.

## User-ID Agent

The User-ID Agents identifies the user on the network using one or all of the mechanisms described previously in this chapter.

- **Gathering user and login information**
  The User-ID Agent can be configured to monitor up to 100 Microsoft Windows Servers for user login events. When the Agent first connects to a server, it automatically retrieves a list of the last login events from the domain controller. During normal operations, it continues to receive new event information. The User-ID Agent provides the collected information to the firewall to enforce policy based on users and groups.
- **Providing users and network addresses to connected devices**
  To provide user and network address information, the firewall establishes a persistent connection to the User-ID Agent and retrieves a list of all identified users and network addresses on its first connection and every hour. During each hour, the firewall retrieves changes that the Agent detects.
- **On demand user identification**
  If the firewall identifies a new network address in the network traffic for which no user is listed, it can contact the User-ID Agent and request it to identify the user. This is done through a WMI or NetBIOS probe to the specific network address. When the client identifies the user, a new network address and username association is created and provided to the firewall.

## PAN-OS User Mapping

The PAN-OS User Mapping feature performs the same functions as the User-ID Agent, but does not require an agent installation on domain servers. This feature communicates directly with Microsoft servers and Novell eDirectory servers to gather user to IP and user to group mapping information. The enumeration of the individual users in a user group is also performed on the firewall. LDAP search and NTLM authentication is also supported. Refer to "User Mapping Tab" on page 286 and "PAN-OS User Mapping Configuration" on page 291.

You can also configure the firewall to share the user mapping information with other PAN-OS firewalls in your network. This is useful if you want to designate one or more devices to perform user mapping functions and then share that information with other firewalls. By using the include and exclude lists, you can also filter certain networks from the collection process. Refer to "PAN-OS User Mapping Configuration" on page 291.

## Terminal Services Agent

The Terminal Services Agent (TS Agent) solves the problem of multiple users using the same machine at the same time, for example on a Microsoft Terminal Server. After it is installed on the server, it allocates specific port ranges to each individual user. Every user connection is established using a port within the specific allocated port range.

When a port range is allocated for a particular user, the Terminal Services Agent notifies every connected firewall about the allocated port range so that policy can be enforced based on user and user groups.

### PAN-OS LDAP Group Query

In addition to enforcing policy based on individual users, the firewall can also be configured to allow or block traffic for groups of users. The enumeration of the individual users in a user group is performed by the firewall.

For this purpose, a LDAP server entry and group mapping settings need to be configured. The resulting LDAP query retrieves user groups and the corresponding list of group members.

This operation is performed every time a new configuration is submitted. Changes in group membership are detected through specific LDAP searches that retrieve only the groups and their member list that changed since the last search was performed.

## User Identification Agents

The User Identification Agent (User-ID Agent) is a Palo Alto Networks application that is installed on your network to obtain needed mapping information between IP addresses and network users. The User-ID Agent collects user-to-IP address mapping information from the domain controller security logs and provides it to the firewall for use in security policies and logs.

Refer to "PAN-OS User Mapping" on page 283, which performs the same functions as the User-ID Agent, but does not require an agent to be installed on the domain servers.

The IP address-to-user name mapping relies on the following mechanisms:

- For Active Directory, the security logs are continually monitored on the domain controller to detect user login events that contain user and IP address information.
- For Active Directory, a direct connection is required to all Domain Controllers to monitor user session activity and determine the user IP addresses.
- For eDirectory, when a user logs in, the IP address information is stored in eDirectory and retrieved by the User-ID Agent.
- The host PC is polled to verify IP address and user information using Windows Management Instrumentation (WMI) or Network Basic Input/Output System (NetBIOS). This occurs every 20 minutes to verify that the IP address-to-user name mapping is still correct and also when an IP address is seen that does not have an associated user name.
- The User-ID Agent application programming interface (API) is used to send information on user IP addresses to the User-ID Agent.
- User group mapping is performed through LDAP queries on directory servers. The firewall performs LDAP queries directly, but can use a configured User-ID agent as a LDAP proxy in cases where caching is desirable or direct access from the firewall to the directory server is not possible."

***Note:*** *User identification mapping requires that the firewall obtain the source IP address of the user before the IP address is translated with NAT. If multiple users appear to have the same source address, due to NAT or use of a proxy device, accurate user identification is not possible.*

In addition to the User-ID Agents, the firewall supports a Terminal Services Agent (TS Agent) that allows the firewall to identify individual users who are supported by the same terminal server. The firewall also supports captive portals for situations in which the User-ID Agent is unable to associate a user with an IP address.

Refer to the following sections for further information:

- "Captive Portals" in the next section
- "Configuring the Firewall for User Identification" on page 286
- "Setting Up the User-ID Agent" on page 296
- "Setting Up the Terminal Services Agent" on page 301

## Captive Portals

If the User-ID Agent is unable to associate a user with an IP address, a captive portal can take over and authenticate the user with a web form or NT LAN Manager (NTLM) challenge.

To receive the web form, users must be using a web browser and be in the process of connecting. Upon successful authentication, users are automatically directed to the originally requested web site. The firewall can now execute policies based on the user information for any applications passing through the firewall, not just for applications that use a web browser.

The following rules apply to captive portals:

- Captive portal rules work for HTTP and HTTPS web traffic.
- If the action for the rule is "web form," a web form is presented to the user to prompt for a password.
- If the rule is "NTLM" and the browser is Internet Explorer or Firefox, the firewall performs an NTLM authentication challenge (transparent to the user). If another browser is used, the web form is presented.

If the above-mentioned captive portal rules do not apply because the traffic is not HTTP or there is no rule match, then the firewall applies its IP-based security policies (as opposed to user-based security policies).

## Configuring the Firewall for User Identification

▶ *Device > User Identification*

Use the settings on this page to configure the firewall for user identification.

- **User Mapping tab**—Specify settings to use the PAN-OS User Mapping feature to provides accurate mappings between IP addresses and logged in users as well as user to group membership mapping. This option performs the same functions as the User-ID Agent directly from the firewall, so no agent is required on the domain controllers.
- **User-ID Agents tab**—Specify settings to support the user identification agent, which provides accurate mappings between IP addresses and logged in users.
- **Terminal Services tab**—Specify settings to support the terminal services agent. Refer to "Setting Up the Terminal Services Agent" on page 301.
- **Group Mappings Settings tab**—Specify settings to support mappings that associate users with user groups. User group mapping is performed by the firewall.
- **Captive Portal tab**—Specify settings to support use of a captive portal for user identification. Refer to "Captive Portals" on page 285.

**Table 129. User-ID Agent Settings**

| Field | Description |
|---|---|
| **User Mapping Tab** | |
| WMI Authentication tab | **User Name**—Specify the domain\username account that has permissions to perform WMI queries on client computers.<br>**Password/Confirm Password**—Specify the account password. |
| Server Monitor tab | **Enable Security Log**—Select the check box to enable security log monitoring on Windows servers. Security logs will be queried to locate user to IP mapping information on the servers specified in the **Server Monitoring** list.<br>**Server Log Monitor Frequency (sec)**—Specify how often the firewall will query Windows servers for user to IP mapping information (default 1 second, range 1-3600 seconds).<br>**Enable Session**—Select the check box to enable monitoring of user sessions on the servers specified in the **Server Monitoring** list. Each time a user connects to a server, a session is created and this information can also be used to identify the user IP address.<br>**Server Session Read Frequency (sec)**—Specify how often the firewall will query Windows server user sessions for user to IP mapping information (default 10 second, range 1-3600 seconds).<br>**Novell eDirectory Query Interval (sec)**—Specify how often the firewall will query Novell eDirectory servers for user to IP mapping information (default 30 second, range 1-3600 seconds). |

**Table 129. User-ID Agent Settings (Continued)**

| Field | Description |
|---|---|
| Client Probing tab | **Enable Probing**—Select this check box to enable WMI/NetBIOS probing to each client PC identified by the user mapping process. Probing will help ensure that the same user is still logged into the client PC in order to provide accurate user to IP information.<br>**Probe Interval (min)**—Specify the client PC probe interval (default 20 minutes, range 1-1440 minutes).<br>In large deployments, it is important to set the probe interval properly to allow time to probe each client that has been identified. Example, if you have 6,000 users and an interval of 10 minutes, it would require 10 WMI request a second from each client.<br>***Note:*** *For WMI polling to work effectively, the* ***User Mapping*** *profile must be configured with a domain administrator account, and each probed client PC must have a remote administration exception configured in the Windows firewall. For NetBIOS probing to work effectively, each probed client PC must allow port 139 in the Windows firewall and must also have file and printer sharing services enabled.* |
| Cache tab | **Enable User Identification timeout**—Select this check box to enable a timeout value for user to IP mapping entries. When the timeout value is reached, the user to IP mapping will be cleared and a new mapping will be collected. This will ensure that the firewall has the most current information as users roam around and obtain new IP addresses.<br>**User Identification Timeout (min)**—Set the timeout value for user to IP mapping entries (default 45 minutes, range 1440). |
| NTLM tab | **Enable NTLM authentication processing—**Select this check box to enable NT LAN Manager (NTLM) authentication processing. When Captive Portal is set up with a web form to capture user to IP information, the client will be transparently authenticated through an NTLM challenge. With this option enabled, the firewall will collect this information from the NTLM domain.<br>If both the PAN-OS User-ID collector and the User-ID Agent is installed on domain controllers, NTLM responses will go directly to the domain controller. When the firewall is configured to share its User-ID information with other firewalls, it can serve NTLM requests coming from other PAN-OS firewalls, performing the function of the User-ID Agent.<br>**NTLM Domain**—Enter the NTLM domain name.<br>**Admin User Name**—Enter the administrator account that has access to the NTLM domain.<br>**Password/Confirm Password**—Enter the password for the administrator account that has access to NTLM domain.<br>**Note:** You cannot enable this check box in more than one virtual system. |

**Table 129. User-ID Agent Settings (Continued)**

| Field | Description |
|---|---|
| Redistribution tab | **Collector Name**—Specify the collector name if you want this firewall to act as a user mapping redistribution point for other firewalls on your network.<br>The collector name and pre-shared key are used when configuring the User-ID Agents on the firewalls that will pull the user mapping information.<br>To enable a firewall to act as a re-distribution point, you also need to enable the<br>**User-ID Service** in **Network > Network Profiles > Interface Mgmt**.<br><br>**Pre-Shared Key/Confirm Pre-Shared Key**—Enter the pre-shared key that is used by other firewalls to establishing a secure connection for user mapping transfers. |
| Server Monitoring | Click **Add** to configure the domain server(s) that the firewall will contact to gather user IP mapping and user to group mapping information.<br>**Name**—Enter the domain server network address.<br>**Network Address**—Enter the network address of the domain server.<br>**Type**—Select the type of domain server (Microsoft Active Directory, Microsoft Exchange, or Novell eDirectory).<br>**Enable**—Select the check box to enable the domain server profile.<br>**Discover**—Click this option to discover Microsoft Active Directory servers via DNS. You can then select check box next to the servers you want to use to obtain user mapping information.<br>The firewall will discover domain controllers based on the domain name entered in the **Device > Setup > Management** tab **> General Settings** page **Domain** field. |
| Include/Exclude Networks | **Name**—Enter a name to identify the profile that will include or exclude a network for User-ID discovery purposes. This option allows you to include or exclude a network range for IP address-to-user name mapping. Example, if you exclude 10.1.1.0/24, User-ID will not try to find user names for IP addresses in the excluded range. This in turn will also include or exclude ranges for mappings sent to other PAN-OS firewalls.<br>When defining an include or exclude network range, an implicit exclude-all will be performed. For example, if you include 10.1.1.0/24, all other networks will be excluded. If you exclude 10.1.1.0/24, all networks will be excluded, so when using exclude you must also have an include network, otherwise all networks are excluded.<br>**Enabled**—Select this option to enable the include/exclude profile.<br>**Discovery**—Select the option to either **Include** or **Exclude** the defined network range.<br>**Network Address**—Enter a network range that you would like to include or exclude for IP address-to-user name mapping discovery. For example, 10.1.1.0/24. |
| **User-ID Agents Tab** | |
| Name | Enter a name to identify the User-ID Agent (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |

**Table 129. User-ID Agent Settings (Continued)**

| Field | Description |
|---|---|
| Virtual System | Select the virtual system from the drop-down list (if supported on the firewall model). |
| IP Address | Enter the IP address of the Windows PC on which the User-ID Agent is installed. |
| Port | Enter the port number on which the User-ID Agent service is configured on the remote host.<br>When using a PAN-OS firewall as a redistribution point for user mapping information and you configure the User-ID Agent to connect to that device, you must use port 5007. |
| Collector Name | Enter the collector name that the User-ID Agent will pull from to obtain user mapping information. Refer to the "User Mapping Tab" on page 286. |
| Collector Pre-shared Key/Confirm Collector Pre-shared key | Enter the pre-shared key that will be used to allow SSL connectivity between the User-ID Agent and the firewall that is acting as a distribution point for user mapping. |
| Use as LDAP Proxy | Select the check box if the User-ID Agent is to be used as a LDAP proxy instead of the firewall connecting directly to the directory service. |
| Use for NTLM Authentication | Select the check box to use the configured User-ID Agent to verify NTLM client authentication from the captive portal with the Active Directory domain. |
| Enabled | Select the check box to enable the user identification agent. |
| Refresh Connected | Click to refresh the connection status of User-ID Agent profiles. This button is located to the right of the Add and Delete buttons. |
| Custom Agent Sequence | This option allows you to define the sequence order in which the User-ID agent profiles will connect to the defined server. For example, if you have four agents identified in the sequence list, it will attempt to connect to the first agent listed, if that connection fails, it will connect to the next agent listed, and so on. If this option is not configured, the connection sequence will follow the order of the agents listed in the main page. |
| **Terminal Services Agent Tab** | |
| Name | Enter a name to identify the TS Agent (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Virtual system | Select the virtual system from the drop-down list (if supported on the firewall model). |
| Host | Enter the IP address of the Windows PC on which the TS Agent will be installed. You can also specify alternative IP addresses (see the last entry in this table). |
| Port | Enter the port number on which the User-ID Agent service is configured on the remote host. |
| Alternative IP Addresses | Enter additional IP addresses, if the server has multiple IP addresses that can appear as the source IP address for the outgoing traffic. |

**Table 129. User-ID Agent Settings (Continued)**

| Field | Description |
|---|---|
| **Group Mapping Settings Tab** | |
| Name | Enter a name to identify the user-to-group mapping for user identification (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Virtual system | Select the virtual system from the drop-down list (if supported on the firewall model). |
| Server Profile subtab | Specify the following settings:<br>• Select an LDAP server profile from the drop-down list, and specify the interval (seconds) after which the configuration is updated with any new server profile information.<br>• Group objects<br>– **Search Filter**—Specify an LDAP query that can be used to control which groups are retrieved and tracked.<br>– **Object Clas**s—Specify the definition of a group. For example, the default is objectClass=group, which means that the system retrieves all objects in the directory that match the group filter and have object-Class=group.<br>– **Group Name**—Enter the attribute that specifies the name of the group. For example in Active Directory, this attribute is "CN" (Common Name).<br>– **Group Member**—Specify the attribute that contains the members of this group. For example in Active Directory, this attribute is "member."<br>• User Objects<br>– **Search Filter**—Specify an LDAP query that can be used to control which users are retrieved and tracked.<br>– **Object Clas**s—Specify the definition of the a user object. For example in Active Directory, the objectClass is "user."<br>– **User Name**—Specify the attribute for user name. For example in Active Directory, this attribute is "samAccountName." |
| Group Include List | Locate groups in the **Available Groups** list. Click the ⊞ icon to add the groups to the **Included** list and click the ⊟ icon to remove groups from the list. |
| **Captive Portal Settings Tab** | |
| Enable Captive Portal | Select to enable the captive portal option for authentication. |
| Location | Select the virtual system from the drop-down list (if supported on the firewall model). |
| Idle Timer | Enter the length of time after which the captive portal page times out (1-1440 minutes, default 15 minutes). |
| Expiration | Specify the timeout interval (range 1 - 1440 minutes, default 60 minutes). |
| Redirect Host | Specify the hostname used for the HTTP redirect used to initiate the NTLM challenge sent to the client. |

**Table 129. User-ID Agent Settings (Continued)**

| Field | Description |
|---|---|
| Server Certificate | Select the HTTP SSL certificate used for captive portal.<br>**Note:** If you select **None**, the firewall will use the local default certificate to provide an SSL connection. |
| Certificate | Choose the certificate profile to use for client authentication. |
| Authentication Profile | Choose the profile to determine the authentication source for captive portal logins. |
| NTLM Authentication | For NTLM authentication, specify the following:<br>• **Attempts**—Specify the number of attempts after which the NTLM authentication fails.<br>• **Timeout**—Specify the number of seconds after which the NTLM authentication times out.<br>• **Reversion Time**—Specify the time after which the firewall will again try to contact the first agent in the list of User-ID Agents after the agent becomes unavailable.<br>***Note:*** *These options only apply to the User-ID Agent installed on domain servers and does not apply to the PAN-OS User-ID feature configured in the User Mapping tab on the User Identification page.* |
| Mode | Choose whether the captive portal will use redirection or be transparent to the user.<br>Redirection is required for NTLM and session cookie retention. With the redirection option, the firewall can set a cookie for future login requests. Future redirection then becomes transparent to the user if the browser has not been closed.<br>For session cookies, specify the following settings:<br>• **Enable**—Select the check box to configure an interval after which the redirection times out.<br>• **Timeout**—If **Enable** is selected, specify the timeout interval (range 60 - 10080 minutes, default 1440 minutes).<br>• **Roaming**—Select the check box if to retain the cookie if the IP address changes while the browser is open (for example, if the client moves from a wired to wireless network). The cookie is lost when the browser closes, whether or not **Roaming** is selected.<br>***Note:*** *To use the captive portal in redirect mode, you must enable response pages on the interface management profile assigned to the Layer 3 interface to which you are redirecting the active portal. Refer to "Defining Interface Management Profiles" on page 175 and "Configuring Layer 3 Interfaces" on page 130.* |

# PAN-OS User Mapping Configuration

This section describes the basic steps needed to configure a firewall to retrieve IP address-to-user name mapping data directly from domain servers. This feature does not require the installation of a User-ID Agent on the domain servers. The firewall can also be configured to redistribute the user mapping information to other firewalls.

Refer to the following sections:

- "Configuring PAN-OS User Mapping" in the next section

- "Configure a Firewall to Share User Mapping Data" on page 295

# Configuring PAN-OS User Mapping

This section describes the configuration information needed to gather IP address-to-user name mapping and group mapping data for User Identification.

In this example, there is no need to install a User-ID Agent client on the domain controller. The following components need to be configured:

- **Domain Account**—A domain account is needed to query Microsoft Active Domain Controllers to obtain user information from security logs and to perform LDAP queries.
- **User-ID Agent**—As of PAN-OS 5.0, you configure the User-ID agent using the **User Mapping** tab, which is used to configure the native version of the agent.
  In large environments where performing user mapping enumeration may start to cause performance issues on the firewall, you will want to use the agent installed on domain controllers, which is configured in the **User-ID Agents** tab. For information on installing this agent, refer to "Setting Up the User-ID Agent" on page 296.
- **LDAP Server Profile**—This profile is used to define the domain controller server information that the firewall will use to perform queries for gathering user and group mapping information.
- **Group Mappings**—These settings allow the firewall to associate users with user groups, which enables you to create policies based on directory groups. The LDAP Server Profile is used in the Group Mappings settings to define the servers that will be queried.
- **Policies**—You need to configure the appropriate security profiles so the firewall can communicate with the defined directory servers.

The following outlines the basic steps needed to configure PAN-OS User Mapping:

1. Obtain a login account and password that has permissions to the servers and hosts that you will use to retrieve user mapping information. The permissions needed is based on the methods you will enable to gather the user mapping information, which may be from

Microsoft Active Directory servers, Microsoft Exchange servers, Microsoft file servers, Novell eDirectory, or using WMI to access client PCs.

**Note:** In Windows 2008 or later domains, you can add an account to the "Event Log Readers" group to access event logs to obtain IP address-to-user name mapping information from event logs. In Windows 2003 domains, the account should be assigned "Manage Auditing and Security logs" permissions through group policy.

You can also add the account to Server Operators to grant permissions to view current open server sessions to obtain IP address-to-user name mapping information for Windows 2003 and 2008 domains.

For the LDAP group queries to identify user to group mappings, no special membership is needed, most accounts can obtain group membership in Active Directory.

WMI is reliable and is secured by NTLM or Kerberos based authentication. To perform WMI queries, an account is needed that has rights to read CIMV2 namespace on the client system. By default, domain administrators have this permissions.

2. Navigate to **Device > User Identification** and click the **User Mapping** tab.
3. Click the **Edit** icon on the upper right side of the **Palo Alto Networks User ID Agent Setup** window. On this page, you define the settings that will be used when collecting IP address-to-user name mapping information on the servers defined in the **Server Monitoring** list. Populate each tab based on your requirements. Refer to "User Mapping Tab" on page 286 for descriptions of each of the user mapping settings. The **Redistribution** tab is only used if you plan on using this firewall to distribute user mapping information to other devices.
4. Click **OK** to save the settings.
5. In the **Server Monitoring** section, click **Add** to add the domain servers that you will access to gather user information. Enter the server Name, Network Address, and Type (Microsoft Active Directory, Microsoft Exchange, or Novel eDirectory).
   You can also click the **Discover** icon to discover domain controllers using DNS lookups. The firewall will discover domain controllers based on the domain name entered in the Device > Setup > Management > General Settings page.
6. Select the check box next to each domain server that you will monitor.
7. To specify networks that will be included or excluded in the user mapping data, click the Add icon in the Include/Exclude section and define the networks you want to filter. This allows you to send filtered user mapping data to the other firewalls in your network that use this device to pull user mapping information.

***Note:*** *You can also exclude a list of user accounts from being mapped by creating an ignore-user list. When using the Palo Alto Networks User Mapping feature, the list of user accounts to exclude is created in the CLI by using the command* `set user-id-collector ignore-user <value>`.

*There is no limit to the number of accounts that can be added to this list.*

8. Click Commit to make the changes active.

   You can check the status of the directory server connection by running the `show user server-monitor state` or `show user server-monitor statistics` commands.

Now that the User-ID Agent is configured, you need to configure an LDAP profile.

1. Name your configuration and leave the **Administrator use only** check box unchecked.
2. List the directory servers that you want the firewall to use in the server list. You need to provide at least one server; two or more are recommended for failover purposes. The standard LDAP port for this configuration is 389.
3. Leave the "Domain" field empty, unless you want to configure multiple independent directories.
4. Select a directory "Type". Based on the selected directory type, the firewall can populate default values for attributes and objectclasses used for user and group objects in the directory server.
5. Enter the base of the LDAP directory in the "Base" field. For example, if your Active Directory Domain is "paloaltonetworks.local", your base would be "dc=paloaltonetworks, dc=local", unless you want to leverage an Active Directory Global Catalog. In the "Bind DN" field, enter a user name for a user with sufficient permission to read the LDAP tree. In an Active Directory environment, a valid username for this entry could be the "User Principal Name", e.g. "administrator@paloaltonetworks.local" but also the users distinguished name, e.g. "cn=Administrator,cn=Users,dc=paloaltonetworks,dc=local".
6. Enter and confirm the authentication password for the user account that you entered above.

If you want to create policies based on directory groups, you need to configure Group Mapping. This configuration defines how groups and users are retrieved from the directory and which users groups should be included for use in policies.

1. Navigate to **Device > User Identification**, click the **Group Mapping Settings** tab and then click **Add**.
2. In the **Server Profile** drop-down, select the LDAP profile that you created in the previous section. All LDAP attributes and ObjectClasses will be pre-populated based on the directory server type you selected in the LDAP Server Profile page.
3. Adjust the **Update Interval** field if needed. The default is 3600 seconds (1 hour).
4. In order to optimize LDAP queries and policy configurations you can specify a list of user groups you would like to include in policies. To do this, click the **Group Include List** tab.
5. The left pane will show **Available Groups**, either navigate to the desired group, or search for groups that you want to include in your queries. You can use the asterisks (*) to do pattern matching in your searches.
6. Select the desired group(s) and then click the symbol to add the group(s) to the **Included Groups** pane.
7. Click **OK** to save group mapping.

# Configure a Firewall to Share User Mapping Data

Once you configure a firewall to retrieve user mapping information as described in "Configuring PAN-OS User Mapping" on page 292, you can designate the firewall to provide this information to other PAN-OS firewalls on your network.

The illustration in Figure 35 shows that a redistribution firewall communicates with the domain server to retrieve user to IP mapping information. The redistribution firewall can use any method to collect user mapping and group mapping information as described in "How User Identification Works" on page 281, and will then act as a User-ID Agent to share this information with other firewalls. Firewalls FW1, FW2, and so on, are configured to pull the mapping information directly from the redistribution firewall and do not need to communicate directly with any domain servers.

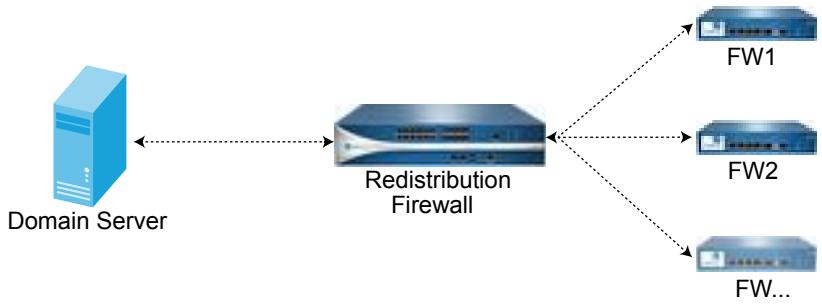

**Figure 35. Firewall configured to share user mapping information**

1. Navigate to **Device > User Identification** and click the **User Mapping** tab.
2. Click the **Edit** icon on the upper right side of the **Palo Alto Networks User ID Agent Setup** window and then click the **Redistribution** tab.
3. Enter a **Collector Name** and a **Pre-shared Key**. This information will be used by the firewall(s) that will pull user mapping information.
4. Click **OK** to save your changes.
5. Navigate to **Network > Network Profiles > Interface Mgmt** to enable the User-ID Agent Service.
6. Either **Add** a new Interface Management Profile, or modify an existing profile. Select the **User-ID Service** check box to enable the service.

The firewall is now ready to redistribute user mapping information to other firewalls.

To configure a firewall to retrieve information from a user mapping redistribution firewall, perform the following steps:

1. Navigate to **Device > User Identification** and click the **User-ID Agents** tab. Refer to "User-ID Agents Tab" on page 288 for setting details.
2. Click **Add** and enter a **Name** for the User Identification Agent profile and then populate the following fields:
   a. **Host**—Enter the host name or IP address of the firewall that is configured as a user mapping redistribution point.

b. **Port**—Enter 5007 for the port number. This is the designated port used for this service and cannot be modified.

c. **Collector**—Enter the collector name of the firewall that is configured as a user mapping redistribution point.

d. **Collector Pre-Shared Key**—Enter the collector pre-shared key of the firewall that is configured as a user mapping redistribution point.

e. **Use as LDAP Proxy**—Select this check box to use the firewall as an LDAP Proxy, instead of connecting directly to the directory server. This is used to query directory group and group membership information.

f. **Use for NTLM Authentication**—Select this check box to use the firewall to verify NTLM client authentication from the captive portal with the Active Directory domain.

g. Select the **Enabled** check box and click **OK** to save your settings and then **Commit** the configuration.

3. In the User-ID Agent window, look at the **Connected** column for the new User-ID Agent configuration. A green icon indicates that communication has been established with the firewall that is serving user mapping data.

   If a red icon appears, check traffic logs to determine why communications is not working properly. You can also check to see if any user mapping data has been received by running the operational command **show user ip-user-mapping** to view user mapping information on the dataplane, or **show user ip-user-mapping-mp** to view mappings on the management plane.

**Note:** When redistributing user mapping information to systems with multiple virtual systems, the following configuration is needed:

- Distribution Firewall—Each virtual system must have the collector configured with a pre-shared key. Refer to "Redistribution tab" on page 288. You also need to allow the User-ID Agent services from Network > Network Profiles > Interface Mgmt.
- Receiving Firewall—The collector name and pre-shared secret is needed in order to decide which virtual system User-ID information should be received.

# Setting Up the User-ID Agent

The User-ID Agent interfaces with Active Directory or eDirectory to communicate IP address-to-user name mapping information to the firewall.

The User-ID Agent is available for download from Palo Alto Networks. You can install the agent on one or more Windows PCs on your network to obtain user-specific information. When user identification is configured, the firewall's Application Command Center, App-Scope, and logs all include the user name in addition to the user IP address.

Follow the instructions in this section to install and configure the User-ID Agent.

***Note:*** *If the multiple virtual system capability is on, you can configure one or more agents per virtual system. This is useful to separate user identification in support of ISPs or other entities that maintain separate user records.*

## Installing the User-ID Agent

The system on which the User-ID Agent is installed must be running one of the following operating systems/directory server versions:

***Note:*** *The 32-bit or 64-bit versions of the below operating systems are supported.*

### Host Computers

- Microsoft Windows XP/Vista/7
- Microsoft Windows Server 2003/2008

### Directory Servers

- Microsoft Exchange
  - 2003 (6.5)
  - 2007 (8.0)
  - 2010 (14.0)
- Microsoft Active Directory
  - 2003
  - 2003r2
  - 2008
  - 2008r2
- Novell eDirectory Server 8.8

***Note:*** *Make sure that you choose the correct installation option for your client operating system (32-bit or 64-bit).*

Each PC that is included for user identification must be part of the authentication domain. For machines that are not part of the domain, you can use the captive portal capability to screen users and verify user names and passwords.

Refer to these sections for additional information:

- "Configuring the Firewall for User Identification" on page 286—Describes how to set up the firewall to communicate with the User-ID Agents and support captive portals.
- "Captive Portal Policies" on page 206—Describes how to set up captive portal policies.

To install the User-ID Agent, open the installer file and follow the on-screen instructions.

## Configuring the User-ID Agent

To open the User-ID Agent:

1. Choose **Start > All Programs > Palo Alto Networks > User-ID Agent**.

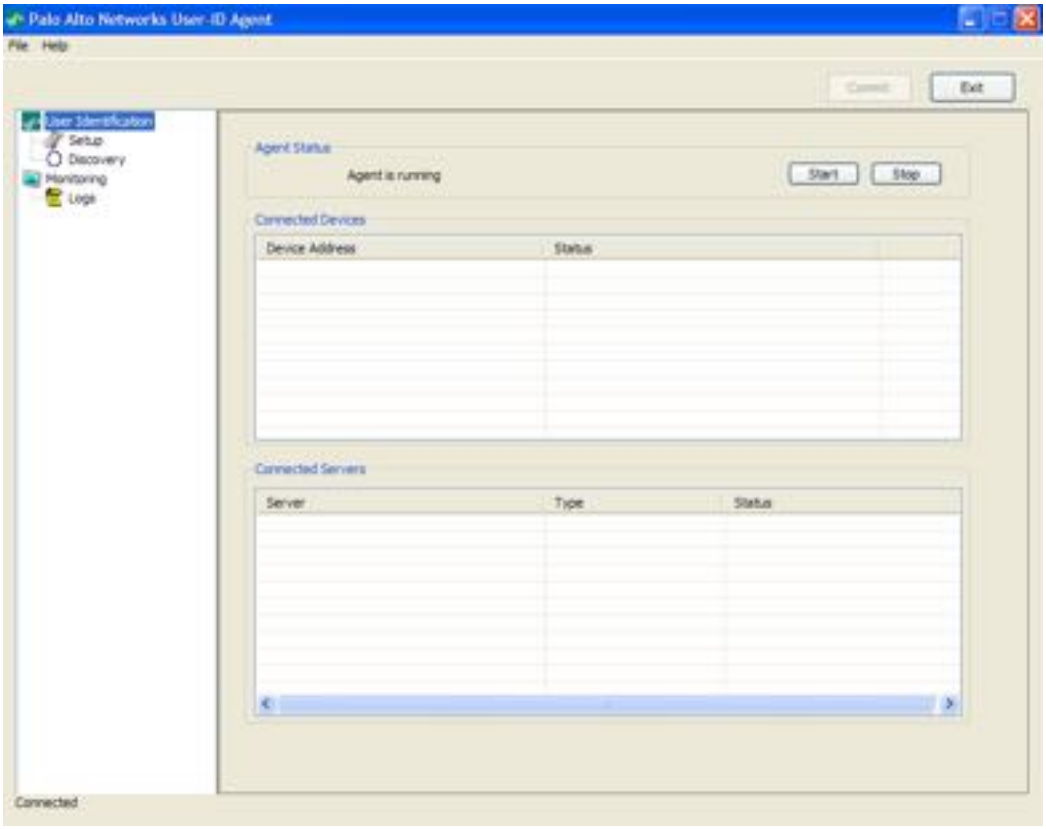

**Figure 36. User-ID Agent Window**

The window contains the following areas and functions:

- **Agent Status**—Displays the current status of the User-ID Agent.
- **Connected Devices**—Displays the list of devices that the User-ID Agent is currently connected to with associated status.
- **Connected Servers**—Displays the list of servers that the User-ID Agent is currently connected to with associated type and status.

To configure the User-ID Agent:

1. Choose **Start > All Programs > Palo Alto Networks > User Identification Agent**.
2. Click **Setup** to open the configuration window.

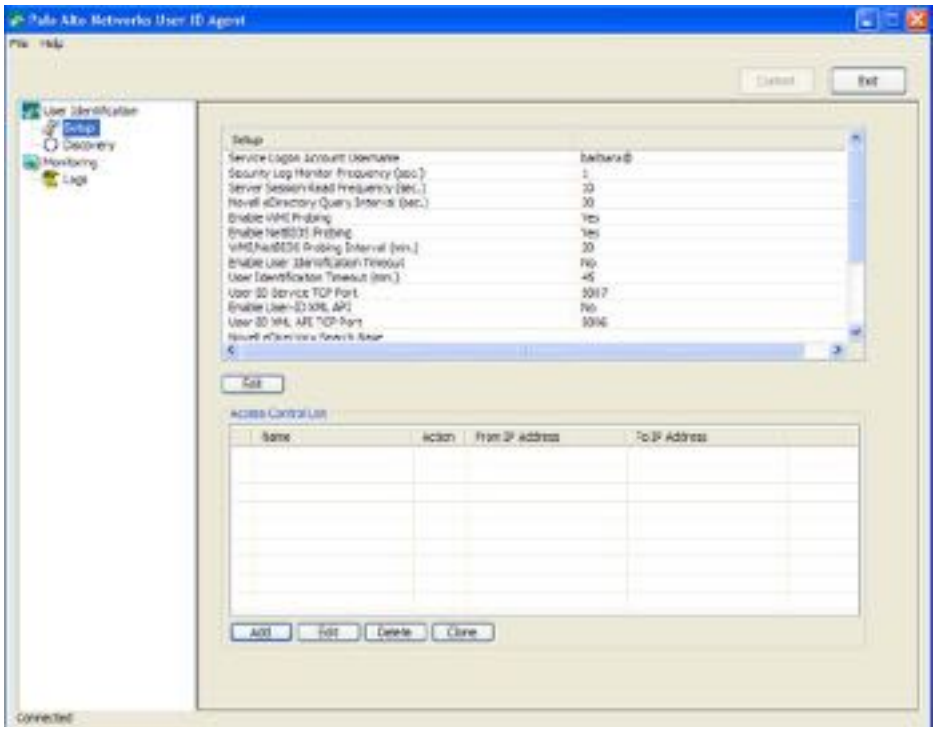

**Figure 37. User Identification Configuration Window**

3. The top of the window lists the current configuration settings. To modify the settings, click **Edit** just below the configuration summary and specify the following settings:
   - **Authentication**—Specify the user name and password to authenticate for Active Directory, WMI, NetBIOS, or eDirectory.
   - **Server Monitor**—Specify the frequency in seconds (default 1 second) for security log monitor and server session read (default 10 seconds) for Windows server and the query interval for Novell eDirectory query interval. (default 30 seconds).
   - **Client Probing**—Select the **Enable WMI Probing** check box if you want to enable WMI probing for each workstation and the **Enable NetBIOS Probing** check box if you want to enable NetBIOS probing for each workstation. Specify an interval between probes (seconds, default 20). An interval of 0 disables this feature.

***Note:*** *For WMI polling to work effectively, the Pan Agent service must be configured with a domain administrator account, and each probed client PC must have a remote administration exception configured in the Windows firewall.*

***Note:*** *For NetBIOS probing to work effectively, each probed client PC must allow port 139 in the Windows firewall and must also have file and printer sharing services enabled.*

- **Cache**—Select the check box to enable timeout for the user ID and group cache, and specify the interval (minutes) after which the timeout occurs. Default 45 minutes.
- **Agent Service**—Specify the TCP ports for the user ID service (default 5007) and the user ID XML API (default 5006). Select the check box to enable use of the API.
- **eDirectory**—Specify the following settings:
  - **Search Base**—Specify the starting point or root context for agent queries. Example: dc=domain1, dc=example, dc=com.
  - **Bind Distinguished Name**—Specify the account to bind to the LDAP server. Example: cn=admin, ou=IT, dc=domain1, dc=example, dc=com.
  - **Bind Password**—Specify the bind account password. The agent saves the encrypted password in the configuration file.
  - **Search Filter**—Specify the search query for LDAP entries (default is objectClass=Person).
  - **Search Interval**—Specify the time interval between consecutive queries from the User-ID Agent (range 1-36000 secs, default 30 secs).
  - **Server Domain Prefix**—Specify a prefix to uniquely identify the user. Use if there are overlapping name spaces. Example: Different users with the same name from two different directories.
  - **Use SSL**—Select the check box to use SSL for eDirectory binding. If SSL is not selected, a pop-up window warns that clear text will be used for the login account and password.
  - **Verify Server Certificate**—Select the check box to verify the eDirectory server certificate when using SSL. Select the **Enable Group Cache** check box to enable the user-group membership cache. When this check box is selected, the user-group membership is cached, and when started, it first reloads the user-group membership from the cache to speed up the restart process.

4. Click **Save** to save the configuration.

   The User-ID Agent is restarted if the configuration is saved successfully. You can also click the **OK** button to save the configuration and restart the User-ID Agent. If you do not want to restart the User-ID Agent, click **Cancel** to close the dialog box.

***Note:*** *You can exclude a list of user accounts from being mapped by creating an ignore-user list. To do this, you create an ignore_user_list.txt file that is placed in the User-ID Agent folder on the domain server where the agent is installed.*

*As of PAN-OS 4.1 and later, there is no limit to the number of accounts that can be added to these lists. In PAN-OS 4.0 and earlier, the limit was 100 users.*

### Discovering Domain Controllers

The list of domain controllers available for domain login can be retrieved via DNS. To display the discovery options, click **Discover** on the side menu. You can perform the following tasks in this window:

- Add a configuration setting that allows an administrator to configure the User-ID agent to automatically discover available domain controllers for event log monitoring. Click **Add** or **Edit** in the **Servers** area and specify a server name, IP address, and type (Microsoft Active Directory, Microsoft Exchange, or Novell eDirectory).
- Specify an access control list for networks. Click **Add** or **Edit** in the **Include/exclude lists of configured networks** area, choose the include or exclude option, and specify the network name and address. You can also clone and then modify an existing entry.
- Click **Auto Discover** to automatically retrieve the list of available domain controllers from DNS and add those to the list of monitored servers.

### Monitoring User-ID Agent Operation

To view the list of currently discovered IP address-to-user name mapping information, click **Monitoring** on the side menu. You can search for users, or delete users from the list.

To view log entries for the User-ID agent, click **Logs** on the side menu. From this window you can search for log entries or clear the log.

### Uninstalling and Upgrading the User-ID Agent

To uninstall the User-ID Agent, open the Control Panel on the PC, select **Add or Remove Programs**, and remove the program **User Identification Agent**.

If you install a new version of the agent and the installer detects an existing installation on your PC, the installer automatically removes the older version before performing the installation.

We recommend that you back up the config.xml file before upgrading the User-ID Agent.

## Setting Up the Terminal Services Agent

The Terminal Server Agent (TS Agent) allows the firewall to support multiple users with the same source IP address by identifying the individual firewall users that the terminal server supports.

The TS Agent monitors the remote user sessions and reserves a different TCP/UDP source port range for each user. After a port range is allocated for the user, the TS Agent provides information to map the source port range to the user name.

In addition, the TS Agent requests that the TCP/UDP transport driver in the terminal server allocate the TS-Agent-specified source port instead of the operating system-determined ephemeral port for outbound TCP/UDP traffic. When the firewall receives the TCP/UDP traffic from the terminal server, it checks the source port and obtains the user ID in the ports-to-user map data for the terminal server.

For information on configuring the firewall for terminal services, refer to "Configuring the Firewall for User Identification" on page 286.

## Installing or Upgrading the Terminal Server Agent on the Terminal Server

You can install the TS Agent on the following platforms:

- Microsoft Terminal Services 2003
- Microsoft Terminal Services 2008
- Citrix Metaframe Presentation Server 4.0
- Citrix Metaframe Presentation Server 4.5, Citrix XenApp 5, 6

To install the TS Agent on the terminal server:

1. Download and open the installation file.
2. The installer first checks for platform compatibility. If the platform is not compatible, an error message is displayed.
3. The installer checks whether an existing TS Agent exists on the system. If the installer detects that the TS Agent already exists on the system (you are upgrading the TS Agent), it first uninstalls the agent before running the installer.
   - If you are installing a TS Agent that has a newer driver than the existing installation, the installation wizard prompts you to reboot the system after upgrading in order to use the new driver.
   - If you are installing a TS Agent with the same driver version as the existing installation, you can perform the installation as prompted, and do not need to reboot the system afterwards.
4. Follow the installer instructions to specify an installation location and complete the installation.

***Note:*** *If you specify a destination folder other than the default one, make sure that you use the same destination when you upgrade the TS Agent in the future. If you do not, the existing configuration will be lost and the default configuration will be used.*

5. Following installation, reboot the terminal server, if prompted to do so.

## Configuring the Terminal Server Agent on the Terminal Server

To configure the TS Agent on the terminal server:

1. Launch the TS Agent application from the **Start** menu.
2. The configuration panel opens with **Terminal Server Agent** highlighted on the left side of the window.

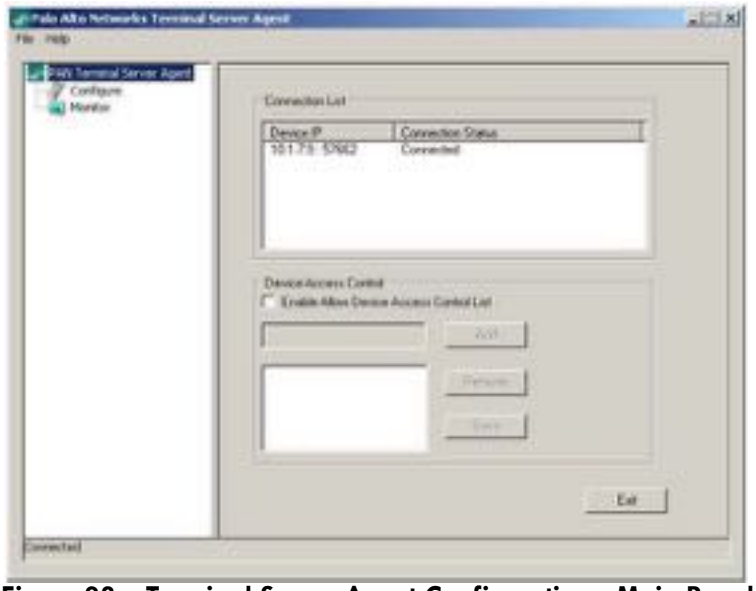

**Figure 38. Terminal Server Agent Configuration - Main Panel**

The connection list box shows all the Palo Alto Networks devices that connect to the TS Agent. The **Device IP** column shows the device IP and port; and the **Connection Status** column indicates whether the status is Connected, Disconnected, or Connecting. Disconnected items are removed from the **Connection List** box when you close and then reopen the TS Agent configuration window.

3. Select the **Enable Device Access Control List** check box if you want to explicitly list the firewalls that the TS Agent will accept. Add each device IP address and click **Add**. Click **Remove** to delete an address from the list. Click **Save** to save the allow list.

4. Click **Configure** to display the configuration settings.

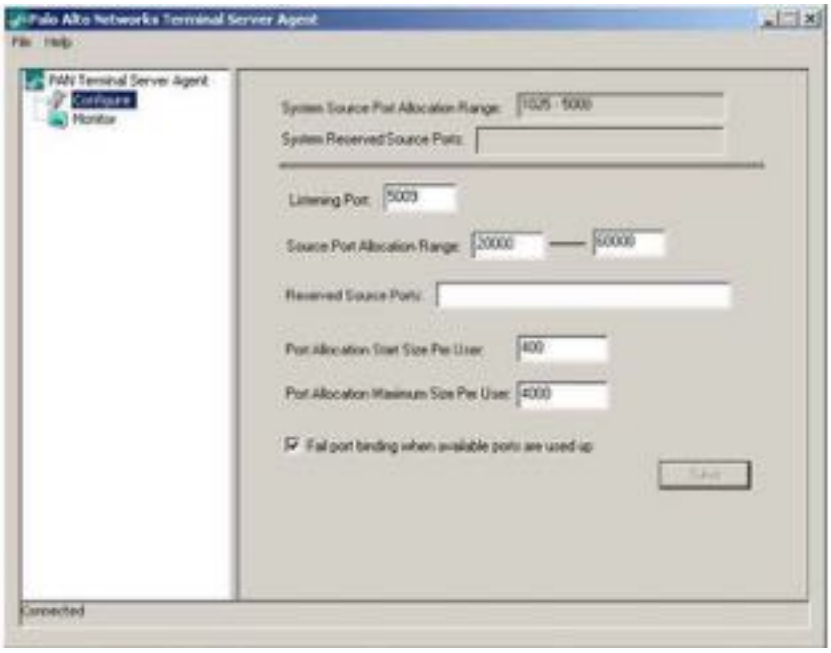

**Figure 39. Terminal Server Agent Configuration - Configure Panel**

5. Configure settings as described in the following table, and then click **Save**.

***Note:*** *If you enter an incorrect parameter and then attempt to save the configuration, a message is displayed to indicate that the configuration will not be saved unless you modify the parameter correctly.*

**Table 130. Terminal Server Agent Configuration Settings**

| Field | Description |
|---|---|
| System Source Port Allocation Range | Displays the port range for system processes that are not associated with individual users. When a server process opens a socket to send a UDP packet or set up a TCP connection, it must obtain a source port from the server operating system. The server automatically allocates a source port (an ephemeral port) for this process. Format is low-high (default 1025-5000).<br>The system port range must not overlap with the Source Port Allocation Range. If they overlap, an application using the system ephemeral source port range could mistakenly be identified as a particular user if the operation system allocated source port falls within the port range allocated for that user.<br>***Note:*** *Modifying this value requires a Registry change and cannot be done from this panel.* |
| System Reserved Source Ports | Displays the port or ports to be excluded from the operating system source port allocation (because other server processes may use them).<br>You can enter a range: *low-high* (no default).<br>***Note:*** *Modifying this value requires a Registry change and cannot be done from this panel.* |

**Table 130. Terminal Server Agent Configuration Settings (Continued)**

| Field | Description |
|---|---|
| Listening Port | Enter the port on which the terminal server will listen for communications from Palo Alto Networks firewalls (default 5009). |
| Source Port Allocation Range | Enter a port allocation range for user sessions.<br>This setting controls the source port allocation for processes belonging to remote users (default 20000-39999). If a port allocation request comes from system services that cannot be identified as a particular user process, the TS Agent lets the system allocate the source port from the system port range, excluding system reserved source ports.<br>***Note:*** *Make sure that this port range does not overlap with the System Source Port Allocation Range. If they overlap, an application using the system ephemeral source port range could mistakenly be identified as a particular user if the operation system allocated source port falls within the port range allocated for that user.* |
| Reserved Source Ports | Enter the reserved port allocation range for user sessions. These ports are unavailable for user sessions.<br>To include multiple ranges, use commas with no spaces, as in this example: 2000-3000,3500,4000-5000.<br>Format is *low-high* (no default). |
| Port Allocation Start Size Per User | Enter the number of ports that the TS Agent will first allocate when the remote user logs in (default 200).<br>When the remote user logs on, the TS Agent allocates a port range from the Source Port Allocation Range with this specified size. This allows identification of user traffic based on the source port. |
| Port Allocation Maximum Size Per User | Enter the maximum number of ports that the TS Agent can allocate for a remote user session (default 200).<br>If the **Port Allocation Start Size Per User** setting is not sufficient for the user session, the TS Agent will allocate additional ports up to this maximum. |
| Fail port binding when available ports are used up | Select the check box as appropriate:<br>• If the check box is selected (default), the port request from this user's application fails if the user application has used all available ports. As a result, the application may fail to send traffic.<br>• If the check box is not selected, the port request from this user's application is granted from the **System Source Port Allocation Range** even if the user application has used all the available ports. The application can send traffic; however, the user ID of the traffic is unknown. |

6. Click **Monitor** to display the port allocation information for all terminal server users.

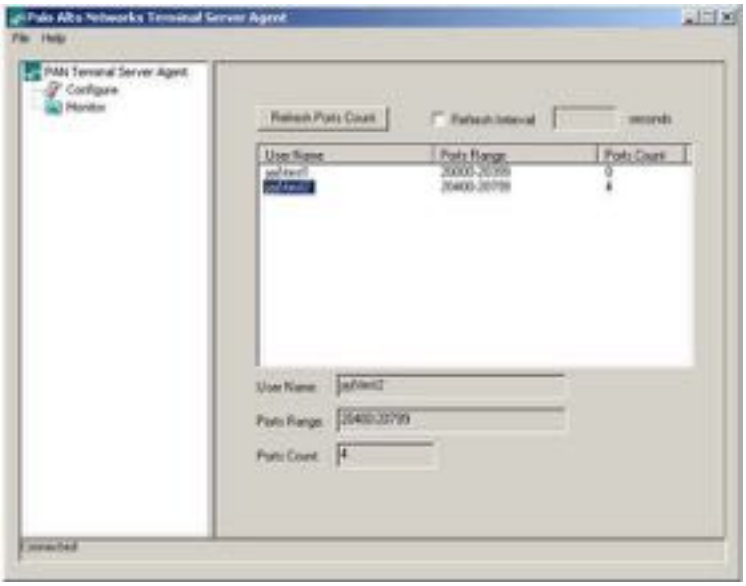

**Figure 40. Terminal Server Agent Configuration - Monitor Panel**

7. View the displayed information. For a description of the type of information displayed, refer to the following table.

**Table 131. Terminal Server Agent Monitor Information**

| Field | Description |
|---|---|
| User Name | Displays the user name. |
| Ports Range | Displays the current allocated source ports for this user. Multiple ranges are separated by commas (for example, "20400-20799, 20500-20599").<br>The size of the port ranges is limited by the "Port Allocation Start Size Per User" and "Port Allocation Maximum Size Per User" configuration parameters, as described in Table 130. |
| Ports Count | Indicates the number of ports in use. |

8. Click the **Refresh Ports Count** button to update the **Ports Count** field manually, or select the **Refresh Interval** check box and configure a refresh interval to update this field automatically.

The following table lists the menu options available in the TS Agent application window.

**Table 132. Terminal Server Agent Menu Options**

| Field | Description |
|---|---|
| Configure | Open the Configuration panel. |
| Monitor | Open the Monitor panel. |
| Restart Service | Restart the TS Agent service. This option is not normally required and is reserved for troubleshooting. |
| Show Logs | Display the troubleshooting log. |

**Table 132. Terminal Server Agent Menu Options (Continued)**

| Field | Description |
|---|---|
| Debug | Select debugging options (None, Error, Information, Debug, or Verbose). |
| Exit | Quit the TS Agent application. |
| Help | Display TS Agent version information. |

## Uninstalling the Terminal Server Agent on the Terminal Server

To uninstall the TS Agent, use the **Add/Remove Programs** control panel on the server. Remove the "Terminal Server Agent" application. You must reboot the system to complete the uninstallation.

## Chapter 8
# Configuring IPSec Tunnels

This chapter describes basic virtual private network (VPN) technology and provides details on configuring IP Security (IPSec) VPNs on Palo Alto Networks firewalls.

Refer to the following sections:

- "Virtual Private Networks" in the next section
- "IPSec and IKE" on page 311
- "Setting Up IPSec VPNs" on page 313
- "Sample VPN Configuration" on page 320
- "GlobalProtect Large Scale VPN Deployment" on page 323

# Virtual Private Networks

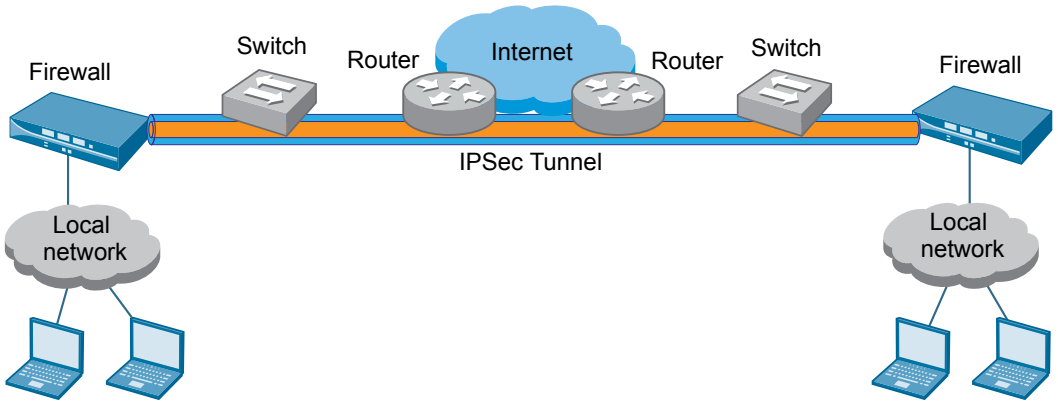
Virtual private networks (VPNs) allow systems to connect securely over a public network as if they were connecting over a local area network (LAN). The IP Security (IPSec) set of protocols is used to set up a secure tunnel for the VPN traffic, and the private information in the TCP/IP packets is encrypted when sent through the IPSec tunnel. The Palo Alto Networks firewall supports IPv4 tunnels as well as the option to enable IPv6 in the tunnel configuration. This option allows you to route IPv6 traffic over the IPv4 tunnel to provide confidentiality between IPv6 networks when IPv6 WAN connectivity is not available.

The Palo Alto Networks GlobalProtect Large Scale VPN feature provides a greatly simplified mechanism to roll out a hub and spoke VPN that utilizes certificates for authentication and automatically refreshes the authentication credentials periodically. Refer to "GlobalProtect Large Scale VPN Deployment" on page 323.

***Note:*** *In addition to IPSec VPNs, the firewall also supports Secure Sockets Layer (SSL) VPNs, which allow remote users to establish VPN connections through the firewall. Refer to* ***Chapter 9, "Configuring GlobalProtect"*** *for more information.*

The following figure shows a standard IPSec tunnel between two devices. The configuration can include a tunnel monitor on each side to alert the device administrator of tunnel failure and provide automatic failover. Tunnel monitors are useful if you want to be able to provide failover of IPSec traffic to another interface.

**Figure 41. IPSec Standard Configuration**



You can configure route-based VPNs to connect Palo Alto Networks firewalls at central and remote sites or to connect Palo Alto Networks firewalls with third-party security devices at other locations. With route-based VPNs, the firewall makes a routing decision based on the destination IP address. If traffic is routed to a specific destination through a VPN tunnel, then it is encrypted as VPN traffic. It is not necessary to define special rules or to make explicit reference to a VPN tunnel; routing and encryption decisions are determined only by the destination IP address.

The firewall can also interoperate with third-party policy-based VPN devices. To connect with a policy-based VPN, configure the Proxy ID for the tunnel. If multiple phase 2 tunnels are required, configure different Proxy IDs on each. Refer to "Setting Up IPSec Tunnels" on page 315.

For the IPSec connection between the firewalls, the full IP packet (header and payload) is embedded in another IP payload, and a new header is applied. The new header uses the IP address of the outgoing firewall interface as the source IP address and the incoming firewall interface at the far end of the tunnel as the destination IP address. When the packet reaches the firewall at the far end of the tunnel, the original packet is decrypted and sent to the actual destination host.

IPSec Security Associations (SAs) are defined at each end of the IPSec tunnel to apply all of the parameters that are required for secure transmission, including the security parameter index (SPI), security protocol, cryptographic keys, and the destination IP address. Encryption, data authentication, data integrity, and endpoint authentication are provided by IPSec SAs.

### VPN Tunnels

To set up VPNs, it is important to understand your network topology and be able to determine the required number of tunnels. For example:

- A single VPN tunnel may be sufficient for connection between a single central site and a remote site.
- Connections between a central site and multiple remote sites require VPN tunnels for each central - remote site pair.

Each tunnel is bound to a tunnel interface. It is necessary to assign the tunnel interface to the same virtual router as the incoming (clear text) traffic. In this way, when a packet comes to the firewall, the route lookup function can determine the appropriate tunnel to use. The tunnel interface appears to the system as a normal interface, and the existing routing infrastructure can be applied.

Each tunnel interface can have a maximum of 10 IPSec tunnels. This allows you to set up IPSec tunnels for individual networks that are all associated with the same tunnel interface on the firewall.

## IPSec and IKE

There are two ways to secure IPSec VPN tunnels:

- Configure the tunnel using manual security keys. This method is not recommended.
- Generate keys using Internet Key Exchange (IKE)

The same method must be applied to both ends of the IPSec tunnel. In the case of manual keys, the same key is entered at both ends; in the case of IKE, the same methods and attributes are applied at both ends.

IKE provides a standard mechanism for generating and maintaining security keys:

- **Identification**—The identification process involves recognition of the peers at both ends of the IPSec tunnel. Each peer is identified by IP address or peer ID (contained in the payload of the IP packet). The firewall or other security device at each end of the tunnel adds the identification of the peer at the other end into its local configuration.
- **Authentication**—There are two types of authentication methods: pre-shared key and PKI. Currently only the pre-shared key method is supported by Palo Alto Networks firewalls.

The firewall supports definition of IKE gateways, which specify the configuration information necessary to perform IKE protocol negotiation with peer gateways.

IKE configuration options include Diffie-Hellman Group for key agreement, Encryption algorithm, and hash for message authentication.

## IPSec and IKE Crypto Profiles

Crypto profiles are related to standard proposal fields in IKE negotiation.

- IKE Phase-1 authenticates the firewalls to each other and sets up a secure control channel. It uses the IKE-crypto profile for IKE SA negotiation.
- IKE Phase-2 is the negotiation, through the Phase 1 SA, of an actual tunnel for traffic between networks behind the respective firewalls. It uses the IPSec crypto profile for IPSec SA negotiation.

You can define IPSec and IKE crypto profiles that determine the protocols and algorithms used to negotiate the IPSec and IKE SAs.

Options for IKE SA:

- **Diffie-Hellman (DH) Group**—Select DH groups to use when generating public keys for IKE.
- **Encryption**—Select encryption algorithms.
- **Hash Algorithm**—Select hash algorithms.
- **Lifetime**—Specify the length of time that the negotiated key will stay effective.

Options for IPSec SA:

- **Encapsulating Security Payload (ESP)**—Select options for authentication, data integrity, confidentiality, and encryption.
- **Authentication Header (AH)**—Select options for authentication and data integrity. This option is not generally used.
- **Perfect Forward Security (PFS) Diffie-Hellman (DH) group**—Select DH groups to use in generating independent keys for IPSec.
- **Lifetime**—Specify the length of time that the negotiated key will stay effective.

For details on the specific protocols and algorithms supported for IPSec and IKE crypto profiles, refer to “Defining IKE Crypto Profiles” on page 318 and “Defining IPSec Crypto Profiles” on page 319.

# Setting Up IPSec VPNs

This section describes the multi-step process involved in setting up IPSec VPN tunnels. For detailed instructions, refer to the specified sections in this guide. For a sample configuration, refer to "Sample VPN Configuration" on page 320.

***Note:*** *Before you begin, make sure that your Ethernet interfaces, virtual routers, and zones are configured properly. Refer to "Firewall Interfaces" on page 127, "Virtual Routers and Routing Protocols" on page 153, and "Defining Security Zones" on page 151.*

To set up IPSec VPNs:

1. Plan the network topology and determine the required number of tunnels.
2. Define IKE gateways with the configuration information for IKE protocol negotiation with peer gateways. Refer to "Defining IKE Gateways" on page 314.
3. Configure the protocols and algorithms for identification, authentication, and encryption in VPN tunnels using IKE SA negotiation:
   - For IKEv1 Phase-1, refer to "Setting Up IPSec Tunnels" on page 315.
   - For IKEv1 Phase-2, refer to "Defining IPSec Crypto Profiles" on page 319.
4. Configure the parameters that are needed to establish IPSec VPN tunnels. Refer to "Setting Up IPSec Tunnels" on page 315.
5. Specify how the firewall will monitor the IPSec tunnels. Refer to "Viewing IPSec Tunnel Status on the Firewall" on page 319.
6. Set up static routes or assign routing protocols to redirect traffic into the newly established tunnels. The Border Gateway Protocol, Routing Information Protocol (RIP), and Open Shortest Path First (OSPF) options are supported; you can enable these protocols on the tunnel interface. Refer to "Virtual Routers and Routing Protocols" on page 153.
7. Set security policies to filter and inspect the traffic as described in "Security Policies" on page 187. Define the source and destination zones and specify the policy attributes as follows:
   - **Outgoing traffic entering the tunnel**—For source, use the clear text zone. For destination, use the tunnel interface zone.
   - **Incoming traffic egressing the tunnel**—For source, use the tunnel interface zone. For destination, use the clear text zone.

   After defining the zones for the security policy rule, set the source and destination addresses, applications, services, and security profiles to control access across the VPN tunnel.

***Note:*** *If the tunnel interface is in the same zone as the destination clear text traffic, the same policies will be used for VPN and clear text traffic. Ideally, you will want to put the tunnel interface in a separate zone, so tunneled traffic can use different policies.*

When these tasks are complete, the tunnel is ready for use. Traffic destined for the addresses defined for the tunnels is automatically routed properly and encrypted as VPN traffic based on the specific destination route added to the routing table.

***Note:*** *Without matching security rules, VPN traffic will be dropped by the firewall, when a security rule is required.*

*The IKE protocol will be triggered when necessary (for example, when traffic is routed to an IPSec tunnel with no keys or expired keys).*

*If there is a deny rule at the end of the security rulebase, intra-zone traffic is blocked unless otherwise allowed. Rules to allow IKE and IPSec applications must be explicitly included above the deny rule.*

## Defining IKE Gateways

▶ ***Network > Network Profiles > IKE Gateways***

Use the **IKE Gateways** page to define gateways that include the configuration information necessary to perform IKE protocol negotiation with peer gateways.

**Table 133. IKE Gateway Settings**

| Field | Description |
|---|---|
| Name | Enter a name to identify the gateway (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Interface | Specify the outgoing firewall interface. |
| Local IP Address | Select the IP address for the local interface that is the endpoint of the tunnel. |
| Peer Type | Static IP address or dynamic option for the peer on the far end of the tunnel. |
| Peer IP Address | If the Static option is selected for peer type, specify the IP address for the peer on the far end of the tunnel. |
| Pre-Shared Key<br>Confirm Pre-Shared Key | Enter a security key to use for authentication across the tunnel. Applies for static and dynamic peer types. |
| ***Note:*** *The following advanced fields are visible if you select the check box for the* ***Show advanced Phase 1 options*** *link.* | |
| Local Identification | Choose from the following types and enter the value: IP address, FQDN (hostname), User FQDN (email address), KEYID (binary format ID string in HEX). If no value is specified, the local IP address will be used as the local identification value. |
| Peer Identification | Choose from the following types and enter the value: IP address, FQDN (hostname), User FQDN (email address), KEYID (binary format ID string in HEX). If no value is specified, the peer IP address will be used as the peer identification value. |
| Exchange Mode | Choose auto, aggressive, or main. |

**Table 133. IKE Gateway Settings (Continued)**

| Field | Description |
|---|---|
| IKE Crypto Profile | Select an existing profile or keep the default profile. |
| Enable Passive Mode | Select to have the firewall respond only to IKE connections and never initiate them. |
| Enable NAT Traversal | Select to have UDP encapsulation used on IKE and UDP protocols, enabling them to pass through intermediate NAT devices.<br>NAT traversal is used when NAT addressing is in place between the IPSec VPN terminating points. |
| Dead Peer Detection | Select the check box to enable and enter an interval (2 - 100 seconds) and delay before retrying (2 - 100 seconds). Dead peer detection identifies inactive or unavailable IKE peers through ICMP ping and can help restore resources that are lost when a peer is unavailable. |

***Note:*** *When a device is set to use the* ***auto*** *exchange mode, it can accept both main mode and aggressive mode negotiation requests; however, whenever possible, it initiates negotiation and allows exchanges in main mode.*

*You must configure the peer device with the matching exchange mode to allow it to accept negotiation requests initiated from the first device.*

## Setting Up IPSec Tunnels

▶ ***Network > IPSec Tunnels***

Use the **IPSec Tunnels** page to set up the parameters to establish IPSec VPN tunnels between firewalls.

**Table 134. IPSec Tunnel Settings**

| Field | Description |
|---|---|
| **General Tab** | |
| Name | Enter a name to identify the tunnel (up to 63 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores.<br>The 63 character limit for this field includes the tunnel name in addition to the Proxy ID, which is separated by a colon character. |
| Tunnel Interface | Select an existing tunnel interface, or click **New Tunnel Interface** to create a new tunnel interface. For information on creating a tunnel interface, refer to "Configuring Tunnel Interfaces" on page 147. |
| Type | Select whether to use an automatically generated or manually entered security key. **Auto key** is recommended. |

**Table 134. IPSec Tunnel Settings (Continued)**

| Field | Description |
|---|---|
| Auto Key | If you choose **Auto Key**, specify the following:<br>• **IKE Gateway**—Refer to "Defining IKE Gateways" on page 314 for descriptions of the IKE gateway settings.<br>• **IPSec Crypto Profile**—Select an existing profile or keep the default profile. To define a new profile, click **New** and follow the instructions in "Defining IPSec Crypto Profiles" on page 319.<br>**Advanced**<br>• **Enable Replay Protection**—Select this option to protect against replay attacks.<br>• **Copy TOS Header**—Copy the (Type of Service) TOS header from the inner IP header to the outer IP header of the encapsulated packets in order to preserve the original TOS information.<br>• **Tunnel Monitor**—Select this option to alert the device administrator of tunnel failures and to provide automatic failover to another interface. Note that you need to assign an IP address to the tunnel interface for monitoring.<br>– Destination IP—Specify an IP address on the other side of the tunnel that the tunnel monitor will use to determine if the tunnel is working properly.<br>– Profile—Select an existing profile that will determine the actions that are taken if the tunnel fails. If the action specified in the monitor profile is wait-recover, the firewall will continue to use the tunnel interface in routing decisions as if the tunnel remained active. If the fail-over action is used, the firewall will disable the tunnel interface, thereby disabling any routes in the routing table that use the interface. For more information, see "Defining Monitor Profiles" on page 177. |
| Manual Key | If you choose **Manual Key**, specify the following:<br>• **Local SPI**—Specify the local security parameter index (SPI) for packet traversal from the local firewall to the peer. SPI is a hexadecimal index that is added to the header for IPSec tunneling to assist in differentiating between IPSec traffic flows.<br>• **Interface**—Select the interface that is the tunnel endpoint.<br>• **Local Address**—Select the IP address for the local interface that is the endpoint of the tunnel.<br>• **Remote SPI**—Specify the remote security parameter index (SPI) for packet traversal from the remote firewall to the peer.<br>• **Protocol**—Choose the protocol for traffic through the tunnel (**ESP** or **AH**).<br>• **Authentication**—Choose the authentication type for tunnel access (**SHA1**, **SHA256**, **SHA384**, **SHA512**, **MD5**, or **None**).<br>• **Key/Confirm Key**—Enter and confirm an authentication key.<br>• **Encryption**—Choose an encryption option for tunnel traffic (**3des**, **aes128**, **aes192**, **aes256**, aes128ccm16, or **null** [no encryption]).<br>• **Key/Confirm Key**—Enter and confirm an encryption key. |

**Table 134. IPSec Tunnel Settings (Continued)**

| Field | Description |
|---|---|
| GlobalProtect Satellite | If you choose **GlobalProtect Satellite**, specify the following:<br>For an overview of the concept of GlobalProtect Satellites, refer to "GlobalProtect Large Scale VPN Deployment" on page 323.<br>• **Name**—Enter a name to identify the tunnel (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores.<br>• **Tunnel Interface**—Select an existing tunnel interface, or click New Tunnel Interface. For information on creating a tunnel interface, refer to "Configuring Tunnel Interfaces" on page 147.<br>• **Portal Address**—Enter the IP address of the GlobalProtect Portal.<br>• **Interface**—Select the interface from the drop-down that is the egress interface to reach the GlobalProtect Portal.<br>• **Local IP Address**—Enter the IP address of the egress interface that connects to the GlobalProtect Portal.<br>**Advanced Options**<br>• **Publish all static and connected routes to Gateway**—Select this option to publish all routes from the satellite device to the GlobalProtect Gateway in which this satellite is connected.<br>• **Subnet**—Click **Add** to manually add local subnets for the satellite location. If other satellites are using the same subnet information, you must NAT all traffic to the tunnel interface IP. Also, the satellite must not share routes in this case, so all routing will be done through the tunnel IP.<br>• **External Certificate Authority**—Select this option if you will use an external CA to manage certificates. Once you have your certificates generated, you will need to import them into the device and select the **Local Certificate** and the **Certificate Profile** to be used. |
| **Proxy ID Tab** | |
| Proxy ID | Click **Add** and enter a name to identify the proxy. |
| Local | Enter an IP address or subnet in the format *ip_address/mask* (for example, 10.1.2.1/24). |
| Remote | If required by the peer, enter an IP address or subnet in the format *ip_address/mask* (for example, 10.1.1.1/24). |
| Protocol | Specify the protocol and port numbers for the local and remote ports:<br>• **Number**—Specify the protocol number (used for interoperability with third-party devices).<br>• **Any**—Allow TCP and/or UDP traffic.<br>• **TCP**—Specify the local and remote TCP port numbers.<br>• **UDP**—Specify the local and remote UDP port numbers.<br>***Note:*** *Each configured proxy ID will count towards the IPSec VPN tunnel capacity of the firewall.* |

### Important items to consider when configuring IPSec VPNs

Keep the following in mind when configuring IPSec VPNs:

- There must be a route to the remote network that is being tunneled.

- Pre-shared keys may be entered incorrectly on one of the devices. Pre-shared keys must always match.
- Phase 1 negotiation mode (aggressive/main) may not match on the devices. The negotiation mode must always match.
- A common misconfiguration is to enable perfect forward secrecy on only one side. It must be enabled on both sides.
- If the dynamic routing protocols advertise routes to public IP addresses through the IPSec tunnel, the device establishing the tunnel may attempt phase 1 negotiation with the destination set to the public IP rather than the endpoint of the IPSec tunnel. As a result, the connection is never created and routing fails. To address this problem, ensure that only private IP addresses route through the tunnel and that no public IP addresses or default routes exist in the routing table that points to the tunnel.
- A Proxy ID may be improperly entered for the device at the far end of the IPSec tunnel. This can occur because some vendors generate a default Proxy ID for IPSec communications that is not easily identified by the end user.

## Defining IKE Crypto Profiles

▶ *Network > Network Profiles > IKE Crypto*

Use the **IKE Crypto Profiles** page to specify protocols and algorithms for identification, authentication, and encryption in VPN tunnels based on IPSec SA negotiation (IKEv1 Phase-1). Refer to "Virtual Private Networks" on page 310 for more information.

To change the ordering in which an algorithm or group is listed, select the item and then click the **Move Up** or **Move Down** icon. The ordering determines the first choice when settings are negotiated with a remote peer. The setting at the top of the list is attempted first, continuing down the list until an attempt is successful.

**Table 135. IKE Crypto Profile Settings**

| Field | Description |
|---|---|
| DH Group | Specify the priority for Diffie-Hellman (DH) groups. Click **Add** and select groups. For highest security, select an item and then click the **Move Up** or **Move Down** icon to move the groups with higher numeric identifiers to the top of the list. For example, move **group14** above **group2**. |
| Authentication | Specify the priority for hash algorithms. Click **Add** and select algorithms (md5, sha1, sha256, sha384, or sha512). For highest security, use the arrows to move **sha1** to the top of the list. |
| Encryption | Select the check boxes for the desired Encapsulating Security Payload (ESP) authentication options. Click **Add** and select algorithms (aes256, aes192, aes128, or 3des). For highest security, select an item and then click the **Move Up** or **Move Down** icon to change the order to the following: **aes256**, **aes192**, **aes128**, **3des**. |
| Lifetime | Select units and enter the length of time that the negotiated key will stay effective. |

## Defining IPSec Crypto Profiles

▶ *Network > Network Profiles > IPSec Crypto*

Use the **IPSec Crypto Profiles** page to specify protocols and algorithms for identification, authentication, and encryption in VPN tunnels based on IPSec SA negotiation (IKEv1 Phase-2). Refer to "Virtual Private Networks" on page 310 for more information.

**Table 136. IPSec Crypto Profile Settings**

| Field | Description |
|---|---|
| Name | Enter a name to identify the profile (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| IPSec Protocol | Choose an option from the drop-down list.<br>**ESP:**<br>• Click **Add** under Encryption and select the desired ESP encryption algorithms. For highest security, use the arrows to change the order to the following: 3des, aes128, aes192, aes256, or aes128ccm16.<br>• Click **Add** under Authentication and select the desired ESP authentication algorithms (md5, sha1, sha256, sha384, sha512, or none).<br>**AH:**<br>• Click **Add** under Authentication and select the desired AH authentication algorithms (md5, sha1, sha256, sha384, or sha512). |
| DH Group | Select the DH group. For highest security, choose the group with the highest identifier. |
| Lifetime | Select units and enter the length of time that the negotiated key will stay effective. The default is 1 hour. |
| Lifesize | Select optional units and enter the amount of data that the key can use for encryption. |

To change the ordering in which an algorithm or group is listed, select an item and then click the **Move Up** or **Move Down** icon to change the order. The listed order determines the order in which the algorithms are applied and can affect tunnel performance.

## Viewing IPSec Tunnel Status on the Firewall

▶ *Network > IPSec Tunnels*

To view the status of currently defined IPSec VPN tunnels, open the **IPSec Tunnels** page. The following status information is reported on the page:

- **Tunnel Status (first status column)**—Green indicates an IPSec SA tunnel. Red indicates that IPSec SA is not available or has expired.
- **IKE Gateway Status**—Green indicates a valid IKE phase-1 SA. Red indicates that IKE phase-1 SA is not available or has expired.
- **Tunnel Interface Status**—Green indicates that the tunnel interface is up (because tunnel monitor is disabled, or because tunnel monitor status is UP). Red indicates that the tunnel interface is down, because the tunnel monitor is enabled and the status is down.

# Sample VPN Configuration

This section describes a sample VPN configuration. In this sample, a branch office is connected with a headquarters office and branch office users are allowed to access a central server farm.

Refer to the following topics:

- "Existing Topology" in the next section
- "New Topology" on page 321
- "Configure the VPN Connection" on page 321
- "VPN Connectivity Troubleshooting" on page 322

## Existing Topology

Headquarters:

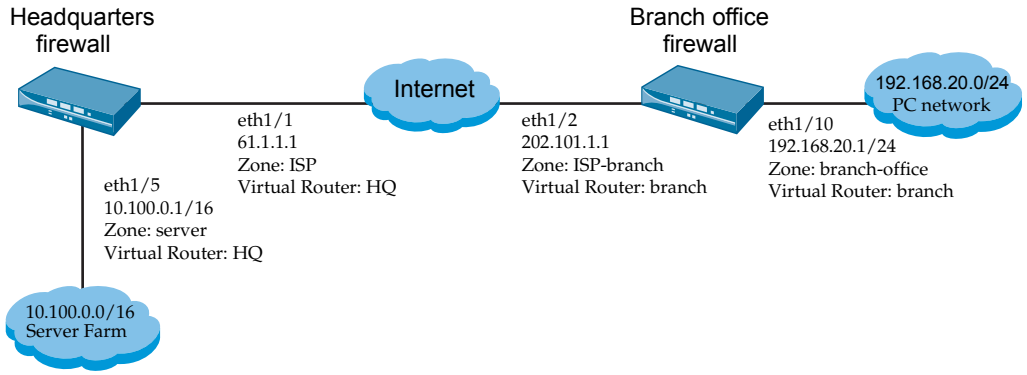
- Firewall public IP 61.1.1.1, on interface ethernet1/1, which is in zone "ISP", virtual-router "HQ"
- Server farm network is 10.100.0.0/16, connected through interface ethernet1/5 (IP 10.100.0.1), which is on zone "server", virtual-router "HQ"

Branch office:

- Firewall public IP is 202.101.1.1, on interface ethernet1/2, which is in zone "ISP-branch", virtual-router "branch"
- A PC network of 192.168.20.0/24, connected through interface ethernet1/10, which is on zone "branch-office", virtual-router "branch" (same as ethernet1/2)
- Security policy to allow traffic from zone "branch-office" to zone "ISP-branch" for Internet access from the PC network

The following figure shows the existing topology.

**Figure 42. Sample VPN Configuration - Existing Topology**



## New Topology

Headquarters:

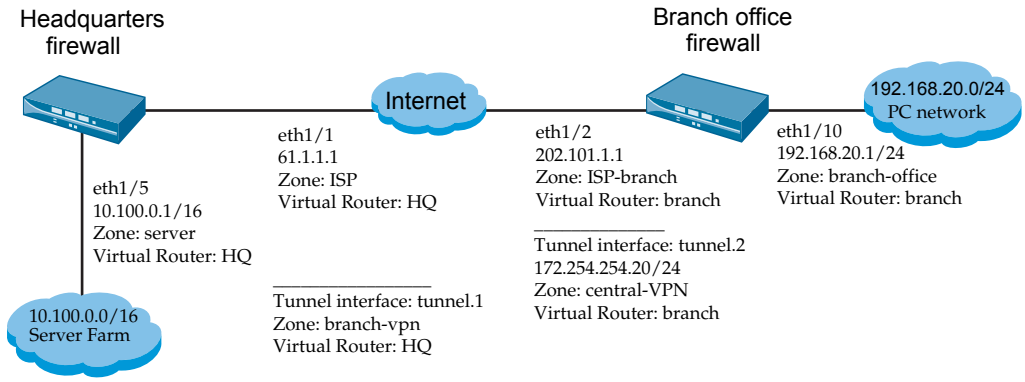
- Create a new security zone “branch-vpn.”
- Add a tunnel interface tunnel.1 to zone “branch-vpn” and assign an IP address from a private range (for example, 172.254.254.1/24)
- Add a static route to direct traffic to 192.168.20.0/24 (the branch office network) to the tunnel interface tunnel.1.
- Add a security policy to allow traffic from zone “branch-vpn” to zone “server.”

Branch office:

- Create a new security zone “central-vpn.”
- Add a tunnel interface tunnel.2 to zone “central-vpn” and assign an IP address from private range (for example, 172.254.254.20/24).
- Add a static route to direct traffic to 10.100.0.0/16 (the server farm network) to the tunnel interface tunnel.2.
- Add a security policy to allow traffic from zone “branch-office” to zone “central-vpn.”

The following figure shows the tunnel information for the new topology.

**Figure 43. Sample VPN Configuration - new Tunnel Information**



## Configure the VPN Connection

Headquarters:

- Create an IKE gateway “branch-1-gw” with these parameters:
  - Peer-address: **dynamic (or 202.101.1.1)**
  - Local-address: **ethernet1/1**
  - Peer-ID: type is FQDN: **branch1.my.domain**
  - Authentication: **pre-shared-key newvpn**
  - Protocol: keep default values

- Create an IPSec tunnel “branch-1-vpn” with these parameters:
  - ike-gateway-profile: **branch-1-gw**
  - ipsec-crypto-profile: leave as default
  - Tunnel interface: **bind with tunnel.1**
- On servers in the server farm, check the routing table and verify that the destination 192.168.20.0/24 is reachable through 10.100.0.1.

Branch office:

- Create an IKE gateway “central-gw” with these parameters:
  - Peer-address: **61.1.1.1**
  - Local-address: **ethernet1/2**
  - Local-ID: type is FQDN: **branch1.my.domain**
  - Authentication: pre-shared-key **newvpn**
  - Protocol: keep default values
- Create an IPSec tunnel “central-vpn” with these parameters:
  - ike-gateway-profile: **central-gw**
  - ipsec-crypto-profile: leave as default
  - Tunnel interface: bind with **tunnel.2**

Configuration Notes:

- If 202.101.1.1 is set as the peer-address parameter in “branch-1-gw” on the central site, setting the local-id and peer-id parameters becomes unnecessary (the field can be left empty). Note that treatment of these two parameters must be the same, because these two fields are matched during IKE negotiation.
- The proxy-id is left empty for route-based VPNs such as this.

After configuring the parameters and committing the configuration, the new VPN should work. If connectivity issues arise, refer to “VPN Connectivity Troubleshooting” in the next section.

## VPN Connectivity Troubleshooting

***Note:*** *The parameter values in this section refer to the sample configuration. Refer to “Configure the VPN Connection” on page 321.*

To troubleshoot issues regarding VPN connectivity:

1. Double check configurations on both sites.
2. Use the **ping** utility to verify connectivity between the central and branch offices (202.101.1.1 and 61.1.1.1). For this to work, there must be a management profile on the interface that allows **ping**.

3. Use the **ping** utility to verify connectivity between the server farm and the central firewall (ethernet1/5). For this to work, there must be a management profile on the interface that allows **ping**.
4. Use the **ping** utility to verify connectivity between the branch network and the branch firewall interface (ethernet1/10). For this to work, there must be a management profile on the interface that allows **ping**.
5. On the branch-office site, use the CLI commands **test vpn ike-sa gateway central-gw** and **show vpn ike-sa gateway central-gw** to verify that IKE phase-1 SA can be created from the branch office.
6. On the central site, use the CLI command **show vpn ike-sa gateway branch-1-gw** to verify that IKE phase-1 SA can be created from the branch office.
7. On the branch office site, use the CLI command **test vpn ipsec-sa tunnel central-vpn** and **show vpn ipsec-sa tunnel central-vpn** to verify that IKE phase-2 SA can be created from the branch office.
8. On the central site, use the CLI command **show vpn ipsec-sa tunnel branch-1-vpn** to verify that IKE phase-2 SA can be created from the branch office.
9. Check the server routing table in the server farm. The destination 192.168.20.0/24 must be reachable through the central firewall's ethernet1/5 interface IP address.
10. To check the route setting, run the **traceroute** command from any PC in the branch office network, where the destination is one of servers in the server farm.
11. Run the **ping** utility from any PC in the branch office network, where the destination is one of servers in the server farm. Check the encryption and decryption counters shown in the output of the **show vpn flow** CLI command. Verify that these counters are incrementing and that none of the error counters are incrementing.
12. Examine the detailed error messages for IKE negotiation in the syslog or use the **debug ike pcap** command to capture IKE packets in PCAP format.

# GlobalProtect Large Scale VPN Deployment

This section contains the following topics:

- "Overview" in the next section
- "Deploying a Large Scale VPN Network" on page 324
- "Dynamic Routing Protocols and Large Scale VPNs" on page 333
- "Backing up a GlobalProtect Portal" on page 334

## Overview

Deploying large scale VPN networks can be a very time consuming and complicated process. Challenges include planning, authentication requirements, tunnel configuration, route planning, and the provisioning and the decommissioning of components and devices. With

Palo Alto Networks firewalls, this process has been greatly simplified by taking advantage of the deployment and management methods used in the GlobalProtect VPN feature, which has previously only been used for remote access for client PCs.

The illustration in Figure 44 shows that each satellite connects to the portal to obtain a certificate for authentication and then downloads an initial VPN configuration. Once the initial configuration is completed, the satellite device establishes a VPN to all configured gateways defined on the portal using the same trusted certificate, creating a hub-and-spoke VPN network. Network and routing information is then shared between the gateway and satellite devices to create multiple paths to ensure that connectivity between the corporate and branch offices are always maintained.

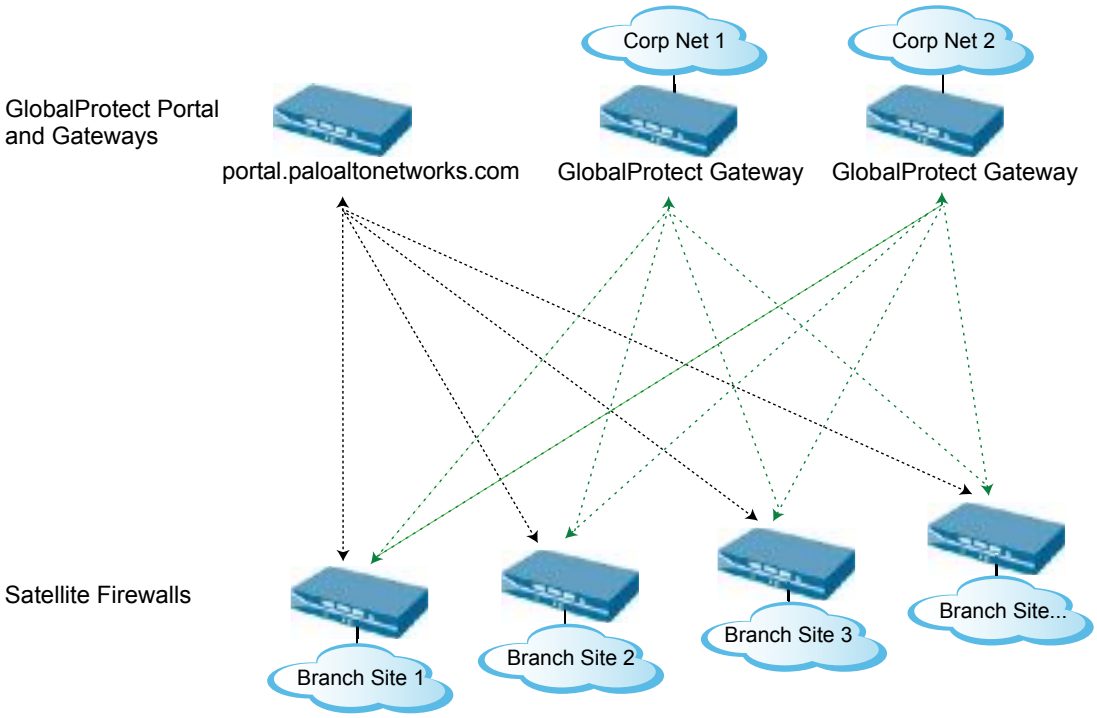


**Figure 44. Large Scale VPN Deployment**

# Deploying a Large Scale VPN Network

When deploying a large scale VPN network using Palo Alto Networks firewalls and GlobalProtect, you first configure the GlobalProtect Gateway(s), GlobalProtect Portal, and certificates that will be used for authentication of satellite devices. Once the portal and gateway devices are configured, you simply establish WAN connectivity from the satellite device, provision a tunnel interface, enter the host name of the Internet accessible GlobalProtect Portal interface and the satellite device configuration is initiated. The satellite device will then establish and maintain tunnels between all configured gateway devices and utilize tunnel monitoring to discover failures and initiate a failover. Once the portal and gateways are configured, you can easily add additional satellite devices.

It is important to keep a couple things in mind when deploying multiple branch offices:

- If you have branch offices that will use duplicate subnets, the satellite device must NAT all traffic to a unique IP or subnet. One of the simplest options is to source NAT all satellite-initiated traffic to the tunnel interface IP. When specifying the tunnel interface as a source NAT translated address, the firewall will use the IP address assigned to the tunnel interface by the highest priority gateway. If multiple gateways service different networks, it is recommended that you provision a unique IP address or subnet for each satellite that will be routable from all gateway devices. When duplicate subnets are in use, be sure that the satellites are not permitted to share connected routes with the gateways, otherwise routing issues will occur.
- Satellites must use tunnel monitoring (utilizing a configuration provided by the gateways) in order to recognize when a gateway fails. This also ensures that tunnels are maintained when there is no traffic flowing to the gateway.

The following section describes the components and basic steps needed to deploy a large scale VPN network using GlobalProtect.

- "Certificates and the OCSP Responder" on page 325
- "Global Protect Gateway Configuration" on page 328
- "GlobalProtect Portal Configuration" on page 330
- "GlobalProtect Satellite Configuration" on page 332
- "Dynamic Routing Protocols and Large Scale VPNs" on page 333

## Certificates and the OCSP Responder

Certificates are used in the large scale VPN environment to provide a mutual authentication scheme for the satellite devices and to automate deployment to reduce the steps needed to prepare the satellite devices.

The GlobalProtect Portal is configured as a root CA that will sign certificates for authentication for the satellite and gateway devices. The gateway uses a certificate profile with the portal's root CA in order to allow satellites to authenticate to the gateways. To add a new satellite device to the VPN network, you simply add the device serial number to the portal configuration or create a username and password that the satellite administrator will use to start the initial configuration. On the satellite, you enter the portal address in the IPSec Tunnels page and the satellite will connect to the portal and will send a certificate signing request (CSR). The portal then signs and returns the client certificate to the satellite as well as the root CA certificate to allow communication.

In the case of the gateway certificates, the portal will create a server certificate that is imported to the gateway, and the portal's root CA certificate is defined in the certificate profile on the gateway. This will allow all satellites to authenticate to the defined gateways.

To manage certificates in the environment, you create an Online Certificate Status Protocol (OCSP) profile on the portal that will be used to manage revocation status for local certificates issued to the satellite and gateway devices. On each satellite and gateway device, you will configure the OCSP option to point to the portal.

***Note:*** *You can also use an external root certificate authority (CA) for the GlobalProtect VPN deployment.*

For information on certificates, refer to "Importing, Exporting and Generating Security Certificates" on page 86. For information on the OCSP responder, refer to "OCSP Responder" on page 90.

Configure the OCSP Responder:

The OCSP responder needs to be configured first since it will be used when creating certificates for the satellite and gateway devices.

1. Navigate to **Device > Certificate Management > OCSP Responder**.
2. Click **Add** and enter a name for the OCSP responder.
3. Enter the **Host Name** of the portal.

Configure an OCSP Responder Management Profile:

This profile is used to allow the satellite and gateway devices to connect to the portal for OCSP requests over HTTP.

1. Navigate to **Network > Network Profiles > Interface Mgmt**.
2. Click **Add** and name the profile.
3. Select the **HTTP OCSP** check box. You may also want to enable ping for testing purposes.
4. Click **OK** to save your changes.
5. Assign the new management profile to the ingress interface of the portal by navigating to **Network > Interfaces**.
6. Select the interface that will be used as the ingress for the VPN devices and click the **Advanced** tab.
7. From the **Other Info** tab and the **Management Profile** drop-down, select the OCSP management profile that you created.
8. Click **Commit** to activate your changes.

Generate a root Certificate Authority (CA) certificate:

The portal root CA will sign and issue certificates for the satellite and gateway devices to provide mutual authentication for devices that are part of the large scale VPN network. The gateway will also have a certificate profile with the portal's root CA to allow authentication from the satellite devices.

1. Navigate to **Device > Certificate Management > Certificates**.
2. Click **Generate** and name the certificate.

3. Enter the **Common Name**, which is the IP or FQDN that will appear on the certificate. The common name is the FQDN or IP address of the interface where satellites will connect.
4. Check the **Certificate Authority** box.
5. In the **OCSP Responder** field, enter the OCSP responder name that you created earlier.

Generate a server certificate for the portal:

This certificate is used to authenticate satellite devices and to allow OCSP queries from the satellites and gateways.

1. On the GlobalProtect Portal, navigate to **Device > Certificate Management > Certificates**.
2. Click **Generate** and name the certificate and enter a common name.
   **Important:** The common name is the FQDN or IP address of the interface used for the satellite connections and will be unique to the portal.
3. In the **Signed By** drop-down, select the root CA of the portal. Set the desired cryptographic settings and other attributes and then click **Generate.**

Generate and import the gateway certificates:

Each gateway that will participate in the VPN network needs to have a server certificate that is signed by the GlobalProtect Portal root CA and the portal root CA certificate must also be imported into each gateway. This will allow the gateways to communicate with the portal and allows satellites devices to connect to the gateway to establish VPN connectivity.
In the below steps, you can alternatively export the root CA from the portal to the gateway, and then generate the gateway certificate directly on the gateway using the imported root CA to sign the certificate.

On the GlobalProtect Portal, navigate to **Device > Certificate Management > Certificates**.

1. Click **Generate** and name the certificate and enter a common name.
   **Important:** The common name is the FQDN or IP address of the interface used for the satellite to connect to the gateway and will be unique for each gateway.
2. In the **Signed By** drop-down, select the root CA of the portal.
3. In the **OCSP Responder**, it is important that you enter the URL of the portal using the following format: **http://*IP address or FQDN*/CA/ocsp**, for example http://paloaltonetworks.com/CA/ocsp. Certificates issued by the portal will have this path automatically generated in the certificate.
4. Set the desired cryptographic settings and other attributes and then click **Generate**.
5. Select the certificate you just created and then click **Export**, select the File Format **Encrypted Private Key and Certificate (PKCS12)**. Enter and confirm a passphrase that will be used when you import the certificate.
6. Follow the same steps to export the root CA certificate.
7. On the GlobalProtect Gateway, navigate to **Device > Certificate Management > Certificates**.
8. Click **Import**, enter a **Certificate Name** and then click **Browse** and select the gateway server certificate you exported earlier.

9. Select the file format **Encrypted Private Key and Certificate (PKCS12)**. Enter and confirm the passphrase you used when you exported the certificate and click **OK**.
10. Do the same for the portal root CA.

Configure a certificate profile on the gateway:

The certificate profile is used to authenticate the satellite device to the gateway to establish a the VPN.

1. Navigate to **Device > Certificate Management > Certificate Profile**.
2. Click **Add** and name the profile. The **Username Field** and **Domain** are optional when only Palo Alto Networks devices will connect to the gateway. You will need to configure these options if you have third-party VPN clients connecting to the gateway, such as with iOS and Android devices.
3. In the **CA Certificates** window, click **Add** and in the **CA Certificate** drop-down, select the root CA certificate that you imported from the portal.
4. In the **Default OCSP URL** field, enter the URL of the OCSP responder using the IP or FQDN of the portal. It is important that you enter the URL of the portal using the following format: **http://*IP address or FQDN*/CA/ocsp**, for example http://paloaltonetworks.com/CA/ocsp.

   If you have another device that can also handle OCSP requests, you can add a certificate for that profile in the **OCSP Verify CA Certificate** drop-down.
5. Click **OK**.
6. In the **Certificate Profile** window, click the **Use OCSP** check box.
7. Click **OK** to save your changes.
8. Click **Commit** to active the certificate configuration.

## Global Protect Gateway Configuration

The branch office satellite device will connect to the GlobalProtect Gateway to establish VPN connectivity to corporate resources. The satellite will use each gateway that is defined in the GlobalProtect Portal satellite configuration in order to create a hub and spoke VPN network. The gateway devices are also able to maintain multiple tunnels on a single tunnel interface, so you don't need a separate tunnel interface for each satellite device that is deployed. Authentication from the satellite to the gateway is handled by the certificates signed by the portal CA. Once configured and the VPN is established, routing information is also dynamically shared between the satellite and gateway devices.

Configuring the GlobalProtect Gateway device:

1. You should have already generated and imported the gateway server certificate and the portal root CA certificate. Refer to "Certificates and the OCSP Responder" on page 325.
2. Create a tunnel interface that is a logical interface used to terminate VPN tunnels. You can use the pre-defined tunnel interface, or create a new one. The interface also needs to be bound to the virtual router and placed in a security zone.
   It is recommended that you create a new zone, so you can control policies between the branch office and the zone that contains your protected resources. You could put the tunnel interface in the same zone as the protected resources, which will give the satellite

devices access to the resources, but that will not give you granular policy control for the satellite networks.
Refer to "Configuring Tunnel Interfaces" on page 147.

3. On the firewall that will be used as a GlobalProtect Gateway, navigate to **Network > GlobalProtect > Gateways** and click the **General** tab.
4. Click **Add** and name the gateway.
5. Select the interface with Internet connectivity that satellite devices will connect to in order to establish VPN connectivity and also select the **IP Address**.
6. Select the gateway server certificate that was signed by the portal and imported to the gateway.
7. Select the certificate profile in the **Certificate Profile** drop-down.
8. Click the **Satellite Configuration** subtab and check the **Tunnel Configuration** box.
9. Select the tunnel interface you created or select the default tunnel interface. You can also set **Replay attack detection** or **Copy TOS** (optional).
10. Set the **Configuration Refresh Interval**. This is the setting that each satellite will use to determine how often the satellite device should check the portal for configuration updates, such as the addition of a new gateway that the satellites can use. The default is 24 hours and the range is 1-48 hours.
11. Click the **Tunnel Monitoring** check box and enter a **Destination IP**. You can enter any desired IP address that is reachable, or if you leave this field blank, the monitoring profile will ping the gateway's tunnel interface IP address.
12. In the **Tunnel Monitor Profile** drop-down, configure a new profile and make sure the action is **failover**.
13. In the **IPSec Crypto Profile** you configure a new profile or select the default.
14. Click the **Network Settings** subtab and populate the DNS, IP Pool and Access route information that the satellite devices will use. The IP Pool is a range of IP addresses that will be assigned to the satellite device's tunnel interface that connects to the gateway when a VPN is established. The pool must be large enough to manage all satellites that will connect to the gateway.
    For the primary and secondary DNS fields, you can select **Inheritance Source** and select an existing interface that will be used to provide this information to the satellite devices.
15. Enter any desired **Access Route** information that you would like to have pushed down to the satellite devices. For example, you could provide access routes to implement split tunneling, so Internet traffic from the branch office does not pass through the VPN. If no access routes are provided, all traffic will pass through the tunnel.
16. Click the **Route Filter** tab and either leave this option unchecked to accept all routes sent by the satellite, or click **Accept published routes** and provide a list of subnets, which will cause all other routes to be filtered out. If you are using NAT, which will use the tunnel interface IP, you don't need to filter since no routes need to be published to the gateway.
17. Click **Commit** to activate the gateway configuration.

## GlobalProtect Portal Configuration

The portal is used to manage the VPN environment. It handles the enrollment process for new satellite devices, maintains the list of gateways to be used by satellites, and can acts as the root CA for the gateways and satellites. You can also use an external certificate authority (CA) if desired.

Once the satellite device receives its initial configuration and certificates from the portal, a VPN connection is established with all defined gateways, so it's not required to have a VPN between the portal and the gateways. The only time the gateway needs to communicate with the portal is for OCSP requests, which only requires HTTP access.
You can configure the portal as a gateway as well. This will allow you to have a gateway access point for satellite devices at the same location as the portal. You can then add additional external gateways for other locations throughout your global VPN network.

- "Create an Authentication Profile" on page 330
- "Security Zone and Interface" on page 331
- "Configuring the GlobalProtect Portal" on page 331

### Create an Authentication Profile

The authentication profile determines the authentication method that will be used by satellite devices to connect to the portal. When using this method, the satellite device administrator will enter a login and password when connecting to the portal for the first time. Once the device is authenticated, it will add the serial number and host name to the portal. You can use a Local DB account, RADIUS, LDAP using active directory, or Kerberos. In this case, the portal administrator does not need to add the satellite device serial number in the portal satellite configuration. Refer to "Authentication Profiles" on page 62.
You can also add the serial number of the satellite device as described in "Configuring the GlobalProtect Portal" on page 331. In both cases though, you must have an authentication profile defined in order to commit your configuration. If you manually add a device serial number to the portal configuration, the authentication profile is not used, but it is still required.

Configure the authentication profile:

1. To use a local account for authentication, on the portal navigate to **Device > Local Users Database > Users** and click **Add**.
2. Enter a username in the **Name** field and then enter a password in the Password/Confirm Password fields. You can also use a password hash by selecting the Password Hash button and pasting a password hash in the field.
3. Click **OK** to create the account.
4. Navigate to **Device > Authentication Profile** and click **Add**.
5. Enter a profile name in the **Name** field and in the **Authentication** drop-down, select **Local Database**. If you will be using RADIUS, LDAP, or Kerberos, select one of those options and configure the server. Once configured, you can then select usernames that are available on those systems.
6. In the **Allow List**, click **Add** and then select the local user you created.

### Security Zone and Interface

On each device that will participate in the VPN (Portal, Gateway, Satellite), you will need to configure an interface that will have access to the other devices in the VPN environment and put them in the desired security zone. This will allow each device to communicate over the WAN. It is recommended that you create a new zone, so you can control policies between the branch office and the zone that contains your protected resources.

The initial connection from the satellite to the portal for the certificate download and initial configuration will use SSL. Once the satellite is configured, it will establish an IPSec VPN with the configured gateways. Make sure that the security zones that you create have the **Enable User Identification** check box enabled, so users from the branch office can be identified if User-ID is configured. This is required for zones that will be used on the GlobalProtect Gateway. Refer to "Security Zones" on page 151.

### Configuring the GlobalProtect Portal

The portal configuration defines the network interface that will be used for satellite enrollment, authentication, and appearance of the portal. It can also act as a root CA and OCSP responder.

1. Navigate to **Network > GlobalProtect > Portals**.
2. Click **Add** and name the portal.
3. Select the interface that will act as the ingress interface for the satellite devices and then select the Internet accessible IP address from the drop-down.
4. Select the portal server certificate that you created earlier. Refer to "Certificates and the OCSP Responder" on page 325.
5. Select the **Authentication Profile** that you created earlier. The authentication profile is required, even though the satellite device will not use it if you add the satellite device serial number to the portal configuration.
6. In this case, a client certificate is not required on the portal since the portal automatically generates client certificates for satellite devices using the root CA.
7. Select a certificate profile to be used for satellite authentication. Alternatively, you can enter the satellite serial number in the **Satellite Configuration** sub tab, so the satellite administrator does not have to enter login credentials.
8. You can optionally configure appearance settings.
9. Click the **Satellite Configuration** tab that will define options for the satellite devices that will connect to the portal.
10. Click **Add** and name the **GlobalProtect Satellite** profile. This profile will define the satellite devices, enrollment method, and the list of gateways that the satellites will use in the VPN environment.
11. Set the **Configuration Refresh Interval**. This is the setting that each satellite will use to determine how often the satellite device should check the portal for configuration updates, such as new gateways being added.
12. In the **Devices** tab, you can manually add satellite device serial numbers, or the list will be updated when a satellite device connects to the portal for the first time using a login and password authentication.
    The next step provides information on the enrollment methods.

13. The portal can be configured to allow two types of authentication methods for the initial enrollment (you can configure both of the below options):

    – Manually add the satellite device serial number to the portal in the **Network > GlobalProtect > Portals > Satellite Configuration** page. Click **Add** > **Devices** then click **Add** again and enter the satellite device serial number. When the satellite device is configured at the branch office and establishes the initial connection to the portal, no authentication is required. Once the satellite device connects, the host name will be added to the portal configuration automatically.

    – Use a login name and password prompt from the satellite device by adding an enrollment user or group to the portal in the **Network > GlobalProtect > Portals > Satellite Configuration** page. Click **Add** > **Enrollment User/User Group** then click **Add** again and select a user or group from the drop down list or select **Any**.
    When using this method, you do not need to enter the satellite device information on the portal. When the device connects, the administrator configuring the satellite device will be prompted to login. Once authenticated, the satellites serial number and host name will automatically be added to the portal satellite list.

14. In the **Gateways** tab, enter the IP address or hostname of the gateway(s) that the defined list of satellite devices will use for VPN connectivity.
    You can also set the routing priority of the gateway from this page. If the satellite device has tunnels to multiple gateways, duplicate routes may exist. By setting a priority, the gateway with the highest priority will be used first. If the gateway fails, the next highest priority will be used. The priority range is from 1-25, since 25 is the limit on the number of gateways that a satellite can use.

15. Click **OK** to save your changes and then under **Trusted Root CA,** click **Add** and select the portal root CA.

16. In the **Issuing Certificate** drop-down, also select the portal root CA. This is the certificate that will be used to automatically generate certificates for the satellite devices during enrollment.

17. You can modify the validity period and certificate renewal period if desired. The validity period defines the lifetime of the certificate and the renewal period defines how often the certificate will be renewed. If you do not want your certificates to expire, just make sure the renewal period is lower than the validity period.

18. In the **OCSP Responder** drop-down, select the portal's OCSP responder that you created earlier and then click **OK** to save your changes.

19. Click **Commit** to activate your changes.

## GlobalProtect Satellite Configuration

On the branch office satellite device, you first configure an interface with WAN connectivity and set up a security zone and policy to allow the branch office LAN to communicate with the Internet. The satellite device is then configured with the host or IP address of the portal. Once the configuration is committed, the satellite will communicate with the GlobalProtect Portal, certificates are signed and downloaded with the initial VPN configuration and routing information. The satellite then connects to all configured GlobalProtect gateways to establish VPN connectivity from the branch to the corporate office. Refer to "GlobalProtect Satellite" on page 317 for field descriptions).

1. On the portal devices, you should have already entered the serial number of the satellite device you are configuring, or have created a username and login that can be used for the initial configuration. Refer to "Configuring the GlobalProtect Portal" on page 331.
2. Navigate to **Network** > **IPSec Tunnels** page.
3. Click **Add** to create a new IPSec Tunnel.
4. Enter a **Name** for the tunnel profile and select the default **Tunnel Interface** from the drop down, or create a new tunnel interface.
5. Choose **Type GlobalProtect Satellite** and enter the **Portal Address** (IP or hostname).
6. Select the **Interface** to be used to connect to the portal and then select the **Local IP Address** of the interface. In the example illustration shown in Figure 44 on page 324, the **Portal Address** would be "portal.paloaltonetworks.com".
7. Click the **Advanced** tab and configure the desired advanced options. It is recommended that you enable **Publish all static and connected routes to Gateway**, so that routes are shared between all devices in the VPN network.
   **Note:** If this branch office has the subnets as other branch offices in the VPN, do not enable this option unless you are using NAT.
8. Click **Commit** to activate the changes on the satellite device.

You can now test connectivity between the satellite devices and gateways. To view the status of the VPN on the satellite device, navigate to **Network > IPSec Tunnels**. You should see a green status indicator in the **Status** column.

# Dynamic Routing Protocols and Large Scale VPNs

When using dynamic routing protocols over your large scale VPN network, the following behavior should be noted in relation to flooding and replication:

- Routing Information Protocol (RIP)—Control packets are flooded to all tunnels (spokes) on the egress interface (hub to all spokes). Control packets are not replicated to remaining tunnels (spokes) when one tunnel receives a packet from the incoming spoke to the remaining spokes.
- OSPF—It is recommended that you use Point to Multipoint (P2MP). In broadcast mode, the replication behavior is the same as RIP.

Multicast replication behavior is the same as RIP and data packets are not replicated. Also, multicast distribution in a large scale VPN environment is supported where the multicast source resides behind the gateway and receivers reside behind the satellite VPN devices. Deployments in which the multicast source resides in a satellite location are not currently supported.

# Backing up a GlobalProtect Portal

In a large scale VPN configuration, the GlobalProtect Portal is a critical piece of the environment that manages the VPN configuration, all certificates used for authentication, and the list of satellite firewalls that are part of the VPN network. The certificate and satellite information is dynamic and changes often and is not part of the device configuration.

The "Export device state" feature is used to export the configuration and dynamic information from a firewall that is configured as a GlobalProtect Portal with the large scale VPN feature enabled. The export file contains a list of all satellite devices managed by the Portal, the running configuration at the time of the export, and all certificate information (Root CA, Server, and Satellite certificates). If the Portal experiences a failure, the export file can be imported to restore the Portal's dynamic information.

**Important:** You must manually run the device state export from **Device > Setup > Operations** by clicking the **Export device state** option, or you can create a scheduled XML API script to export the file to a remote server. This should be done on a regular basis since satellite certificates may change often.

To create the device state file from the CLI, run `save device state`.
The file will be named device_state_cfg.tgz and is stored in /opt/pancfg/mgmt/device-state.
The operational command to export the device state file is `scp export device-state` (you can also use tftp device-state export).

For information on using the XML API, refer to the document "PAN-OS XML-Based Rest API Usage Guide" at *https://live.paloaltonetworks.com/community/documentation.*

# Chapter 9
# Configuring GlobalProtect

This chapter describes GlobalProtect, which allows secure login from client systems located anywhere in the world:

- "Overview" in the next section
- "Setting Up GlobalProtect" on page 337
- "Setting Up and Activating the GlobalProtect Agent" on page 352

## Overview

GlobalProtect provides security for client systems, such as laptops, that are used in the field by allowing easy and secure login from anywhere in the world. With GlobalProtect, users are protected against threats even when they are not on the enterprise network by sending their traffic through a Palo Alto Networks firewall that is within close geographic proximity. The user's access level is determined by a host information profile (HIP) that notifies the firewall about the user's local configuration. The HIP information can be used for granular access control based on the security programs that are running on the host, registry values, and many other checks such as whether the host has disk encryption enabled.

The GlobalProtect agent can also be a Palo Alto Networks satellite device (firewall), but instead of agent software being downloaded, only the necessary certificate for authentication and VPN configuration is needed. For information on satellite devices, refer to "GlobalProtect Large Scale VPN Deployment" on page 323.

The following elements are used to provide GlobalProtect functionality:

- **Portal**—Palo Alto Networks firewall that provides centralized management for the GlobalProtect system.
- **Gateways**—Palo Alto Networks firewalls that provide security enforcement for traffic from GlobalProtect agents.
- **Agent**—Application that is installed on the client system and configured to connect to the portal and gateways to provide network access for user systems. The agent also provides information about the user's local configuration to the gateways.
- **Satellite**—A satellite device is a Palo Alto Networks firewall that is typically installed at a branch office and is initialized and managed by a GlobalProtect portal. After the satellite receives its initial configuration from the portal, it connects to all configured gateways to

establish VPN connectivity. By using GlobalProtect, firewalls can be quickly installed at branch offices with very little initial configuration. Refer to "GlobalProtect Large Scale VPN Deployment" on page 323.

The connection process works as follows:

1. The user downloads the GlobalProtect agent from the portal onto a client system, such as a laptop. The agent connects to the portal through an SSL connection and downloads a configuration file. This configuration file includes information about the various GlobalProtect gateways that can be used for connectivity.
2. The agent performs a reverse Domain Name System (DNS) lookup to determine whether the client system is currently on the internal enterprise network or on an external network.
3. If the connection is to the external network, the agent attempts to make SSL connections to all external gateways and then selects the best gateway.
4. Based on the configuration, an IPSec or SSL tunnel is established between the agent and the gateway and a default route is inserted to direct all traffic through the tunnel for the purpose of policy control and threat scanning.
5. The agent submits the client system posture, the HIP.

GlobalProtect allows the use of HIP profiles in security profiles. A HIP object specifies a set of criteria for the client system that is treated as a unit when defining HIP profiles. For example, a HIP object might specify full disk encryption or software patching.

HIP profiles can incorporate HIP objects on a match or no-match basis. For example, a HIP profile might include a match for HIP objects that specify that the client system includes both full disk encryption and certain software patches to be installed.

The portal stores client configurations and maintains internal and external gateways lists. It also lists the CA that is used by gateways and agents for mutual authentication.

Each gateway can operate in tunnel mode (external gateways) or non-tunnel mode (internal gateways). Gateways in non-tunnel mode receive only the HIP from clients. All communication is between agents and gateways; there is no inter-gateway communication.

Policies are enforced on gateways based on user or HIP information, and HIP objects and profile matches are logged in the gateway's HIP database. This information is displayed in the Application Control Center (ACC), logs, and custom reports.

## GlobalProtect Authentication

Connectivity between all parts of the GlobalProtect infrastructure is authenticated using SSL certificates. The portal can act as a certificate authority (CA) for the system (using a self-signed or imported subordinate issuing CA certificate within the portal), or customers can generate certificates using their own CAs. It is recommended (but not required) that the portal, gateways, and the GlobalProtect software agents use certificates signed by the same CA. Prior to transferring any information, the agent verifies the portal server certificate. If the certificate presented by the portal is not signed by a Trusted CA, the agent shows a warning dialog and waits for the user response to continue or cancel.

As part of the configuration bundle that is sent to the client, the portal includes the public certificate of the CA and the needed client certificate and key. The client certificate is used by GlobalProtect gateways to authenticate and identify the client.

If an internal CA is used, the certificate is auto-generated and does not require user interaction. The portal can export the necessary server certificate and key for the gateways. If an external CA is used, support is provided to import the CA certificate along with a server certificate and key for the portal and gateways and a client certificate and key for the clients.

For more information on authentication, refer to "Authentication Profiles" on page 62 and "Authentication Sequence" on page 67.

# Setting Up GlobalProtect

Setting up GlobalProtect on the firewall involves the following tasks:

1. Define HIP objects, as described in "Setting Up HIP Objects" on page 337.
2. Create HIP profiles, as described in "Setting Up HIP Profiles" on page 340.
3. Set up the portal, as described in "Setting Up the GlobalProtect Portal" on page 341.
4. Set up gateways, as described in "Setting Up the GlobalProtect Gateways" on page 347.
5. Define security policies that include HIP profiles, as described in "Defining Security Policies" on page 187.
6. Distribute the GlobalProtect agent, as described in "Setting Up the GlobalProtect Agent" on page 353.
7. Monitor client activity, as described in "Viewing the Logs" on page 264.

### Setting Up HIP Objects

▶ ***Objects > GlobalProtect > HIP Objects***

Use this page to define settings for use in HIP profiles for GlobalProtect. Each HIP object defines a set of criteria for the client system that is treated as a unit when defining HIP profiles.

**Table 137. HIP Object Settings**

| Field | Description |
|---|---|
| **General Tab** | |
| Name | Enter a name for the HIP object (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Shared | Select the check box to make the object available to all virtual systems. |
| Description | Enter an optional description. |
| Host Info | Select the check box to specify host information. |
| Domain | To match domains, choose an operator from the drop-down list and enter a string to match. |
| OS | Use the drop-down lists to specify the operating system (OS) for the GlobalProtect agent. |
| Client Versions | To match OS versions on the client, choose an operator from the drop-down list and enter a string to match. |

**Table 137. HIP Object Settings (Continued)**

| Field | Description |
|---|---|
| **Patch Management Tab** | |
| Patch Management | Select the check box to include software patch management in the HIP. When the check box is selected, the settings are activated. You can then define patch management vendors, such as Microsoft, and only allow clients that have certain patch levels installed. |
| Criteria | Specify the following settings on this subtab:<br>• **Is Enabled**—Choose whether the settings on this tab are enabled (yes) or disabled (no), or not available.<br>• **Is Installed**—Select the check box to verify if the client has the defined software patch installed.<br>• **Severity**—Choose the level of importance for missing patches.<br>• **Check**—Choose how the system should check for patches.<br>• **Patches**—Click **Add** and enter patch file names. |
| Vendor | Click **Add** to specify patch management products. Choose a vendor from the drop-down list, and then click **Add** to choose a specific product. Click **OK** to save the settings and return to the **Patch Management** tab. |
| **Firewall Tab** | |
| Firewall | Select the check box to activate this tab and then specify the following settings:<br>• **Is Enabled**—Choose whether the settings on this tab are enabled (yes) or disabled (no), or not available.<br>• **Is Installed**—Select the check box to verify if the client has the defined firewall software installed.<br>• **Vendor and Product**—Click **Add** to specify specific firewalls. Choose a vendor from the drop-down list, and then click **Add** to choose a specific firewall version. Click **OK** to save the settings and return to the **Firewall** tab.<br>• **Exclude Vendor**—Select the check box if you want to exclude rather than include the specified vendors and products. |

**Table 137. HIP Object Settings (Continued)**

| Field | Description |
|---|---|
| **Antivirus Tab** | |
| Antivirus | Select the check box to activate this tab and then specify the following settings:<br>• **Real Time Protection**—Choose whether to require real-time protection (if available).<br>• **Is Installed**—Select the check box to verify if the client has the defined antivirus software installed.<br>• **Virus Definition Version**—Choose from the drop-down list. If you choose **Within** or **Not Within**, specify the number of **Days** or **Hours** to match.<br>• **Product Version**—Choose an operator from the drop-down list and specify a matching string.<br>• **Last Scan Time**—Choose from the drop-down list. If you choose **Within** or **Not Within**, specify the number of **Days** or **Hours** to match.<br>• **Vendor and Product**—Click **Add** to specify antivirus products. Choose a vendor from the drop-down list, and then click **Add** to choose a specific product. Click **OK** to save the settings and return to the **Antivirus** tab.<br>• **Exclude Vendor**—Select the check box if you want to exclude rather than include the specified vendors and products. |
| **Anti-spyware Tab** | |
| Anti-spyware | Select the check box to activate this tab and then specify the following settings:<br>• **Real Time Protection**—Choose whether to require real-time protection (if available).<br>• **Is Installed**—Select the check box to verify if the client has the defined anti-spyware software installed.<br>• **Virus Definition Version**—Choose from the drop-down list. If you choose **Within** or **Not Within**, specify the number of **Days** or **Hours** to match.<br>• **Product Version**—Choose an operator from the drop-down list and specify a matching string.<br>• **Last Scan Time**—Choose from the drop-down list. If you choose **Within** or **Not Within**, specify the number of **Days** or **Hours** to match.<br>• **Vendor and Product**—Click **Add** to specify anti-spyware products. Choose a vendor from the drop-down list, and then click **Add** to choose a specific product. Click **OK** to save the settings and return to the **Anti-spyware** tab.<br>• **Exclude Vendor**—Select the check box if you want to exclude rather than include the specified vendors and products. |

**Table 137. HIP Object Settings (Continued)**

| Field | Description |
|---|---|
| **Disk Backup Tab** | |
| Disk Backup | Select the check box to activate this tab and then specify the following settings:<br>• **Is Installed**—Select the check box to verify if the client has the defined backup software installed.<br>• **Last Backup Time**—Choose from the drop-down list. If you choose **Within** or **Not Within**, specify the number of **Days** or **Hours** to match.<br>• **Vendor and Product**—Click **Add** to specify disk backup products. Choose a vendor from the drop-down list, and then click **Add** to choose a specific product. Click **OK** to save the settings and return to the **Disk Backup** tab.<br>• **Exclude Vendor**—Select the check box if you want to exclude rather than include the specified vendors and products. |
| **Disk Encryption Tab** | |
| Disk Encryption | Select the check box to activate this tab and then specify the following settings: |
| Criteria | Specify the following settings on this subtab:<br>• **Is Installed**—Select the check box to verify if the client has the defined disk encryption software installed.<br>• **Encrypted Locations**—Click **Add** to specify the drive or path that refers to an encrypted data store:<br>– **Encrypted Locations**—Choose the location from the drop-down list.<br>– **State**—Specify the state of the encrypted location by choosing an operator and value from the drop-down list.<br>Click **OK** to save the settings and return to the **Disk Encryption** tab. |
| Vendor | Click **Add** to specify specific disk encryption products. Choose a vendor from the drop-down list, and then click **Add** to choose a specific product. Click **OK** to save the settings and return to the **Disk Encryption** tab. |
| **Custom Checks Tab** | |
| Process List | Click **Add** to specify the list of processes to be checked on the client system to see if they are running. For example, to determine whether a software application is running, add the name of the executable file to the process list. |
| Registry Key | Click **Add** to specify that a particular registry key is present or has a specified value. |
| Plist | Plists are preferences files on MacOS. Define the path to a specific plist file. You can also include preference keys and values to check for within the file. |

## Setting Up HIP Profiles

▶ *Objects > GlobalProtect > HIP Profiles*

After defining HIP objects (refer to "Setting Up HIP Objects" on page 337), use this page to create HIP profiles for GlobalProtect. When defining HIP profiles, you specify match criteria that are built from the previously-defined HIP objects.

**Table 138. HIP Profile Settings**

| Field | Description |
|---|---|
| Name | Enter a name for the profile (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Description | Enter an optional description. |
| Shared | Select the check box to make the profile available to all virtual systems. |
| Match | Define one or more HIP objects that you want to check for on the client. Enter the HIP objects to include, or click **Add Match Criteria** to create objects. When including multiple HIP objects, you can use AND, OR and NOT operators to create a Boolean expression. Using this method, you can establish complex HIP profiles, for example, to test if your clients have antivirus installed AND disk encryption installed and enabled. |

## Setting Up the GlobalProtect Portal

▶ *Network > GlobalProtect > Portals*

Use this page to configure portals for GlobalProtect.

**Table 139. GlobalProtect Portal Settings**

| Field | Description |
|---|---|
| **Portal Configuration tab** | |
| Name | Enter a name for the portal (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Location | Select the virtual system, if the multiple virtual systems option is enabled. |
| **Network Settings** | |
| Interface | Select the firewall interface that will be used as the ingress for remote clients/firewalls. |
| IP Address | Specify the IP address on which GlobalProtect portal web service will be running. |
| Server Certificate | Select the SSL certificate for the GlobalProtect portal. |
| **Authentication** | |
| Authentication Profile | Choose an authentication profile to authenticate access to the portal. Refer to "Authentication Profiles" on page 62. |
| Client Certificate | Select the certificate the client will use to connect to the gateways. |
| Certificate Profile | Select the certificate profile that is used to authenticate smartcard users on the portal. |
| **Appearance** | |
| Custom Login Page | Choose an optional custom login page for user access to the portal. |
| Custom Help Page | Choose an optional custom help page to assist the user with access to the portal. |

**Table 139. GlobalProtect Portal Settings (Continued)**

| Field | Description |
|---|---|
| **Client Configuration tab** | |

**Table 139. GlobalProtect Portal Settings (Continued)**

| Field | Description |
|---|---|
| General subtab settings | Click **Add** to display the subtabs, and specify the following settings on the **General** subtab:<br>• **Name**—Enter a name to identify this client configuration.<br>• **Use single sign-on**—Select the check box to have GlobalProtect use the users' Windows login credentials to transparently connect and authenticate to the GlobalProtect portal and gateways. No username and password is needed in the GlobalProtect agent configuration.<br>• **Config Refresh Interval (hours)**—Specify the interval in days to refresh the GlobalProtect agent configuration (default 24 hours, range 1-168days).<br>• **Connect Method:**<br>– **on-demand**—Select this option to allow users to establish a connection on demand. With this option, the user must explicitly initiate the connection. This function is primarily used for remote access connections.<br>– **user-logon**—When this option is set, the GlobalProtect agent will automatically establish a connection after users log in to their computers. If you select **Use single sign-on**, the username and password used to log in to Windows is captured by the GlobalProtect agent and used to authenticate.<br>– **pre-logon**—Select this option to preserve pre-logon and post-logon services provided by a corporate infrastructure regardless of where the user machine is located. GlobalProtect will establish a connection prior to user login to the computer. By doing this, a company can create a "logical network" that maintains the security and management features normally achieved by a physical network. Tunnel selection and establishment happens pre-logon based on machine certificates that need to be pre-deployed on client systems outside of GlobalProtect.<br>Examples of some of the services that can be maintained include: Active Directory group policy enforcement, maintaining drive mapping to server resources, and the ability to receive central software deployment downloads while remote. One specific example of how the pre-logon feature works is if a remote user forgets his/her password, since GlobalProtect would connect and use the cached credentials and establish a VPN before the login prompt even appears, a domain administrator could reset the user's password as if they were logged in directly to a domain controller on the physical network. You could also push new Active Directory Group Policies<br><br>With the pre-logon option enabled, you can also use this feature in from the Users tab when configuring Security Policies or in the Source tab in Decryption policies. For example, you may want to set a security policy to only allow access to AD servers and DNS servers on your network for machines that are in the pre-logon state. Note that each user is identified with the name **pre-logon** and you would need to check their machine name in HIP reports to determine specific users.<br>– **Third Party VPN**—Click **Add** to add a list of third party remote access VPN clients that might be present on the system. If configured, GlobalProtect will ignore those clients and their route settings to ensure that it does not interfere or conflict with them. |

**Table 139. GlobalProtect Portal Settings (Continued)**

| Field | Description |
|---|---|
| General subtab (Continued) | – **Internal Host Detection**—With this option, GlobalProtect tries to resolve the configured hostname to the configured IP address. If this fails, GlobalProtect assumes the computer to be outside of the corporate network and will establish a tunnel with any of the available external gateways configured in the **Gateways** tab. Select the check box to enable internal host detection using DNS lookup. Specify the following:<br>– **IP Address**—Enter an internal IP address for the internal host detection.<br>– **Hostname**—Enter the hostname that resolves to the above IP address within the internal network. |
| User/User Group subtab settings | Specify the user or user group to which the particular client configuration is applied. |
| Gateways subtab | Specify gateway settings:<br>• **Cutoff Time**—Specify the timeout (seconds) after which the agent will dismiss a gateway response. The agent dismisses gateway responses after either the configured cutoff time or the socket timeout is reached. If 0 is specified, the cutoff time is ignored by the agent.<br>• **Internal Gateways**—Specify the internal firewalls that the agent will authenticate and provide HIP reports to.<br>• **External Gateways**—Specify the list of firewalls the agent will try to establish a tunnel with when not on the corporate network. The agent will contact all of the gateways and establish a tunnel with the firewall that provides the fastest response and the lowest priority value. Select the **Manual** check box if you want to allow users to manually select a different gateway while their VPN is connected. The GlobalProtect agent will have the option to connect to any external gateway that has the manual selection. When connecting to the new gateway, the existing tunnel will be disconnected and a new tunnel will be established. The manual gateways can also have different authentications mechanism than the primary gateway. If the client system is restarted, or if a rediscovery is performed, the GlobalProtect agent will connect to the primary gateway. This feature is useful if you have a group of users who need to temporarily connect to a specific gateway to access a secure segment of your network.<br><br>**Note:** You can only connect to gateways defined in the portal, you cannot connect to different portals and gateways. |

**Table 139. GlobalProtect Portal Settings (Continued)**

| Field | Description |
|---|---|
| Agent subtab | Specify the following settings:<br>• **Enable advanced view**—Deselect this check box to restrict the user interface on the client side to the basic minimum view. By default, the advanced view setting is enabled on all GlobalProtect agents.<br>• **User can save password**—Select the check box to allow users to save their passwords.<br>• **Agent User Override**—Select an override option:<br>– **disabled**—User override is disabled.<br>– **with-comment**—The user is prompted to enter a comment when disabling the GlobalProtect agent.<br>– **with-passcode**—The user must provide the passcode to use the GlobalProtect agent override.<br>– **with-ticket**—This option enables a challenge-response mechanism to authorize disabling GlobalProtect on the client side. When this option is selected, the user is prompted with a challenge when disabling GlobalProtect. The challenge is then communicated to the firewall administrator out-of-band, and the administrator can validate the challenge through the firewall management interface. The firewall produces a response that is read back to the user who can then disable GlobalProtect by entering the response in GlobalProtect.<br>• **Agent User Override Timeout**—Specify the maximum wait time (seconds) before data collection times out.<br>• **Max Agent User Overrides**—Specify the maximum number of times a user can disable GlobalProtect before a successful connection to a firewall is required.<br>• **Display welcome page**—Select the check box to allow display of a welcome page for the portal.<br>• **Welcome Page**—Choose the factory default welcome page, or click **Import** to import another page. If you choose **None** and select the **Display Welcome Page** option, a blank page is displayed.<br>• **Enable rediscover network option**—Select this check box to allow the user to manually trigger network rediscovery.<br>• **Enable resubmit host information option**—Select this check box to allow the user to manually trigger resubmission of the latest HIP.<br>• **Client Upgrade**—Specify whether to prompt the client to update after configuration changes (**prompt**) or to perform the upgrade silently without a user prompt (**transparent**). |

**Table 139. GlobalProtect Portal Settings (Continued)**

| Field | Description |
|---|---|
| Data Collection Subtab | Specify the following settings on this subtab:<br>• **Max Wait Time**—Specify the maximum wait time (seconds) before data collection times out.<br>• **Exclude Categories**—Click **Add** to specify particular software and client configuration categories to exclude from the data collection. Choose a vendor from the drop down list and click **Add** to choose a specific product. Click **OK** to save settings.<br>• **Custom Checks**—Specify the following information:<br>– **Registry Key**—(Windows) Click **Add** to specify that a particular registry key is present or has a specified value.<br>– **Plist**—(Mac) Click **Add** to specify that a particular plist key is present or has a specified value.<br>– **Process List**—Click **Add** to specify the list of processes to be checked on the end user systems to see if they are running. For example, to determine whether a software application is running, add the name of the executable file to the process list. |
| Trusted Root CA | Specify the Root CA or issuing certificates that the GlobalProtect agent will trust when connecting to a gateway. If a gateway presents a certificate to the client that hasn't been issued by one of the listed CAs, the client will reject the handshake and terminate the connection.<br>Click **Add** to specify a root CA certificate. |
| Agent User Override Key/Confirm Agent User Override Key | When you create a GlobalProtect Agent override with ticket, which can be used to allow users to disable the Agent, you can use this hash key to validate the client when they try to disable with the ticket. |
| **Satellite Configuration** | For information on using GlobalProtect for deploying large scale VPNs, refer to "GlobalProtect Large Scale VPN Deployment" on page 323. |
| General subtab | Click **Add** to display the subtabs, and specify the following on the **GlobalProtect Satellite > General** subtab:<br>• **Name**—Enter a name to identify the GlobalProtect satellite device profile.<br>• **Configuration Refresh Interval (hours)**—Specify how often satellite devices should check the portal for configuration updates (default 24 hours, range 1-48 hours). |
| Devices subtab | Click **Add** to manually add a satellite device using the device serial number. If you use this option, when the satellite device first connects to receive the authentication certificate and the initial configuration, no user login prompt is required. After the satellite device authenticates, the **Name** (host name) will be added automatically to the Portal. |
| Enrollment User/User Group subtab | Click **Add** to add a User or User Group that will be used to authenticate the satellite device when it first connects to the portal. Select **Any** to allow authentication by any user or user group. When the satellite device first connects to the portal, the administrator will be prompted for a login/password. |

**Table 139. GlobalProtect Portal Settings (Continued)**

| Field | Description |
|---|---|
| Gateways subtab | Click **Add** to enter the IP address or hostname of the gateway(s) that will be part of the VPN network. Each satellite device that is added to the portal will create an IPSec tunnel to each gateway. Routing information is also shared between the satellites and gateways.<br>You can also define a routing priority to gateways. When a satellite has VPN tunnels to multiple gateways, duplicate routes may exist. By setting a priority, the gateway with the highest priority will be used first. If the gateway fails, the next highest priority will be used. The priority range is from 1-25, since 25 is the limit on the number of gateways that a satellite can connect to.<br>The satellite will also share its network and routing information with the gateways if the **Publish all static and connect routers to Gateway** (configured on the satellite in Network > IPSec tunnels > GlobalProtect Satellite > Advanced tab) option is selected. Refer to "GlobalProtect Satellite" on page 317.<br>When adding a gateway, in the portal configuration, you create a new key and certificate using the same issuing CA used to create satellite and other gateway certificates. You export the certificate as a PKCS12 file and import it into the gateway together with the issuing CA certificate. |
| Trusted Root CA | Click **Add** and select an existing Trusted Root CA (Certificate Authority), or generate a new Trusted Root CA that will be used to issue client certificates to all satellite and gateway devices for the GlobalProtect satellite profile. |
| Issuing Certificate | Defines the certificate that the portal will use to issue new IPSec client certificates to satellite and gateway devices. |
| Validity Period (days) | Specify the issued GlobalProtect satellite certificate lifetime (default 7 days, range 7-365 days). |
| Certificate Renewal Period (days) | Specify the GlobalProtect satellite certificate renewal period (default 3 days, range 3-30 days). This will determines how often certificates should be renewed. |
| OCSP Responder | Select the OCSP responder that will be used by the portal to determine the revocation status of the gateway and satellite devices. |

## Setting Up the GlobalProtect Gateways

▶ *Network > GlobalProtect > Gateways*

Use this page to configure gateways for GlobalProtect. The gateway can be used to provide VPN connections for client PCs or GlobalProtect satellite devices.

**Table 140. GlobalProtect Gateway Settings**

| Field | Description |
|---|---|
| **General tab** | |
| Name | Enter a name for the gateway (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Location | Select the virtual system, if the multiple virtual systems option is enabled. |
| Network Settings | |

**Table 140. GlobalProtect Gateway Settings (Continued)**

| Field | Description |
|---|---|
| Interface | Select the firewall interface that will be used as the ingress for remote clients/firewalls. |
| IP Address | Specify the IP address on which GlobalProtect portal web service will be running. |
| Server Certificate | Choose the server certificate for the gateway. |
| Authentication | |
| Authentication Profile | Choose an authentication profile or sequence to authenticate access to the portal. Refer to "Authentication Profiles" on page 62. |
| Certificate Profile | Choose the certificate profile for client authentication. |
| **Client Configuration tab** | |
| Tunnel Settings subtab | |
| Tunnel Mode | Select the check box to enable tunnel mode and specify the following settings:<br>• **Tunnel Interface**—Choose the tunnel interface for access to the gateway.<br>• **Max Users**—Specify the maximum number of users that can access the gateway at the same time. If the maximum number of users is reached, subsequent users are denied access with an error message indicating that the maximum number of users has been reached.<br>• **Enable IPSec**—Select the check box to enable IPSec mode for client traffic, making IPSec the primary and SSL-VPN the fall back method.<br>• **Enable X-Auth Support**—Select the check box to enable Extended Authentication (X-Auth) support in the GlobalProtect gateway when IPSec is enabled. With X-Auth support, third party IPSec VPN clients that support X-Auth (such as the IPSec VPN client on Apple iOS and Android devices) can establish a VPN tunnel with the GlobalProtect gateway. The X-Auth option simply provides remote access from the VPN client to a specific GlobalProtect gateway and does not provide the full control and HIP features that are part of the GlobalProtect agent installed on PCs. For details on configuring a GlobalProtect gateway to allow IPSec X-Auth clients, refer to the tech notes "GlobalProtect Config for Apple iOS VPN" and "GlobalProtect Config for Android VPN" in the Tech Note area at *https://live.paloaltonetworks.com/community/documentation.*<br>– If the group name and group password are specified, the first authentication phase requires both parties to use this credential to authenticate. The second phase requires a valid user name and password, which is verified through the authentication profile configured in the Authentication section.<br>– If no group name and group password are defined, the first authentication phase is based on a valid certificate presented by the third party VPN client. This certificate is then validated through the certificate profile configured in the authentication section. |

**Table 140. GlobalProtect Gateway Settings (Continued)**

| Field | Description |
|---|---|
| Timeout Configuration | Specify the following timeout settings:<br>• **Login Lifetime**—Specify the number of days, hours, or minutes allowed for a single gateway login session.<br>• **Inactivity Logout**—Specify the number of days, hours, or minutes after which an inactive session is automatically logged out. |
| **Network Settings subtab** | |
| Inheritance Source | Select a source to propagate DNS server and other settings from the selected DHCP client or PPPoE client interface into the GlobalProtect agents' configuration. With this setting all client network configuration, such as DNS servers and WINS servers, are inherited from the configuration of the interface selected in the Inheritance Source. |
| Primary DNS<br>Secondary DNS | Enter the IP addresses of the primary and secondary servers that provide DNS to the clients. |
| Primary WINS<br>Secondary WINS | Enter the IP addresses of the primary and secondary servers that provide Windows Internet Naming Service (WINS) to the clients. |
| Check inheritance source status | Click the link to see the server settings that are currently assigned to the client interfaces. |
| | Click **Add** to enter a suffix that the client should use locally when an unqualified hostname is entered that it cannot resolve. You can enter multiple suffixes by separating them with commas. |
| Inherit DNS Suffixes | Select this check box to inherit the DNS suffixes from the inheritance source. |
| IP Pool | Click **Add** to specify IP pool settings.<br>Use this section to create a range of IP addresses to assign to remote users. When the tunnel is established, an interface is created on the remote user's computer with an address in this range.<br>***Note:*** *The IP pool must be large enough to support all concurrent connections. IP address assignment is dynamic and not retained after the user disconnects. Configuring multiple ranges from different subnets will allow the system to offer clients an IP address that does not conflict with other interfaces on the client.*<br>The servers/routers in the networks must route the traffic for this IP pool to the firewall.<br>For example, for the 192.168.0.0/16 network, a remote user may be assigned the address 192.168.0.10. |
| Access Route | Click **Add** to specify access route options.<br>Use this section to add routes that will be pushed to the remote user's computer and therefore determine what the user's computer will send through the VPN connection.<br>For example, you can set up split tunneling to allow remote users to access the Internet without going through the VPN tunnel.<br>If no route is added, then every request is routed through the tunnel (no split tunneling). In this case, each Internet request passes through the firewall and then out to the network. This method can prevent the possibility of an external party accessing the user's computer and then gaining access to the internal network (with the user's computer acting as bridge). |

**Table 140. GlobalProtect Gateway Settings (Continued)**

| Field | Description |
|---|---|
| **HIP Notification subtab** | |
| HIP Notification | Click **Add** to specify notification options. Select **Enable** to enable the option to match or not match a message.<br>Choose a notification option from the **Show Notification As** section and choose the radio button for a **System Tray Balloon** or **Pop Up Message**, and then specify a message to match or not match. Use these settings to notify the end user about the state of the machine, for example, to provide a warning message.<br>***Note:*** *The HIP notification pages can be formatted in rich HTML, which can include links to external web sites and resource. Use the link icon* *in the rich text settings toolbar to add links.* |
| **Satellite Configuration tab** | |
| **Tunnel Settings subtab** | |
| Tunnel Configuration | Select the **Tunnel Configuration** check box and select an existing tunnel interface, or click New Tunnel Interface. For information on creating a tunnel interface, refer to "Configuring Tunnel Interfaces" on page 147.<br>**Replay attack detection**—Protect against replay attacks.<br>**Copy TOS**—Copy the (Type of Service) TOS header from the inner IP header to the outer IP header of the encapsulated packets in order to preserver the original TOS information.<br>**Configuration refresh interval (hours)**—Specify how often satellite devices should check the portal for configuration updates (default 24 hours, range 148 hours). |
| Tunnel Monitoring | Select the **Tunnel Monitoring** check box to enable monitoring of the VPN tunnels between the satellite device and gateways. This is recommended to allow failover if one of the gateways cannot communicate with the satellite.<br>**Destination IP**—Specify an IP address on the other side of the tunnel that the tunnel monitor will use to determine if the tunnel is working properly.<br>**Tunnel Monitor Profile**—Select the default monitor profile, or create a new profile. A monitor profile is used to perform automatic failover to another tunnel. Refer to "Defining Monitor Profiles" on page 177. |
| Crypto Profiles | Select an **IPSec Crypto Profile**, or create a new profile. This will determine the protocols and algorithms for identification, authentication, and encryption for the VPN tunnels. Refer to "Defining IPSec Crypto Profiles" on page 319. |
| **Network Settings subtab** | |
| Inheritance Source | Select a source to propagate DNS server and other settings from the selected DHCP client or PPPoE client interface into the GlobalProtect satellite configuration. With this setting all network configuration, such as DNS servers, are inherited from the configuration of the interface selected in the Inheritance Source. |

**Table 140. GlobalProtect Gateway Settings (Continued)**

| Field | Description |
|---|---|
| Primary DNS<br>Secondary DNS | Enter the IP addresses of the primary and secondary servers that provide DNS to the satellites. |
| DNS Suffix | Click **Add** to enter a suffix that the satellite should use locally when an unqualified hostname is entered that it cannot resolve. You can enter multiple suffixes by separating them with commas. |
| Inherit DNS Suffix | Select this check box to send the DNS suffix to the satellite devices to use locally when an unqualified hostname is entered that it cannot resolve. |
| IP Pool | Click **Add** to specify IP pool settings.<br>Use this section to create a range of IP addresses to assign to satellite devices. When the tunnel is established, an interface is created on the satellite device with an address in this range.<br>***Note:*** *The IP pool must be large enough to support all concurrent connections. IP address assignment is dynamic and not retained after the satellite disconnects. Configuring multiple ranges from different subnets will allow the system to offer satellites an IP address that does not conflict with other interfaces on the device.*<br>The servers/routers in the networks must route the traffic for this IP pool to the firewall.<br>For example, for the 192.168.0.0/16 network, a satellite may be assigned the address 192.168.0.10. |
| Access Route | Click **Add** to specify access route options.<br>Use this section to add routes that will be pushed to the satellites and therefore determining what routes the satellite will use to send traffic through the VPN connection.<br>For example, you can set up split tunneling to allow satellites to access the Internet without going through the VPN tunnel.<br>If no route is added, then every request is routed through the tunnel (no split tunneling).<br>Click **Add** to enter a route. |
| Route Filter subtab | Click the **Accept published routes** check box and enter the satellite subnets that will be added to the gateway's route table when routing information is shared. Satellite subnets that are not part of the list will be filtered out. |

# Setting Up and Activating the GlobalProtect Agent

▶ *Device > GlobalProtect Client*

The **GlobalProtect Client** page lists the available GlobalProtect releases. When the client connects, the system checks the version and installs the currently activated version of the agent software if it is different from the version that is on the client.

***Note:*** *For initial download and installation of the GlobalProtect agent, the user on the client system must be logged in with administrator rights. For subsequent upgrades, administrator rights are not required.*

To download and activate the GlobalProtect agent:

1. Click the **Download** link for the desired release. The download starts and a pop-up window opens to display the progress of the download. When the download is complete, click **Close**.
2. To activate a downloaded release, click the **Activate** link for the release. If an existing version of the client software has already been downloaded and activated, a pop-up message is displayed to indicate that the new version will be downloaded the next time that the clients connect.
3. To activate the client that was previously installed by way of the **Upload** button, click the **Activate From File** button. A pop-up window opens. Select the file from the drop-down list and click **OK**.
4. To remove a downloaded release of the client software from the firewall, click the **Remove** icon in the rightmost column.

# Setting Up the GlobalProtect Agent

The GlobalProtect agent (PanGP Agent) is an application that is installed on the client system (typically a laptop) to support GlobalProtect connections with portals and gateways and is supported by the GlobalProtect service (PanGP Service).

***Note:*** *Make sure that you choose the correct installation option for your host operating system (32-bit or 64-bit). If installing on a 64-bit host, use 64-bit browser/Java combo for the initial installation.*

To install the agent, open the installer file and follow the on-screen instructions.

To configure the agent:

1. Choose **Start > All Programs > Palo Alto Networks > GlobalProtect > GlobalProtect**.

   The client interface opens to show the **Settings** tab.

**Figure 45. GlobalProtect - Settings Tab**

2. Specify the username and password to use for GlobalProtect authentication, and optionally select the **Remember Me** check box.
3. Enter the IP address of the firewall that serves as the GlobalProtect Portal.
4. Click **Apply**.

### Using the GlobalProtect Agent

The tabs in the GlobalProtect agent contain useful information about status and settings, and provide information to assist in troubleshooting connection issues.

- **Status tab**—Displays current connection status and lists any warnings or errors.
- **Details tab**—Displays information about the current connection, including portal IP addresses and protocol, and presents byte and packet statistics about the network connection.
- **Host State tab**—Displays the information stored in the HIP. Click a category on the left side of the window to display the configured information for that category on the right side of the window.

- **Troubleshooting tab**—Displays information to assist in troubleshooting.
  - **Network Configurations**—Displays the current client system configuration.
  - **Routing Table**—Displays information on how the GlobalProtect connection is currently routed.
  - **Sockets**—Displays socket information for the current active connections.
  - **Logs**—Allows you to display logs for the GlobalProtect agent (PanGP Agent) and service (PanGP Service). Choose the log type and debugging level. Click **Start** to begin logging and **Stop** to terminate logging.

Chapter 10

# Configuring Quality of Service

This chapter describes how to configure quality of service (QoS) on the firewall:

- "Firewall Support for QoS" in the next section
- "Defining QoS Profiles" on page 358
- "Defining QoS Policies" on page 359
- "Displaying QoS Statistics" on page 362

## Firewall Support for QoS

The firewall supports fine grained QoS settings for clear text and tunneled traffic upon egress from the firewall. (Ingress QoS processing is not supported.) QoS profiles are attached to physical interfaces to specify how traffic classes map to bandwidth (guaranteed, maximum) and priority. QoS policy is then used to map specific sessions to QoS classes. QoS classification is supported with all interface types except Aggregate Ethernet.

The firewall supports the following QoS settings:

- Use the Network > QoS page to configure QoS settings for firewall interfaces and specify criteria for the clear text and tunneled traffic that leaves the firewall through those interfaces. Refer to "Configuring QoS for Firewall Interfaces" on page 356.
- For each interface, you can define QoS profiles that determine how the QoS traffic classes are treated. You can set overall limits on bandwidth regardless of class and also set limits for individual classes. You can also assign priorities to different classes. Priorities determine how traffic is treated when contention occurs. Refer to "Defining QoS Profiles" on page 358.
- Use the Policies > QoS page to configure policies to activate the QoS restrictions. Refer to "Defining QoS Policies" on page 359.

### Important items to consider when configuring firewall support for QoS

- When setting up the QoS profile, the guaranteed and maximum egress settings defined for the classes must not exceed the guaranteed and maximum egress settings defined for the profile itself.
- Traffic that does not match QoS policy will be assigned a default class of 4. Be sure to assign a maximum guaranteed bandwidth and priority with this in mind.
- Each firewall model supports a maximum number of ports that can be configured with QoS. Refer to the spec sheet for your firewall model at *http://www.paloaltonetworks.com*.

# Configuring QoS for Firewall Interfaces

▶ *Network > QoS*

Use the **QoS** page to configure bandwidth limits for firewall interfaces.

**Table 141. QoS Settings**

| Field | Description |
|---|---|
| **Physical Interface** | |
| Interface Name | Select the firewall interface. |
| Egress Max (Mbps) | Enter the limit on traffic leaving the firewall through this interface (Mbps). |
| Turn on QoS feature on this interface | Select the check box to enable QoS features. |
| Default Profile:<br>Clear Text<br>Tunnel Interface | Select the default QoS profiles for clear text and for tunneled traffic. You must specify a default profile for each. For clear text traffic, the default profile applies to all clear text traffic as an aggregate. For tunneled traffic, the default profile is applied individually to each tunnel that does not have a specific profile assignment in the detailed configuration section. For instructions on defining QoS profiles, refer to "Defining QoS Profiles" on page 358. |
| **Clear Text Traffic and Tunneled Traffic** | Specify the following settings on the **Tunneled** and **Clear Text Traffic** tabs. These values apply unless they are overridden by setting in the Detail Configuration area, as described later in this table. |
| Egress Guaranteed (Mbps) | Enter the bandwidth that is guaranteed for tunneled traffic from this interface. |
| Egress Max (Mbps) | Enter the limit on traffic leaving the firewall through this interface (Mbps). |

**Table 141. QoS Settings (Continued)**

| Field | Description |
|---|---|
| Add | Click **Add** from the **Clear Text Traffic** or **Tunneled Traffic** tabs to define additional granularity to the treatment of clear text traffic or to override the default profile assignment for specific tunnels. If this section is left blank, the values specified in Group Configuration are used.<br>For example, assume a configuration with two sites, one of which has a 45 Mbps connection and the other a T1 connection to the firewall. You can apply restrictive QoS settings to the T1 site so that the connection is not overloaded while also allowing more flexible settings for the site with the 45 Mbps connection.<br>To add granularity for clear text traffic, click the **Clear Text** tab, click **Add**, and then click individual entries to configure the following settings:<br>• **Name**—Enter a name to identify these settings.<br>• **QoS Profile**—Select the QoS profile to apply to the specified interface and subnet. For instructions on defining QoS profiles, refer to "Defining QoS Profiles" on page 358.<br>***Note:*** *The QoS rules for clear text are applied in the specified order. Refer to the following tech note for more details on QoS https://live.paloaltonetworks.com/docs/DOC-3439.*<br>• **Source Interface**—Select the firewall interface.<br>• **Source Subnet**—Select a subnet to restrict the settings to traffic coming from that source, or keep the default **any** to apply the settings to any traffic from the specified interface.<br>To override the default profile for a specific tunnel, click the **Tunneled Traffic** tab, click **Add**, and then click individual entries to configure the following settings:<br>• **Tunnel Interface**—Select the tunnel interface on the firewall.<br>• **QoS Profile**—Select the QoS profile to apply to the specified tunnel interface.<br>To remove a clear text or tunneled traffic entry, select the check box for the entry and click **Remove**. |

# Defining QoS Profiles

▶ *Network > Network Profiles > QoS Profiles*

For each interface, you can define QoS profiles that determine how the QoS traffic classes are treated. You can set overall limits on bandwidth regardless of class and also set limits for individual classes. You can also assign priorities to different classes. Priorities determine how traffic is treated in the presence of contention.

***Note:*** *Refer to "Configuring QoS for Firewall Interfaces" on page 356 for information on configuring firewall interfaces for QoS and refer to "Defining QoS Policies" on page 359 to configure the policies that will activate the QoS restrictions.*

**Table 142. QoS Profile Settings**

| Field | Description |
|---|---|
| Profile Name | Enter a name to identify the profile (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Egress Max | Enter the maximum bandwidth allowed for this profile (Mbps). |
| Egress Guaranteed | Enter the bandwidth that is guaranteed for this profile (Mbps). |
| Classes | Specify how to treat individual QoS classes. You can select one or more classes to configure:<br>• **Class**—If you do not configure a class, you can still include it in a QoS policy. In this case, the traffic is subject to overall QoS limits. Traffic that does not match a QoS policy will be assigned to class 4.<br>• **Priority**—Click and select a priority to assign to this class. These are prioritized in the order listed (highest first):<br>– real-time<br>– high<br>– medium<br>– low<br>• **Egress Max**—Click and enter a value (Mbps) for this class.<br>• **Egress Guaranteed**—Click and enter a value (Mbps) for this class.<br>When contention occurs, traffic that is assigned a lower priority is dropped. Real-time priority uses its own separate queue. |

# Defining QoS Policies

▶ *Policies > QoS*

The QoS policy determines how traffic is classified for treatment when it passes through an interface with QoS enabled. For each rule, you specify one of eight classes. You can also assign a schedule to specify which rule is active. Unclassified traffic is automatically assigned to class 4.

***Note:*** *Refer to "Configuring QoS for Firewall Interfaces" on page 356 for information on configuring firewall interfaces for QoS and refer to "Defining QoS Profiles" on page 358 for information on configuring classes of service.*

To view just the rules for a specific virtual system, select the system from the **Virtual System** drop-down list and click **Go**. To apply a filter to the list, select from the **Filter Rules** drop-down list. To view just the rules for specific zones, select a zone from the **Source Zone** and/or **Destination Zone** drop-down lists, and click **Filter by Zone**.

***Note:*** *Shared polices pushed from Panorama are shown in green and cannot be edited at the device level.*

To add a new QoS rule, do one of the following:

- Click **Add** at the bottom of the page and configure the rule. A new rule is added to the bottom of the list.
- Select **Clone Rule**, or select a rule by clicking the white space of the rule, and select **Clone** at the bottom of the page (a selected rule has a yellow background). The copied rule is inserted below the selected rule.

**Table 143. QoS Rule Settings**

| Field | Description |
|---|---|
| **General Tab** | |
| Name | Enter a name to identify the rule (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Description | Enter an optional description. |
| Tag | If you need to tag the policy, click **Add** to specify the tag.<br>A policy tag is a keyword or phrase that allows you to sort or filter policies. This is useful when you have defined many policies and want to view those that are tagged with a particular keyword. For example, you may want to tag certain security policies with Inbound to DMZ, decryption policies with the words Decrypt and No-decrypt, or use the name of a specific data center for policies associated with that location. |
| **Source Tab** | |

**Table 143. QoS Rule Settings (Continued)**

| Field | Description |
|---|---|
| Source Zone | Select one or more source zones (default is any). Zones must be of the same type (Layer 2, Layer 3, or virtual wire). To define new zones, refer to "Defining Security Zones" on page 151. |
| Source Address | Specify a combination of source IPv4 or IPv6 addresses for which the identified application can be overridden. To select specific addresses, choose **select** from the drop-down list and do any of the following:<br>• Select the check box next to the appropriate addresses and/or address groups in the **Available** column, and click **Add** to add your selections to the **Selected** column.<br>• Enter the first few characters of a name in the **Search** field to list all addresses and address groups that start with those characters. Selecting an item in the list will set the check box in the **Available** column. Repeat this process as often as needed, and then click **Add**.<br>• Enter one or more IP addresses (one per line), with or without a network mask. The general format is:<br><ip_address>/<mask><br>• To remove addresses, select the appropriate check boxes in the **Selected** column and click **Remove**, or select **any** to clear all addresses and address groups.<br>To add new addresses that can be used in this or other policies, click **New Address** (refer to "Defining Applications" on page 233). To define new address groups, refer to "Defining Address Groups" on page 230. |
| Source User | Specify the source users and groups to which the QoS policy will apply. |
| Negate | Select the check box to have the policy apply if the specified information on this tab does NOT match. |
| **Destination Tab** | |
| Destination Zone | Select one or more source zones (default is any). Zones must be of the same type (Layer 2, Layer 3, or virtual wire). To define new zones, refer to "Defining Security Zones" on page 151. |
| Destination Address | Specify a combination of source IPv4 or IPv6 addresses for which the identified application can be overridden. To select specific addresses, choose **select** from the drop-down list and do any of the following:<br>• Select the check box next to the appropriate addresses and/or address groups in the **Available** column, and click **Add** to add your selections to the **Selected** column.<br>• Enter the first few characters of a name in the **Search** field to list all addresses and address groups that start with those characters. Selecting an item in the list will set the check box in the **Available** column. Repeat this process as often as needed, and then click **Add**.<br>• Enter one or more IP addresses (one per line), with or without a network mask. The general format is:<br><ip_address>/<mask><br>• To remove addresses, select the appropriate check boxes in the **Selected** column and click **Remove**, or select **any** to clear all addresses and address groups.<br>To add new addresses that can be used in this or other policies, click **New Address** (refer to "Defining Applications" on page 233). To define new address groups, refer to "Defining Address Groups" on page 230. |

**Table 143. QoS Rule Settings (Continued)**

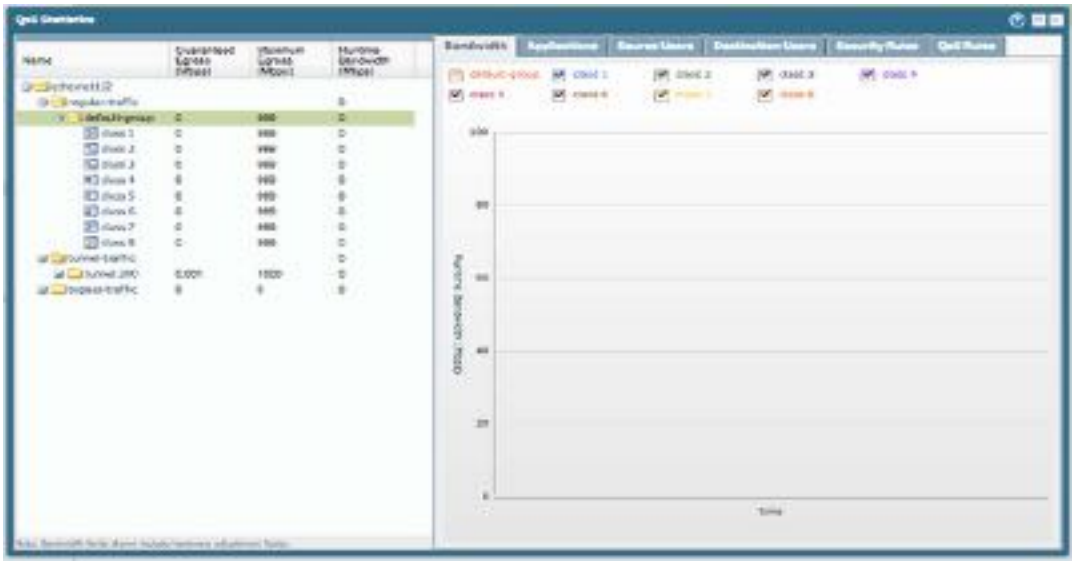
| Field | Description |
|---|---|
| Negate | Select the check box to have the policy apply if the specified information on this tab does NOT match. |
| **Application Tab** | |
| Application | Select specific applications for the QoS rule. To define new applications, refer to "Defining Applications" on page 233. To define application groups, refer to "Defining Application Groups" on page 238.<br>If an application has multiple functions, you can select the overall application or individual functions. If you select the overall application, all functions are included, and the application definition is automatically updated as future functions are added.<br>If you are using application groups, filters, or container in the QoS rule, you can view details on these objects by holding your mouse over the object in the **Application** column, click the down arrow and select **Value**. This enables you to easily view application members directly from the policy without having to go to the Object tabs. |
| **Service/ URL Category Tab** | |
| Service | Select services to limit to specific TCP and/or UDP port numbers. Choose one of the following from the drop-down list:<br>• **any**—The selected applications are allowed or denied on any protocol or port.<br>• **application-default**—The selected applications are allowed or denied only on their default ports defined by Palo Alto Networks. This option is recommended for allow policies.<br>• **Select**—Click **Add**. Choose an existing service or choose **Service** or **Service Group** to specify a new entry. Refer to "Services" on page 239 and "Service Groups" on page 240. |
| URL Category | Select URL categories for the QoS rule.<br>• Choose **any** to ensure that a session can match this QoS rule regardless of the URL category.<br>• To specify a category, click **Add** and select a specific category (including a custom category) from the drop-down list. You can add multiple categories. Refer to "Custom URL Categories" on page 242 for information on defining custom categories. |
| **Other Settings Tab** | |
| Class | Choose the QoS class to assign to the rule, and click **OK**. Class characteristics are defined in the QoS profile. Refer to "Defining QoS Profiles" on page 358 for information on configuring settings for QoS classes. |
| Schedule | Choose the calendar icon to set a schedule for the QoS policy to apply. |

# Displaying QoS Statistics

▶ *Network > QoS*

The table on the **QoS Policies** page indicates when QoS is enabled, and includes a link to display QoS statistics. An example is shown in the following figure.

**Figure 46. QoS Statistics**



The left panel shows the QoS tree table, and the right panel shows data in the following tabs:

- **QoS Bandwidth**—Shows the real time bandwidth charts for the selected node and classes. The information is updated every two seconds.
- **Session Browser**—Lists the active sessions of the selected node and/or class.
- **Application View**—Lists all active applications for the selected QoS node and/or class.

Chapter 11

# Setting Up a VM-Series Firewall

This chapter describes how to install the VM-Series firewall:

- "Overview" in the next section
- "System Requirements and Limitations" on page 364
- "About Licensing the VM-Series Firewall" on page 365
- "Installing and Licensing the VM-Series Firewall" on page 366
- "Troubleshooting" on page 370

## Overview

The Palo Alto Networks VM-Series firewall is the virtualized form of the Palo Alto Networks firewall. It is positioned for use in a virtualized data center environment and is particularly well suited for private and public cloud deployments. By using virtual machine technology, you can install this solution on any x86 device that is capable of running VMware ESXi, without the need to deploy Palo Alto Networks hardware.

The VM-Series firewall has many characteristics in common with the Palo Alto Networks hardware firewalls, including common features and management interfaces. The main difference is in the deployment methods used in a virtual environment in order to fit your needs. Once the virtual firewall is installed, you will use it and manage it much like you do with the hardware firewalls.

The VM-Series firewall is distributed using the Open Virtualization Format (OVF), which is a standard method of packaging and deploying virtual machines.

***Note:*** This section covers the basic installation steps needed to deploy a VM-Series firewall. For more details and uses cases, refer to the VM-Series firewall Tech Note at *https://live.paloaltonetworks.com/community/documentation*.

# System Requirements and Limitations

This section lists requirements and limitations for the VM-Series firewall.

## Requirements

You can create and deploy multiple instances of the VM-Series firewall on an ESX(i) server. Because each instance of the firewall requires a minimum resource allocation — number of CPUs, memory and disk space— on the ESX(i) server, make sure to conform to the specifications below to ensure optimal performance.

The VM-Series firewall has the following requirements:

- VMware ESX(i) with vSphere 4.1 and 5.0.
- Minimum of two vCPUs per VM-Series firewall. One will be used for the for the management plane and one for the dataplane. You can add up to eight additional vCPUs for the dataplane in the following increments: 2, 4, or 8 vCPUs.
- Minimum of two network interfaces (vmNICs). One will be a dedicated vmNIC for the management interface and one for the data port. You can then add up to eight more vmNICs for data traffic.
  The VM-Series firewall requires that promiscuous mode is set to "accept" on the port group of the virtual switch to which the data ports on the firewall are attached.
- Minimum of 4GB of memory. Any additional memory will be used by the management plane only.
- Minimum of 40GB of virtual disk space. You can add an additional disk of up to 2TB for logging purposes.

## Limitations

The VM-Series firewall functionality is very similar to the Palo Alto Networks hardware firewalls, but with the following limitations:

- Dedicated CPU cores are required.
- Only High Availability (HA) lite is supported (active/passive with no stateful failover).
- High Availability (HA) "Link Monitoring" is only supported on VMware ESXi installations that support DirectPath I/O.
- Up to 10 total ports can be configured; this is a VMware limitation. One port will be used for management traffic and up to 9 can be used for data traffic.
- Only the vmxnet3 driver is supported.
- Virtual systems are not supported.
- vMotion is not supported.
- Jumbo frames are not supported.
- Link Aggregation is not supported.

# About Licensing the VM-Series Firewall

The VM-Series firewall is available in three models — VM-100, VM-200, and VM-300— and each model is licensed for a maximum capacity. Capacity is defined in terms of the number of sessions, rules, security zones, address objects, IPSec VPN tunnels and SSL VPN tunnels that the VM-Series firewall is optimized to handle. When purchasing a license, make sure to purchase the correct model for your network requirements. While each model has a distinct orderable part number, the software package that is used to create the VM-Series firewall is the same across all models.

When you purchase a VM-Series firewall, you will receive a set of auth-codes over email. Typically the email includes a capacity auth-code for the model purchased (VM-100, VM-200, VM300), a software and support auth-code (for example, PAN-SVC-PREM-VM-100 SKU auth-code) that provides access to software/content updates and support. If you purchased additional subscriptions for Threat Prevention, URL Filtering, GlobalProtect, or WildFire, a list of the other auth-codes purchased with the order are included.

If you do not have an existing support account, you must use the capacity auth-code to register and create an account on the Support Portal. After your account is verified and the registration is complete, you will be able to log in and download the software package required to install the VM-Series firewall. If you have an existing support account, you can access the "VM-Series Authentication Code" link on the support software page to manage your VM-Series firewall licenses and download the software.

***Note:*** *If you have an evaluation copy of the VM-Series firewall and would like to convert it to a fully licensed (purchased) copy, clone your VM-Series firewall and use the instructions in the following sections to register and license the purchased copy of your VM-Series firewall.*

# Registering the VM-Series Firewall

You are required to register your capacity auth-code with your support account.

1. Log in to https://support.paloaltonetworks.com with your account credentials.
2. Select **My VM-Series Auth-Codes** link on the home page and click **Add VM-Series Auth-Code.**
3. Enter the capacity auth-code you received by email, and click the **Add VM-Series Auth-Code** button. The page will refresh and you will see the list of auth-codes registered to your support account.
4. Continue with "Installing and Licensing the VM-Series Firewall" on page 366.

# Installing and Licensing the VM-Series Firewall

This section describes the steps needed to install and license the VM-Series firewall.

Installing a VM-Series firewall:

1. Obtain a VM-Series license then download the Open Virtualization Format (OVF) template from *https://support.paloaltonetworks.com* software site.

   The OVF is downloaded as a zip archive that is expanded into three files:

   – OVF extension—The OVF descriptor file that contains all metadata about the package and its contents.

   – MF extension—The OVF manifest file that contains the SHA-1 digests of individual files in the package.

   – VMDK extension—The disk image file that contains the virtualized version of the PAN-OS firewall.

   ***Note:*** *The above files contain the base installation. After the base installation is complete, you will need to download and install the latest version of the VM-Series firewall software from the support site. This will ensure that you have the latest fixes that were implemented since the base OVF file was created.*

2. Before deploying the template, it is helpful to setup virtual standard switch(es) and virtual distributed switch(es) that you will need for the VM-Series firewall. The VM-Series firewall requires that any attached virtual switch has promiscuous mode enabled.

   To configure a virtual standard switch:

   a. Configure a virtual standard switch from the vSphere Client by navigating to **Home > Inventory > Hosts and Clusters**.

   b. Click the **Configuration** tab and under **Hardware** click **Networking.** For each VM-Series firewall attached virtual switch, click on **Properties**.

   c. Highlight the virtual switch and click **Edit**. In the vSwitch properties, click the **Security** tab and set **Promiscuous Mode:** to **Accept** and then click **OK**. This change will propagate to all port groups on the virtual switch.

   To configure a virtual distributed switch:

   a. Navigate to **Home > Inventory > Networking**. Highlight the **Distributed Port Group** you want to edit and select the **Summary** tab.

   b. Click on **Edit Settings** and select **Policies > Security** and set **Promiscuous Mode:** to **Accept** and then click **OK**.

3. Deploy the OVF template:

   a. Log in to vCenter using the vSphere client. You can also go directly to the target ESXi host if needed.

   b. From the vSphere client, select **File > Deploy OVF Template**.

c. Browse to the OVF template that you downloaded in step 1, select the file and then click **Next**. Review the templates details window and then click **Next** again.

d. Name the VM-Series firewall instance and in the **Inventory Location:** window, select a Data Center and folder and click **Next**.

e. Select an ESXi host for the VM-Series firewall and click **Next**.

f. Select the datastore to use for the VM-Series firewall and click **Next**.

g. Leave the default settings for the datastore provisioning and click **Next**. The default is "Thick Provision Lazy Zeroed".

h. Select the networks to use for the two initial vmNICs. The first vmNIC will be used for the management interface and the second vmNIC for the first data port. Make sure that the **Source Networks** is mapped to the correct **Destination Networks**.

i. Review the details window, click the **Power on after deployment** check box and then click **Next**.

You can monitor the **Recent Tasks** list to view the progress of the deployment. When the deployment is complete, click the **Summary** tab to review the current status.

4. To perform the initial configuration of the VM-Series firewall, follow these steps:
   a. The default management IP is 192.168.1.1. To change this, launch the vSphere console, click the **Summary** tab and under **Commands** click **Open Console**. You can also right click the VM and select Open Console.
   b. Log in with the default login user name **admin** password **admin** and then type **configure** to enter configuration mode.
   c. Set the desired IP, netmask, gateway, and DNS IP. Example:
      ```
      set deviceconfig system ip-address 10.1.1.5 netmask
      255.255.255.0 default-gateway 10.1.1.1 dns-setting servers
      primary 10.0.0.245
      ```
   d. Type **commit** to make the changes active.
   e. Test network connectivity to your default gateway and a known server. Example: `ping host 10.1.1.1` or `ping host 10.0.0.245`.
5. Activate the license. Pick one of the following options based on whether or not the VM-Series firewall has direct internet access.
   a. If your firewall has direct internet access:
      i. Navigate to the **Device >Licenses** tab and select the **Activate feature using authentication code** link.
      ii. Enter the capacity auth-code that you registered on the Support website. The firewall will connect to the update server (updates.paloaltonetworks.com), and download the license and reboot automatically.
      iii. Log back in to the web interface and confirm that the **Dashboard** displays a valid serial number. If the term *Unknown* displays, it means the device is not licensed.
      iv. On the **Device-> Licenses** tab, verify that "PA-VM" license is added to the device.

b. In case the ESXi server that your VM-Series firewall is installed on does not have internet access:

   i. Navigate to the **Device > Licenses** tab and click the **Activate Feature using Auth Code** link.

   ii. Click D**ownload Authorization File**, and download the *authorizationfile.txt* on the client machine.

   iii. Copy the *authorizationfile.txt* to a computer that has access to the internet and log in to the support portal. Click **My VM-Series Auth-Codes** link and select the applicable auth-code from the list and click the **Register V**M link.

   iv. On the **Register VM Device** tab upload the authorization file. This will complete the registration process and the serial number of your VM-Series firewall will be attached to your account records.

   v. Navigate to the **My Devices** tab and search for the VM-Series device just registered and click the **PA-VM** link. This will download the VM-Series license key to the client machine.

   vi. Copy the license key to the machine that can access the web interface of the VM-Series firewall and navigate to the **Device -> Licenses** tab.

   vii. Click **Manually Upload License** link and enter the license key. The license will be activated on the device and the device will reboot.

   viii. Log in to the device and confirm that the **Dashboard** displays a valid serial number and that the PA-VM license displays in the **Device > Licenses** tab.

***Note:*** *In order to complete the license installation process, you must reboot your VM-Series firewall instance.*

6. Now that the VM-Series firewall has network connectivity and the base PAN-OS software is installed, you need to upgrade to the latest version of PAN-OS (a support license is required).

***Note:*** *The base VM-Series firewall software is installed with the OVF file. It's recommended that you upgrade to the latest content update and PAN-OS release to ensure you have all of the latest fixes. At each feature release, a new base image will be created as part of the OVF file.*

   a. From the web interface, navigate to **Device > Licenses** and make sure you have the correct VM-Series firewall license and that the license is activated.

   b. To upgrade the VM-Series firewall PAN-OS software, navigate to **Device > Software**.

   c. Click **Refresh** to view the latest software release and also review the **Release Notes** to view a description of the changes in a release and to view the migration path to install the software.

   d. Click **Download** to retrieve the software then click **Install** to install it.

   For details on downloading and installing PAN-OS software, refer to "Upgrading/ Downgrading the PAN-OS Software" on page 50.

# Troubleshooting

Many of the troubleshooting steps for the VM-Series firewall are very similar to the hardware versions of PAN-OS. When problems occur, you should check interface counters, system log files, and if necessary, use debug to create captures. For more details on PAN-OS troubleshooting, refer to the Packet Based Troubleshooting Tech Note at *https://live.paloaltonetworks.com/community/documentation*.

Similar to a physical environment, it is sometimes useful to have a separate troubleshooting client to capture traffic in the virtualized environment. It can be helpful to build a fresh OS from scratch with common troubleshooting tools installed, such as: tcpdump, nmap, hping, traceroute, iperf, tcpedit, netcat, etc. Going forward, each time it is needed, the troubleshooting client can be quickly deployed to the virtual switch(es) in question and used to isolate networking problems.

For performance related issues on the firewall, first check the **Dashboard** from the firewall web interface. For information in the VM server, in vSphere Client go to **Home > Inventory > VMs and Templates**, select the VM-Series firewall instance and click the **Summary** tab. Under **Resources**, check the statistics for consumed memory, CPU and storage. For resource history, click the **Performance** tab and monitor resource consumption over time.

You can also view alerts or create a tech support or stats dump files from **Device > Support**. For more information, refer to "Viewing Support Information" on page 117.

Chapter 12

# Setting Up Panorama

This chapter describes how to set up the Panorama centralized management system:

- "Overview" in the next section
- "Setting Up Panorama as a Virtual Appliance" on page 372
- "Setting up Panorama on an M-Series Appliance" on page 376
- "Configuring High Availability (HA)" on page 377

***Note:*** *For information on using Panorama, see "Central Device Management Using Panorama" on page 381.*

## Overview

Panorama is the centralized management system for the Palo Alto Networks family of next-generation firewalls, and is available both as a dedicated hardware platform and as a VMware virtual appliance that meets your server consolidation needs.

Panorama provides centralized visibility and management for all the devices on your network. Because Panorama shares the same web-based look and feel as the individual device interface, you can seamlessly transition in to managing the devices centrally and reducing the administrative effort in managing multiple devices.

For information on installing Panorama on VMware ESX(i) 3.5 or later, see "Setting Up Panorama as a Virtual Appliance" on page 372

For information on setting up the hardware based M-100 management appliance, see "Setting up Panorama on an M-Series Appliance" on page 376.

# Setting Up Panorama as a Virtual Appliance

The pre-requisites for setting up a Panorama virtual appliance are:

- System requirements
  - VMware ESX(i) 3.5 or later
  - Quad Core CPU (3GHz) (use 4 GHz if you have 10 or more active firewalls)
  - 2-4 GB RAM (use 4 GB if you have 10 or more active firewalls)
  - 34 GB disk space
  - VMware vSphere Client 4.x or VMware Infrastructure Client 3.5
- Use the assigned serial number to register Panorama on the support site at *https://support.paloaltonetworks.com*. After you register Panorama on the support site, you will have access to the Panorama software downloads page.
- Download the latest Panorama base image zip file to the server on which you will be installing Panorama.The virtual appliance installation procedure uses the Open Virtual Machine Format (OVF) template file, which is included in the base image.

## Installing Panorama

Follow these steps to install Panorama on your ESX(i) server:

1. Unzip the Panorama zip file to find the *panorama-esx.ovf* template file for installation.
2. Open the VMware vSphere Client and connect to your VMware server from the login screen.
3. Choose **File > Deploy OVF Template**.
4. Browse to select the *panorama-esx.ovf* file from the recently unzipped Panorama base image, and click **Next**.
5. Confirm that the product name and description match the downloaded version, and click **Next**.
6. Choose a name for the Panorama image, and click **Next**.
7. Select a datastore location to install the Panorama image, and click **Next**.
8. If prompted, choose **Thick provisioned format** for the disk format, and click **Next**.
9. Confirm the options you selected and then click **Finish** to begin the installation process.
10. When the installation is complete, choose the newly installed Panorama image and click the **Power On** button.

When the Panorama virtual machine boots, the installation process is complete. Continue with the next section to use the console and perform initial set up.

# Configuring the Panorama Network Interface

To configure the Panorama network interface using the Panorama virtual machine console on your ESX(i) server:

1. Log in to the CLI. Enter **admin** for both the username and password fields.
2. At the prompt, type **configure** to switch to the configuration mode.
3. Define the network access configuration for the management interface. Enter the following commands on one line.
   **set deviceconfig system ip-address** <Panorama-IP> **netmask** <netmask> **default-gateway** <gateway-IP> **dns-setting servers primary** <DNS-IP>

   where <*Panorama-IP*> is the IP address, <*netmask*> is the subnet mask, <*gateway-IP*> is the IP address of the network gateway, and <*DNS-IP*> is the IP address of the Domain Name System (DNS) server.
4. Type **commit** to save the changes and activate them.
5. Type **Exit** to leave the configuration mode.
6. Test network connectivity to your default gateway or another server (<*target-IP*>).
   **ping host <target-IP>**

   Make sure that you can successfully ping the gateway and the Internet.

### Next Steps

- To log in to Panorama, and to change the default password, see "Logging in to Panorama" on page 377.
- To set up additional log storage capacity for your Panorama virtual appliance, see "Expanding the Log Storage Capacity" on page 373.
- To configure high availability, see "Configuring High Availability (HA)" on page 377.
- To start managing devices using Panorama, see the following sections:
  - To add devices, see "Panorama Administrator Roles, Profiles, and Accounts" on page 387.
  - Top verify that each managed device is configured with the IP address of the Panorama server, see "System Setup, Configuration, and License Management" on page 30.

# Expanding the Log Storage Capacity

By default, Panorama maintains internal storage for log files and statistical data. The default Panorama installation is set up with a single disk partition for all data; 10 GB of space is allocated for log storage on the partition. To support environments that require more storage space, you can select from two options:

- Create a custom virtual disk up to 2TB for ESX or ESXi. For instructions, see "Adding a Virtual Disk" on page 374.

  or,

- Configure an external NFS data store. For instructions, see"Setting Up Storage Partitions" on page 374.

# Adding a Virtual Disk

If you require more storage space than the 10GB that is provided by default on the Panorama device, use the following steps to create a custom virtual disk:

1. On your ESX(i) server, select the Panorama virtual machine.
2. Click **Edit Settings**.
3. Click **Add** to launch the Add Hardware wizard.
4. Choose **Hard Disk** from the list of hardware types and click **Next**.
5. Choose the **Create a new virtual disk** option and click **Next**.
6. Choose **SCSI** for the Virtual Disk Type and click **Next**.
7. Select **Specify a datastore** in the location field and enter a name and path or select using the **Browse** button.
8. Click **Finish**.

   The new disk is shown in the list of devices for the virtual machine.
9. Start the Panorama virtual machine.

   On the first start after adding the new disk, Panorama initializes the new disk for use. This process may take several minutes to a few hours, depending on the size of the newly added disk.

After the system starts with the new disk, any existing logs on the default disk are moved to the new virtual disk, and all future log entries are written to the new disk. If the virtual disk is removed, Panorama automatically reverts back to logging to the default internal 10 GB disk.

If you have already added a virtual disk and would like to replace it with a larger or different virtual disk, you must first remove the installed virtual disk. However, when a first virtual disk is removed you can no longer access the logs on that disk.

***Note:*** *To allow for redundancy, use the virtual disk in a RAID configuration. RAID 10 provides the best write performance for applications with high logging characteristics. For further performance improvements, optimize the drives for sequential writing of a small number of large files.*

# Setting Up Storage Partitions

▶ ***Panorama > Setup > Storage Partition Setup***

To configure an external NFS data store:

Click the **Storage Partition Setup** link on the Panorama **Setup** page, and specify the following settings.

***Note:*** *You must reboot the Panorama server after configuring the storage partition settings.*

**Table 144. Storage Partition Settings**

| Field | Description |
|---|---|
| Internal | Maintains storage space for log files and statistical date on the Panorama device. |
| NFS v3 | Specifies an external NFS server mount point for storage. Configure the following settings:<br>• **Server**—Specify the fully qualified domain name (FQDN) or IP address of the NFS server.<br>• **Log Directory**—Specify the full path name of the directory where the logs will be stored.<br>• **Protocol**—Specify the protocol for communication with the NFS server (UDP or TCP).<br>• **Port**—Specify the port for communication with the NFS server.<br>• **Read Size**—Specify the maximum size (bytes) for NFS read operations (range 256 - 32768).<br>• **Write Size**—Specify the maximum size (bytes) for NFS write operations (range 256 - 32768).<br>• **Copy On Setup**—Select the check box to mount the NFS partition and copy any existing logs to the destination directory on the server when the Panorama device boots.<br>• **Test Logging Partition**—Click to perform a test that mounts the NFS partition and presents a success or failure message. |

# Setting up Panorama on an M-Series Appliance

The hardware-based Panorama solution uses the M-100 device. Refer to the *M-100 Hardware Reference Guide* for information on rack-mounting the appliance and powering it on.

Complete the following tasks before you begin with performing initial setup.

- Register your M-100 device at http://support.paloaltonetworks.com to obtain the latest software updates and to activate support.
- Obtain an IP address for Panorama from your system administrator.
- Set your computer's IP address to 192.168.1.2 and the subnet mask to 255.255.255.0.

## Performing Initial Setup

The initial setup allows you to use the default IP address to access the Panorama Management Console and then assign an IP address on the management interface so that you can manage the device across your network.

To perform initial setup:

1. Connect your computer to the management port (MGT) using an RJ-45 Ethernet cable (provided).
2. Power on your computer.
3. Log in to Panorama.
   a. Launch an Internet browser on your computer and enter **https://192.168.1.1**.
   b. Type admin in both the **Name** and **Password** fields.
   c. Click **Login**.
4. Click **Panorama > Setup**. Click the small gear icon (Edit…) on the **Management Interface Settings** table.
5. Enter the new IP address and related network access information for using the management interface (MGT) on your enterprise management network. Click **OK**.
6. Commit your changes to the device. Click **Commit** and select Panorama as the **Commit Type**, then click **OK**.
7. Disconnect your computer from the M-100 device.
8. Connect the MGT port on the front panel of the M-100 to the enterprise management network. Your device is now set up for access across your network.

Next steps:

- To log in and verify access to the Panorama Management Console. See “Logging in to Panorama” on page 377.
- To change the default login credentials, see “Changing the Default Password” on page 377.

# Logging in to Panorama

To log in to the web interface of Panorama:

1. Launch a web browser and enter **https://<Panorama IP address>**.
   The browser automatically opens the Palo Alto Networks login page.
2. Enter **admin** in both the **Name** and **Password** fields.
3. Click **Login**.

## Changing the Default Password

Panorama is configured with a default password. To improve security, you are encouraged to strengthen the password on first-time login.

1. Choose **Panorama > Administrators > admin**.
2. Enter **admin** in the **Old Password** field.
3. Enter a new password (case-sensitive, up to 15 characters) in the **New Password** field and re-enter the password in the **Confirm New Password** field.
4. Click **OK**.
5. Click **Commit** and select **Panorama** as the **Type.**
6. Click **OK**.

# Configuring High Availability (HA)

▶ ***Panorama > High Availability***

***Note:*** *HA is supported only for managed devices running Release 4.0 or later. It is not backward compatible with Release 3.1 or earlier.*

High availability (HA) allows for redundancy in the event of a device failure. For ensuring HA, you can deploy a pair of hardware-based Panorama appliances or a pair of Panorama virtual appliances in a HA peer configuration that provide synchronized connections to the managed firewalls. Among the peers on the HA configuration, one device must be designated as active and the other as passive. The peers maintain a heartbeat, or a periodic ICMP ping, to verify operational status. If the active Panorama device becomes unavailable, the passive server takes over temporarily. With preemption enabled, the default setting, when the active device becomes available again, the passive device relinquishes control and returns to the passive state.

***Note:*** *To configure a HA pair of Panorama virtual appliances, you must have two Panorama licenses with unique serial numbers for each virtual instance.*

When configuring HA for Panorama virtual appliances, you also need to designate a priority level of either primary or secondary for each peer in the pair. This primary or secondary configuration determines which peer is designated as the primary recipient for logs sent by the managed firewalls. You can configure Panorama to use the same log external storage facility for the assigned primary and secondary devices (Network File System or NFS option) or configure logging internally. If you use the NFS option, only the primary recipient receives the logs that are sent from the managed firewalls. However, if local logging is enabled, by default the logs are sent to both the primary and the secondary recipient.

To enable HA on Panorama, configure the followings settings.

**Table 145. Panorama HA Settings**

| Field | Description |
|---|---|
| **Setup** | |
| Enable HA | Select the check box to enable HA. |
| Peer HA IP Address | Enter the IP address of the MGT interface of the Panorama peer. |
| Enable Encryption | Enable encryption after exporting the HA key from the HA peer and importing it onto this device. The HA key on this device must also be exported from this device and imported on the HA peer. When enabled, the MGT interface encrypts communication between the HA peers.<br>The key import/export is done on the **Panorama > Certificate Management > Certificates** page. See "Importing, Exporting and Generating Security Certificates" on page 86.<br>***Note:*** *HA connectivity uses TCP port 28 with encryption enabled and 28769 when encryption is not enabled.* |
| Monitor Hold Time (ms) | Enter the length of time (ms) that the system will wait before acting on a control link failure (1000-60000 ms, default 3000 ms). |
| **Election Settings** | |
| Priority | Choose **Primary** or **Secondary**. |
| Preemptive | Select the check box to enable the primary Panorama device to resume active operation after recovering from a failure. If this setting is off, then the secondary device remains active even after the higher priority device recovers from a failure. |
| Preemption Hold Time (min) | Enter the time a passive device will wait before taking over as the active device (range 1-60 min, default 1). |
| Promotion Hold Time (ms) | Enter the time that the secondary device will wait before taking over (range 0-60000 ms, default 2000). |
| Hello Interval (ms) | Enter the number of milliseconds between the hello packets sent to verify that the other device is operational (ranges 8000-60000 ms, default 8000). |
| Heartbeat Interval (ms) | Specify how frequently Panorama sends ICMP pings to the HA peer (range 1000-60000 ms, default 1000). |
| Monitor Fail Hold Up Time (ms) | Specify the interval that Panorama waits following a path monitor failure before attempting to re-enter the passive state (default 0 ms). During this period, the device is not available to take over for the active device in the event of failure. |
| Additional Master Hold Up Time (ms) | Specify the interval during which the preempting device remains in the passive state before taking over as the active device (default 7000 ms). |

**Table 145. Panorama HA Settings (Continued)**

| Field | Description |
|---|---|
| **Path Monitoring** | |
| Enabled | Select the check box to enable path monitoring. Path monitoring enables Panorama to monitor specified destination IP addresses by sending ICMP ping messages to make sure that they are responsive. |
| Failure Condition | Select whether a failover occurs when any or all of the monitored path groups fail to respond. |
| Path Groups | Define one or more path groups to monitor specific destination addresses. To add a path group, specify the following and click **Add**:<br>• **Name**—Specify a name for the path group.<br>• **Enabled**—Select the check box to enable the path group.<br>• **Failure Condition—**Select whether a failure occurs when any or all of the specified destination addresses fails to respond.<br>• **Ping interval**—Specify a length of time between ICMP echo messages to verify that the path is up (range 1000-60000 ms, default 5000).<br>• **Destination IPs**—Enter one or more destination addresses to be monitored (multiple addresses must be separated by commas).<br>• **Ping Interval**—Specify the interval between pings that are sent to the destination address (range 1000-60000 milliseconds, default 5000 milliseconds).<br>• **Ping Count**—Specify the number of failed pings before declaring a failure (range 3-10 pings, default 3 pings).<br>To delete a path group, select the group, and click **Delete**. |

# Switching the Logging Priority in an HA Pair

When a failover occurs for Panorama virtual appliances in an HA configuration with NFS-based logging, the logging functionality is interrupted. To re-enable logging following a failure, you must promote the secondary Panorama device to function as the primary so that it can establish a connection with the NFS-based log partition.

***Note:*** *For configurations that use internal logging instead of NFS, follow the instructions through Step 2 of the procedure in this section to switch the logging priority of the secondary device to primary.*

For the following procedure, assume that the active primary is running on server S1 and the passive secondary is running on S2. Failover has occurred, and S2 has become the active secondary.

To assign S2 as the primary log recipient, follow these steps:

1. Power S1 off.
2. Configure S2 to be primary and commit the configuration:
   a. Choose **Panorama > High Availability.**
   b. Edit the election settings and change **Priority** from **Secondary** to **Primary**.
   c. Commit the changes, rebooting the device when prompted. The reboot is required because the configuration refers to NFS storage.

3. Execute the CLI command **`request high-availability convert-to-primary`**.

   If S1 is connected as the HA peer to S2 and NFS storage is specified, then the **convert-to-primary** command will fail, indicating that the HA peer (S1) needs to be powered down before the operation can succeed. If the peer is not connected, the system dynamically mounts the NFS disk, converts the ownership of the partition to S2, and unmounts the partition.

4. Reboot S2.

   When S2 comes up, it is able to write to the NFS-based log partition.

# Chapter 13
# Central Device Management Using Panorama

This chapter describes how to use the Panorama centralized management system to manage multiple firewalls:

- "Accessing the Panorama Web Interface" in the next section
- "Using the Panorama Interface" on page 382
- "Adding Devices" on page 385
- "Panorama Administrator Roles, Profiles, and Accounts" on page 387
- "Specifying Panorama Access Domains for Administrators" on page 392
- "Working with Objects" on page 395
- "Working with Policies" on page 393
- "Templates" on page 399
- "Logging" on page 403
- "Viewing Firewall Deployment Information" on page 416
- "Backing Up Firewall Configurations" on page 417
- "Scheduling Configuration Exports" on page 417
- "Upgrading the Panorama Software" on page 419

# Accessing the Panorama Web Interface

To access the Panorama interface for centralized firewall management, log in to the Panorama server web interface:

1. Launch your preferred web browser and enter **https://*Panorama IP address***

   The browser automatically opens the Palo Alto Networks login page.

2. Enter the login name and password and click **Login**.

# Using the Panorama Interface

Panorama allows you to view information about multiple devices in your network and to manage devices from a central web interface.

To display information regarding the Palo Alto Networks firewalls in the network, the devices must be connected to the Panorama server.

Perform these steps to allow the devices to connect:

1. Add the IP address of the Panorama server to each device. Refer to "Defining Management Settings" on page 30.

2. Use the Panorama interface to add the devices. Refer to "Panorama Administrator Roles, Profiles, and Accounts" on page 387.

Certain Panorama configuration tabs will not appear until their respective components are configured. For instance, the Policies and Objects tab will only appear after adding device groups **Panorama > Device Groups** and **Device** and **Network** will only appear after adding templates from P**anorama > Templates**.

The Panorama tabs are described in the following table.

**Table 146. Summary of Panorama Tabs**

| Page | Description |
|---|---|
| Dashboard | Displays general information about the managed devices, such as the software version, the operational status of each interface, resource utilization, and up to 10 of the most recent entries in the threat, configuration, and system logs. All of the available charts are displayed by default, but each user can remove and add individual charts, as needed. |
| ACC | Displays the overall risk and threat levels for the managed devices. Refer to "Using the Application Command Center" on page 253 and "Identifying Unknown Applications and Taking Action" on page 276. |
| Monitor | Allows you to view logs and reports. Refer to "Viewing Reports" on page 273. |
| Policies | Allows you to define policies to share across managed firewalls. Refer to "Logging and Reporting" on page 403 for information using the pages in this tab. |
| Objects | Allows you to define policy objects that are shared across the managed firewalls. Refer to "Logging and Reporting" on page 403. |
| Network | Allows you to apply network configuration options across managed firewalls using templates. Refer to "Templates" on page 399. |

**Table 146. Summary of Panorama Tabs (Continued)**

| Page | Description |
|---|---|
| Device | Allows you to apply device configuration options across managed firewalls using templates. Refer to "Templates" on page 399. |
| Panorama | Allows you to configure Panorama and manage deployed firewalls. Refer to "Panorama Tab" in the next section. |

# Panorama Tab

The **Panorama** tab is similar to the **Devices** tab for the firewall, but the settings apply to the Panorama device, not the managed firewalls. The following table describes the pages on this tab. To access a page, click the page name link on the side menu.

**Table 147. Summary of Panorama Pages**

| Page | Description |
|---|---|
| Setup | Allows you to specify the Panorama host name, the network settings of the management interface, and the addresses of network servers (DNS and NTP). Refer to "Defining Management Settings" on page 30. |
| Templates | Allows you to create Templates that can be used to manage configuration options based on the Device and Network tabs, enabling you to deploy templates to multiple devices that have similar configurations. Refer to "Templates" on page 399. |
| Config Audit | Allows you to view and compare configuration files. Refer to "Defining Operations Settings" on page 37. |
| Managed Devices | Allows you to add devices for management by Panorama, push shared configuration to managed devices, and run comprehensive configuration audits on devices or entire device groups. Refer to "Adding Devices" on page 385. |
| Device Groups | Allows you to define sets of devices that are treated as a unit when creating objects and applying policies in Panorama. Refer to "Defining Device Groups" on page 386. |
| Managed Collectors | Allows you to configure and manage the log collector devices that will be used in your environment to distribute logging information for firewalls that are managed by Panorama. You can also use this pages to upgrade the software on your log collectors. You first download the latest Panorama software and you can then push the updated version to your log collectors by clicking **Install** on the Managed Collectors page.<br><br>***Note:*** *Log collectors are comprised of the log collector software (part of the Panorama software package) and the M-100 hardware platform. The M-100 can be configured as a Panorama manager, a log collector, or both. The operational command to change the mode of an M-100 is* **`request system logger-mode [panorama | logger]`**.*To view the current mode, run* **`show system info | match logger_mode`**.<br>*When an M-100 is in log collector mode, only the CLI is available for management.*<br><br>Refer to "Managing Log Collectors" on page 407. |

**Table 147. Summary of Panorama Pages (Continued)**

| Page | Description |
|---|---|
| Collector Groups | Allows you to group log collectors together so you can apply the same configuration settings to all collectors in the group. You also use the collector group to assign firewalls to log collectors.<br>***Note:*** *You can add up to 4 log collector devices per collector group. Refer to "Defining Log Collector Groups" on page 411.* |
| Admin Roles | Allows you to specify the privileges and responsibilities that are assigned to users who require access to Panorama. Refer to "Defining Administrator Roles" on page 58. |
| Password Profiles | Allows you to define password profiles, which can then be applied to Panorama administrators. You can configure the following profile options:<br>• Required password change period (days)<br>• Expiration warning period (days)<br>• Post Expiration Admin Login Count<br>• Post Expiration Grace Period (days) |
| Administrators | Allows you to define the accounts for users who require access to Panorama. Refer to "Creating Administrative Accounts" on page 59.<br>***Note:*** *On the* ***Administrators*** *page for "," a lock icon is shown in the right column if an account is locked out. The administrator can click the icon to unlock the account.* |
| High Availability | Allows you to configure a pair of Panorama devices to support high availability (HA). Refer to "Configuring High Availability (HA)" on page 377. |
| Certificate Management | Allows you to configure and manage certificate profiles, trusted certificate authorities, and OCSP responders. Refer to "Importing, Exporting and Generating Security Certificates" on page 86. |
| Log Settings | Allows you to define Simple Network Management Protocol (SNMP) trap sinks, syslog servers, and email addresses for distributing log messages. Refer to "Logging Configuration" on page 70. |
| Server Profiles | Allows you to specify profiles for servers that provide services to Panorama.<br>Refer to the following sections:<br>• "Configuring Email Notification Settings" on page 83<br>• "Configuring SNMP Trap Destinations" on page 75<br>• "Configuring Syslog Servers" on page 76<br>• "Configuring RADIUS Server Settings" on page 65<br>• "Configuring LDAP Server Settings" on page 66<br>• "Configuring Kerberos Settings (Native Active Directory Authentication)" on page 67.<br>• "Configuring Netflow Settings" on page 85 |
| Authentication Profile | Allows you to specify a profile to authentication access to Panorama. Refer to "Authentication Profiles" on page 62. |
| Authentication Sequence | Allows you to specify sets of authentication profiles to use for access to Panorama. Refer to "Authentication Sequence" on page 67. |
| Access Domain | Provides the capability to limit administrators access to Device Groups, Templates, and the device contexts that administrators can switch to based on profiles. Refer to "Panorama Administrator Roles, Profiles, and Accounts" on page 387. |

**Table 147. Summary of Panorama Pages (Continued)**

| Page | Description |
|---|---|
| Scheduled Config Export | Allows you to collect running configurations from managed devices and deliver them daily to a File Transfer Protocol (FTP) server or by using Secure Copy (SCP) to securely transfer data between the Panorama server and a remote host. Refer to "Scheduling Configuration Exports" on page 417. |
| Software | Allows you to view the available Panorama software releases and download and install a selected software version. Refer to "Upgrading the Panorama Software" on page 419. |
| Dynamic Updates | Allows you to view the latest application definitions and information on new security threats, such as antivirus signatures (threat prevention license required) and update Panorama with the new definitions. Refer to "Updating Threat and Application Definitions" on page 55. |
| Support | Allows you to access product and security alerts from Palo Alto Networks. Refer to "Viewing Support Information" on page 117. |
| Deployment | Allows you to view current license information on the managed devices and install software, clients, and dynamic content on the devices. Refer to "Viewing Firewall Deployment Information" on page 416. |
| Master Key and Diagnostics | Allows you to specify a master key to encrypt private keys on the firewall. Private keys are stored in encrypted form by default even if a new master key is not specified. Refer to "Encrypting Private Keys and Passwords on the Firewall" on page 90. |

# Adding Devices

▶ *Panorama > Managed Devices*

The **Managed Devices** page allows you to create a list of devices for centralized management.

If devices are part of an HA pair, you must add both devices or virtual systems of the peers (if in multi-virtual system mode) to the same device group, and Panorama must push the configuration to both HA peer devices at the same time. If you target a rule to specific firewalls that are in an HA configuration, make sure to include both firewalls in the target selection.

***Note:*** *Panorama can manage PAN-OS devices running the same major release or earlier supported versions, but not devices running a later release version. For example, Panorama 4.0 can manage PAN-OS devices running 4.0 or earlier supported versions, but it cannot manage PAN-OS devices running 4.1.*

***Note:*** *Managed devices communicate with Panorama using SSL through TCP port 3978.*

To add devices:

1. Under the **Panorama** tab, click **Managed Devices** to open the **Managed Devices** page.
2. Click **Add** to open an editing window.
3. Enter the serial number of the device to be added, and click **Add**.

4. Add additional devices, as needed.
5. Click **OK**. The window closes and the **Managed Devices** page refreshes to show the newly added devices.
6. To delete a device:
   a. Select the check box next to the device in the Managed Devices table.
   b. Click **Delete**.
   c. Click **OK**.
7. Select the **Group HA Peers** check box to group devices in high availability (HA) mode together.

   This option allows you to easily identify devices that are in HA mode. When pushing shared policies, you can push to the grouped pair, instead of each device individually. Also, when adding a new device in Managed Devices, if they are in HA mode, both devices will be displayed together, so you can add both devices.

   When viewing an HA pair, if the configuration does not match, a warning indicator will appear. You will also see an indicator if the HA devices are in different device groups.

   This option is also independent for each section, so enabling and disabling in one area, will not enable/disable for all areas. The Group HA Peers option is present in the following Panorama areas:

   – Managed Devices
   – Templates
   – Device Groups
   – Policies tab (Target tab for all policy types)
   – Commit dialog

# Defining Device Groups

▶ ***Panorama > Device Groups***

Device groups are used to manage shared policies and objects. You can define device groups that consist of firewalls and/or virtual systems that you want to manage as a group, such as the firewalls that manage a group of branch offices or individual departments in a company. Each group is treated as a single unit when applying policies in Panorama.

You can add each device to at most one device group. Because virtual systems are considered distinct entities in Panorama, you can assign virtual systems within a device to different device groups.

The **Device Groups** page lists the device groups along with the information listed in the following table.

**Table 148. Device Group Settings**

| Field | Description |
|---|---|
| Device Group Name | Enter a name to identify the group (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Description | Enter a description for the group. |
| Devices | Select the check box next to the device in the Managed Devices table and click **Move,** choose the new group and click **OK**. |
| Master Device | Select a device to use as the master. The master device is the firewall from which Panorama gathers User-ID information for use in policies. The gathered user and group mapping information is specific to a device group and can come from only one device (the master) inside the group. |
| Group HA Peers | Select the check box to group devices in high availability (HA) mode together.<br>This option allows you to easily identify devices that are in HA mode. When pushing shared policies, you can push to the grouped pair, instead of each device individually. Also, when adding a new device in Managed Devices, if they are in HA mode, both devices will be displayed together, so you can add both devices.<br>When viewing an HA pair, if the configuration does not match a warning indicator will appear. You will also see an indicator if the HA devices are in different device groups.<br>This option is also independent for each section, so enabling and disabling in one area, will not enable/disable for all areas. The Group HA Peers option is present in the following Panorama areas:<br>• Managed Devices<br>• Templates<br>• Device Groups<br>• Policies tab (Target tab for all policy types)<br>• Commit dialog |

# Panorama Administrator Roles, Profiles, and Accounts

Panorama supports the following options to authenticate administrative users who attempt to log in to the device:

- **Local database**—The user login and password information is entered directly into the Panorama database.
- **RADIUS**—Existing Remote Authentication Dial In User Service (RADIUS) servers are used to authenticate users.

- **LDAP**—Existing Lightweight Directory Access Protocol (LDAP) servers are used to authenticate users.
- **Kerberos**—Existing Kerberos servers are used to authenticate users.
- **Client Certificate**—Existing client certificates are used to authenticate users.

When you create an administrative account, you specify client certificate (no authentication profile), or an authentication profile (RADIUS, LDAP, Kerberos, or local DB authentication). This setting determines how the administrator password is checked. If you do not specify a profile, the account will use local authentication.

***Note:*** *You may have certain Panorama administrators that may not have access to the* ***Panorama > Administrators*** *menu. In this case, the administrator can click on their username located to the left of the logout link on the bottom of the web interface to change their password.*

Administrator roles determine the functions that the administrator is permitted to perform after logging in. You can assign roles directly to an administrator account, or define role profiles, which specify detailed privileges, and assign those to administrator accounts.

Refer to the following sections for additional information:

- "Setting Up Authentication Profiles" on page 62.
- "Defining Panorama Administrator Roles" on page 388.
- "Certificate Profile" on page 89.
- "Specifying Panorama Access Domains for Administrators" on page 392.
- "Certificate Profile" on page 89.

# Defining Panorama Administrator Roles

▶ ***Panorama > Admin Roles***

Use the **Admin Roles** page to define role profiles that determine the access and responsibilities available to administrative users. For instructions on adding administrator accounts, refer to "Creating Panorama Administrative Accounts" on page 389.

***Note:*** *The Admin Role can be mapped via RADIUS Vendor-Specific Attributes (VSA) using the following attribute: "PaloAlto-Panorama-Admin-Role = <AdminRoleName>,".*

**Table 149. Panorama Administrator Role Settings**

| Field | Description |
|---|---|
| Name | Enter a name to identify this administrator role (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Description | Enter an optional description of the role. |
| Permission | Select the scope of administrative responsibility (Panorama or Device Group and Template). |

**Table 149. Panorama Administrator Role Settings (Continued)**

| Field | Description |
|---|---|
| WebUI | Click the icons for specified areas to indicate the type of access permitted for the web interface:<br>• Read/write access to the indicated page.<br>• Read only access to the indicated page.<br>• No access to the indicated page. |
| XML API | Select the type of access for the XML API<br>• **Report**—Access to the device reports.<br>• **Log**—Access to the device logs.<br>• **Configuration**—Permissions to retrieve or modify the device configuration.<br>• **Operational Requests**—Permissions to run operational commands.<br>• **Commit**—Permissions to commit the configuration.<br>• **User-ID Agent**—Access to the User-ID Agent.<br>• **Export**—Permissions to export files from the device, including the configuration, block or response pages, certificates, keys, and more.<br>• **Import**—Permissions to import files to the device, including software, content, license, configuration, certificates, block pages, custom logs, and more. |
| Command Line | Select the type of role for CLI access:<br>• **None**—Access to the device CLI not permitted.<br>• **superuser**—Full access to the current device.<br>• **superreader**—Read-only access to the current device.<br>• **panorama-admin**—Full access to a selected device, except for defining new accounts or virtual systems. |

# Creating Panorama Administrative Accounts

▶ *Panorama* > *Administrators*

Administrator accounts control access to Panorama. Each administrator can have full or read-only access to Panorama and all managed devices, or can be assigned Panorama administrator access, but will not have permissions to create admin accounts or edit admin roles, which allows access to Panorama configuration and not the managed devices. The predefined **admin** account has full access to Panorama and the managed devices.

The following authentication options are supported:

- Password authentication—The user enters a user name and password to log in. No certificates are required.
- Client certificate authentication (web)—If you select this check box, a user name and password are not required; the certificate is sufficient to authenticate access to the firewall.
- Public key authentication (SSH)—The user can generate a public/private key pair on the machine that requires access to the firewall, and then upload the public key to the firewall to allow secure access without requiring the user to enter a user name and password.

***Note:*** *To ensure that the device management interface remains secure, it is recommended that administrative change their passwords periodically using a mixture of lower-case letters, upper-case letters, and numbers. You can also enforce "Minimum Password Complexity" from Setup > Management.*

**Table 150. Administrator Account Settings**

| Field | Description |
|---|---|
| Name | Enter a login name for the user (up to 15 characters). The name is case-sensitive and must be unique. Use only letters, numbers, hyphens, and underscores. |
| Authentication Profile | Select an authentication profile for administrator authentication according to the settings in the specified authentication profile. This setting can be used for RADIUS, LDAP, or Kerberos authentication.<br>For instructions on setting up authentication profiles, refer to "Setting Up Authentication Profiles" on page 62. |
| Use only client certificate authentication (Web) | Select the check box to use client certificate authentication for web access. If you select this check box, a user name and password are not required; the certificate is sufficient to authenticate access Panorama. |
| Password/Confirm Password | Enter and confirm a case-sensitive password for the user (up to 15 characters). *You can also enforce "Minimum Password Complexity" from Setup > Management.*<br>You may have certain Panorama administrators that do not have access to the Panorama > Administrators menu, in this case, the administrator can click on their username located to the left of the logout link on the bottom of the web interface and change their local password from there. |

**Table 150. Administrator Account Settings (Continued)**

| Field | Description |
|---|---|
| Use Public Key Authentication (SSH) | Select the check box to use SSH public key authentication. Click **Import Key** and browse to select the public key file. The uploaded key is displayed in the read-only text area.<br>Supported key file formats are IETF SECSH and OpenSSH. Supported key algorithms are DSA (1024 bits) and RSA (768-4096 bits).<br>***Note:*** *If the public key authentication fails, a login and password prompt is presented to the user.* |
| Role | Select an option for assigning a role to this user. The role determines what the user can view and modify.<br>• **Dynamic**, you can select any of the following pre-specified roles from the drop-down list:<br>– **Superuser—**Full access to the current device.<br>– **Superuser (Read Only)—**Read-only access to the current device.<br>– **Panorama administrator—**Full access to the Panorama instances.<br>• **Role Based —**Access based on assigned roles, as defined in "Defining Panorama Administrator Roles" on page 388.<br>If you choose Role Based, select a previously-defined role profile from the drop-down list. For instructions on defining role profiles, refer to "Defining Panorama Administrator Roles" on page 388<br>For role based access, when you select a profile assigned to the **Device Group and Template** administrator role, the **Access Control** tab is displayed. On this **Access Control** tab, you can define access to Device Groups, Templates, and Device Context. The definitions for these fields are the same as the information in "Specifying Panorama Access Domains for Administrators" on page 392. |

***Note:*** *On the Panorama* ***Administrators*** *page for "," a lock icon is shown in the right column if an account is locked out. The administrator can click the icon to unlock the account.*

# Specifying Panorama Access Domains for Administrators

▶ *Panorama > Access Domain*

Use the **Access Domain** page to specify domains for role-based administrators who have access to device groups and templates. Adding a device group to an access domain allows you to manage policies and objects for that device group. Adding an individual firewall to an access domain allows you to switch into the device context for that firewall.

The access domain is linked to RADIUS vendor-specific attributes (VSAs) and is supported only if a RADIUS server is used for administrator authentication. If RADIUS is not used, the access domain settings on this page are ignored.

***Note:*** *The Access Domain can be mapped via RADIUS VSA using the following attribute: "PaloAlto-Panorama-Admin-Access-Domain = <AccessDomainName>,".*

**Table 151. Access Domain Settings**

| Field | Description |
|---|---|
| Name | Enter a name for the access domain (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, hyphens, and underscores. |
| Device Groups | Click **Add** to specify pre-defined device groups to include in the access domain. |
| Device Context | Select the device(s) that the administrator can do a context switch to in order to allow local configuration edits. |
| Templates | Click **Add** to specify pre-defined templates to include in the access domain. |

# Device Groups

Panorama device groups allow you to group firewall devices and then define policies and objects that can be shared across those device groups.

The following sections describe how to define policies and objects for device groups:

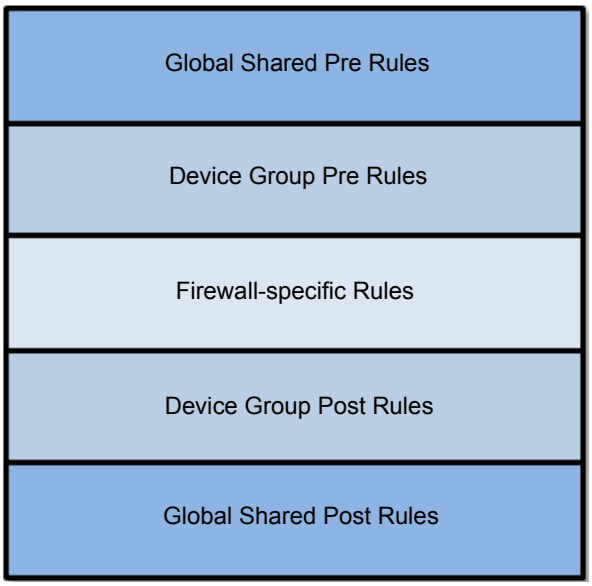
- "Working with Policies" in the next section
- "Working with Objects" on page 395

## Working with Policies

▶ *Policies*

Panorama allows you to define policies that are shared across the managed firewalls. You can apply pre and post rules that will apply to a device group and you can add additional global pre and post rules that apply to all device groups. This creates a layered approach of applying policies to managed devices. The first layer is the device level rules that are local to the device, you can then apply pre and post rules to device groups, and then you can add another layer of global pre and post rules that apply to all device group in the Panorama instance as shown in Figure 47.

**Figure 47. Shared Policy Ordering**



General information about working with policies is found in "Policies" on page 183. This section describes the modifications and best practices that apply to policies in Panorama.

The following best practices apply to policies in Panorama:

- **Pre rules:** Pre rules are evaluated before any device specific rules and generally make up the majority of a deployment's shared rulebase. Do not add any pre rules if you will need device-level exceptions.

  If you do not want administrators to be able to allow any applications at specific sites, you can include a deny rule for all zones, users, and applications as your last rule in the set of pre rules.

- **Firewall-specific rules:** Define rules for an individual firewall to create site-specific policies.
- **Post rules**: Use these rules to specify what happens to traffic that is not covered by the pre rules and firewall-specific rules. For example, if a pre rule specifies certain allowed applications and the post rule is "deny all," then applications not covered by the pre rule are stopped. You can then add rules to allow additional applications based on user request. You can also create device level "allow" rules as exceptions for specific applications that are permitted at an individual location.
- **Global pre rules:** Global pre rules are evaluated before any firewall-specific, or device group rules and are applied to all devices in managed device groups.
- **Global post rules:** Use these rules to specify what happens to traffic that is not covered by device group pre rules and firewall-specific rules. These rules are evaluated last, and only after the device group pre rules.

  Global shared rules can only be created and modified by the Panorama Admin or superuser. So these rules can be used to apply policies before and after any rules applied by device group administrators.

The following applies when defining policies in Panorama:

Panorama applies policies to specified device groups and global shared policies applies another layer of policies to the device groups.

When you create a device group rule from the Panorama instance, you select the **Policies** tab, choose the device group that you want to create rules for and then define your rules. To create global rules that apply to all managed devices in device groups, you choose the **Shared** option in the **Device Group** drop down, as shown in Figure 48.

**Figure 48. Panorama Shared Policy**

You can also specify that shared objects take precedence over device group objects by selecting the check box **Shared Objects Take Precedence** in **Panorama > Setup > Management > Panorama Settings**. This option is a system-wide setting and is off by default. When this option is off, device groups override corresponding objects of the same name. If the option is on (checked), device group objects cannot override corresponding objects of the same name from a shared location and any device group object with the same name as a shared object will be discarded.

- You can target a policy rule to individual devices within the device group for which the rule is defined. To target a device after a policy is created, click an entry in the **Target** column and select the devices in the pop-up window. If you do not select devices to target, the policy is added to all of the (unchecked) devices in the device group.

  To apply the rule to all devices in a device group EXCEPT the targeted device, select the **Install on all but specified devices** check box and select the devices that you want to exclude. If you do not select any device, the policy is added to none of the devices in the device group.

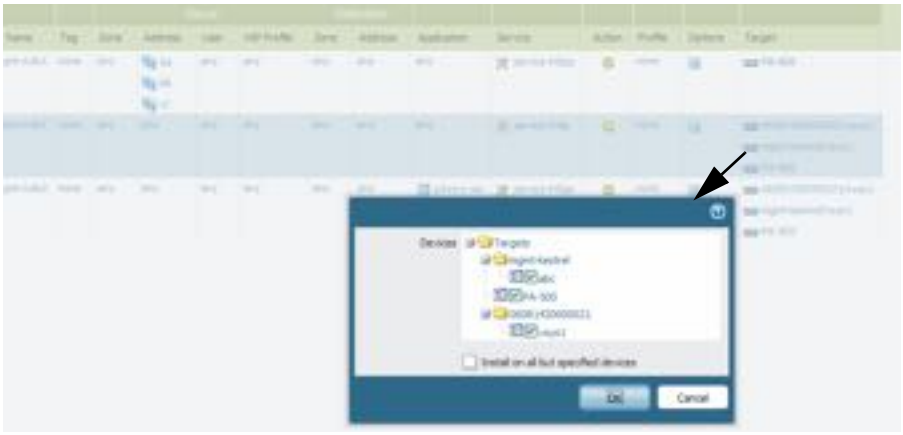


**Figure 49. Targeting Policy Rules to Individual Devices in Panorama**

- Zones are not created in Panorama, but you can select zones based on zone names that are gathered from any template which maps to the same devices as the ones included in a device group. If a zone is not available from the templates, you must manually type a zone name when you first create a rule. For subsequent rules, you can enter new zones or select from previously entered zones.

***Note:*** *The gathering of objects from templates not only applies to zones, it applies to all objects that can be referenced from the Policy/Objects tab, which comes from the Device/Network tabs. This includes: zones, interfaces, certificates, Network Profiles > Monitor, server profiles (Syslog, Email, SNMP Traps), virtual systems in PBF rules, and the local user databases for users/groups.*

- Each policy type listed on the side menu includes pages to define pre rules and post rules as well as global shared rules that are applied on top of the device group pre and post rules. See page 393 for information on best practices when using policies.

# Working with Objects

Panorama supports sharing of objects defined in Panorama. You can create objects on Panorama and then push the object configurations to the managed firewalls. The objects become available for use in policies that are defined on the individual managed firewalls.

***Note:*** *All custom objects should have unique names, and predefined names such as "any" or "default" should be avoided. In particular, using the same object names with different device groups can cause confusion on devices and on Panorama.*

All objects in the **Objects** tab and some objects in the **Device** tab can be managed centrally. **Device** tab objects are managed under the **Panorama** tab and include the following: certificates, response pages, server profiles (SNMP trap, syslog, email, RADIUS, LDAP, and Kerberos), authentication profiles and sequences, and certificate profiles. These objects have a **Location** field that allows you to select where the object should exist in the deployment (for example, "device-group-test"). The following table explains the available object assignment and sharing options for the **Location** field.

**Table 152. Object Assignment and Sharing Options**

| Field | Description |
|---|---|
| Panorama | Panorama supports keeping objects locally and not pushing the objects to any managed devices. To do this, choose **Panorama** from the **Location** drop-down list when defining the object.<br>This option is available only on the **Panorama** tab and only for the following:<br>• Server profiles, including SNMP Trap, Syslog, Email, Remote Authentication Dial In User Service (RADIUS), Lightweight Directory Access Protocol (LDAP), and Kerberos<br>• Authentication profiles, authentication sequences, and certificate profiles |
| Device Groups | Device groups are used to make objects and policies defined in Panorama available to specified sets of devices. For information on creating device groups, see "Defining Device Groups" on page 386.<br>• On the **Policies** or **Objects** tab, choose the device group from the **Device Groups** drop-down list when defining the object.<br>***Note:*** *If you have objects of the same name where one is shared and another is device group specific, the device group specific object will be used for that device group.*<br>  <br>• On the **Panorama** tab, choose a device group from the **Location** drop-down list when defining the object. |
| Shared | Creating a shared object makes the object available for use in any device group. Only Panorama and administrators can create objects in the shared location.<br>• On the **Panorama** tab, choose **Shared** from the **Location** drop-down list when defining the object.<br>• On the **Objects** tab, select the **Shared** check box when defining the object. |

# Working with Devices

Switching context allows an administrator to switch from managing shared policy on Panorama to managing device-specific settings on an individual firewall (such as device specific policy, networking, and device setup). Use the **Context** drop-down list above the side menu to choose an individual device or the full Panorama view. You can select the name of any device that has been added for management by Panorama (refer to "Panorama Administrator Roles, Profiles, and Accounts" on page 387). When you select a device, the web interface refreshes to show all the device tabs and options, allowing you to manage all aspects of the device from Panorama.

***Note:*** *You can only switch context to connected devices. Disconnected devices are not shown in the drop-down list.*

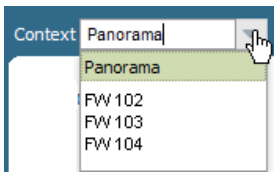

**Figure 50. Choosing Context**

# Commit Operation in Panorama

To commit Panorama configuration changes click the **Commit** icon to bring up the commit dialog box. This dialog box allows you to commit specific areas of the Panorama environment, see Figure 51.

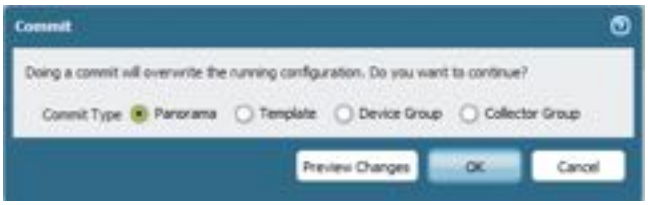

**Figure 51. Panorama Commit Dialog Box**

The following options are available in the commit dialog box:

*Note: When performing commit operations in Panorama, it is suggested that you commit the Panorama configuration first, before committing configuration updates to managed devices.*

- **Commit Type**—Choose the commit type:
  - **Panorama**—Commit the current candidate configuration for Panorama.
  - **Template**—Commit template changes from Panorama to the selected devices. When committing templates, you can select a subset of devices if desired.
  - **Device Group**—Commit device configuration changes from Panorama to the selected device/virtual system(s).
  - **Collector Groups**—Only commit changes to Panorama log collector groups. This will commit changes made in the **Panorama > Collector Groups** page and will apply those changes to the log collector device.
- **Include Device and Network Templates**—This option is available when committing a Device Group from Panorama and is a combo operation that will include both the device and network template changes. The template that will be applied to the device is the template that the device belongs to as defined in Panorama > Templates. You can also select Commit Type Template to commit templates to devices.
- **Force Template Values**—When doing a Commit Type Template, you can select this option to remove objects on the selected devices or virtual systems that have been overridden by the local configuration. When doing a Commit Type "Device Group", you need to also select the "Include Device and Network Templates" check box since overriding can only occur for Template pushed configuration options. This will cause the overridden objects to inherit settings from the template. Refer to "Overriding Template Settings" on page 402.
- **Merge with Candidate Config**—Choose this option to cause the device to include its local candidate configuration when the commit is invoked from Panorama. If this option is not checked, the device local candidate config is not included.

It is important to leave this option unchecked when you have local administrators making changes on a device and you don't want to include their changes when pushing a configuration from Panorama.

– **Preview Changes**—Click this button to bring up a configuration audit window that shows proposed changes in the candidate configuration compared to the current running configuration. You can choose the number of lines of context to display, or show all lines based on items that have been added, modified, or deleted. This option is available when using Commit Type Device Group, Template, or Panorama.
You can also view the commit state for devices by navigating to **Panorama > Managed Devices** and viewing the **Last Commit State** column.
The **Device > Config Audit** feature performs the same function, refer to "Comparing Configuration Files" on page 49.

After the commit is complete, you will see a "Commit succeeded" messages, if there are warning messages, you will see "Commit succeeded with warnings". To view warnings, navigate to **Panorama > Managed Devices** and see the **Last Commit State** column and click the text to view details.

## Panorama Backward Compatibility

When upgrading Panorama to 5.0, and you are managing devices with PAN-OS 4.0 or earlier, simple style vulnerability protection and anti-spyware profiles are automatically converted to rules of equivalent meaning on those devices. Custom style profiles are converted to exceptions that specify signature-specific actions, with no rules required. After migration, a limited set of changes can be made to the migrated profiles in Panorama if compatibility with devices running PAN-OS 4.0 and earlier is required.

For rules created during conversion from a simple style profile, the action of the migrated rules can be modified, and additional allow exceptions can be added to the exceptions list. If a custom style profile was converted to an exceptions-based profile, the exceptions list can be freely modified, but no rules can be created. If the administrator attempts to commit using an incompatible profile, the commit will fail and the failure will be noted in the Managed Devices list under the Last Commit All State column.

To manage devices running different versions of software you must select, in the Device Groups configuration, a master device which is running the lowest software version of the User-ID agent to remain backward compatible and be able to push user based rules to older firewalls.

# Templates

▶ ***Panorama > Templates***

The Panorama **Templates** page is used to create templates that can be used to manage configuration options based on the Device and Network tabs, enabling you to deploy configurations to multiple devices that require similar settings. You can also deploy a base configuration and if needed, override specific settings on the device. For example, you can deploy a base config to a global group of devices, but configure specific time zones settings directly on the devices based on their location.

When managing device configuration with Panorama, you can use a combination of **Device Group** configuration (to manage shared policies and objects) settings and **Templates** settings (to apply device and network settings), but these features are managed separately because of the differences in what can be configured. For information on adding and configuring Panorama templates, refer to "Configuring Panorama Templates" on page 401.

**Table 153 Template Settings (Panorama)**

| Field | Description |
|---|---|
| **Name** | Enter a template name (up to 31 characters). Use only letters, numbers, spaces, hyphens, periods, and underscores. The name is case-sensitive and must be unique.<br>This name will appear in the **Device** and **Network** tab in the **Template** drop-down menu. When selecting a template from one of these tabs, the settings that are modified will only apply to the selected template. |
| **Description** | Enter a description for the template. |
| **Virtual Systems**<br><br>**Note:** You cannot use a template to create virtual systems on the device. | Select the check box if the template will be used on devices with multiple virtual systems. When defining template settings for multi-virtual system devices, you need to configure settings for each virtual system on the device.<br>**Note:** A template enabled for devices with multi-virtual systems (multi-vsys) cannot be pushed to devices with a single virtual system. When you upgrade your Panorama server to v5.0 and later, by default templates are created for configurations relating to the network and device tabs. If, for example, you have defined a server profile for the managed firewall(s), a template is automatically generated for the server profile. This auto-generated template is enabled for multiple virtual systems. To prevent a commit failure, make sure to clear the **Virtual Systems** checkbox before you push the template to a device that is not multi-vsys capable or if the multi- vsys capability is disabled on the device. |
| **Operational Mode** | Set the PAN-OS operational mode for the template: normal, fips, or cc. |
| **VPN Disable Mode** | Selecting this check box will hide all VPN related options in the **Device** and **Network** tabs. The ability to install GlobalProtect Portal or Gateway licenses is also disabled in this mode.<br>**Note:** This option is designed for countries that do not allow VPN connectivity. Palo Alto Networks hardware models that have the -NV indicator in the model name are hard coded to not allow VPN configurations, so this option should be used when creating templates for these models. |

**Table 153 Template Settings (Panorama)**

| Field | Description |
|---|---|
| **Devices** | This window lists all devices managed by Panorama and will also show device groups. Click the check box next to devices to make them a member of the template. You can also add all devices in a device group by clicking the check box next to the device group.<br>**Note:** Templates are based on individual devices, not device groups. Adding a new device to a device group will not automatically add it to a template. |
| **Group HA Peers** | Select the check box to group devices in high availability (HA) mode together.<br>This option allows you to easily identify devices that are in HA mode. When pushing shared policies, you can push to the grouped pair, instead of each device individually. Also, when adding a new device in Managed Devices, if they are in HA mode, both devices will be displayed together, so you can add both devices.<br>When viewing an HA pair, if the configuration does not match a warning indicator will appear. You will also see an indicator if the HA devices are in different device groups.<br>This option is also independent for each section, so enabling and disabling in one area, will not enable/disable for all areas. The Group HA Peers option is present in the following Panorama areas:<br>• Managed Devices<br>• Templates<br>• Device Groups<br>• Policies tab (Target tab for all policy types)<br>• Commit dialog |

# Configuring Panorama Templates

▶ *Panorama > Templates*

To configure Panorama templates, you first create the template and then add devices to it. After the first template is created, you will then see a **Template** drop-down menu in the **Device** and **Network** tabs. Select the desired template from the **Template** drop-down menu and configure device and network settings as if you were managing a single device, but all options that are set will only be applied to the selected template. After the template is configured, you can do a commit from Panorama that only applies to templates.

To create and configure a template, follow these steps:

## Adding a New Template

1. Under the **Panorama** tab, click **Templates** to open the templates page.
2. Click **Add** and enter the template configuration options. Refer to "Template Settings (Panorama)" on page 400.
3. In the **Devices** field, you will see a list of all devices that are managed by Panorama. Click the check box next to each item to make them a member of the new template. If you select a device group, all devices in that group will be selected.
4. Click **OK** to save the template.

## Configuring a Template

1. Now that a template has been created, click the **Device** or **Network** tab and you will see a **Template** drop-down menu, as shown in Figure 52.

**Figure 52. Template Menu**

2. Click the **Template** drop-down and select the template that you want to configure.
3. Click the **Device** or **Network** tab and set the desired configuration options for the template.

***Note:*** *When a template is selected from the Device or Network tabs, you can only set options that are part of the configuration. You can not set operational type options such as changing the device to multi-virtual system mode, and setting a Master Key.*

4. After making all of the configuration changes, click **Commit** and from the **Commit Type** drop-down menu select **Template**. You can also use the **Device Group** commit option and select **Include Device and Network Templates** check box to push templates to a device group.
5. Click the check box next to each template that you want to commit and then click **OK**. You can also preview your changes from the **Commit** window by clicking the **Preview Changes** button. A pop-up will appear showing commit status.

## Overriding Template Settings

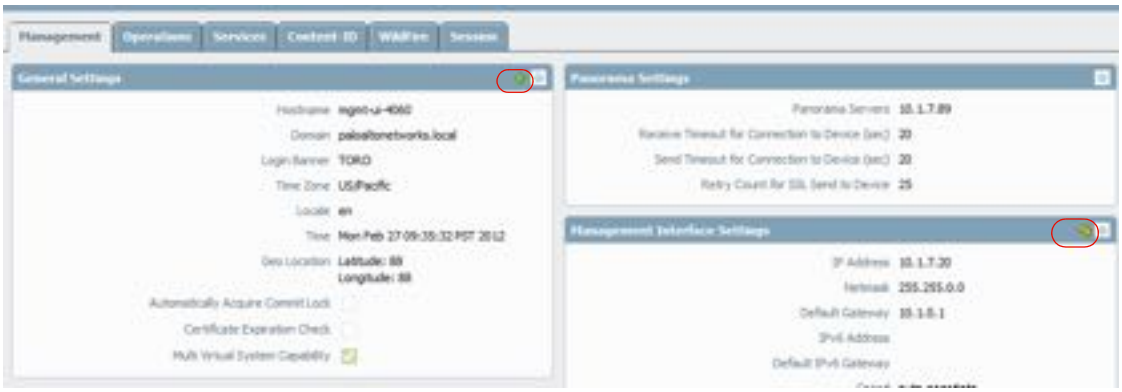
When you apply a template to control device and network settings on a firewall, you may want to override some of those settings and have them controlled by the local device configuration. Example, you can deploy a base config to a global group of devices, but configure specific time zones settings directly on the devices based on their location using an override.

To override device and network setting applied by a template, you simply change to the device context, or access the device directly, navigate to the desired setting and then click the **Override** button. The setting will be copied to the local configuration of the device and will no longer be controlled by the template. You can also revert the change by clicking the **Restore** button and the setting will once again be inherited from the template. When doing a commit from Panorama to a managed device that contains overrides, you can select the **Force Template Values** check box to have Panorama templates take over any overridden objects.

When overriding **Device > Setup and Device > High Availability** settings, the overrides are for individual values and parameters inside of configuration trees, and are not applied to an entire tree configuration. This includes items such as DNS servers, Management IP, or NTP server settings. For items such as interfaces and RADIUS server profiles, you apply overrides to the entire object, not internal values.

To identify settings that have templates applied, you will see the following indicators as shown in Figure 53:

**Figure 53. Template Indicators**



The single green icon indicates that a templates has been applied and there are no overrides. The green and orange icon indicates that a template has been applied and some settings have been overridden.

### Removing Templates

To remove a template, you must disable the template on the local device. On the managed device, navigate to **Device > Setup > Management** tab, then edit the **Panorama Settings** page and click the **Disable Device and Network Template** button. Removing the device from the configuration in **Panorama > Templates** will not delete the template values on the local device.

# Logging

Panorama performs two functions: device management and log collection. To facilitate scalability in large deployments, you can use the M-100 appliance to separate the management and log collection functions on Panorama.

The following sections describe options available for log collection:

- "Logging and Reporting" in the next section
- "Using Panorama for Log Collection" on page 404

## Logging and Reporting

The Panorama logs and reports provide information about user activity in the managed network. Report statistics are aggregated every 15 minutes for use in scheduled predefined and custom reports and statistics are forwarded to Panorama on an hourly basis. If log forwarding is enabled, logs are sent when they are generated on the device.

The **ACC** tab in Panorama displays information from the connected firewalls, all the tables pull information dynamically from the firewalls; they do not require explicit log forwarding. Log forwarding is required for long term log storage and for reporting on logs stored locally in Panorama.

# Generating User Activity Reports

▶ ***Monitor > PDF Reports > User Activity Report***

The Panorama user activity report summarizes user activity across all of the managed firewalls. It is based on firewall data that has been forwarded to Panorama. Refer to "Managing User Activity Reports" on page 272 for general information on creating user activity reports.

# Using Panorama for Log Collection

The M-100 appliance provides a comprehensive log collection solution for Palo Alto Networks firewalls. It helps offload the intensive log collection process from your Panorama management server. Once deployed, each firewall in your managed environment can be configured to send logs to one or more log collectors. By configuring multiple log collectors per firewall, storage capacity is spread out among the collectors creating a more flexible environment with redundancy.

The ACC, PDF Reports, and Logs viewer on Panorama are used to query aggregated information for all managed firewalls. This is the same process that is used if logs were sent directly to Panorama, but in this case, Panorama queries the log collectors to gather the information.

For information on the M-100 hardware, refer to the *M-100 Hardware Reference Guide.*

***Note:*** *The M-100 appliance is shipped with Panorama pre-loaded and both Panorama management and log collection functions are enabled by default. However, if you plan to use the M-100 for log collection only, you need to follow these steps:*

1. *Perform initial configuration to set up an IP address for the management interface and change the default password on the appliance.*
2. *Apply the license on the appliance.*
3. *Verify that the firewalls on your network are running PAN-OS 5.0. If not, you must first upgrade to you PAN-OS 5.0 because support for separate appliances for Panorama management and log collection is not available on earlier versions of PAN-OS*
4. *Change the operational mode on the appliance to log collector mode. For details on the CLI commands, see "Configuring the M-100 as a Log Collector" on page 405.*
   *When the M-100 is in log collector mode, there is no Web interface; Only CLI is available for managing/configuring the appliance.*

The following sections describe how to deploy log collectors:

- "Deploying Distributed Log Collection" in the next section
- "Configuring the M-100 as a Log Collector" on page 405
- "Configuring the Panorama Server for Log Collector Management" on page 406
- "Managing Log Collectors" on page 407
- "Defining Log Collector Groups" on page 411
- "Log Collector Storage" on page 414

## Deploying Distributed Log Collection

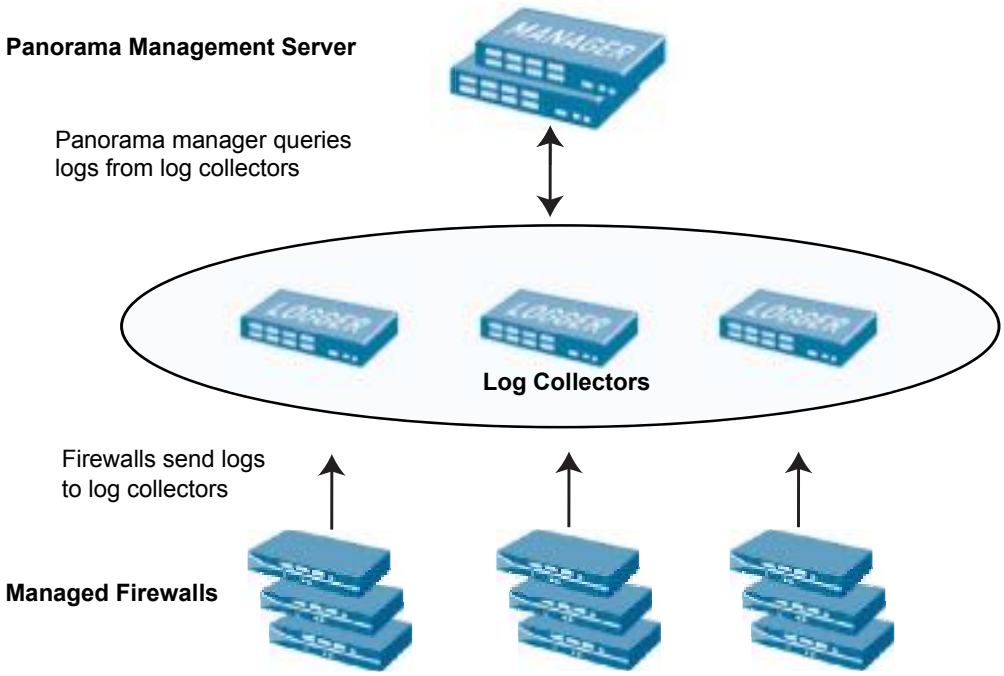
Several things should be considered when deploying a distributed log collection solution, including:

- Determine the location of the M-100 appliances based on your network topology and the location of your firewalls. Ideally, the Panorama management server, firewalls, and log collectors should all be connected over a management network. You can configure the firewalls to connect to multiple log collectors in case of failures, so its important that each firewall can reach its assigned collector(s). Typically, the Panorama server and log collectors would be installed in data centers.
- Determine the disk storage needs for log collection based on the number of firewalls that it will handle and the desired retention time. You should analyze your current environment to determine the amount of logs and reports that are being generated.

The illustration in Figure 54 shows a basic log collection deployment. Managed firewalls are configured to send log information to the M-100 log collector. The Panorama servers in HA mode then communicate with the log collectors to perform reporting and to view log information collected from the managed firewalls.

In large deployments where multiple log collectors are available, you assign two or more log collectors to each firewall in a preference order. The first log collector you specify will be the primary log collector for the firewall. If the primary log collector fails, the firewall will momentarily cache log information, so nothing is lost, and will then send logs to the secondary log collector. Regardless of firewall to log collector assignments, logs are balanced across all log collectors in the group to maintain even storage usage among the collector group.

**Figure 54. Distributed Log Collection**



### Configuring the M-100 as a Log Collector

To configure the M-100 appliance as a log collector, follow these steps:

1. Perform initial configuration to set up an IP address for the management interface (MGT port) and change the default password on the appliance. The MGT port is used for all communications, including device management, log collection, and log collector to log collector communications.
2. Apply a license to the M-100.
3. Before you proceed, verify that the firewalls on your network are running PAN-OS 5.0. If not, you must first upgrade the firewalls to PAN-OS 5.0. This upgrade is necessary because support for separate appliances that perform the Panorama management and log collection functionality is not available on earlier versions of PAN-OS.
4. Convert the appliance to function as a log collector only. To change the functionality of the appliance to logger-mode:
   a. Log in to the CLI. For instructions on accessing the CLI, refer to the *Command Line Interface Reference Guide*.
   b. Enter the following CLI command:

      **`request system logger-mode logger`**

      Answer **Yes** to confirm the change. The device will reboot.
   c. After the appliance boots up, verify that the device is in logger mode, using the CLI command:

      **`show system info | match logger_mode`**

      The output should display: **`logger-mode: True`**

***Note:*** *When the M-100 is in log collector mode, only the CLI is available for management. Most of the configuration is performed on the Panorama manager.*

5. Configure the IP address or FQDN of the Panorama server that will be used to manage the log collector.
   `set deviceconfig system panorama-server ip-address <Panorama-IP>.`
   If your Panorama server is in HA mode, enter the IP address of the peer device:
   `set deviceconfig system panorama-server-2 ip-address <Panorama-IP>.`
6. Type **commit** to make the change active and then **exit** to leave configuration mode.

Now that the log collector has the basic configuration needed, for further configuration on the log-collector, use the Panorama Management server to complete the configuration. Refer to "Configuring the Panorama Server for Log Collector Management" in the next section.

### Configuring the Panorama Server for Log Collector Management

The Panorama management server is used to configure and manage the M-100 log collector once network connectivity is established between the two systems. From Panorama, you manage all of the log collector settings, storage, log retention, SNMP settings, and the assignment of managed firewall to log collectors using collector groups. Once the log collectors are in place, Panorama then queries those log collectors for aggregated reporting. Refer to "Defining Log Collector Groups" on page 411.

***Note:*** *You cannot migrate existing firewall logs to the M-100; only new log data will be forwarded after the configuration is completed.*

For detailed descriptions of each of the Managed Collectors fields, refer to "Managing Log Collectors" on page 407.

To configure log collectors from Panorama:

1. Make sure the log collector you want to manage has basic network connectivity so the Panorama management server can communicate with it. Refer to "Configuring the M-100 as a Log Collector" on page 405.
2. From the Panorama management server, navigate to **Panorama > Managed Collectors** and then click **Add** to start adding a log collector.
3. In the **General** tab, specify the log collector serial number and log collector name (hostname). Then specify the Panorama server IP address, DNS, NTP, Timezone, and location information.
4. Use the **Authentication** tab to update the local admin account password on the log collector. You can only use a password hash for this field. You can create a password hash using the Panorama CLI command **`request password-hash password`** ***`password`***. Press enter and the hash value will be displayed. Copy the hash and paste into the **Password Hash** field and **Confirm Password hash** field.
5. The **Management** tab is used to configure the management port on the log collector and is labeled MGT on the front of the M-100. You can set the MTU and other interface settings, the allowed services and define a list of permitted IP addresses that will be allowed to manage the log collector. The MGT port will be used for all communications between the log collector and managed devices. Refer to "Defining Log Collector Groups" on page 411.
6. If you are increasing storage capacity, see "Log Collector Storage" on page 414 for information on configuring the additional disks as a RAID pair.
7. Click **Commit** and in the **Commit Type** drop down select **Panorama** and click **OK**.
8. Click **Commit** and in the **Commit Type** drop down select **Collector Group**, select the log collector or group that you would like to commit and then click **OK**. This will push the changes to the selected log collector(s).
   You will see a pop-up window that will show the commit state.
9. The log collector should now be configured. The next procedure is to create **Collector Groups** to assign firewalls to log collectors. Refer to "Defining Log Collector Groups" on page 411.

## Managing Log Collectors

▶ ***Panorama > Managed Collectors***

Use the Managed Collectors page to configure, manage, and update log collector devices. The settings on this page also exist in the log collector CLI.

After you add log collectors, you can click the **Statistics** link for each collector. This will show the **Collector Statistics** window where you can view Disk Information, Performance numbers for the CPU and Average Logs/sec. You can also view information on the Oldest log received by the collector to get a better understanding of the log range you are looking at.

**Table 154 Managed Collectors Page**

| Field | Description |
|---|---|
| **General Tab** | |
| Collector S/N | Enter the serial number of the log collector device. |
| Collector Name | Enter a name to identify this log collector (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores.<br>This is the hostname of the log collector. |
| Panorama Server IP | Specify the IP address of the Panorama server used to manage this collector. |
| Panorama Server IP 2 | Specify the IP address of the secondary device if the Panorama management server is in HA mode. |
| Primary DNS Server | Enter the IP address of the primary DNS server. The server is used for DNS queries from the log collector, for example, to find the Panorama server. |
| Secondary DNS Server | Enter the IP address of a secondary DNS server to use if the primary server is unavailable (optional). |
| Primary NTP Server | Enter the IP address or host name of the primary NTP server, if any. If you do not use NTP servers, you can set the device time manually. |
| Secondary NTP Server | Enter the IP address or host name of secondary NTP servers to use if the primary server is unavailable (optional). |
| Timezone | Select the time zone of the log collector. |
| Latitude | Enter the latitude (-90.0 to 90.0) of the log collector that is used in the traffic and threat maps for App-Scope. |
| Longitude | Enter the longitude (-180.0 to 180.0) of the log collector that is used in the traffic and threat maps for App-Scope. |
| **Authentication Tab** | |
| User Name | This field will always show **admin** and is used for the local CLI login name on the log collector. |

**Table 154 Managed Collectors Page**

| Field | Description |
|---|---|
| Mode | Select **Password** to manually enter and confirm a password to be used for local CLI authentication, or select **Password Hash** to enter a hash value.<br>To create a password hash from the Panorama management server CLI, run the following:<br>`request password-hash password password123`<br>This will return a hash value for the password *password123 (Example- $1$urlishri$aLP2by.u2A1IQ/Njh5TFy9).*<br>Copy the hash value from the CLI and paste to the **Password Hash** field. When you commit your changes, the new hash will be pushed to the log collector and the new local admin login password will be *password123*. |
| Failed Attempts | Specify the number of failed login attempts that are allowed for the web interface and CLI before the account is locked. (1-10, default 0). 0 means that there is no limit. |
| Lockout Time (min) | Specify the number of minutes that a user is locked out (0-60 minutes) if the number of failed attempts is reached. The default 0 means that there is no limit to the number of attempts. |
| **Management Tab** | Configure the management port settings labeled **MGT** on the front of the device. This port is used for all log collector communication. |
| Interface | The interface cannot be changed and the default label is MGT. |
| Speed and Duplex | Select the interface speed in Mbps (10, 100, or 1000) and the interface transmission mode full-duplex (Full), half-duplex (Half), or negotiated automatically (Auto). |
| IP Address | Enter the IP Address of the log collector management interface.<br>The default IP address is 192.168.1.1. |
| Netmask | Enter the network mask for the IP address, such as "255.255.255.0". |
| Default Gateway | Enter the IP address of the default router (must be on the same subnet as the management port). |
| IPv6 Address | Enter the IPv6 address of the log collector management interface. |
| IPv6 Default Gateway | Enter the IPv6 address of the default router (must be on the same subnet as the management port). |
| MTU | Enter the maximum transmission unit (MTU) in bytes for packets sent on this interface (range 512 to 1500, default 1500). |
| Management Interface Services | Select the services that are enabled on the managed interface on the log collector device:<br>• SSH—Select the check box to enable secure shell.<br>• Ping—Select the check box to enable ping.<br>• SNMP—Select the check box to enable the Simple Network Managed Protocol. |

**Table 154 Managed Collectors Page**

| Field | Description |
|---|---|
| Permitted IP Addresses | Click **Add** to enter the list of IP addresses from which management is allowed. |
| **Disks Tab** | Click **Add** to define the RAID 1 disk pair that will be used to store logs. You can then add additional disk pairs as needed to expand your storage capacity.<br>By default, the M-100 is shipped with the first RAID 1 pair enabled with drives installed in bays A1/A2. You can add up to 3 more RAID 1 pairs to increase storage capacity by putting in new RAID 1 pairs in bays B1/B2, C1/C2, and D1/D2. In the software, the RAID 1 pair in bays A1/A2 is named Drive Pair <A\|B\|C\|D>.<br>Refer to "Log Collector Storage" on page 414. |

## Defining Log Collector Groups

▶ *Panorama > Collector Groups*

Collector groups are used to assign Panorama managed firewalls to log collectors that will be used to offload the work of log collection that would normally be handled by the Panorama management server. Once the log collectors are in place and the firewalls are configured, the defined logs for each device will be sent to the log collectors and Panorama will then query the log collectors for aggregated log viewing or investigation. You also use collector groups to define storage retention and SNMP settings.

For detailed descriptions of each of the Collector Groups settings, refer to "Collector Groups Settings" on page 412.

To configure log collector groups:

1. From the Panorama management server, navigate to **Panorama > Collector Groups**.
2. Click **Add** and enter a name to identify the collector group.
3. In the **Min Retention Period (days)** field, enter the number of days that should be maintained across all log collectors in the group before an alert is generated. An alert violation in the form of a system log will be generated if the current date minus the oldest log is less than the defined min retention period.
4. Click the **Monitoring** tab and enter the SNMP settings for your environment in order to manage your devices through a system management solution.
5. Click the **Log Forwarding** tab and in the **Collectors** window, click **Add** and select the log collectors that will be part of this collector group. This list is generated by the collectors defined in **Panorama > Managed Collectors**.

***Note:*** *When you add the device serial number to the collector group, the managed device will start to send all logs to the collector group. To have the managed device revert back to sending logs to the Panorama manager, just remove the device from the collector group. This would also be required when migrating managed devices to a different install of Panorama manager. If you forget to do this, you will need to run the operational command* `delete log-collector preference-list` *from the managed device.*

6. Configure the mapping that defines which devices forward to a preferred list of collectors in preference order. In the **Log Forwarding** tab, click **Add** under **Devices** and **Collectors** list windows and the **Devices** window will appear.
7. In the **Devices** drop-down, select a managed firewall and then under **Collectors** click **Add** and select a log collector. If you select multiple collectors the first collector added will be the primary collector, the second will be the secondary collector, and so on. If the primary fails, logs will be sent to the secondary.
   Click **OK** to save your changes.
8. Click **Commit** and in the **Commit Type** drop down select **Panorama** and click **OK**.
9. Click **Commit** and in the **Commit Type** drop down select **Collector Group** and click **OK**. Once the collector group commit completes, the managed firewalls that have been assigned to collectors will start forwarding logs to the collectors.

   Now that firewall logs are being sent to the log collectors, you then use Panorama's ACC, PDF Reports, and the Logs viewer to query aggregated information for all of your managed firewalls. The ACC will query data directly from the log collectors, which

means that the ACC is looking at forwarded data from the firewall. If you deploy an M-100 as a Panorama manager and log collector, the ACC will also query the data forwarded to the log collector that is on the same device in this case.

**Table 155 Collector Groups Settings**

| Field | Description |
|---|---|
| **General Tab** | |
| Name | Enter a name to identify this collector group name that will be used to group log collectors for configuration and software update purposes (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, spaces, hyphens, and underscores. |
| Log Storage | Indicates the current log storage quotas for the collector group. If you click on the capacity text, the **Log Storage Settings** window will appear. From here, you can allocate storage to various log features, such as Traffic, Threat, Config, System, and Alarm. You can also click **Restore Defaults** to use the default log allocation settings. |
| Min Retention Period (days) | Specify the retention period in days that should be maintained across all log collectors in the group before an alert is generated. An alert violation in the form of a system log will be generated if the current date minus the oldest log is less than the defined min retention period (range 1-2000 days). |
| **Monitoring Tab** | |

**Table 155 Collector Groups Settings (Continued)**

| Field | Description |
|---|---|
| SNMP | The SNMP option enables you to collect information about the log collectors, including: connection status, Disk drive statistics, software version, average CPU, Average log/second, and storage duration per DB type (e.g. minutes, hours, days, weeks). SNMP information is based on a per-collector group.<br><br>Specify the SNMP settings:<br>• Location—Specify the location of the log collector device.<br>• Contact—Specify an email contact for this device.<br>• Access Setting—Specify the SNMP version that will be used to communicate with the Panorama management server (V2c or V3).<br>If you select V3, specify the following:<br>– Views— Click Add and configure the following settings:<br>› View—Specify a name for a view.<br>› OID—Specify the object identifier (OID).<br>› Option (include or exclude)—Choose whether the OID is to be included or excluded from the view.<br>› Mask—Specify a mask value for a filter on the OID in hexadecimal format (for example, 0xf0)<br>– Users—Click **Add** and configure the following settings:<br>› Users—Specify a user name that will be used for authentication between the log collector and SNMP management server.<br>› View—Specify the group of views for the user.<br>› Authpwd—Specify the user's authentication password (minimum 8 characters). Only Secure Hash Algorithm (SHA) is supported.<br>› Privpwd—Specify the user's encryption password (minimum 8 characters). Only Advanced Encryption Standard (AES) is supported.<br>• SNMP Community—Specify the SNMP community string that is used by your SNMP management environment. SNMPv2c Only (default is public). |
| **Log Forwarding Tab** | |

**Table 155 Collector Groups Settings (Continued)**

| Field | Description |
|---|---|
| Collectors | Click **Add** and select the log collector from the drop-down that will be part of this group. The drop-down will show all log collectors that are available in the **Panorama > Managed Collectors** page. |
| Devices | Click **Add** and then click the **Devices** drop-down and select the managed firewall that will be part of this collector group.<br>Click **Add** in the **Collectors** window and select the collector that you would like to assign this firewall for log forwarding.<br>Click **OK** to save your changes.<br>When viewing the **Devices** window, the **Devices** column will list each firewall and the **Collectors** column will list the assigned collector(s) for the firewall.<br>The first collector you specify will be the primary collector for the firewall. If the primary collector fails, the firewall will then send logs to the secondary collector. If the secondary fails, then the tertiary collector will be used, and so on.<br>**Note:** When you add the device serial number to the collector group, the managed device will start to send all logs to the collector group. To have the managed device revert back to sending logs to the Panorama manager, just remove the device from the collector group. This would also be required when migrating managed devices to a different install of Panorama manager. If you forget to do this, you will need to run the operational command `delete log-collector preference-list` from the managed device. |

### Log Collector Storage

As your environment grows, you will need to increase the storage capacity of the log collector M-100 appliances, or you may need to add new log collectors.

By default, the M-100 is shipped with the first RAID 1 pair enabled with drives installed in bays A1/A2. You can add up to 3 more RAID 1 pairs to increase storage capacity by adding in new RAID 1 pairs in bays B1/B2, C1/C2, and D1/D2. In the software, the RAID 1 pair in bays A1/A2 is named Disk Pair A, B1/B2 is Disk Pair B, C1/C2 is Disk Pair C, D1/D2 is Disk Pair D.

For information on physically replacing drives on the M-100, refer to the *M-100 Hardware Reference Guide*.

***Note:*** *The RAID 1 disk arrays on the M-100 requires that each mirrored disk pair be installed in the appropriate disk bays. The device ships with A1/A2 drives installed and mirrored. To add more disks, you install the next pair into the next Disk Pair, which is bays B1/B2, then C1/C2, and then D1/D2. You cannot install new disks in B1 and C1 for example, and then try to mirror those.*

To expand disk storage on an M-100 using the B1/B2 drive bay:

1. Obtain two identical M-100 disk drives from Palo Alto Networks.
2. You do not have to power down the log collector to add new drives. If you prefer to power down the device, run **`request shutdown system`** from the CLI.

3. Remove the empty drives bays B1/B2 and install the new disks into the drive bays for Disk Pair B.
4. Insert the drive bays back into bays B1/B2.
5. Go to the CLI on the log collector and run **`request system raid add B1`**. This will initialize and format the B1 drive.
6. Run the command again on drive B2 **`request system raid add B2`**. The Raid 1 mirror will be created and the drives are now ready to be added to the collector group from the Panorama management server.

***Note:*** *The time taken to mirror the data on the drive may vary from several minutes to a couple hours, depending on the amount of data on the drive. Use the command* `show system raid detail` *to monitor the progress of the RAID configuration.*

7. Go to the Panorama management server that is managing this log collector, navigate to **Panorama > Manage Collectors** and click the log collector to open the **Collector** window. Select the **Disks** tab.
8. Disk A should already exist. Click **Add** and select **Disk Pair B** and then click **OK** to make the new disk pair available to the system.

When you increase or decrease storage on a log collector, the new storage capacity information is recognized by the Panorama management server and the log collector groups will be updated to re-balance logging. Regardless of firewall to collector assignments, logs are balanced across all collectors in the group to maintain even storage usage among the collector group. Note that during this re-balancing process, you may see heavy network traffic as log data is moved between collectors.

To view the disk capacity for a log collector group, or an individual log collector, go to the web interface on the Panorama management server, navigate to **Panorama > Collector Groups**, click a group name and then click the **General** tab. Next to **Log Storage**, you will see a link that displays the total and free storage information. If you click this link, the **Log Storage Settings** windows will appear where you can allocate storage for various features.

# Viewing Firewall Deployment Information

▶ *Panorama > Device Deployment*

Open the **Device Deployment** pages to view current deployment information on the managed devices and manage software versions on the devices, as described in the following table.

**Table 156. Panorama Deployment Pages**

| Field | Description |
|---|---|
| **Software** | Lists the versions of firewall software that are available for installation on the managed firewalls. |
| **SSL VPN Client** | Lists the versions of SSL VPN client software that are available for installation on the managed firewalls. |
| **GlobalProtect Client** | Lists the versions of GlobalProtect client software that are available for installation on the managed firewalls. |
| **Dynamic Updates** | Lists the threat and application definitions that are available for use on the managed firewalls. Refer to "Updating Threat and Application Definitions" on page 55 for information on using this page. |
| **Licenses** | Lists each managed device and the current license status. Each entry indicates whether the license is active ( icon) or inactive ( icon), along with the expiration date for active licenses.<br>Perform either of the following functions on this page:<br>• Click **Refresh** to update the list.<br>• Click **Activate** to activate a license. Select the managed devices for activation and enter the authentication code that Palo Alto Networks provided for the device. |

Perform any of the following functions on the **Software**, **SSL VPN**, or **GlobalProtect** pages:

- Click **Refresh** to view the latest software releases available from Palo Alto Networks.
- Click **Release Notes** to view a description of the changes in a release.
- Click **Download** to install a new release from the download site. When the download is complete, a checkmark is displayed in the **Downloaded** column. To install a downloaded release, click **Install** next to the release.

  During installation, you are asked whether to reboot when installation is complete. When the installation is complete, you will be logged out while the firewall is restarted. The firewall will be rebooted, if that option was selected.
- Click **Upload** to install or activate a release that you previously stored on your PC. Browse to select the software package, and click **Install from File**. Choose the file that you just selected from the drop-down list, and click **OK** to install the image.
- Click the **Delete** icon to delete an outdated release.

# Backing Up Firewall Configurations

▶ *Panorama > Setup*

Panorama automatically saves every committed configured from the managed firewalls. You can configure the number of versions to keep on the Panorama device by using the Management settings under **Setup** on the **Panorama** tab. The default is 100. For instructions on configuring the number of versions, refer to "Defining Management Settings" on page 30.

To manage backups on Panorama, choose **Panorama > Managed Devices** and click **Manage** in the **Backups** column for a device. A window opens to show the saved and committed configurations for the device. Click a **Load** link to restore the backup to the candidate configuration, and then make any desired changes and click **Commit** to restore the loaded configuration to the device. To remove a saved configuration, click the icon.

# Scheduling Configuration Exports

▶ *Panorama > Scheduled Config Export*

Panorama saves a backup of running configurations from all managed devices in addition to its own running configurations. Use the **Scheduled Config Export** page to collect the running configurations from all of the managed devices, package them in one gzip file, and schedule the package for daily delivery to an FTP server or by using Secure Copy (SCP) to transfer data securely to a remote host. The files are in XML format with file names that are based on the device serial numbers.

Use this page to set up a schedule for collection and export of the managed device configurations.

**Table 157. Scheduling Configuration Bundle Exports**

| Field | Description |
|---|---|
| Name | Enter a name to identify the configuration bundle export job (up to 31 characters). The name is case-sensitive and must be unique. Use only letters, numbers, hyphens, and underscores. |
| Description | Enter an optional description. |
| Enable | Select the check box to enable the export job. |
| Scheduled export start time (daily) | Specify the time of day to start the export (24 hour clock, format HH:MM). |
| Protocol | Select the protocol to use to export logs from the firewall to a remote host. You can use SCP to export logs securely, or you can use FTP, which is not a secure protocol. |
| Hostname | Enter the IP address or host name of the target FTP server. |
| Port | Enter the port number on the target server. |
| Path | Specify the path located on the FTP server that will be used to store the exported information. |
| Enable FTP Passive Mode | Select the check box to use FTP passive mode. |
| Username | Specify the user name on the target system. |

**Table 157. Scheduling Configuration Bundle Exports (Continued)**

| Field | Description |
|---|---|
| Password<br>Confirm Password | Specify the password for the user on the target system. |
| Test SCP server connection | Click this button to test communication between the firewall and the SCP host/server.<br>To enable the secure transfer of data, you must verify and accept the host key of the SCP server. The connection is not established until the host key is accepted. |

# Upgrading the Panorama Software

▶ *Panorama > Software*

To upgrade to a new release of Panorama software, you can view the latest versions of the Panorama software available from Palo Alto Networks, read the release notes for each version, and then select the release you want to download and install (a support license is required).

To upgrade the Panorama software, click **Refresh** to view the latest software releases available from Palo Alto Networks. To view a description of the changes in a release, click **Release Notes** next to the release.

***Note:*** *Panorama periodically performs a file system integrity check (FSCK) to prevent corruption of the Panorama system files. This check occurs after 8 reboots or at a reboot that occurs 90 days after the last file system integrity check was executed. If Panorama is running a FSCK, you will see a warning on the web interface and SSH login screens indicating that an FSCK is in progress and you cannot log in until it completes. The time to complete this process varies by the size of the storage system; depending on the size, it can take several hours before you can log back into Panorama.*
*To view progress, set up console access to Panorama.*

1. To install a new release:

   a. Click **Download** next to the release to be installed. When the download is complete, a checkmark is displayed in the **Downloaded** column.

   b. To install a downloaded release, click **Install** next to the release.

   When the installation is complete, you will be logged out while the Panorama system is restarted.

2. To delete an outdated release, click ☒ next to the release.

***Note:*** *Software is deleted to make room for newer version downloads. This happens automatically and cannot be manually controlled.*

Chapter 14

# Configuring WildFire

This chapter describes how to use WildFire for analysis and reporting on malware that traverses the firewall:

- "About WildFire" in the next section
- "Setting Up WildFire on the Firewall" on page 423
- "Configuring WildFire Forwarding" on page 424
- "WildFire Data Filtering Log" on page 425
- "Using the WildFire Portal" on page 425

## About WildFire

WildFire allows you to securely send files to the Palo Alto Networks cloud-based malware analysis center, where the files are automatically analyzed in a virtual sandbox for malicious activity. Files can be submitted automatically from firewalls through the use of a file blocking policy, manually through the WildFire Portal, or using the WildFire API (WildFire subscription required). The WildFire system executes the file in a virtual environment and watches for many potentially malicious behaviors and techniques, such as modifying critical system files, disabling security features, or using a variety of methods to evade detection. As new malware is detected, WildFire automatically generates antivirus signatures and distributes these signatures to firewalls with a threat prevention subscription via the daily antivirus signature updates. If you are a WildFire subscriber, signatures are available on a sub-hourly basis.

Supported file types include Win32 Portable Executable (PE) files (e.g. exe, dll, and scr). When choosing file types in the objects profile, you can choose **PE** to cover all Win32 PE file types.

File types can be analyzed even if they are compressed (zip, gzip) or over SSL if decryption is enabled in the policy. You do not need to add (zip, gzip) to the file blocking profile to support analysis of compressed PE files since this is done automatically.

***Note:*** *When choosing **PE** in the objects profile **File Types** column to select a category of file types, do not add an individual file type that is part of that category or you will receive redundant entries in the **Data Filtering** logs. For example, if you choose **PE** you would not want to additionally include **exe**. This also applies to the **zip** file type, since supported file types that are zipped will automatically be sent to WildFire.*

*Choosing a category will also ensure that as new file type support is added to a given category, they will automatically be part of your object profile. You can also select **any** to cause all supported file types to be uploaded to WildFire.*

As new malware is detected, WildFire will automatically generate antivirus signatures and will distribute these signatures to firewalls that have a threat prevention subscription. The signatures will be part of the daily antivirus signatures that are updated every 24-48 hours.

If you have a WildFire subscription, you will have several new features enabled, including:

- **WildFire Dynamic Updates**—A new WildFire section in **Device > Dynamic Updates** is now available. As new malware is detected, WildFire signatures are generated every 30 minutes, and the firewall's WildFire update schedule can be configured to poll for new WildFire signatures every 15, 30, or 60 minutes. As new WildFire signatures are downloaded to your firewall, you can configure the firewall to take specific actions on these signatures, separate from the regular antivirus signature actions in the antivirus profile.

- **Integrated WildFire Logs**—As files are uploaded and analyzed by WildFire, log data is sent back to the device after analysis, along with the analysis results. Logs are written to **Monitor > Logs > WildFire**.

- **WildFire API**—The WildFire license provides access to the WildFire API, which allows for programmatic access to the WildFire service in the cloud, apart from use by Palo Alto Networks firewalls. The WildFire API can be used to submit, analyze, and review reports for files submitted to the WildFire system. You can upload up to 100 files per day and query the WildFire portal up to 1000 times per day.

Results of the detailed analysis of the submitted files are also available through the WildFire portal and you can view this information without a subscription. You can use the WildFire portal to see which users were targeted, the applications that were used, and the malicious behavior that was observed. You can also configure the WildFire portal to send email notifications when results are available for review. Refer to “Using the WildFire Portal” on page 425.

# Setting Up WildFire on the Firewall

Perform these tasks to set up your environment to use WildFire.

1. On the firewall, configure WildFire settings on the **Device > Setup** page. Refer to "Configuring WildFire Settings on the Firewall" on page 423.
2. On the firewall, configure your file blocking profiles to include the **forward** or **continue-and-forward** action. Refer to "Configuring WildFire Forwarding" on page 424 for procedures, or refer to "File Blocking Profiles" on page 220 for more information.
3. Incorporate the file blocking profiles in a security policy, as you would for any other file blocking profiles. Refer to "Security Policies" on page 187.
4. Access the WildFire portal and configure optional settings. Refer to "Using the WildFire Portal" on page 425.

You can now access the WildFire portal to view reports. Refer to "Viewing WildFire Reports" on page 427.

# Configuring WildFire Settings on the Firewall

▶ *Device > Setup > WildFire*

Use the **WildFire** tab to control the information to be sent to the WildFire server.

***Note:*** *To forward decrypted content to WildFire, you need to select the "Allow Forwarding of Decrypted Content" check box in* ***Device > Setup > Content-ID > URL Filtering*** *Settings box.*

**Table 158. WildFire Settings on the Firewall**

| Field | Description |
|---|---|
| **General Settings** | |
| WildFire Server | Specify the URL of a WildFire server. Specify the value **default-cloud** to allow the firewall to automatically find the closest WildFire server. |
| Maximum File Size (MB) | Specify the maximum file size that will be forwarded to the WildFire server (range 1-10 MB, default 2 MB). Files larger than the specified size are not sent. |

**Table 158. WildFire Settings on the Firewall (Continued)**

| Field | Description |
|---|---|
| **Session Information Settings** | |
| Settings | Specify the information to be forwarded to the WildFire server. By default, all are selected:<br>• **Source IP**—Source IP address that sent the suspected file.<br>• **Source Port**—Source port that sent the suspected file.<br>• **Destination IP**—Destination IP address for the suspected file.<br>• **Destination Port**—Destination port for the suspected file.<br>• **Vsys**—Firewall virtual system that identified the possible malware.<br>• **Application**—User application that was used to transmit the file.<br>• **User**—Targeted user.<br>• **URL**—URL associated with the suspected file.<br>• **Filename**—Name of the file that was sent. |

# Configuring WildFire Forwarding

After configuring the WildFire settings on the firewall, you are now ready to configure forwarding to allow files to be sent to the WildFire system for analysis. You first create a file blocking profile and then include that profile in a security policy.

To configure a file blocking profile for WildFire:

1. Navigate to **Objects > Security Profiles > File Blocking**.
2. Click **Add** to add a new profile and enter a **Name** and **Description**.
3. Click **Add** in the **File Blocking Profile** window. Click in the **Names** field and enter a rule name.
4. Select the **Application(s)** that will be identified for this profile. For example, if you choose the application **web-browsing**, the profile will identify files downloaded when the user downloads files from a web page.
5. In the **File Type** field select the file types that you would like to forward for analysis.
6. In the **Direction** field, select **upload**, **download**, or **both**. If you select **both,** this will identify files that are uploaded or downloaded by the user.
7. In the **Action** field, select **forward**. This will cause any identified file to be forwarded to the WildFire system, analysis will occur and the file will then be delivered to the user. If you select **continue-and-forward**, the user will be prompted with a continue page before the download will occur.

If WildFire determines that the file is a malware file, a report will be generated on the WildFire Portal and a new antivirus signature will be created within 24-48 hours. If you are a WildFire subscriber, you will also see a **WildFire** log entry on the firewall and a signature will be created within an hour.

To configure a security policy for WildFire:

1. Navigate to **Policies** > **Security.**

2. Click on **Add** to create a new policy, or select an existing policy.
3. Click the **Actions** tab and under **Profile Setting** click the drop-down next to **File Blocking** and choose the Security Profile that you created.
4. Click **Commit** to active your changes.

***Note:*** *When you create a file blocking profile with the action* ***continue*** *or* ***continue-and-forward*** *(used for WildFire forwarding), you can only choose the application* ***web-browsing****. If you choose any other application, traffic that matches the security policy will not flow through the firewall due to the fact that the users will not be prompted with a continue page.*

# WildFire Data Filtering Log

This section describes the various forwarding actions that you will see in the logs when WildFire is configured and files are forwarded for analysis. The logs will be located in Monitor > Logs > Data Filtering.

**Table 159. WildFire Data Filtering Log Descriptions**

| Log | Description |
|---|---|
| wildfire-upload-success | The file was sent to the cloud. This means the file is not signed by a trusted file signer, it has not been previously analyzed by WildFire. |
| wildfire-upload-skip | This action will be displayed for all files identified as eligible to be sent to WildFire by a file blocking profile/security policy, but did not need to be analyzed by WildFire because it has already been analyzed previously. In this case, the "forward" action will appear in the Data Filtering log because it was a valid forward action, but it was not sent to WildFire and analyzed because the file has already been sent to the WildFire cloud from another session, possibly from another firewall. |

# Using the WildFire Portal

To access the WildFire portal, go to *https://wildfire.paloaltonetworks.com* and log in using your Palo Alto Networks support credentials or your WildFire account.

The portal opens to display the dashboard, which lists summary report information for all of the firewalls associated with the specific WildFire license or support account (as well as any files that have been uploaded manually). The display includes the number of analyzed files and indicates how many are infected with malware, are benign, or are pending analysis.

***Note:*** *To upload a file manually, click* ***Upload File*** *in the upper right corner of the WildFire page.*

**Figure 55. WildFire Dashboard**

# Configuring Settings on the WildFire Portal

Click the **Settings** link at the top of the WildFire portal to configure the following settings:

**Table 160. Settings on the WildFire Portal**

| Field | Description |
|---|---|
| Password | To change your password, enter values in the following fields:<br>• **Current Password**—Enter your current password.<br>• **New Password/Confirm Password**—Enter and then reenter a new password. |
| Time Zone | Select the time zone from the drop-down list. This is the time zone that is used to indicate when WildFire receives files. |

**Table 160. Settings on the WildFire Portal (Continued)**

| Field | Description |
|---|---|
| Email Notifications | Choose the email notifications that you would like to receive. The email notifications are sent to the currently logged in WildFire user. For each device, and for files that are manually uploaded to the WildFire server, you can choose any of the following email notifications:<br>• **Malware**—Select this check box to have an Email notification sent when the file is determined to be malware.<br>• **Benign**—Select this check box to have an Email notification sent when the file is determined to be benign.<br>***Note:*** *You can also select both check boxes to receive Email notifications for all files (malware/benign).* |

# Viewing WildFire Reports

Click the **Reports** button at the top of the WildFire portal to view the list of available reports. Search options are available at the top of the page, and pagination controls are included.

To view an individual report, click the icon to the left of the report name. To print a detailed report, use the print option on your browser.

**Figure 56. WildFire Reports Page**

# Appendix A
# Custom Pages

Custom response pages allow you to notify end users of policy violations and special access conditions. Each page can include references to the user's IP address, the URL for which access is attempted, and the URL category. These parameters can also be used in links to trouble-ticketing systems.

This appendix provides HTML code for the following default custom response pages:

- "Default Antivirus Response Page" in the next section
- "Default Application Block Page" on page 431
- "Default File Blocking Block Page" on page 431
- "Default URL Filtering Response Page" on page 432
- "Default Anti-spyware Download Response Page" on page 433
- "Default Decryption Opt-out Response Page" on page 433
- "Captive Portal Comfort Page" on page 434
- "URL Filtering Continue and Override Page" on page 434
- "SSL VPN Login Page" on page 435
- "SSL Certificate Revoked Notify Page" on page 436

***Note:*** *For information on importing and exporting custom response pages, refer to "Defining Custom Response Pages" on page 115.*

# Appendix B
# Application Categories, Subcategories, Technologies, and Characteristics

The appendix lists application-related categories defined by Palo Alto Networks:

- "Application Categories and Subcategories" in the next section
- "Application Technologies" on page 439
- "Application Characteristics" on page 439

The Applipedia database can also be found on the firewall in **Objects > Applications**, online at http://apps.paloaltonetworks.com/applipedia/ and an App is available on the Apple App Store.

## Application Categories and Subcategories

The following application categories and subcategories are supported:

- business-system
  - auth-service
  - database
  - erp-crm
  - general-business
  - management
  - office-programs
  - software-update
  - storage-backup
- collaboration
  - email
  - instant-messaging
  - internet-conferencing

  - social-business
  - internet-utility
  - social-networking
  - voip-video
  - web-posting
- general-internet
  - file-sharing
  - internet-utility
- media
  - audio-streaming
  - gaming
  - photo-video
- networking
  - encrypted-tunnel
  - infrastructure
  - ip-protocol
  - proxy
  - remote-access
  - routing
- unknown

# Application Technologies

The following application technologies are supported.

**Table 161. Application Technologies**

| Item | Description |
|---|---|
| browser-based | An application that relies on a web browser to function. |
| client-server | An application that uses a client-server model where one or more clients communicate with a server in the network. |
| network-protocol | An application that is generally used for system to system communication that facilitates network operation. This includes most of the IP protocols. |
| peer-to-peer | An application that communicates directly with other clients to transfer information instead of relying on a central server to facilitate the communication. |

# Application Characteristics

The following application characteristics are supported.

**Table 162. Application Characteristics**

| Item | Description |
|---|---|
| Evasive | Uses a port or protocol for something other than its originally intended purpose with the hope that it will traverse a firewall. |
| Excessive Bandwidth | Consumes at least 1 Mbps on a regular basis through normal use. |
| Prone to Misuse | Often used for nefarious purposes or is easily set up to expose more than the user intended. |
| Transfers Files | Has the capability to transfer a file from one system to another over a network. |
| Tunnels Other Apps | Is able to transport other applications inside its protocol. |
| Used by Malware | Malware has been known to use the application for propagation, attack, or data theft, or is distributed with malware. |
| Vulnerability | Has publicly reported vulnerabilities. |
| Widely Used | Likely has more than 1,000,000 users. |
| Continue Scanning for Other Applications | Instructs the firewall to continue looking to see if other application signatures match. If this option is not selected, the first matching signature is reported and the firewall stops looking for additional matching applications. |

# Appendix C
# Common Criteria/Federal Information Processing Standards Support

You can configure the firewall to support the Common Criteria Evaluation Assurance Level 4+ (CCEAL4+) and the Federal Information Processing Standards 140-2 (FIPS 140-2), which are security certifications that ensure a standard set of security assurances and functionalities. These certifications are often required by civilian U.S. government agencies and government contractors.

For more details on these certifications, refer to the following documents:

- **FIPS**—http://csrc.nist.gov/groups/STM/cmvp/documents/140-1/140sp/140sp1877.pdf
- **CCEAL4+**—http://www.niap-ccevs.org/st/vid10392/

***Note:*** *PAN-OS 5.0 certification is in process. Visit http://csrc.nist.gov/groups/STM/cmvp/documents/140-1/140InProcess.pdf and search for Palo Alto Networks in the Cryptographic Module Validation Program FIPS 140-1 and FIPS 140-2 Modules In Process List for details.*

## Enabling CC/FIPS Mode

Use the following procedure to enable CC/FIPS mode on a software version that supports CC/FIPS. Keep in mind that when you enable CC/FIPS, the device will be reset the factory default settings; all configuration will be removed.

1. Boot the firewall into maintenance mode as follows:
   a. Establish a serial connection with the firewall.
   b. Reboot the device and press the **m** key on the keyboard when you see the following prompt: **Press m to boot to maint partition**.
   c. Press any key on your keyboard when prompted to stop the automatic boot, and then select **PANOS (maint)** as the booting partition.

      For more detailed information about maintenance mode, refer to the *PAN-OS Command Line Interface Reference Guide*.
2. Select **Set CCEAL4 Mode** from the menu.
3. Select **Enable CCEAL4 Mode** from the menu.

4. When prompted, select **Reboot**.

   After successfully switching to CC/FIPS mode, the following status displays: **`CCEAL4 mode enabled successfully`**. In addition, **`CC`** will display at all times in the status bar at the bottom of the web interface. In addition, the console port will now be available as a status output port only. In addition, the default admin login credentials change to admin/paloalto.

# CC/FIPS Security Functions

When CC/FIPS is enabled, the following apply:

- To log into the firewall, the browser must be TLS 1.0 compatible.
- All passwords on the firewall must be at least six characters.
- Accounts are locked after the number of failed attempts that is configured on the **Device > Setup > Management** page. If the firewall is not in CC/FIPS mode, it can be configured so that it never locks out; however in CC/FIPS mode, and lockout time is required.
- The firewall automatically determines the appropriate level of self-testing and enforces the appropriate level of strength in encryption algorithms and cipher suites.
- Non-CC/FIPS approved algorithms are not decrypted and are thus ignored during decryption.
- When configuring IPSec, a subset of the normally available cipher suites is available.
- Self-generated and imported certificates must contain public keys that are 2048 bits (or more).
- The serial port is disabled.
- Telnet, TFTP, and HTTP management connections are unavailable.
- Surf control is not supported.
- High availability (HA) encryption is required.
- PAP authentication is disabled.

# Appendix D
# Open Source Licenses

The software included in this product contains copyrighted software that is licensed under the General Public License (GPL). A copy of that license is included in this document. You may obtain the complete Corresponding Source code from us for a period of three years after our last shipment of this product by sending a money order or check for $5 to:

Palo Alto Networks
Open Source Request
4401 Great America Parkway
Santa Clara, Ca. 95054

Some components of this product may be covered under one or more of the open source licenses listed in this appendix:

- "Artistic License" on page 446
- "BSD" on page 447
- "GNU General Public License" on page 448
- "GNU Lesser General Public License" on page 452
- "MIT/X11" on page 458
- "OpenSSH" on page 458
- "PSF" on page 462
- "PHP" on page 462
- "Zlib" on page 463

# Artistic License

This document is freely plagiarized from the 'Artistic License', distributed as part of the Perl v4.0 kit by Larry Wall, which is available from most major archive sites

This documents purpose is to state the conditions under which these Packages (See definition below) viz: "Crack", the Unix Password Cracker, and "CrackLib", the Unix Password Checking library, which are held in copyright by Alec David Edward Muffett, may be copied, such that the copyright holder maintains some semblance of artistic control over the development of the packages, while giving the users of the package the right to use and distribute the Package in a more-or-less customary fashion, plus the right to make reasonable modifications.

Definitions:

A "Package" refers to the collection of files distributed by the Copyright Holder, and derivatives of that collection of files created through textual modification, or segments thereof.

"Standard Version" refers to such a Package if it has not been modified, or has been modified in accordance with the wishes of the Copyright Holder.

"Copyright Holder" is whoever is named in the copyright or copyrights for the package.

"You" is you, if you're thinking about copying or distributing this Package.

"Reasonable copying fee" is whatever you can justify on the basis of media cost, duplication charges, time of people involved, and so on. (You will not be required to justify it to the Copyright Holder, but only to the computing community at large as a market that must bear the fee.)

“Freely Available” means that no fee is charged for the item itself, though there may be fees involved in handling the item. It also means that recipients of the item may redistribute it under the same conditions they received it.

1. You may make and give away verbatim copies of the source form of the Standard Version of this Package without restriction, provided that you duplicate all of the original copyright notices and associated disclaimers.

2. You may apply bug fixes, portability fixes and other modifications derived from the Public Domain or from the Copyright Holder. A Package modified in such a way shall still be considered the Standard Version.

3. You may otherwise modify your copy of this Package in any way, provided that you insert a prominent notice in each changed file stating how and when AND WHY you changed that file, and provided that you do at least ONE of the following:

a) place your modifications in the Public Domain or otherwise make them Freely Available, such as by posting said modifications to Usenet or an equivalent medium, or placing the modifications on a major archive site such as uunet.uu.net, or by allowing the Copyright Holder to include your modifications in the Standard Version of the Package.

b) use the modified Package only within your corporation or organization.

c) rename any non-standard executables so the names do not conflict with standard executables, which must also be provided, and provide separate documentation for each non-standard executable that clearly documents how it differs from the Standard Version.

d) make other distribution arrangements with the Copyright Holder.

4. You may distribute the programs of this Package in object code or executable form, provided that you do at least ONE of the following:

a) distribute a Standard Version of the executables and library files, together with instructions (in the manual page or equivalent) on where to get the Standard Version.

b) accompany the distribution with the machine-readable source of the Package with your modifications.

c) accompany any non-standard executables with their corresponding Standard Version executables, giving the non-standard executables non-standard names, and clearly documenting the differences in manual pages (or equivalent), together with instructions on where to get the Standard Version.

d) make other distribution arrangements with the Copyright Holder.

5. You may charge a reasonable copying fee for any distribution of this Package. You may charge any fee you choose for support of this Package. YOU MAY NOT CHARGE A FEE FOR THIS PACKAGE ITSELF. However, you may distribute this Package in aggregate with other (possibly commercial) programs as part of a larger (possibly commercial) software distribution provided that YOU DO NOT ADVERTISE this package as a product of your own.

6. The name of the Copyright Holder may not be used to endorse or promote products derived from this software without specific prior written permission.

7. THIS PACKAGE IS PROVIDED "AS IS" AND WITHOUT ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, WITHOUT LIMITATION, THE IMPLIED WARRANTIES OF MERCHANTIBILITY AND FITNESS FOR A PARTICULAR PURPOSE.

# BSD

The following copyright holders provide software under the BSD license:

- Julian Steward
- Thai Open Source Software Center Ltd
- The Regents of the University of California
- Nick Mathewson
- Niels Provos
- Dug Song
- Todd C. Miller
- University of Cambridge
- Sony Computer Science Laboratories Inc.

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:

1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.

2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.

3. The names of the authors may not be used to endorse or promote products derived from this software without specific prior written permission.

THIS SOFTWARE IS PROVIDED ``AS IS'' AND WITHOUT ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, WITHOUT LIMITATION, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE.

# GNU General Public License

Version 2, June 1991

Copyright (C) 1989, 1991 Free Software Foundation, Inc.

51 Franklin Street, Fifth Floor, Boston, MA 02110-1301, USA

Everyone is permitted to copy and distribute verbatim copies of this license document, but changing it is not allowed.

Preamble:

The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public License is intended to guarantee your freedom to share and change free software--to make sure the software is free for all its users. This General Public License applies to most of the Free Software Foundation's software and to any other program whose authors commit to using it. (Some other Free Software Foundation software is covered by the GNU Lesser General Public License instead.) You can apply it to your programs, too.

When we speak of free software, we are referring to freedom, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish), that you receive source code or can get it if you want it, that you can change the software or use pieces of it in new free programs; and that you know you can do these things.

To protect your rights, we need to make restrictions that forbid anyone to deny you these rights or to ask you to surrender the rights. These restrictions translate to certain responsibilities for you if you distribute copies of the software, or if you modify it.

For example, if you distribute copies of such a program, whether gratis or for a fee, you must give the recipients all the rights that you have. You must make sure that they, too, receive or can get the source code. And you must show them these terms so they know their rights.

We protect your rights with two steps: (1) copyright the software, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the software.

Also, for each author's protection and ours, we want to make certain that everyone understands that there is no warranty for this free software. If the software is modified by someone else and passed on, we want its recipients to know that what they have is not the original, so that any problems introduced by others will not reflect on the original authors' reputations.

Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that redistributors of a free program will individually obtain patent licenses, in effect making the program proprietary. To prevent this, we have made it clear that any patent must be licensed for everyone's free use or not licensed at all.

The precise terms and conditions for copying, distribution and modification follow.

TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

0. This License applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License. The "Program", below, refers to any such program or work, and a "work based on the Program" means either the Program or any derivative work under copyright law: that is to say, a work containing the Program or a portion of it, either verbatim or with modifications and/or translated into another language. (Hereinafter, translation is included without limitation in the term "modification".) Each licensee is addressed as "you".

Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running the Program is not restricted, and the output from the Program is covered only if its contents constitute a work based on the Program (independent of having been made by running the Program). Whether that is true depends on what the Program does.

1. You may copy and distribute verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and give any other recipients of the Program a copy of this License along with the Program.

You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

2. You may modify your copy or copies of the Program or any portion of it, thus forming a work based on the Program, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:

a) You must cause the modified files to carry prominent notices stating that you changed the files and the date of any change.

b) You must cause any work that you distribute or publish, that in whole or in part contains or is derived from the Program or any part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License.

c) If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the most ordinary way, to print or display an announcement including an appropriate copyright notice and a notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this License. (Exception: if the Program itself is interactive but does not normally print such an announcement, your work based on the Program is not required to print an announcement.)

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Program, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Program, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Program.

In addition, mere aggregation of another work not based on the Program with the Program (or with a work based on the Program) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

3. You may copy and distribute the Program (or a work based on it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you also do one of the following:

a) Accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

b) Accompany it with a written offer, valid for at least three years, to give any third party, for a charge no more than your cost of physically performing source distribution, a complete machine-readable copy of the corresponding source code, to be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

c) Accompany it with the information you received as to the offer to distribute corresponding source code. (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form with such an offer, in accord with Subsection b above.)

The source code for a work means the preferred form of the work for making modifications to it. For an executable work, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the executable. However, as a special exception, the source code distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

If distribution of executable or object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place counts as distribution of the source code, even though third parties are not compelled to copy the source along with the object code.

4. You may not copy, modify, sublicense, or distribute the Program except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense or distribute the Program is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.

5. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Program or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Program (or any work based on the Program), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Program or works based on it.

6. Each time you redistribute the Program (or any work based on the Program), the recipient automatically receives a license from the original licensor to copy, distribute or modify the Program subject to these terms and conditions. You may not impose any further restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties to this License.

7. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Program at all. For example, if a patent license would not permit royalty-free redistribution of the Program by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Program.

If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply and the section as a whole is intended to apply in other circumstances.

It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system, which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and a licensee cannot impose that choice.

This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

8. If the distribution and/or use of the Program is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Program under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.

9. The Free Software Foundation may publish revised and/or new versions of the General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Program specifies a version number of this License which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Program does not specify a version number of this License, you may choose any version ever published by the Free Software Foundation.

10. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

NO WARRANTY

11. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU. SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

12. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

# GNU Lesser General Public License

Version 2.1, February 1999

Copyright (C) 1991, 1999 Free Software Foundation, Inc.

51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA

Everyone is permitted to copy and distribute verbatim copies of this license document, but changing it is not allowed.

[This is the first released version of the Lesser GPL. It also counts as the successor of the GNU Library Public License, version 2, hence the version number 2.1.]

Preamble:

The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public Licenses are intended to guarantee your freedom to share and change free software--to make sure the software is free for all its users.

This license, the Lesser General Public License, applies to some specially designated software packages--typically libraries--of the Free Software Foundation and other authors who decide to use it. You can use it too, but we suggest you first think carefully about whether this license or the ordinary General Public License is the better strategy to use in any particular case, based on the explanations below.

When we speak of free software, we are referring to freedom of use, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish); that you receive source code or can get it if you want it; that you can change the software and use pieces of it in new free programs; and that you are informed that you can do these things.

To protect your rights, we need to make restrictions that forbid distributors to deny you these rights or to ask you to surrender these rights. These restrictions translate to certain responsibilities for you if you distribute copies of the library or if you modify it.

For example, if you distribute copies of the library, whether gratis or for a fee, you must give the recipients all the rights that we gave you. You must make sure that they, too, receive or can get the source code. If you link other code with the library, you must provide complete object files to the recipients, so that they can relink them with the library after making changes to the library and recompiling it. And you must show them these terms so they know their rights.

We protect your rights with a two-step method: (1) we copyright the library, and (2) we offer you this license, which gives you legal permission to copy, distribute and/or modify the library.

To protect each distributor, we want to make it very clear that there is no warranty for the free library. Also, if the library is modified by someone else and passed on, the recipients should know that what they have is not the original version, so that the original author's reputation will not be affected by problems that might be introduced by others.

Finally, software patents pose a constant threat to the existence of any free program. We wish to make sure that a company cannot effectively restrict the users of a free program by obtaining a restrictive license from a patent holder. Therefore, we insist that any patent license obtained for a version of the library must be consistent with the full freedom of use specified in this license.

Most GNU software, including some libraries, is covered by the ordinary GNU General Public License. This license, the GNU Lesser General Public License, applies to certain designated libraries, and is quite different from the ordinary General Public License. We use this license for certain libraries in order to permit linking those libraries into non-free programs.

When a program is linked with a library, whether statically or using a shared library, the combination of the two is legally speaking a combined work, a derivative of the original library. The ordinary General Public License therefore permits such linking only if the entire combination fits its criteria of freedom. The Lesser General Public License permits more lax criteria for linking other code with the library.

We call this license the "Lesser" General Public License because it does Less to protect the user's freedom than the ordinary General Public License. It also provides other free software developers Less of an advantage over competing non-free programs. These disadvantages are the reason we use the ordinary General Public License for many libraries. However, the Lesser license provides advantages in certain special circumstances.

For example, on rare occasions, there may be a special need to encourage the widest possible use of a certain library, so that it becomes a de-facto standard. To achieve this, non-free programs must be allowed to use the library. A more frequent case is that a free library does the same job as widely used non-free libraries. In this case, there is little to gain by limiting the free library to free software only, so we use the Lesser General Public License.

In other cases, permission to use a particular library in non-free programs enables a greater number of people to use a large body of free software. For example, permission to use the GNU C Library in non-free programs enables many more people to use the whole GNU operating system, as well as its variant, the GNU/Linux operating system.

Although the Lesser General Public License is Less protective of the users' freedom, it does ensure that the user of a program that is linked with the Library has the freedom and the wherewithal to run that program using a modified version of the Library.

The precise terms and conditions for copying, distribution and modification follow. Pay close attention to the difference between a "work based on the library" and a "work that uses the library". The former contains code derived from the library, whereas the latter must be combined with the library in order to run.

TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

0. This License Agreement applies to any software library or other program which contains a notice placed by the copyright holder or other authorized party saying it may be distributed under the terms of this Lesser General Public License (also called "this License"). Each licensee is addressed as "you".

A "library" means a collection of software functions and/or data prepared so as to be conveniently linked with application programs (which use some of those functions and data) to form executables.

The "Library", below, refers to any such software library or work which has been distributed under these terms. A "work based on the Library" means either the Library or any derivative work under copyright law: that is to say, a work containing the Library or a portion of it, either verbatim or with modifications and/or translated straightforwardly into another language. (Hereinafter, translation is included without limitation in the term "modification".)

"Source code" for a work means the preferred form of the work for making modifications to it. For a library, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the library.

Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running a program using the Library is not restricted, and output from such a program is covered only if its contents constitute a work based on the Library (independent of the use of the Library in a tool for writing it). Whether that is true depends on what the Library does and what the program that uses the Library does.

1. You may copy and distribute verbatim copies of the Library's complete source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and distribute a copy of this License along with the Library.

You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

2. You may modify your copy or copies of the Library or any portion of it, thus forming a work based on the Library, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:

* a) The modified work must itself be a software library.

* b) You must cause the files modified to carry prominent notices stating that you changed the files and the date of any change.

* c) You must cause the whole of the work to be licensed at no charge to all third parties under the terms of this License.

* d) If a facility in the modified Library refers to a function or a table of data to be supplied by an application program that uses the facility, other than as an argument passed when the facility is invoked, then you must make a good faith effort to ensure that, in the event an application does not supply such function or table, the facility still operates, and performs whatever part of its purpose remains meaningful.

(For example, a function in a library to compute square roots has a purpose that is entirely well-defined independent of the application. Therefore, Subsection 2d requires that any application-supplied function or table used by this function must be optional: if the application does not supply it, the square root function must still compute square roots.)

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Library, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Library, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Library.

In addition, mere aggregation of another work not based on the Library with the Library (or with a work based on the Library) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

3. You may opt to apply the terms of the ordinary GNU General Public License instead of this License to a given copy of the Library. To do this, you must alter all the notices that refer to this License, so that they refer to the ordinary GNU General Public License, version 2, instead of to this License. (If a newer version than version 2 of the ordinary GNU General Public License has appeared, then you can specify that version instead if you wish.) Do not make any other change in these notices.

Once this change is made in a given copy, it is irreversible for that copy, so the ordinary GNU General Public License applies to all subsequent copies and derivative works made from that copy.

This option is useful when you wish to copy part of the code of the Library into a program that is not a library.

4. You may copy and distribute the Library (or a portion or derivative of it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange.

If distribution of object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place satisfies the requirement to distribute the source code, even though third parties are not compelled to copy the source along with the object code.

5. A program that contains no derivative of any portion of the Library, but is designed to work with the Library by being compiled or linked with it, is called a "work that uses the Library". Such a work, in isolation, is not a derivative work of the Library, and therefore falls outside the scope of this License.

However, linking a "work that uses the Library" with the Library creates an executable that is a derivative of the Library (because it contains portions of the Library), rather than a "work that uses the library". The executable is therefore covered by this License. Section 6 states terms for distribution of such executables.

When a "work that uses the Library" uses material from a header file that is part of the Library, the object code for the work may be a derivative work of the Library even though the source code is not. Whether this is true is especially significant if the work can be linked without the Library, or if the work is itself a library. The threshold for this to be true is not precisely defined by law.

If such an object file uses only numerical parameters, data structure layouts and accessors, and small macros and small inline functions (ten lines or less in length), then the use of the object file is unrestricted, regardless of whether it is legally a derivative work. (Executables containing this object code plus portions of the Library will still fall under Section 6.)

Otherwise, if the work is a derivative of the Library, you may distribute the object code for the work under the terms of Section 6. Any executables containing that work also fall under Section 6, whether or not they are linked directly with the Library itself.

6. As an exception to the Sections above, you may also combine or link a "work that uses the Library" with the Library to produce a work containing portions of the Library, and distribute that work under terms of your choice, provided that the terms permit modification of the work for the customer's own use and reverse engineering for debugging such modifications.

You must give prominent notice with each copy of the work that the Library is used in it and that the Library and its use are covered by this License. You must supply a copy of this License. If the work during execution displays copyright notices, you must include the copyright notice for the Library among them, as well as a reference directing the user to the copy of this License. Also, you must do one of these things:

* a) Accompany the work with the complete corresponding machine-readable source code for the Library including whatever changes were used in the work (which must be distributed under Sections 1 and 2 above); and, if the work is an executable linked with the Library, with the complete machine-readable "work that uses the Library", as object code and/or source code, so that the user can modify the Library and then relink to produce a modified executable containing the modified Library. (It is understood that the user who changes the contents of definitions files in the Library will not necessarily be able to recompile the application to use the modified definitions.)

* b) Use a suitable shared library mechanism for linking with the Library. A suitable mechanism is one that (1) uses at run time a copy of the library already present on the user's computer system, rather than copying library functions into the executable, and (2) will operate properly with a modified version of the library, if the user installs one, as long as the modified version is interface-compatible with the version that the work was made with.

* c) Accompany the work with a written offer, valid for at least three years, to give the same user the materials specified in Subsection 6a, above, for a charge no more than the cost of performing this distribution.

* d) If distribution of the work is made by offering access to copy from a designated place, offer equivalent access to copy the above specified materials from the same place.

* e) Verify that the user has already received a copy of these materials or that you have already sent this user a copy.

For an executable, the required form of the "work that uses the Library" must include any data and utility programs needed for reproducing the executable from it. However, as a special exception, the materials to be distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

It may happen that this requirement contradicts the license restrictions of other proprietary libraries that do not normally accompany the operating system. Such a contradiction means you cannot use both them and the Library together in an executable that you distribute.

7. You may place library facilities that are a work based on the Library side-by-side in a single library together with other library facilities not covered by this License, and distribute such a combined library, provided that the separate distribution of the work based on the Library and of the other library facilities is otherwise permitted, and provided that you do these two things:

* a) Accompany the combined library with a copy of the same work based on the Library, uncombined with any other library facilities. This must be distributed under the terms of the Sections above.

* b) Give prominent notice with the combined library of the fact that part of it is a work based on the Library, and explaining where to find the accompanying uncombined form of the same work.

8. You may not copy, modify, sublicense, link with, or distribute the Library except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense, link with, or distribute the Library is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.

9. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Library or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Library (or any work based on the Library), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Library or works based on it.

10. Each time you redistribute the Library (or any work based on the Library), the recipient automatically receives a license from the original licensor to copy, distribute, link with or modify the Library subject to these terms and conditions. You may not impose any further restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties with this License.

11. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Library at all. For example, if a patent license

would not permit royalty-free redistribution of the Library by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Library.

If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply, and the section as a whole is intended to apply in other circumstances.

It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and a licensee cannot impose that choice.

This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

12. If the distribution and/or use of the Library is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Library under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.

13. The Free Software Foundation may publish revised and/or new versions of the Lesser General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Library specifies a version number of this License which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Library does not specify a license version number, you may choose any version ever published by the Free Software Foundation.

14. If you wish to incorporate parts of the Library into other free programs whose distribution conditions are incompatible with these, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

NO WARRANTY

15. BECAUSE THE LIBRARY IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE LIBRARY, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE LIBRARY "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE LIBRARY IS WITH YOU. SHOULD THE LIBRARY PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

16. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE LIBRARY AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE LIBRARY (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A

FAILURE OF THE LIBRARY TO OPERATE WITH ANY OTHER SOFTWARE), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

# OpenSSH

This file is part of the OpenSSH software.

The licences which components of this software fall under are as follows. First, we will summarize and say that all components are under a BSD licence, or a licence more free than that.

OpenSSH contains no GPL code.

1) Copyright (c) 1995 Tatu Ylonen <ylo@cs.hut.fi>, Espoo, Finland

All rights reserved

As far as I am concerned, the code I have written for this software can be used freely for any purpose. Any derived versions of this software must be clearly marked as such, and if the derived work is incompatible with the protocol description in the RFC file, it must be called by a name other than "ssh" or "Secure Shell".

[Tatu continues]

However, I am not implying to give any licenses to any patents or copyrights held by third parties, and the software includes parts that are not under my direct control. As far as I know, all included source code is used in accordance with the relevant license agreements and can be used freely for any purpose (the GNU license being the most restrictive); see below for details.

[However, none of that term is relevant at this point in time. All of these restrictively licenced software components which he talks about have been removed from OpenSSH, i.e.,

-RSA is no longer included, found in the OpenSSL library

-IDEA is no longer included, its use is deprecated

-DES is now external, in the OpenSSL library

-GMP is no longer used, and instead we call BN code from OpenSSL

-Zlib is now external, in a library

-The make-ssh-known-hosts script is no longer included

-TSS has been removed

-MD5 is now external, in the OpenSSL library

-RC4 support has been replaced with ARC4 support from OpenSSL

-Blowfish is now external, in the OpenSSL library

[The licence continues]

Note that any information and cryptographic algorithms used in this software are publicly available on the Internet and at any major bookstore, scientific library, and patent office worldwide. More information can be found e.g. at "http://www.cs.hut.fi/crypto".

The legal status of this program is some combination of all these permissions and restrictions. Use only at your own responsibility. You will be responsible for any legal consequences yourself; I am not making any claims whether possessing or using this is legal or not in your country, and I am not taking any responsibility on your behalf.

NO WARRANTY

BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU. SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING,

REPAIR OR CORRECTION.

IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

2) The 32-bit CRC compensation attack detector in deattack.c was contributed by CORE SDI S.A. under a BSD-style license.

Cryptographic attack detector for ssh - source code

Copyright (c) 1998 CORE SDI S.A., Buenos Aires, Argentina.

All rights reserved. Redistribution and use in source and binary forms, with or without modification, are permitted provided that this copyright notice is retained.

THIS SOFTWARE IS PROVIDED ``AS IS'' AND ANY EXPRESS OR IMPLIED WARRANTIES ARE DISCLAIMED. IN NO EVENT SHALL CORE SDI S.A. BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY OR CONSEQUENTIAL DAMAGES RESULTING FROM THE USE OR MISUSE OF THIS SOFTWARE.

Ariel Futoransky <futo@core-sdi.com> <http://www.core-sdi.com>

3) ssh-keyscan was contributed by David Mazieres under a BSD-style license.

Copyright 1995, 1996 by David Mazieres <dm@lcs.mit.edu>.

Modification and redistribution in source and binary forms is permitted provided that due credit is given to the author and the OpenBSD project by leaving this copyright notice intact.

4) The Rijndael implementation by Vincent Rijmen, Antoon Bosselaers and Paulo Barreto is in the public domain and distributed with the following license:

@version 3.0 (December 2000)

Optimised ANSI C code for the Rijndael cipher (now AES)

@author Vincent Rijmen <vincent.rijmen@esat.kuleuven.ac.be>

@author Antoon Bosselaers <antoon.bosselaers@esat.kuleuven.ac.be>

@author Paulo Barreto <paulo.barreto@terra.com.br>

This code is hereby placed in the public domain.

THIS SOFTWARE IS PROVIDED BY THE AUTHORS "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE AUTHORS OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

5) One component of the ssh source code is under a 3-clause BSD license, held by the University of California, since we pulled these parts from original Berkeley code.

Copyright (c) 1983, 1990, 1992, 1993, 1995

The Regents of the University of California. All rights reserved.

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:

1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.

2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.

3. Neither the name of the University nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission.

THIS SOFTWARE IS PROVIDED BY THE REGENTS AND CONTRIBUTORS ``AS IS'' AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE REGENTS OR CONTRIBUTORS

BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

6) Remaining components of the software are provided under a standard 2-term BSD licence with the following names as copyright holders:

-Markus Friedl

-Theo de Raadt

-Niels Provos

-Dug Song

-Aaron Campbell

-Damien Miller

-Kevin Steves

-Daniel Kouril

-Wesley Griffin

-Per Allansson

-Nils Nordman

-Simon Wilkinson

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:

1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.

2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.

THIS SOFTWARE IS PROVIDED BY THE AUTHOR ``AS IS'' AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE AUTHOR BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

# PSF

1. This LICENSE AGREEMENT is between the Python Software Foundation ("PSF"), and the Individual or Organization ("Licensee") accessing and otherwise using Python 2.3 software in source or binary form and its associated documentation.

2. Subject to the terms and conditions of this License Agreement, PSF hereby grants Licensee a nonexclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use Python 2.3 alone or in any derivative version, provided, however, that PSF's License Agreement and PSF's notice of copyright, i.e., "Copyright (c) 2001, 2002, 2003 Python Software Foundation; All Rights Reserved" are retained in Python 2.3 alone or in any derivative version prepared by Licensee.

3. In the event Licensee prepares a derivative work that is based on or incorporates Python 2.3 or any part thereof, and wants to make the derivative work available to others as provided herein, then Licensee hereby agrees to include in any such work a brief summary of the changes made to Python 2.3.

4. PSF is making Python 2.3 available to Licensee on an "AS IS" basis. PSF MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, PSF MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF PYTHON 2.3 WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.

5. PSF SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF PYTHON 2.3 FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF MODIFYING, DISTRIBUTING, OR OTHERWISE USING PYTHON 2.3, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.

6. This License Agreement will automatically terminate upon a material breach of its terms and conditions.

7. Nothing in this License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between PSF and Licensee. This License Agreement does not grant permission to use PSF trademarks or trade name in a trademark sense to endorse or promote products or services of Licensee, or any third party.

8. By copying, installing or otherwise using Python 2.3, Licensee agrees to be bound by the terms and conditions of this License Agreement.

# PHP

The PHP License, version 3.01

Copyright (c) 1999 - 2009 The PHP Group. All rights reserved.

Redistribution and use in source and binary forms, with or without modification, is permitted provided that the following conditions are met:

1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.

2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.

3. The name "PHP" must not be used to endorse or promote products derived from this software without prior written permission. For written permission, please contact group@php.net.

4. Products derived from this software may not be called "PHP", nor may "PHP" appear in their name, without prior written permission from group@php.net. You may indicate that your software works in conjunction with PHP by saying "Foo for PHP" instead of calling it "PHP Foo" or "phpfoo"

5. The PHP Group may publish revised and/or new versions of the license from time to time. Each version will be given a distinguishing version number. Once covered code has been published under a particular version of the license, you may always continue to use it under the terms of that version. You may also choose to use such covered code under the terms of any subsequent version of the license published by the PHP Group. No one other than the PHP Group has the right to modify the terms applicable to covered code created under this License.

6. Redistributions of any form whatsoever must retain the following acknowledgment: "This product includes PHP software, freely available from <http://www.php.net/software/>".

THIS SOFTWARE IS PROVIDED BY THE PHP DEVELOPMENT TEAM ``AS IS'' AND ANY EXPRESSED OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE PHP DEVELOPMENT TEAM OR ITS CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

This software consists of voluntary contributions made by many individuals on behalf of the PHP Group.

The PHP Group can be contacted via Email at group@php.net.

For more information on the PHP Group and the PHP project, please see <http://www.php.net>.

PHP includes the Zend Engine, freely available at <http://www.zend.com>.

# PAN-OS® Administrator's Guide
Version 6.0

## Contact Information

**Corporate Headquarters:**
Palo Alto Networks
4401 Great America Parkway
Santa Clara, CA 95054

www.paloaltonetworks.com/company/contact-us

## About this Guide

This guide provides the concepts and solutions to help you get the most out of your Palo Alto Networks next-generation firewalls. For additional information, refer to the following resources:

- For start-to-finish instruction on how to set up a new firewall, refer to the Palo Alto Networks Getting Started Guide.
- For information on the additional capabilities and for instructions on configuring the features on the firewall, refer to https://www.paloaltonetworks.com/documentation.
- For access to the knowledge base, discussion forums, and videos, refer to https://live.paloaltonetworks.com.
- For contacting support, for information on support programs, to manage your account or devices, or to open a support case, refer to https://www.paloaltonetworks.com/support/tabs/overview.html.
- For the most current PAN-OS 6.0 release notes, go to https://www.paloaltonetworks.com/documentation/60/pan-os/pan-os-6-0-release-notes.html.

To provide feedback on the documentation, please write to us at: documentation@paloaltonetworks.com.

# Getting Started

The following sections provide detailed steps to help you deploy a new Palo Alto Networks next-generation firewall. They provide details for integrating a new firewall into your network and configuring basic security policies and threat prevention features.

After you perform the basic configuration steps required to integrate the firewall into your network, you can use the rest of the topics in this guide to help you deploy the comprehensive enterprise security platform features as necessary to address your network security needs.

- Integrate the Firewall into Your Management Network
- Create the Security Perimeter
- Enable Basic Threat Prevention Features
- Best Practices for Completing the Firewall Deployment

# Integrate the Firewall into Your Management Network

The following topics describe how to perform the initial configuration steps that are necessary to integrate a new firewall into the management network and deploy it in a basic security configuration.

The following topics describe how to integrate a single Palo Alto Networks next-generation firewall into your network. For details on how to deploy a pair of firewalls in a high availability configuration, read the information in HA documentation before proceeding.

- Set Up Management Access to the Firewall
- Activate Firewall Services

© Palo Alto Networks, Inc.

# Set Up Management Access to the Firewall

All Palo Alto Networks firewalls provide an out-of-band management port (MGT) that you can use to perform the firewall administration functions. By using the MGT port, you separate the management functions of the firewall from the data processing functions, safeguarding access to the firewall and enhancing performance. When using the web interface, you must perform all initial configuration tasks from the MGT port even if you plan to use an in-band port for managing your device going forward.

Some management tasks, such as retrieving licenses and updating the threat and application signatures on the firewall require access to the Internet. If you do not want to enable external access to your MGT port, you will need to either set up a data port to provide access to required external services or plan to manually upload updates regularly.

The following sections provide instructions for setting up management access to the firewall:

- Determine Your Management Strategy
- Perform Initial Configuration
- Set Up Network Access for External Services

## Determine Your Management Strategy

The Palo Alto Networks firewall can be configured and managed locally or it can be managed centrally using Panorama, the Palo Alto Networks centralized security management system. If you have six or more firewalls deployed in your network, use Panorama to achieve the following benefits:

- Reduce the complexity and administrative overhead in managing configuration, policies, software and dynamic content updates. Using device groups and templates on Panorama, you can effectively manage device specific configuration locally on a device and enforce shared policies across all devices or device groups.
- Aggregate data from all managed firewalls and gain visibility across all the traffic on your network. The Application Command Center (**ACC**) on Panorama provides a single glass pane for unified reporting across all the firewalls, allowing you to centrally analyze, investigate and report on network traffic, security incidents and administrative modifications.

The procedures in this document describe how to manage the firewall using the local web interface. If you want to use Panorama for centralized management, after you complete the instructions in the Perform Initial Configuration section of this guide and verify that the firewall can establish a connection to Panorama. From that point on you can use Panorama to configure your firewall centrally.

## Perform Initial Configuration

By default, the firewall has an IP address of 192.168.1.1 and a username/password of admin/admin. For security reasons, you must change these settings before continuing with other firewall configuration tasks. You must perform these initial configuration tasks either from the MGT interface, even if you do not plan to use this interface for your firewall management, or using a direct serial connection to the console port on the device.

| Set Up Network Access to the Firewall | | |
|---|---|---|
| Step 1 | Gather the required information from your network administrator. | • IP address for MGT port<br>• Netmask<br>• Default gateway<br>• DNS server address |
| Step 2 | Connect your computer to the firewall. | You can connect to the firewall in one of the following ways:<br>• Connect a serial cable from your computer to the Console port and connect to the firewall using terminal emulation software (9600-8-N-1). Wait a few minutes for the boot-up sequence to complete; when the device is ready, the prompt changes to the name of the firewall, for example `PA-500 login`.<br>• Connect an RJ-45 Ethernet cable from your computer to the MGT port on the firewall. From a browser, go to `https://192.168.1.1`. Note that you may need to change the IP address on your computer to an address in the 192.168.1.0 network, such as 192.168.1.2, in order to access this URL. |
| Step 3 | When prompted, log in to the firewall. | You must log in using the default username and password (admin/admin). The firewall will begin to initialize. |
| Step 4 | Configure the MGT interface. | 1. Select **Device > Setup > Management** and then click the Edit icon in the Management Interface Settings section of the screen. Enter the **IP Address**, **Netmask**, and **Default Gateway**.<br>2. Set the **Speed** to **auto-negotiate**.<br>3. Select which management services to allow on the interface.<br>Best Practice:<br>Make sure **Telnet** and **HTTP** are not selected because these services use plaintext and are not as secure as the other services.<br>4. Click **OK**. |
| Step 5 | (Optional) Configure general firewall settings. | 1. Select **Device > Setup > Management** and click the Edit icon in the General Settings section of the screen.<br>2. Enter a **Hostname** for the firewall and enter your network **Domain** name. The domain name is just a label; it will not be used to join the domain.<br>3. Enter the **Latitude** and **Longitude** to enable accurate placement of the firewall on the world map.<br>4. Click **OK**. |

 © Palo Alto Networks, Inc.

| Set Up Network Access to the Firewall (Continued) | | |
|---|---|---|
| Step 6 | Configure DNS, time and date settings.<br><br>You must manually configure at least one DNS server on the firewall or it will not be able to resolve hostnames; it will not use DNS server settings from another source, such as an ISP. | 1. Select **Device > Setup > Services** and click the Edit icon in the Services section of the screen.<br>2. On the **Services** tab, enter the IP address of your **Primary DNS Server** and optionally your **Secondary DNS Server**.<br>3. To use the virtual cluster of time servers on the Internet, enter the hostname **pool.ntp.org** as the **Primary NTP Server** or add the IP address of your **Primary NTP Server** and optionally your **Secondary NTP Server**.<br>4. Click **OK** to save your settings. |
| Step 7 | Set a secure password for the admin account. | 1. Select **Device > Administrators.**<br>2. Select the **admin** role.<br>3. Enter the current default password and the new password.<br>4. Click **OK** to save your settings. |
| Step 8 | Commit your changes.<br><br>When the configuration changes are saved, you will lose connectivity to the web interface because the IP address will have changed. | Click **Commit**. The device may take up to 90 seconds to save your changes.<br> |
| Step 9 | Connect the firewall to your network. | 1. Disconnect the firewall from your computer.<br>2. Connect the MGT port to a switch port on your management network using an RJ-45 Ethernet cable. Make sure that the switch port you cable the firewall to is configured for auto-negotiation. |
| Step 10 | Open an SSH management session to the firewall. | Using a terminal emulation software, such as PuTTY, launch an SSH session to the firewall using the new IP address you assigned to it. |
| Step 11 | Verify network access to external services required for firewall management, such as the Palo Alto Networks Update Server, in one of the following ways:<br>• If you do not want to allow external network access to the MGT interface, you will need to set up a data port to retrieve required service updates. Continue to Set Up Network Access for External Services.<br>• If you do plan to allow external network access to the MGT interface, verify that you have connectivity and then proceed to Activate Firewall Services. | If you cabled your MGT port for external network access, verify that you have access to and from the firewall by using the ping utility from the CLI. Make sure you have connectivity to the default gateway, DNS server, and the Palo Alto Networks Update Server as shown in the following example:<br>`admin@PA-200> ping host updates.paloaltonetworks.com`<br>`PING updates.paloaltonetworks.com (67.192.236.252) 56(84) bytes of data.`<br>`64 bytes from 67.192.236.252 : icmp_seq=1 ttl=243 time=40.5 ms`<br>`64 bytes from 67.192.236.252 : icmp_seq=1 ttl=243 time=53.6 ms`<br>`64 bytes from 67.192.236.252 : icmp_seq=1 ttl=243 time=79.5 ms`<br>After you have verified connectivity, press Ctrl+C to stop the pings. |

## Set Up Network Access for External Services

By default, the firewall uses the MGT interface to access remote services, such as DNS servers, content updates, and license retrieval. If you do not want to enable external network access to your management network, you must set up a data port to provide access to these required external services.

This task requires familiarity with firewall interfaces, zones, and policies. For more information on these topics, see Create the Security Perimeter.

| Set Up a Data Port for Access to External Services | | |
|---|---|---|
| Step 1 | Decide which port you want to use for access to external services and connect it to your switch or router port. | The interface you use will need to have a static IP address. |
| Step 2 | Log in to the web interface. | Using a secure connection (https) from your web browser, log in using the new IP address and password you assigned during initial configuration (https://<IP address>). You will see a certificate warning; that is okay. Continue to the web page. |
| Step 3 | (Optional) The firewall comes preconfigured with a default virtual wire interface between ports Ethernet 1/1 and Ethernet 1/2 (and a corresponding default security policy and zones). If you do not plan to use this virtual wire configuration, you must manually delete the configuration to prevent it from interfering with other interface settings you define. | You must delete the configuration in the following order:<br>1. To delete the default security policy, select **Policies > Security**, select the rule, and click **Delete**.<br>2. Next, delete the default virtual wire by selecting **Network > Virtual Wires**, selecting the virtual wire and clicking **Delete**.<br>3. To delete the default trust and untrust zones, select **Network > Zones**, select each zone and click **Delete**.<br>4. Finally, delete the interface configurations by selecting **Network > Interfaces** and then select each interface (ethernet1/1 and ethernet1/2) and click **Delete**.<br>5. **Commit** the changes. |

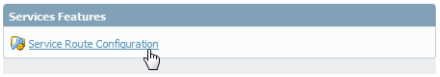
 © Palo Alto Networks, Inc.

| Set Up a Data Port for Access to External Services (Continued) | |
|---|---|
| Step 4 Configure the interface. | 1. Select **Network > Interfaces** and select the interface that corresponds to the port you cabled in Step 1.<br>2. Select the **Interface Type**. Although your choice here depends on your network topology, this example shows the steps for **Layer3**.<br>3. On the **Config** tab, expand the **Security Zone** drop-down and select **New Zone**.<br>4. In the Zone dialog, define a **Name** for new zone, for example L3-trust, and then click **OK**.<br>5. Select the **IPv4** tab, select the **Static** radio button, and click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 192.168.1.254/24.<br>6. Select **Advanced > Other Info**, expand the **Management Profile** drop-down, and select **New Management Profile**.<br>7. Enter a **Name** for the profile, such as allow_ping, and then select the services you want to allow on the interface. These services provide management access to the device, so only select the services that correspond to the management activities you want to allow on this interface. For example, if you plan to use the MGT interface for device configuration tasks through the web interface or CLI, you would not want to enable HTTP, HTTPS, SSH, or Telnet so that you could prevent unauthorized access through this interface. For the purposes of allowing access to the external services you probably only need to enable **Ping** and then click **OK**.<br>8. To save the interface configuration, click **OK**. |

**Set Up a Data Port for Access to External Services (Continued)**

Step 5 Because the firewall uses the MGT interface by default to access the external services it requires, you must change the interface the firewall uses to send these requests by editing the service routes.

1. Select **Device > Setup > Services > Service Route Configuration**.



For the purposes of activating your licenses and getting the most recent content and software updates, you will want to change the service route for **DNS**, **Palo Alto Updates**, **URL Updates**, and **WildFire**.

2. Click the **Customize** radio button, and select one of the following:
   - For a predefined service, select **IPv4** or **IPv6** and click the link for the service for which you want to modify the **Source Interface** and select the interface you just configured.

     If more than one IP address is configured for the selected interface, the **Source Address** drop-down allows you select an IP address.
   - To create a service route for a custom destination, select **Destination**, and click **Add**. Enter a **Destination** name and select a **Source Interface**. If more than one IP address is configured for the selected interface, the **Source Address** drop-down allows you select an IP address.
3. Click **OK** to save the settings.
4. Repeat steps 2-3 above for each service route you want to modify.
5. **Commit** your changes.

 © Palo Alto Networks, Inc.

**Set Up a Data Port for Access to External Services (Continued)**

Step 6 Configure an external-facing interface and an associated zone and then create security and NAT policy rules to allow the firewall to send service requests from the internal zone to the external zone:

1. Select **Network > Interfaces** and then select your external-facing interface. Select **Layer3** as the **Interface Type**, **Add** the **IP** address (on the **IPv4** or **IPv6** tab), and create the associated **Security Zone** (on the **Config** tab), such as l3-untrust. You do not need to set up management services on this interface.
2. To set up a security rule that allows traffic from your internal network to the Palo Alto Networks update server and external DNS servers, select **Policies > Security** and click **Add**. For the purposes of initial configuration, you can create a simple rule that allows all traffic from l3-trust to l3-untrust as follows:

3. If you are using a private IP address on the internal-facing interface, you will need to create a source NAT rule to translate the address to a publicly routable address. Select **Policies > NAT** and then click **Add**. At a minimum you must define a name for the rule (**General** tab), specify a source and destination zone, l3-trust to l3-untrust in this case (**Original Packet** tab), and define the source address translation settings (**Translated Packet** tab) and then click **OK**. For more information on NAT, see Configure NAT Policies.

4. **Commit** your changes.

| | | |
|---|---|---|
| Step 7 | Verify that you have connectivity from the data port to the external services, including the default gateway, DNS server, and the Palo Alto Networks Update Server.<br><br>After you verify you have the required network connectivity, continue to Activate Firewall Services. | Launch the CLI and use the ping utility to verify that you have connectivity. Keep in mind that by default pings are sent from the MGT interface, so in this case you must specify the source interface for the ping requests as follows:<br>`admin@PA-200> ping source 192.168.1.254 host updates.paloaltonetworks.com`<br>`PING updates.paloaltonetworks.com (67.192.236.252) from 192.168.1.254 : 56(84) bytes of data.`<br>`64 bytes from 67.192.236.252: icmp_seq=1 ttl=242 time=56.7 ms`<br>`64 bytes from 67.192.236.252: icmp_seq=2 ttl=242 time=47.7 ms`<br>`64 bytes from 67.192.236.252: icmp_seq=3 ttl=242 time=47.6 ms`<br>`^C`<br><br>After you have verified connectivity, press Ctrl+C to stop the pings. |

# Activate Firewall Services

Before you can begin using the firewall to secure your network, you must register it and activate the licenses for the services you have purchased. In addition, you should ensure that you are running the appropriate version of PAN-OS as described in the following sections:

- Register With Palo Alto Networks
- Activate Licenses
- Manage Content Updates
- Install Software Updates

## Register With Palo Alto Networks

| Register the Firewall | | |
|---|---|---|
| Step 1 | Log in to the web interface. | Using a secure connection (https) from your web browser, log in using the new IP address and password you assigned during initial configuration (https://<IP address>). You will see a certificate warning; that is okay. Continue to the web page. |
| Step 2 | Locate your serial number and copy it to the clipboard. | On the **Dashboard**, locate your **Serial Number** in the General Information section of the screen. |
| Step 3 | Go to the Palo Alto Networks Support site. | In a new browser tab or window, go to https://support.paloaltonetworks.com. |
| Step 4 | Register the device. The way you register depends on whether you already have a login to the support site. | • If this is the first Palo Alto Networks device you are registering and you do not yet have a login, click **Register** on the right side of the page. To register, you must provide your sales order number or customer ID, and the serial number of your firewall (which you can paste from your clipboard) or the authorization code you received with your order. You will also be prompted to set up a username and password for access to the Palo Alto Networks support community.<br>• If you already have a support account, log in and then click **My Devices**. Scroll down to Register Device section at the bottom of the screen and enter the serial number of your firewall (which you can paste from your clipboard), your city and postal code and then click **Register Device**. |

## Activate Licenses

Before you can start using your firewall to secure the traffic on your network, you must activate the licenses for each of the services you purchased. Available licenses and subscriptions include the following:

- Threat Prevention—Provides antivirus, anti-spyware, and vulnerability protection.

 © Palo Alto Networks, Inc.

- Decryption Port Mirroring—Provides the ability to create a copy of decrypted traffic from a firewall and send it to a traffic collection tool that is capable of receiving raw packet captures—such as NetWitness or Solera—for archiving and analysis.
- URL Filtering—In order to create policy rules based on dynamic URL categories, you must purchase and install a subscription for one of the supported URL filtering databases: PAN-DB or BrightCloud. For more information about URL filtering, see Control Access to Web Content.
- **Virtual Systems**—This license is required to enable support for multiple virtual systems on PA-2000 and PA-3000 Series firewalls. In addition, you must purchase a Virtual Systems license if you want to increase the number of virtual systems beyond the base number provided by default on PA-4000 Series, PA-5000 Series, and PA-7050 firewalls (the base number varies by platform). The PA-500, PA-200, and VM-Series firewalls do not support virtual systems.
- WildFire—Although basic WildFire support is included as part of the Threat Prevention license, the WildFire subscription service provides enhanced services for organizations that require immediate coverage for threats, enabling sub-hourly WildFire signature updates, advanced file type forwarding (APK, PDF, Microsoft Office, and Java Applet), as well as the ability to upload files using the WildFire API. A WildFire subscription is also required if your firewalls will be forwarding files to a private WF-500 WildFire appliance.
- GlobalProtect—Provides mobility solutions and/or large-scale VPN capabilities. By default, you can deploy a single GlobalProtect portal and gateway (without HIP checks) without a license. However, if you want to deploy multiple gateways, you must purchase a portal license (one-time, permanent license). If you want to use host checks you will also need gateway licenses (subscription) for each gateway.

| **Activate Licenses** | | |
|---|---|---|
| Step 1 | Locate the activation codes for the licenses you purchased. | When you purchased your subscriptions you should have received an email from Palo Alto Networks customer service listing the activation code associated with each subscription. If you cannot locate this email, contact customer support to obtain your activation codes before you proceed. |
| Step 2 | Launch the web interface and go to the license page. | Select **Device > Licenses**. |
| Step 3 | Activate each license you purchased.<br> If your firewall does not have Internet access from the management port, you can manually download your license files from the support site and upload them to your firewall using the **Manually upload license key** option. | 1. Select **Activate feature using authorization code**.<br>2. When prompted, enter the **Authorization Code** and then click **OK**.<br>3. Verify that the license was successfully activated. For example, after activating the WildFire license, you should see that the license is valid:<br> |

## Manage Content Updates

In order to stay ahead of the changing threat and application landscape, Palo Alto Networks maintains a Content Delivery Network (CDN) infrastructure for delivering content updates to the Palo Alto Networks devices. The devices access the web resources in the CDN to perform various App-ID and Content-ID functions. By default, the devices use the management port to access the CDN infrastructure for application updates, threat and antivirus signature updates, BrightCloud and PAN-DB database updates and lookups, and access to the Palo Alto Networks WildFire Cloud. To ensure that you are always protected from the latest threats (including those that have not yet been discovered), you must ensure that you keep your devices up-to-date with the latest updates published by Palo Alto Networks.

The following content updates are available, depending on which subscriptions you have:

Although you can manually download and install content updates at any time, as a best practice you should schedule updates to occur automatically.

- **Antivirus**—Includes new and updated antivirus signatures, including signatures discovered by the WildFire cloud service. You must have a Threat Prevention subscription to get these updates. New antivirus signatures are published daily.
- **Applications**—Includes new and updated application signatures. This update does not require any additional subscriptions, but it does require a valid maintenance/support contract. New application updates are published weekly.
- **Applications and Threats**—Includes new and updated application and threat signatures. This update is available if you have a Threat Prevention subscription (and you get it instead of the Applications update). New Applications and Threats updates are published weekly.
- **GlobalProtect Data File**—Contains the vendor-specific information for defining and evaluating host information profile (HIP) data returned by GlobalProtect agents. You must have a GlobalProtect portal and GlobalProtect gateway license in order to receive these updates. In addition, you must create a schedule for these updates before GlobalProtect will function.
- **BrightCloud URL Filtering**—Provides updates to the BrightCloud URL Filtering database only. You must have a BrightCloud subscription to get these updates. New BrightCloud URL database updates are published daily. If you have a PAN-DB license, scheduled updates are not required as devices remain in-sync with the servers automatically.
- **WildFire**—Provides near real-time malware and antivirus signatures created as a result of the analysis done by the WildFire cloud service. Without the subscription, you must wait 24 to 48 hours for the signatures to roll into the Applications and Threat update.

If your firewall does not have Internet access from the management port, you can download content updates from the Palo Alto Networks Support Site (https://support.paloaltonetworks.com) and then Upload them to your firewall.

If your firewall is deployed behind existing firewalls or proxy servers, access to these external resources might be restricted using access control lists that allow the firewall to only access a hostname or an IP address. In such cases, to allow access to the CDN, set the update server address to use the hostname staticupdates.paloaltonetworks.com or the IP address `199.167.52.15`

 © Palo Alto Networks, Inc.

| Download the Latest Databases | | |
|---|---|---|
| Step 1 | Verify that the firewall points to the CDN infrastructure. | Select **Device > Setup > Services**.<br>• As a best practice, set the **Update Server** to access `updates.paloaltonetworks.com`. This allows the firewall to receive content updates from the server to which it is closest in the CDN infrastructure.<br>• (Optional) If the firewall has restricted access to the internet, set the update server address to use the hostname staticupdates.paloaltonetworks.com or the IP address 199.167.52.15. For additional security, select Verify Update Server Identity. The firewall verifies that the server from which the software or content package is download has an SSL certificate signed by a trusted authority. |
| Step 2 | Launch the web interface and go to the Dynamic Updates page. | Select **Device > Dynamic Updates**. |
| Step 3 | Check for the latest updates. | Click **Check Now** (located in the lower left-hand corner of the window) to check for the latest updates. The link in the **Action** column indicates whether an update is available:<br>• **Download**—Indicates that a new update file is available. Click the link to begin downloading the file directly to the firewall. After successful download, the link in the **Action** column changes from **Download** to **Install**.<br> <br>You cannot download the antivirus database until you have installed the Application and Threats database.<br>• **Upgrade**—Indicates that there is a new version of the BrightCloud database available. Click the link to begin the download and installation of the database. The database upgrade begins in the background; when completed a check mark displays in the **Currently Installed** column. Note that if you are using PAN-DB as your URL filtering database you will not see an upgrade link because the PAN-DB database automatically stays in sync with the server.<br> <br>To check the status of an action, click **Tasks** (on the lower right-hand corner of the window).<br>• **Revert**—Indicates that the corresponding software version has been downloaded previously. You can choose to revert to the previously installed version of the update. |

**Download the Latest Databases (Continued)**

Step 4 Install the updates.

Installation can take up to 20 minutes on a PA-200, PA-500, or PA-2000 device and up to two minutes on a PA-3000 Series, PA-4000 Series, PA-5000 Series, PA-7050, or VM-Series firewall.

Click the **Install** link in the **Action** column. When the installation completes, a check mark displays in the **Currently Installed** column.

Step 5 Schedule each update.

Repeat this step for each update you want to schedule.

Best Practice:

Stagger the update schedules because the firewall can only download one update at a time. If you schedule the updates to download during the same time interval, only the first download will succeed.

1. Set the schedule of each update type by clicking the **None** link.

2. Specify how often you want the updates to occur by selecting a value from the **Recurrence** drop-down. The available values vary by content type (WildFire updates are available **Every 15 minutes**, **Every 30 minutes** or **Every Hour** whereas all other content types can be scheduled for **Daily** or **Weekly** update).
3. Specify the **Time** and (or, minutes past the hour in the case of WildFire), if applicable depending on the **Recurrence** value you selected, **Day** of the week that you want the updates to occur.
4. Specify whether you want the system to **Download And Install** the update (best practice) or **Download Only**.
5. In rare instances, errors in content updates may be found. For this reason, you may want to delay installing new updates until they have been released for a certain number of hours. You can specify how long after a release to wait before performing a content update by entering the number of hours to wait in the **Threshold (Hours)** field.
6. Click **OK** to save the schedule settings.
7. Click **Commit** to save the settings to the running configuration.

## Install Software Updates

When installing a new firewall, it is a good idea to upgrade to the latest software update (or to the update version recommended by your reseller or Palo Alto Networks Systems Engineer) to take advantage of the latest fixes and security enhancements. Note that before updating the software, you should first make sure you have the latest content updates as detailed in the previous section (the release notes for a software update specify the minimum content update versions that are supported in the release).

 © Palo Alto Networks, Inc.

| Update PAN-OS | | |
|---|---|---|
| Step 1 | Launch the web interface and go to the Software page. | Select **Device > Software**. |
| Step 2 | Check for software updates. | Click **Check Now** to check for the latest updates. If the value in the **Action** column is **Download** it indicates that an update is available. |
| Step 3 | Download the update.<br><br>If your firewall does not have Internet access from the management port, you can download the software update from the Palo Alto Networks Support Site (https://support.paloaltonetworks.com). You can then manually **Upload** them to your firewall. | Locate the version you want and then click **Download**. When the download completes, the value in the Action column changes to **Install**.<br> |
| Step 4 | Install the update. | 1. Click **Install**.<br>2. Reboot the firewall:<br>• If you are prompted to reboot, click **Yes**.<br> <br>• If you are not prompted to reboot, select **Device > Setup > Operations** and click **Reboot Device** in the Device Operations section of the screen.<br> |

# Create the Security Perimeter

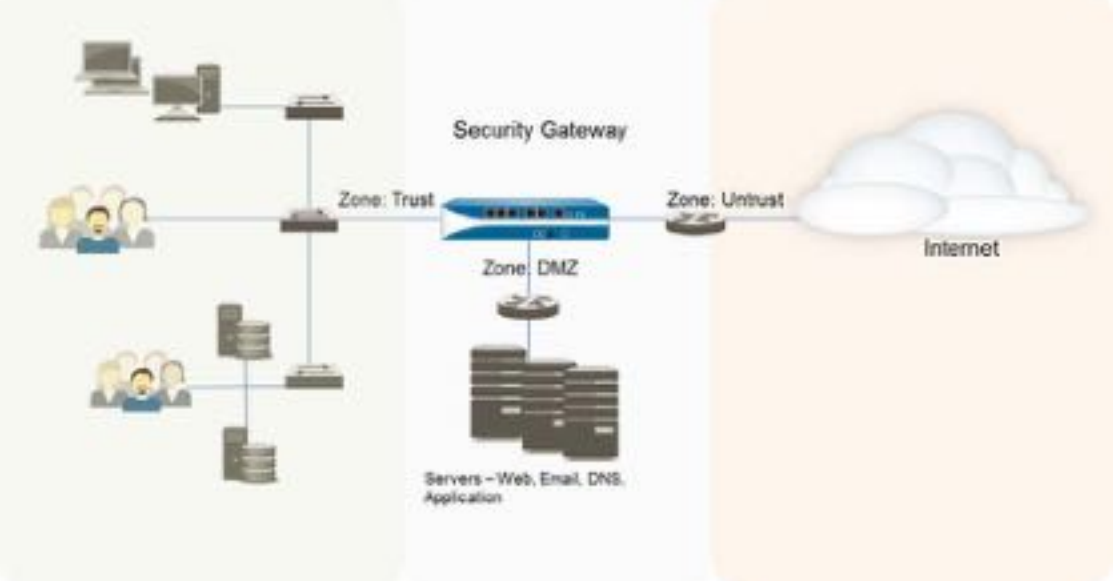
The following topics provide basic steps for configuring the firewall interfaces, defining zones, and setting up a basic security policy:

- Security Perimeter Overview
- Configure NAT Policies
- Set Up Basic Security Policies

© Palo Alto Networks, Inc.

## Security Perimeter Overview

Traffic must pass through the firewall in order for the firewall to manage and control it. Physically, traffic enters and exits the firewall through *interfaces*. The firewall decides how to act on a packet based on whether the packet matches a *security policy*. At the most basic level, the security policy must identify where the traffic came from and where it is going. On a Palo Alto Networks next-generation firewall, security policies are applied between zones. A *zone* is a grouping of interfaces (physical or virtual) that provides an abstraction for an area of trust for simplified policy enforcement. For example, in the following topology diagram, there are three zones: Trust, Untrust, and DMZ. Traffic can flow freely within a zone, but traffic will not be able to flow between zones until you define a security policy that allows it.



The following sections describe the components of the security perimeter and provide steps for configuring the firewall interfaces, defining zones, and setting up a basic security policy that allows traffic from your internal zone to the Internet and to the DMZ. By initially creating a basic policy like this, you will be able to analyze the traffic running through your network and use this information to define more granular policies for safely enabling applications while preventing threats.

- Basic Interface Deployments
- About Network Address Translation (NAT)
- About Security Policies

# Basic Interface Deployments

All Palo Alto Networks next-generation firewalls provide a flexible networking architecture that includes support for dynamic routing, switching, and VPN connectivity, enabling you to deploy the firewall into nearly any networking environment. When configuring the Ethernet ports on your firewall, you can choose from virtual wire, Layer 2, or Layer 3 interface deployments. In addition, to allow you to integrate into a variety of network segments, you can configure different types of interfaces on different ports. The following sections provide basic information on each type of deployment.

- Virtual Wire Deployments
- Layer 2 Deployments
- Layer 3 Deployments

For more detailed deployment information, refer to Designing Networks with Palo Alto Networks Firewalls.

## Virtual Wire Deployments

In a virtual wire deployment, the firewall is installed transparently on a network segment by binding two ports together. By using a virtual wire, you can install the firewall in any network environment without reconfiguring adjacent devices. If necessary, a virtual wire can block or allow traffic based on the virtual LAN (VLAN) tag values. You can also create multiple subinterfaces and classify traffic according to an IP Address (address, range, or subnet), VLAN, or a combination of the two.

By default, the virtual wire (named *default-vwire*) binds Ethernet ports 1 and 2 and allows all untagged traffic. Choose this deployment to simplify installation and configuration and/or avoid configuration changes to surrounding network devices.

A virtual wire is the default configuration, and should be used only when no switching or routing is needed. If you do not plan to use the default virtual wire, you should manually delete the configuration before proceeding with interface configuration to prevent it from interfering with other interface settings you define. For instructions on how to delete the default virtual wire and its associated security policy and zones, see Step 3 in Set Up a Data Port for Access to External Services.

## Layer 2 Deployments

In a Layer 2 deployment, the firewall provides switching between two or more interfaces. Each group of interfaces must be assigned to a VLAN object in order for the firewall to switch between them. The firewall will perform VLAN tag switching when Layer 2 subinterfaces are attached to a common VLAN object. Choose this option when switching is required.

For more information on Layer 2 deployments, refer to the Layer 2 Networking Tech Note and/or the Securing Inter VLAN Traffic Tech Note.

 © Palo Alto Networks, Inc.

## Layer 3 Deployments

In a Layer 3 deployment, the firewall routes traffic between ports. An IP address must be assigned to each interface and a virtual router must be defined to route the traffic. Choose this option when routing is required.

You must assign an IP address to each physical Layer 3 interface you configure. You can also create logical subinterfaces for each physical Layer 3 interface that allows you to segregate the traffic on the interface based on VLAN tag (when VLAN trunking is in use) or by IP address, for example for multi-tenancy.

In addition, because the firewall must route traffic in a Layer 3 deployment, you must configure a virtual router. You can configure the virtual router to participate with dynamic routing protocols (BGP, OSPF, or RIP) as well as adding static routes. You can also create multiple virtual routers, each maintaining a separate set of routes that are not shared between virtual routers, enabling you to configure different routing behaviors for different interfaces.

The configuration example in this chapter illustrates how to integrate the firewall into your Layer 3 network using static routes. For information on other types of routing integrations, refer to the following documents:

- How to Configure OSPF Tech Note
- How to Configure BGP Tech Note

## About Network Address Translation (NAT)

When you use private IP addresses within your internal networks, you must use network address translation (NAT) in order to translate the private addresses to public addresses that can be routed on external networks. In PAN-OS, you create NAT policy rules that instruct the firewall which packets need translation and how to do the translation. The firewall supports both source address and/or port translation and destination address and/or port translation. For more details about the different types of NAT rules, refer to the Understanding and Configuring NAT Tech Note.

It is important to understand the way the firewall applies the NAT and security policies in order to determine what policies you need based on the zones you have defined. Upon ingress, the firewall inspects a packet to see if it matches any of the NAT rules that have been defined, based on source and/or destination zone. It then evaluates and applies any security rules that match the packet based on the original (pre-NAT) source and destination addresses. Finally, it translates the source and/or destination port numbers for any matching NAT rules upon egress. This distinction is important, because it means that the firewall determines what zone a packet is destined for based on the address on the packet, not on the placement of the device based on its internally assigned address.

 © Palo Alto Networks, Inc.

# About Security Policies

Security policies protect network assets from threats and disruptions and aid in optimally allocating network resources for enhancing productivity and efficiency in business processes. On the Palo Alto Networks firewall, security policies determine whether to block or allow a session based on traffic attributes such as the source and destination security zone, the source and destination IP address, the application, user, and the service. By default, intra-zone traffic (that is traffic within the same zone, for example *from* trust *to* trust), is allowed. Traffic between different zones (or inter-zone traffic) is blocked until you create a security policy to allow the traffic.

Security policies are evaluated left to right and from top to bottom. A packet is matched against the first rule that meets the defined criteria; after a match is triggered the subsequent rules are not evaluated. Therefore, the more specific rules must precede more generic ones in order to enforce the best match criteria. Traffic that matches a rule generates a log entry at the end of the session in the traffic log, if logging is enabled for that rule. The logging options are configurable for each rule, and can for example be configured to log at the start of a session instead of, or in addition to, logging at the end of a session.

- Components of a Security Policy
- Policy Best Practices
- About Policy Objects
- About Security Profiles

## Components of a Security Policy

The security policy construct permits a combination of the required and optional components listed below.

| | Field | Description |
|---|---|---|
| **Required Fields** | **Name** | A label that supports up to 31 characters, used to identify the rule. |
| | **Source Zone** | The zone from which the traffic originates. |
| | **Destination Zone** | The zone at which the traffic terminates. If you use NAT, make sure to always reference the post-NAT zone. |
| | **Application** | The application which you wish to control. The firewall uses App-ID, the traffic classification technology, to identify traffic on your network. App-ID provides application control and visibility in creating security policies that block unknown applications, while enabling, inspecting, and shaping those that are allowed. |
| | **Action** | Specifies an *Allow* or *Deny* action for the traffic based on the criteria you define in the rule. |
| **Optional Fields** | **Tag** | A keyword or phrase that allows you to filter security rules. This is handy when you have defined many rules and wish to then review those that are tagged with a particular keyword, for example *Inbound to DMZ*. |
| | **Description** | A text field, up to 255 characters, used to describe the rule. |

| | Field | Description (Continued) |
|---|---|---|
| | **Source IP Address** | Define host IP or FQDN, subnet, named groups, or country-based enforcement. If you use NAT, make sure to always refer to the original IP addresses in the packet (i.e. the pre-NAT IP address). |
| | **Destination IP Address** | The location or destination for the traffic. If you use NAT, make sure to always refer to the original IP addresses in the packet (i.e. the pre-NAT IP address). |
| | **User** | The user or group of users for whom the policy applies. You must have User-ID enabled on the zone. To enable User-ID, see User-ID Overview. |
| | **URL Category** | Using the URL Category as match criteria allows you to customize security profiles (antivirus, anti-spyware, vulnerability, file-blocking, Data Filtering, and DoS) on a per-URL-category basis. For example, you can prevent.exe file download/upload for URL categories that represent higher risk while allowing them for other categories. This functionality also allows you to attach schedules to specific URL categories (allow social-media websites during lunch & after-hours), mark certain URL categories with QoS (financial, medical, and business), and select different log forwarding profiles on a per-URL-category-basis.<br>Although you can manually configure URL categories on your device, to take advantage of the dynamic URL categorization updates available on the Palo Alto Networks firewalls, you must purchase a URL filtering license.<br> To block or allow traffic based on URL category, you must apply a URL Filtering profile to the security policy rules. Define the URL Category as *Any* and attach a URL Filtering profile to the security policy. See Create Security Rules for information on using the default profiles in your security policy and see Control Access to Web Content for more details. |
| | **Service** | Allows you to select a Layer 4 (TCP or UDP) port for the application. You can choose *any*, specify a port, or use *application-default* to permit use of the standards-based port for the application. For example, for applications with well- known port numbers such as DNS, the *application-default* option will match against DNS traffic only on TCP port 53. You can also add a custom application and define the ports that the application can use.<br> For inbound allow rules (for example, from untrust to trust), using *application-default* prevents applications from running on unusual ports and protocols. Application-default is the default option; while the device still checks for all applications on all ports, with this configuration, applications are only allowed on their standard ports/protocols. |
| | **Security Profiles** | Provide additional protection from threats, vulnerabilities, and data leaks. Security profiles are only evaluated for rules that have an *allow* action. |
| | **HIP Profile** (for GlobalProtect) | Allows you to identify clients with Host Information Profile (HIP) and then enforce access privileges. |

 © Palo Alto Networks, Inc.

| | Field | Description (Continued) |
|---|---|---|
| | **Options** | Allow you to define logging for the session, log forwarding settings, change Quality of Service (QoS) markings for packets that match the rule, and schedule when (day and time) the security rule should be in effect. |

## Policy Best Practices

The task of safely enabling Internet access and preventing misuse of web access privileges, and exposure to vulnerabilities and attacks is a continuous process. The key principle when defining policy on the Palo Alto Networks firewall is to use a positive enforcement approach. Positive enforcement implies that you selectively allow what is required for day-to-day business operations as opposed to a negative enforcement approach where you would selectively block everything that is not allowed. Consider the following suggestions when creating policy:

- If you have two or more zones with identical security requirements, combine them into one security rule.
- The ordering of rules is crucial to ensure the best match criteria. Because policy is evaluated top down, the more specific policy must precede the ones that are more general, so that the more specific rule is not *shadowed*. The term shadow refers to a rule that is not evaluated or is skipped because it is placed lower in the policy list. When the rule is placed lower, it is not evaluated because the match criteria was met by another rule that preceded it, thereby shadowing the rule from policy evaluation.
- To restrict and control access to inbound applications, in the security policy, explicitly define the port that the service/application will be listening on.
- Logging for broad allow rules—for example access to well known servers like DNS—can generate a lot of traffic. Hence it is not recommended unless absolutely necessary.
- By default, the firewall creates a log entry at the end of a session. However, you can modify this default behavior and configure the firewall to log at the start of the session. Because this significantly increases the log volume, logging at session start is recommended only when you are troubleshooting an issue. Another alternative for troubleshooting without enabling logging at session start is to use the session browser (**Monitor > Session Browser**) to view the sessions in real time.

## About Policy Objects

A *policy object* is a single object or a collective unit that groups discrete identities such as IP addresses, URLs, applications, or users. With policy objects that are a collective unit, you can reference the object in security policy instead of manually selecting multiple objects one at a time. Typically, when creating a policy object, you group objects that require similar permissions in policy. For example, if your organization uses a set of server IP addresses for authenticating users, you can group the set of server IP addresses as an *address group* policy object and reference the address group in the security policy. By grouping objects, you can significantly reduce the administrative overhead in creating policies.

You can create the following policy objects on the firewall:

| Policy Object | Description |
|---|---|
| Address/Address Group, Region | Allow you to group specific source or destination addresses that require the same policy enforcement. The address object can include an IPv4 or IPv6 address (single IP, range, subnet) or the FQDN. Alternatively, a region can be defined by the latitude and longitude coordinates or you can select a country and define an IP address or IP range. You can then group a collection of address objects to create an *address group* object.<br>You can also use dynamic address groups to dynamically update IP addresses in environments where host IP addresses change frequently. |
| User/User Group | Allow you to create a list of users from the local database or an external database and group them. |
| Application Group and Application Filter | An *Application Filter* allows you to filter applications dynamically. It allows you to filter, and save a group of applications using the attributes defined in the application database on the firewall. For example, you can filter by one or more attributes—category, sub-category, technology, risk, characteristics—and save your application filter. With an application filter, when a PAN-OS content update occurs, any new applications that match your filter criteria are automatically added to your saved application filter.<br>An *Application Group* allows you to create a static group of specific applications that you wish to group together for a group of users or for a particular service. |
| Service/Service Groups | Allows you to specify the source and destination ports and protocol that a service can use. The firewall includes two pre-defined services—service-http and service-https—that use TCP ports 80 and 8080 for HTTP, and TCP port 443 for HTTPS. You can however, create any custom service on any TCP/UDP port of your choice to restrict application usage to specific ports on your network (in other words, you can define the default port for the application).<br> To view the standard ports used by an application, in **Objects > Applications** search for the application and click the link. A succinct description displays. |

Some examples of *address* and *application* policy objects are shown in the security policies that are included in Create Security Rules. For information on the other policy objects, see Enable Basic Threat Prevention Features.

## About Security Profiles

While security policies enable you to allow or deny traffic on your network, security profiles help you define an *allow but scan* rule, which scan allowed applications for threats. When traffic matches the allow rule defined in the security policy, the security profile(s) that are attached to the rule are applied for further content inspection rules such as antivirus checks and data filtering.

Security profiles are not used in the match criteria of a traffic flow. The security profile is applied to scan traffic after the application or category is allowed by the security policy.

The different types of security profiles that can be attached to security policies are: Antivirus, Anti-spyware, Vulnerability Protection, URL Filtering, File Blocking, and Data Filtering. The firewall provides default security profiles that you can use out of the box to begin protecting your network from threats. See Create Security Rules for information on using the default profiles in your security policy. As you get a better understanding about the security needs on your network, you can create custom profiles. See Scan Traffic for Threats for more

 © Palo Alto Networks, Inc.

information.

# Set Up Interfaces and Zones

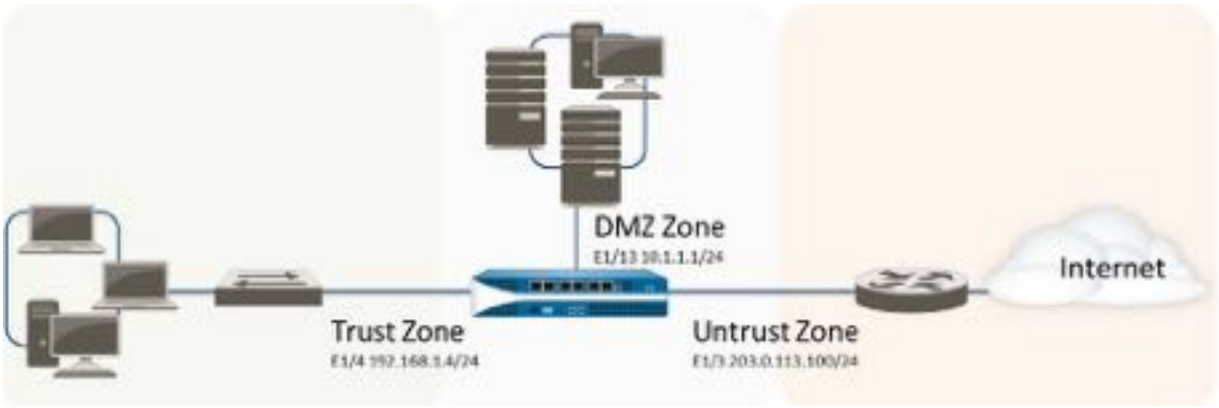
The following sections provide information on configuring interfaces and zones:

- Plan the Deployment
- Configure Interfaces and Zones

## Plan the Deployment

Before you begin configuring interfaces and zones, take some time to plan the zones you will need based on the different usage requirements within your organization. In addition, you should gather all of the configuration information you will need ahead of time. At a basic level, you should plan which interfaces will belong to which zones. For Layer 3 deployments you'll also need to obtain the required IP addresses and network configuration information from your network administrator, including information on how to configure the routing protocol or static routes required for the virtual router configuration. The example in this chapter will be based on the following topology:

**Figure: Layer 3 Topology Example**



The following table shows the information we will use to configure the Layer 3 interfaces and their corresponding zones as shown in the sample topology.

| Zone | Deployment Type | Interface(s) | Configuration Settings |
|---|---|---|---|
| Untrust | L3 | Ethernet1/3 | **IP address:** 203.0.113.100/24<br>**Virtual router:** default<br>**Default route:** 0.0.0.0/0<br>**Next hop:** 203.0.113.1 |
| Trust | L3 | Ethernet1/4 | **IP address:** 192.168.1.4/24<br>**Virtual router:** default |
| DMZ | L3 | Ethernet1/13 | **IP address:** 10.1.1.1/24<br>**Virtual router:** default |

 © Palo Alto Networks, Inc.

## Configure Interfaces and Zones

After you plan your zones and the corresponding interfaces, you can configure them on the device. The way you configure each interface depends on your network topology.

The following procedure shows how to configure a Layer 3 deployment as depicted in Figure: Layer 3 Topology Example.

The firewall comes preconfigured with a default virtual wire interface between ports Ethernet 1/1 and Ethernet 1/2 (and a corresponding default security policy and virtual router). If you do not plan to use the default virtual wire, you must manually delete the configuration and commit the change before proceeding to prevent it from interfering with other settings you define. For instructions on how to delete the default virtual wire and its associated security policy and zones, see Step 3 in Set Up a Data Port for Access to External Services.

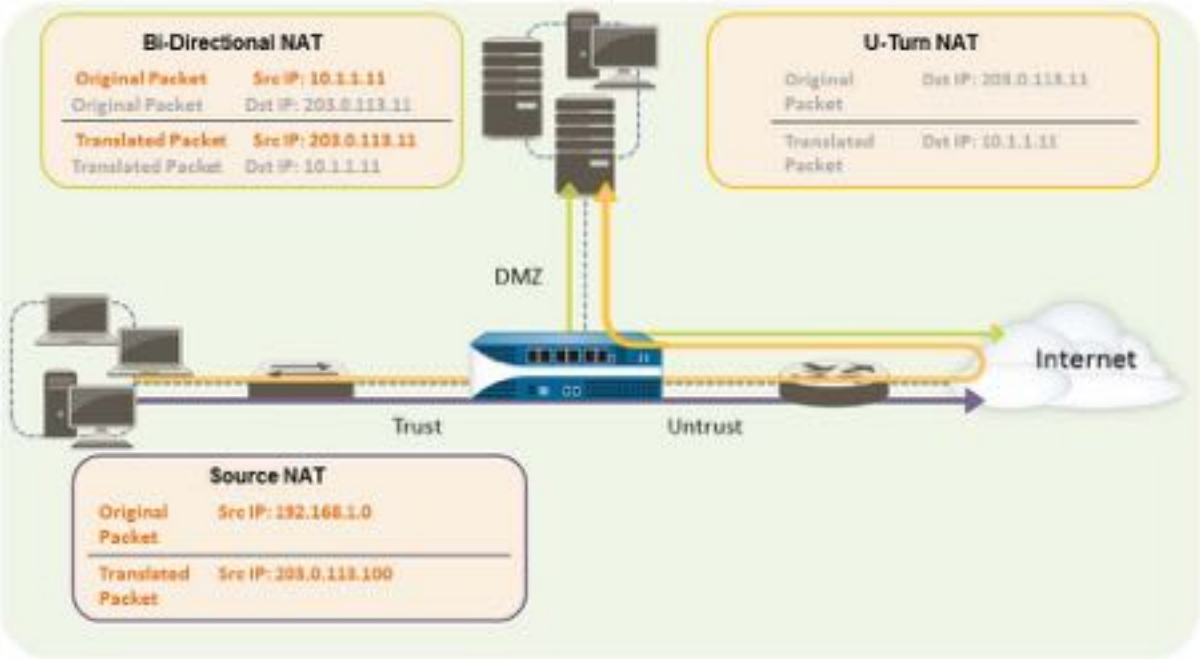
| Set Up Interfaces and Zones | | |
|---|---|---|
| Step 1 | Configure a default route to your Internet router. | 1. Select **Network > Virtual Router** and then select the **default** link to open the Virtual Router dialog.<br>2. Select the **Static Routes** tab and click **Add**. Enter a **Name** for the route and enter the route in the **Destination** field (for example, 0.0.0.0/0).<br>3. Select the **IP Address** radio button in the **Next Hop** field and then enter the IP address and netmask for your Internet gateway (for example, 203.0.113.1).<br>4. Click **OK** twice to save the virtual router configuration. |
| Step 2 | Configure the external interface (the interface that connects to the Internet). | 1. Select **Network > Interfaces** and then select the interface you want to configure. In this example, we are configuring Ethernet1/3 as the external interface.<br>2. Select the **Interface Type**. Although your choice here depends on your network topology, this example shows the steps for **Layer3**.<br>3. On the **Config** tab, select **New Zone** from the **Security Zone** drop-down. In the Zone dialog, define a **Name** for new zone, for example Untrust, and then click **OK**.<br>4. In the **Virtual Router** drop-down, select **default**.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 208.80.56.100/24.<br>6. To enable you to ping the interface, select **Advanced > Other Info**, expand the **Management Profile** drop-down, and select **New Management Profile**. Enter a **Name** for the profile, select **Ping** and then click **OK**.<br>7. To save the interface configuration, click **OK**. |

| Set Up Interfaces and Zones (Continued) | | |
|---|---|---|
| Step 3 | Configure the interface that connects to your internal network.<br><br>In this example, the interface connects to a network segment that uses private IP addresses. Because private IP addresses cannot be routed externally, you will have to configure NAT. See Configure NAT Policies. | 1. Select **Network > Interfaces** and select the interface you want to configure. In this example, we are configuring Ethernet1/4 as the internal interface.<br>2. Select **Layer3** from the **Interface Type** drop down.<br>3. On the **Config** tab, expand the **Security Zone** drop-down and select **New Zone**. In the Zone dialog, define a **Name** for new zone, for example Trust, and then click **OK**.<br>4. Select the same Virtual Router you used in Step 2, default in this example.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 192.168.1.4/24.<br>6. To enable you to ping the interface, select the management profile that you created in Step 2-6.<br>7. To save the interface configuration, click **OK**. |
| Step 4 | Configure the interface that connects to the DMZ. | 1. Select the interface you want to configure.<br>2. Select **Layer3** from the **Interface Type** drop down. In this example, we are configuring Ethernet1/13 as the DMZ interface.<br>3. On the **Config** tab, expand the **Security Zone** drop-down and select **New Zone**. In the Zone dialog, define a **Name** for new zone, for example DMZ, and then click **OK**.<br>4. Select the Virtual Router you used in Step 2, default in this example.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 10.1.1.1/24.<br>6. To enable you to ping the interface, select the management profile that you created in Step 2-6.<br>7. To save the interface configuration, click **OK**. |
| Step 5 | Save the interface configuration. | Click **Commit**. |
| Step 6 | Cable the firewall. | Attach straight through cables from the interfaces you configured to the corresponding switch or router on each network segment. |
| Step 7 | Verify that the interfaces are active.<br><br>  | From the web interface, select **Network > Interfaces** and verify that icon in the Link State column is green. You can also monitor link state from the **Interfaces** widget on the **Dashboard**. |

 © Palo Alto Networks, Inc.

## Configure NAT Policies

Based on the example topology we used to create the interfaces and zones, there are three NAT policies we need to create as follows:



- To enable the clients on the internal network to access resources on the Internet, the internal 192.168.1.0 addresses will need to be translated to publicly routable addresses. In this case, we will configure source NAT, using the egress interface address, 203.0.113.100, as the source address in all packets that leave the firewall from the internal zone. See Translate Internal Client IP Addresses to your Public IP Address for instructions.
- To enable clients on the internal network to access the public web server in the DMZ zone, we will need to configure a NAT rule that redirects the packet from the external network, where the original routing table lookup will determine it should go based on the destination address of 203.0.113.11 within the packet, to the actual address of the web server on the DMZ network of 10.1.1.11. To do this you must create a NAT rule from the trust zone (where the source address in the packet is) to the untrust zone (where the original destination address is) to translate the destination address to an address in the DMZ zone. This type of destination NAT is called *U-Turn NAT*. See Enable Clients on the Internal Network to Access your Public Servers for instructions.
- To enable the web server—which has both a private IP address on the DMZ network and a public-facing address for access by external users—to both send and receive requests, the firewall must translate the incoming packets from the public IP address to the private IP address and the outgoing packets from the private IP address to the public IP address. On the firewall, you can accomplish this with a single bi-directional static source NAT policy. See Enable Bi-Directional Address Translation for your Public-Facing Servers.

## Translate Internal Client IP Addresses to your Public IP Address

When a client on your internal network sends a request, the source address in the packet contains the IP address for the client on your internal network. If you use private IP address ranges internally, the packets from the client will not be able to be routed on the Internet unless you translate the source IP address in the packets leaving the network into a publicly routable address. On the firewall you can do this by configuring a source NAT policy that translates the source address and optionally the port into a public address. One way to do this is to translate the source address for all packets to the egress interface on your firewall as shown in the following procedure.

**Configure Source NAT**

**Step 1** Create an address object for the external IP address you plan to use.

1. From the web interface, select **Objects > Addresses** and then click **Add**.
2. Enter a **Name** and optionally a **Description** for the object.
3. Select **IP Netmask** from the **Type** drop down and then enter the IP address of the external interface on the firewall, 203.0.113.100 in this example.
4. To save the address object, click **OK**.

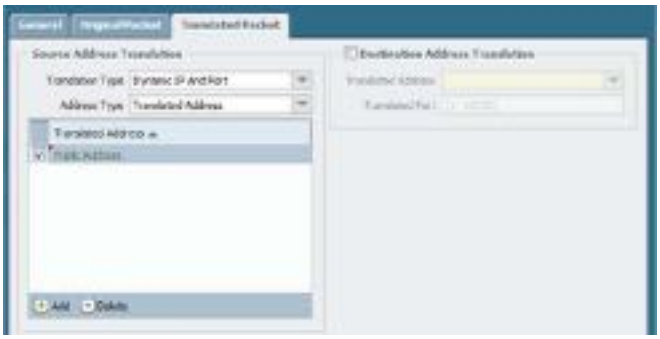
Best Practice:

Although you do not have to use address objects in your policies, it is a best practice because it simplifies administration by allowing you to make updates in one place rather than having to update every policy where the address is referenced.

**Step 2** Create the NAT policy.

1. Select **Policies > NAT** and click **Add**.
2. Enter a descriptive **Name** for the policy.
3. On the **Original Packet** tab, select the zone you created for your internal network in the **Source Zone** section (click **Add** and then select the zone) and the zone you created for the external network from the **Destination Zone** drop down.

4. On the **Translated Packet** tab, select **Dynamic IP And Port** from the **Translation Type** drop-down in the **Source Address Translation** section of the screen and then click **Add**. Select the address object you just created.



5. Click **OK** to save the NAT policy.

**Step 3** Save the configuration. Click **Commit**.

 © Palo Alto Networks, Inc.

## Enable Clients on the Internal Network to Access your Public Servers

When a user on the internal network sends a request for access to the corporate web server in the DMZ, the DNS server will resolve to the public IP address. When processing the request, the firewall will use the original destination in the packet (the public IP address) and route the packet to the egress interface for the untrust zone. In order for the firewall to know that it must translate the public IP address of the web server to an address on the DMZ network when it receives requests from users on the trust zone, you must create a destination NAT rule that will enable the firewall to send the request to the egress interface for the DMZ zone as follows.

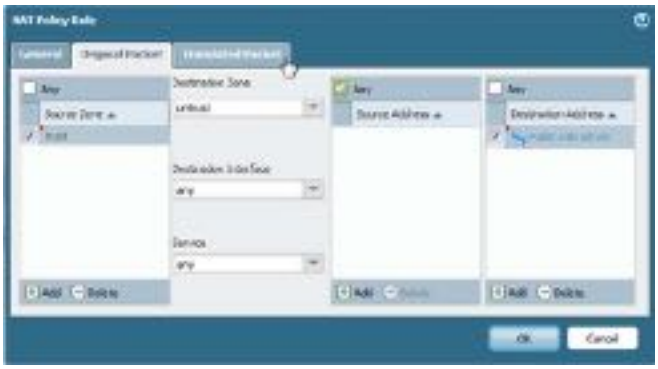
**Configure U-Turn NAT**

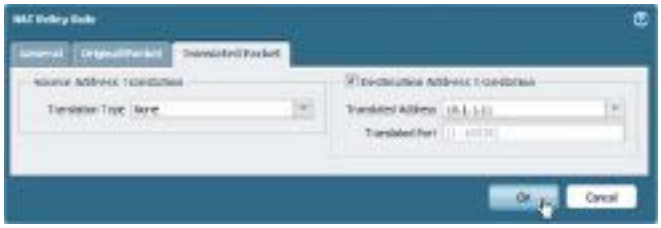
Step 1 Create an address object for the web server.

1. From the web interface, select **Objects > Addresses** and then click **Add**.
2. Enter a **Name** and optionally a **Description** for the object.
3. Select **IP Netmask** from the **Type** drop down and then enter the public IP address of the web server, 203.0.113.11 in this example.
4. To save the address object, click **OK**.

Step 2 Create the NAT policy.

1. Select **Policies > NAT** and click **Add**.
2. Enter a descriptive **Name** for the NAT rule.
3. On the **Original Packet** tab, select the zone you created for your internal network in the **Source Zone** section (click **Add** and then select the zone) and the zone you created for the external network from the **Destination Zone** drop down.
4. In the **Destination Address** section, click **Add** and select the address object you created for your public web server.





5. On the **Translated Packet** tab, select the **Destination Address Translation** check box and then enter the IP address that is assigned to the web server interface on the DMZ network, 10.1.1.11 in this example.
6. Click **OK** to save the NAT policy.

Step 3 Save the configuration. Click **Commit**.

## Enable Bi-Directional Address Translation for your Public-Facing Servers

When your public-facing servers have private IP addresses assigned on the network segment where they are physically located, you will need a source NAT rule for translating the source address of the server to the external address upon egress. You do this by creating a static NAT rule that instructs the firewall to translate the internal source address, 10.1.1.11, to the external web server address, 203.0.113.11 in our example. However, in the case of a public-facing server, the server must both be able to send packets and receive them. In this case, you need a reciprocal policy that will translate the public address that will be the destination IP address in incoming packets from users on the Internet into the private address to enable the firewall to properly route the packet to your DMZ network. On the firewall you do this by creating a bi-directional static NAT policy as described in the following procedure.

**Configure Bi-Directional NAT**

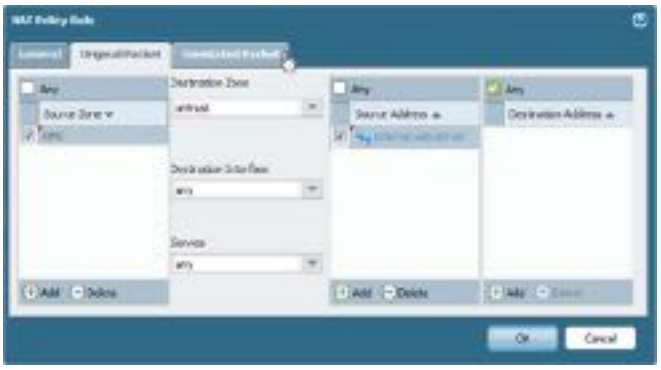
**Step 1** Create an address object for the web server's internal IP address.

1. From the web interface, select **Objects > Addresses** and then click **Add**.
2. Enter a **Name** and optionally a **Description** for the object.
3. Select **IP Netmask** from the **Type** drop down and then enter the IP address of the web server on the DMZ network, 10.1.1.11 in this example.
4. To save the address object, click **OK**.

If you did not already create an address object for the public address of your web server you should also create that object now.

**Step 2** Create the NAT policy.

1. Select **Policies > NAT** and click **Add**.
2. Enter a descriptive **Name** for the NAT rule.
3. On the **Original Packet** tab, select the zone you created for your DMZ in the **Source Zone** section (click **Add** and then select the zone) and the zone you created for the external network from the **Destination Zone** drop down.
4. In the **Source Address** section, click **Add** and select the address object you created for your internal web server address.



5. On the **Translated Packet** tab, select **Static IP** from the **Translation Type** drop down in the **Source Address Translation** section and then select the address object you created for your external web server address from the **Translated Address** drop down.
6. In the **Bi-directional** field, select **Yes**.
7. Click **OK** to save the NAT policy.

**Step 3** Save the configuration. Click **Commit**.

 © Palo Alto Networks, Inc.

# Set Up Basic Security Policies

Policies allow you to enforce rules and take action. The different types of policy rules that you can create on the firewall are: Security, NAT, Quality of Service (QoS), Policy Based Forwarding (PBF), Decryption, Application Override, Captive Portal, Denial of Service, and Zone protection policies. All these different policies work together to allow, deny, prioritize, forward, encrypt, decrypt, make exceptions, authenticate access, and reset connections as needed to help secure your network. This section covers basic security policies and the default security profiles:

- Create Security Rules
- Test Your Security Policies
- Monitor the Traffic on Your Network

## Create Security Rules

Security policies reference security zones and enable you to allow, restrict, and track traffic on your network. Because each zone implies a level of trust, the implicit rule for passing traffic between two different zones is deny, and the traffic within a zone is permitted. To allow traffic between two different zones, you must create a security rule that allows traffic to flow between them.

While setting up the basic framework for securing the enterprise perimeter, it's good idea to start with a simple security policy that allows traffic between the different zones without being too restrictive. As illustrated in the following section, our objective is to minimize the likelihood of breaking applications that users on the network need access to, while providing visibility into the applications and the potential threats for your network.

When defining policies make sure that you do not create a policy that denies all traffic from *any* source zone to *any* destination zone as this will break intra-zone traffic that is implicitly allowed. By default, intra-zone traffic is permitted because the source and destination zones are the same and therefore share the same level of trust.

## Define Basic Security Rules

**Step 1** Permit Internet access for all users on the enterprise network.

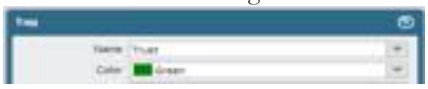
Zone: Trust to Untrust

By default, the firewall includes a security rule named *rule1* that allows all traffic from Trust zone to Untrust zone. You can either delete the rule or modify the rule to reflect your zone-naming convention.

To safely enable applications that are required for day-to-day business operations we will create a simple rule that allows access to the Internet. To provide basic threat protection, we will attach the default security profiles available on the firewall.

1. Select **Policies > Security** and click **Add.**
2. Give the rule a descriptive name in the **General** tab.
3. In the **Source** tab, set the **Source Zone** to Trust.
4. In the **Destination** tab, Set the **Destination Zone** to Untrust.

To scan policy rules and visually identify the zones on each rule, create a tag with the same name as the zone. For example, to color code the Trust zone as green, select **Objects > Tags,** click **Add** and **Name** the tag Trust, and select the **Color** green.



5. In the **Service/ URL Category** tab, select service-http and service-https.
6. In the **Actions** tab, complete these tasks:
   a. Set the **Action Setting** to **Allow**.
   b. Attach the default profiles for antivirus, anti-spyware, vulnerability protection and URL filtering, under **Profile Setting.**
7. Verify that logging is enabled at the end of a session under **Options**. Only traffic that matches a security rule will be logged.

**Step 2** Permit users on the internal network to access the servers in the DMZ.

Zone: Trust to DMZ

If using IP addresses for configuring access to the servers in the DMZ, make sure to always refer to the original IP addresses in the packet (i.e. the pre-NAT addresses), and the post-NAT zone.

1. Click **Add** in the **Policies > Security** section.
2. Give the rule a descriptive name in the **General** tab.
3. In the **Source** tab, set the **Source Zone** to Trust.
4. In the **Destination** tab, set the **Destination Zone** to DMZ.
5. In the **Service/ URL Category** tab, make sure the **Service** is set to **application-default**.
6. In the **Actions** tab, set the **Action Setting** to Allow.
7. Leave all the other options at the default values.

© Palo Alto Networks, Inc.

**Define Basic Security Rules (Continued)**

Step 3 Restrict access from the Internet to the servers on the DMZ to specific server IP addresses only.

For example, you might only allow users to access the webmail servers from outside.

Zone: Untrust to DMZ

To restrict inbound access to the DMZ from the Internet, configure a rule that allows access only to specific servers IP addresses and on the default ports that the applications use.

1. Click **Add** to add a new rule, and give it a descriptive name.
2. In the **Source** tab, set the **Source Zone** to Untrust.
3. In the **Destination** tab, set the **Destination Zone** to DMZ.
4. Set the **Destination Address** to the **Public web server** address object you created earlier. The public web server address object references the public IP address—208.80.56.11/24—of the web server that is accessible on the DMZ.
5. Select the webmail application in the **Application** tab.

   The **Service** is set to **application-default** by default.

6. Set the **Action Setting** to **Allow**.

Step 4 Allow access from the DMZ to your internal network (Trust zone). To minimize risk, you will allow traffic only between specific servers and destination addresses. For example, if you have an application server on the DMZ that needs to communicate with a specific database server in your Trust zone, create a rule to allow traffic between a specific source to a specific destination.

Zone: DMZ to Trust

1. Click **Add** to add a new rule, and give it a descriptive name.
2. Set the **Source Zone** to DMZ.
3. Set the **Destination Zone** to Trust.
4. Create a an address object that specifies the server(s) on your Trust zone that can be accessed from the DMZ.

5. In the **Destination** tab on the Security Policy rule, set the **Destination Address** to the Address object you created above.
6. In the **Actions** tab, complete these tasks:
   a. Set the **Action Setting** to **Allow**.
   b. Attach the default profiles for antivirus, anti-spyware, vulnerability protection, under **Profile Setting.**
   c. In the Other Settings section, select the option to **Disable Server Response Inspection**. This setting disables the antivirus and anti-spyware scanning on the server-side responses, and thus reduces the load on the firewall.

| Define Basic Security Rules (Continued) | | |
|---|---|---|
| Step 5 | Enable the servers on the DMZ to obtain updates and hot fixes from the Internet. Say, for example, you would like to allow the Microsoft Update service.<br><br>Zone: DMZ to Untrust | 1. Add a new rule and give it a descriptive label.<br>2. Set the **Source Zone** to DMZ.<br>3. Set the **Destination Zone** to Untrust.<br>4. Create an application group to specify the applications that you would like to allow. In this example, we allow Microsoft updates (ms-updates) and dns.<br> <br><br>The **Service** is set to **application-default** by default. This allows the firewall to permit the applications only when they use the standard ports associated with these applications.<br>5. Set the **Action Setting** to **Allow**.<br>6. Attach the default profiles for antivirus, anti-spyware, and vulnerability protection, under **Profiles**.<br>  <br> |
| Step 6 | Save your policies to the running configuration on the device. | Click **Commit**. |

## Test Your Security Policies

To verify that you have set up your basic policies effectively, test whether your security policies are being evaluated and determine which security rule applies to a traffic flow.

 © Palo Alto Networks, Inc.

| Verify Policy Match Against a Flow | |
|---|---|
| To verify the policy rule that matches a flow, use the following CLI command:<br>**test security-policy-match source** *<IP_address>* **destination** *<IP_address>* **destination port** *<port_number>* **protocol** *<protocol_number>*<br>The output displays the best rule that matches the source and destination IP address specified in the CLI command. | For example, to verify the policy rule that will be applied for a server on the DMZ with the IP address 208.90.56.11 when it accesses the Microsoft update server, you will try the following command:<br>`test security-policy-match source 208.80.56.11 destination 176.9.45.70 destination-port 80 protocol 6`<br><br>`"Updates-DMZ to Internet" {`<br>`from dmz;`<br>`source any;`<br>`source-region any;`<br>`to untrust;`<br>`destination any;`<br>`destination-region any;`<br>`user any;`<br>`category any;`<br>`application/service[ dns/tcp/any/53 dns/udp/any/53 dns/udp/any/5353 ms-update/tcp/any/80 ms-update/tcp/any/443];`<br>`action allow;`<br>`terminal yes;` |

## Monitor the Traffic on Your Network

Now that you have a basic security policy in place, you can review the statistics and data in the Application Command Center (ACC), traffic logs, and the threat logs to observe trends on your network, to identify where you need to create more granular policies.

Unlike traditional firewalls that use port or protocol to identify applications, the Palo Alto Networks firewalls use the application signature (the App-ID technology) to monitor applications. The application signature is based on unique application properties and related transaction characteristics in combination with the port or protocol. Therefore, even when the traffic uses the right port/protocol, the firewall can deny access to content because the application signature is not a match. This feature allows you to safely enable applications by allowing parts of the application while blocking or controlling functions within the same application. For example, if you allow the application *web-browsing* a user will be able to access content on the Internet. Then, if a user goes to Facebook and then goes on to play Scrabble on Facebook, the firewall will identify the application shifts and recognize Facebook as an *application* and Scrabble as a *Facebook-app*. Therefore, if you create a specific rule that blocks Facebook applications, the user will be denied access to Scrabble while still being able to access Facebook.

To monitor traffic on your network:

- Use the Application Command Center—In the ACC, review the most used applications and the high-risk applications on your network. The ACC graphically summarizes the log information to highlight the applications traversing the network, who is using them (with User-ID enabled), and the potential security

impact of the content to help you identify what is happening on the network in real time. You can then use this information to create appropriate security policies that block unwanted applications, while allowing and enabling applications in a secure manner.

- Determine what updates/modifications are required for your network security rules and implement the changes. For example:
  - Evaluate whether to allow content based on schedule, users, or groups
  - Allow or control certain applications or functions within an application
  - Decrypt and inspect content
  - Allow but scan for threats and exploits

    For information on refining your security policies and for attaching custom security profiles, see Enable Basic Threat Prevention Features.
- View the Log Files—Specifically, view the traffic and threat logs (**Monitor > Logs**).

Traffic logs are dependent on how your security policies are defined and setup to log traffic. The ACC tab, however, records applications and statistics regardless of policy configuration; it shows all traffic that is allowed on your network, therefore it includes the inter zone traffic that is allowed by policy and the same zone traffic that is allowed implicitly.

- Interpret the URL Filtering Logs—Review the URL filtering logs to scan through alerts, denied categories/URL. URL logs are generated when a traffic matches a security rule that has a URL filtering profile attached with an action of alert, continue, override or block.

 © Palo Alto Networks, Inc.

# Enable Basic Threat Prevention Features

The Palo Alto Networks next-generation firewall has unique threat prevention capabilities that allow it to protect your network from attack despite evasive, tunneled, or circumvention techniques. The threat prevention features on the firewall include the WildFire service, the Security Profiles that support Antivirus, Anti-spyware, Vulnerability Protection, URL Filtering, File Blocking and Data Filtering capabilities and the Denial of Service (DoS) and Zone protection functionality.

Before you can apply threat prevention features, you must first configure zones—to identify one or more source or destination interfaces—and security policies. To configure interfaces, zones, and the policies that are needed to apply threat prevention features, see Set Up Interfaces and Zones and Set Up Basic Security Policies.

To begin protecting your network from threats start here:

- Enable WildFire
- Scan Traffic for Threats
- Control Access to Web Content

## Enable WildFire

The WildFire service is included as part of the base product. The WildFire service enables the firewall to forward attachments to a sandbox environment where applications are run to detect any malicious activity. As new malware is detected by the WildFire system, malware signatures are automatically generated and are made available within 24-48 hours in the antivirus daily downloads. Your threat prevention subscription entitles you for antivirus signature updates that include signatures discovered by WildFire.

Consider purchasing the WildFire subscription service for these additional benefits:

- Sub-hourly (as often as every 15 minutes) WildFire signature updates
- Advanced file type forwarding (APK, PDF, Microsoft Office, and Java Applet)
- Ability to upload files using the WildFire API
- Ability to forward files to a private WF-500 WildFire appliance

  While the ability to configure a file blocking profile to forward Portable Executable (PE) files to the WildFire cloud for analysis is free, in order to forward files to a private WildFire appliance, a WildFire subscription is required.

| **Enable WildFire** | | |
|---|---|---|
| Step 1 | Confirm that your device is registered and that you have a valid support account as well as any subscriptions you require. | 1. Go to the Palo Alto Networks Support Site, log in, and select **My Devices**.<br>2. Verify that the firewall is listed. If it is not listed, see Register With Palo Alto Networks.<br>3. (Optional) Activate Licenses. |
| Step 2 | Set the WildFire forwarding options.<br><br>If you do not have a WildFire subscription you can only forward executables. | 1. Select **Device > Setup > WildFire**.<br>2. Click the edit icon in the General Settings section.<br>3. (Optional) Specify the **WildFire Server** to which to forward files. By default, the firewall will forward files to the public WildFire cloud hosted in the United States. To forward files to a different WildFire cloud, enter a new value as follows:<br>• To forward to a private WildFire cloud, enter the IP address or FQDN of your WF-500 WildFire appliance.<br>• To forward files to the public WildFire cloud running in Japan, enter `wildfire.paloaltonetworks.jp`.<br>4. (Optional) If you want to change the maximum file size that the firewall can forward for a specific type of file, modify the value in the corresponding field.<br>5. Click **OK** to save your changes. |

 © Palo Alto Networks, Inc.

| Enable WildFire (Continued) | | |
|---|---|---|
| Step 3 | Set up a file blocking profile to forward files to WildFire. | 1. Select **Objects > Security Profiles > File Blocking** and click **Add**.<br>2. Enter a **Name** and optionally a **Description** for the profile.<br>3. Click **Add** to create a forwarding rule and enter a name.<br>4. In the **Action** column, select **forward**.<br>5. Leave the other fields set to **any** to forward any supported file type from any application.<br>6. Click **OK** to save the profile. |
| Step 4 | Attach the file blocking profile to the security policies that allow access to the Internet. | 1. Select **Policies > Security** and either select an existing policy or create a new policy as described in Create Security Rules.<br>2. Click the **Actions** tab within the security policy.<br>3. In the Profile Settings section, click the drop-down and select the file blocking profile you created for WildFire forwarding. (If you don't see a drop-down for selecting a profile, select **Profiles** from the **Profile Type** drop-down. |
| Step 5 | Save the configuration. | Click **Commit**. |
| Step 6 | Verify that the firewall is forwarding files to WildFire. | 1. Select **Monitor > Logs > Data Filtering**.<br>2. Check the **Action** column for the following actions:<br>• **Forward**— Indicates that the file was successfully forwarded by the file blocking profile attached to the security policy.<br>• **Wildfire-upload-success**—Indicates that the file was sent to WildFire. This means the file is not signed by a trusted file signer and it has not been previously analyzed by WildFire.<br>• **Wildfire-upload-skip**—Indicates that the file was identified as eligible to be sent to WildFire by a file blocking profile/security policy, but did not need to be analyzed by WildFire because it has already been analyzed previously. In this case, the action will display as **forward** in the Data Filtering log because it was a valid forward action, but it was not sent to WildFire and analyzed because the file has already been sent to the WildFire cloud from another session, possibly from another firewall.<br>3. View the WildFire logs by selecting **Monitor > Logs > WildFire Submissions**. If new WildFire logs appear, the firewall is successfully forwarding files to WildFire and WildFire is returning file analysis reports. |

# Scan Traffic for Threats

Security profiles provide threat protection in security policies. For example, you can apply an antivirus profile to a security policy and all traffic that matches the security policy will be scanned for viruses.

The following sections provide steps for setting up a basic threat prevention configuration:

- Set Up Antivirus, Anti-Spyware, and Vulnerability Protection
- Set Up File Blocking

## Set Up Antivirus, Anti-Spyware, and Vulnerability Protection

Every Palo Alto Networks next-generation firewall comes with predefined Antivirus, Anti-Spyware, and Vulnerability Protection profiles that you can attach to security policies. There is one predefined Antivirus profile, **default**, which uses the default action for each protocol (block HTTP, FTP, and SMB traffic and alert on SMTP, IMAP, and POP3 traffic). There are two predefined Anti-spyware and Zone Protection profiles:

- **default**—Applies the default action to all client and server critical, high, and medium severity spyware/vulnerability protection events. It does not detect low and informational events.
- **strict**—Applies the block response to all client and server critical, high and medium severity spyware/vulnerability protection events and uses the default action for low and informational events.

To ensure that the traffic entering your network is free from threats, attach the predefined profiles to your basic web access policies. As you monitor the traffic on your network and expand your policy rulebase, you can then design more granular profiles to address your specific security needs.

| **Set up Antivirus/Anti-Spyware/Vulnerability Protection** | | |
|---|---|---|
| Step 1 | Verify that you have a Threat Prevention license. | • The Threat Prevention license bundles the Antivirus, Anti-Spyware, and the Vulnerability Protection features in one license.<br>• Select **Device > Licenses** to verify that the **Threat Prevention** license is installed and valid (check the expiration date). |
| Step 2 | Download the latest antivirus threat signatures. | 1. Select **Device > Dynamic Updates** and click **Check Now** at the bottom of the page to retrieve the latest signatures.<br>2. In the **Actions** column, click **Download** to install the latest Antivirus, and Applications and Threats signatures. |

 © Palo Alto Networks, Inc.

**Set up Antivirus/Anti-Spyware/Vulnerability Protection (Continued)**

Step 3 Schedule signature updates.

Perform a **download-and-install** on a daily basis for antivirus updates and weekly for applications and threats updates.

1. From **Device > Dynamic Updates**, click the text to the right of **Schedule** to automatically retrieve signature updates for **Antivirus** and **Applications and Threats**.
2. Specify the frequency and timing for the updates and whether the update will be downloaded and installed or only downloaded. If you select **Download Only**, you would need to manually go in and click the **Install** link in the **Action** column to install the signature. When you click **OK**, the update is scheduled. No commit is required.
3. (Optional) You can also enter the number of hours in the **Threshold** field to indicate the minimum age of a signature before a download will occur. For example, if you entered **10**, the signature must be at least 10 hours old before it will be downloaded, regardless of the schedule.
4. In an HA configuration, you can also click the **Sync To Peer** option to synchronize the content update with the HA peer after download/install. This will not push the schedule settings to the peer device, you need to configure the schedule on each device.

Recommendations for HA Configurations:

- **Active/Passive HA**—If the MGT port is used for antivirus signature downloads, you should configure a schedule on both devices and both devices will download/install independently. If you are using a data port for downloads, the passive device will not perform downloads while it is in the passive state. In this case you would set a schedule on both devices and then select the **Sync To Peer** option. This will ensure that whichever device is active, the updates will occur and will then push to the passive device.
- **Active/Active HA**—If the MGT port is used for antivirus signature downloads on both devices, then schedule the download/install on both devices, but do not select the **Sync To Peer** option. If you are using a data port, schedule the signature downloads on both devices and select **Sync To Peer**. This will ensure that if one device in the active/active configuration goes into the active-secondary state, the active device will download/install the signature and will then push it to the active-secondary device.

| Set up Antivirus/Anti-Spyware/Vulnerability Protection (Continued) | |
|---|---|
| Step 4 Attach the security profiles to a security policy.<br><br>Attach a clone of a predefined security profile to your basic security policies. That way, if you want to customize the profile you can do so without deleting the read-only predefined **strict** or **default** profile and attaching a customized profile. | 1. Select **Policies > Security**, select the desired policy to modify it and then click the **Actions** tab.<br>2. In **Profile Settings**, click the drop-down next to each security profile you would like to enable. In this example we choose default for **Antivirus, Vulnerability Protection,** and **Anti-Spyware**.<br>(If you don't see drop-downs for selecting profiles, select **Profiles** from the **Profile Type** drop-down.)<br>  |
| Step 5 Save the configuration. | Click **Commit**. |

## Set Up File Blocking

File blocking profiles allow you to identify specific file types that you want to want to block or monitor. The following workflow shows how to set up a basic file blocking profile that prevents users from downloading executable files from the Internet.

| Configure File Blocking | |
|---|---|
| Step 1 Create the file blocking profile. | 1. Select **Objects > Security Profiles > File Blocking** and click **Add**.<br>2. Enter a **Name** for the file blocking profile, for example *Block_EXE*. Optionally enter a **Description**, such as *Block users from downloading exe files from websites.* |

 © Palo Alto Networks, Inc.

| Configure File Blocking (Continued) | | |
|---|---|---|
| Step 2 | Configure the file blocking options. | 1. Click **Add** to define the profile settings.<br>2. Enter a **Name**, such as *BlockEXE*.<br>3. Set the **Applications** to which to apply file blocking, or leave it set to any.<br>4. Set **File Types** to block. For example, to block download of executables, you would select **exe**.<br>5. Specify the **Direction** in which to block files **download**, **upload**, or **both**.<br>6. Set the **Action** to one of the following:<br>• **continue**—Users will have to click Continue in order to proceed with the download/upload. You must enable response pages on the associated interfaces if you plan to use this option.<br>• **block**—Files matching the selected criteria will be blocked from download/upload.<br>• **alert**—Files matching the selected criteria will be allowed, but will generate a log entry in the data filtering log.<br> <br>7. Click **OK** to save the profile. |
| Step 3 | Attach the file blocking profile to the security policies that allow access to content. | 1. Select **Policies > Security** and either select an existing policy or create a new policy as described in Create Security Rules.<br>2. Click the **Actions** tab within the security policy.<br>3. In the Profile Settings section, click the drop-down and select the file blocking profile you created. (If you don't see drop-downs for selecting profiles, select **Profiles** from the **Profile Type** drop-down.) |
| Step 4 | Enable Response Pages in the management profile for each interface on which you are attaching file blocking profile with a **continue** action. | 1. Select **Network > Network Profiles > Interface Mgmt** and then select an interface profile to edit or click **Add** to create a new profile.<br>2. Select **Response Pages**, as well as any other management services required on the interface.<br>3. Click **OK** to save the interface management profile.<br>4. Select **Network > Interfaces** and select the interface to which to attach the profile.<br>5. On the **Advanced > Other Info** tab, select the interface management profile you just created.<br>6. Click **OK** to save the interface settings. |

**Configure File Blocking (Continued)**

Step 5 To test the file blocking configuration, access a client PC in the trust zone of the firewall and attempt to download an.exe file from a website in the untrust zone. A response page should display. Click **Continue** to download the file. You can also set other actions, such as alert only, forward (which will forward to WildFire), or block, which will not provide a continue page to the user. The following shows the default response page for File Blocking:

**Example: Default File Blocking Response Page**

 © Palo Alto Networks, Inc.

## Control Access to Web Content

URL Filtering provides visibility and control over web traffic on your network. With URL filtering enabled, the firewall can categorize web traffic into one or more (from approximately 60) categories. You can then create policies that specify whether to allow, block, or log (alert) traffic based on the category to which it belongs. The following workflow shows how to enable PAN-DB for URL filtering, create security profiles, and attach them to security policies to enforce a basic URL filtering policy.

| **Configure URL Filtering** | |
|---|---|
| Step 1 Confirm license information for URL Filtering. | 1. Obtain and install a URL Filtering license. See Activate Licenses for details.<br>2. Select **Device > Licenses** and verify that the URL Filtering license is valid.<br> |
| Step 2 Download the seed database and activate the license. | 1. To download the seed database, click **Download** next to **Download Status** in the PAN-DB URL Filtering section of the Licenses page.<br>2. Choose a region (North America, Europe, APAC, Japan) and then click **OK** to start the download.<br>3. After the download completes, click **Activate**.<br> |
| Step 3 Create a URL filtering profile.<br>Best Practice for New Profiles:<br>Because the default URL filtering profile blocks risky and threat-prone content, clone this profile when creating a new profile in order to preserve the default settings. | 1. Select **Objects > Security Profiles > URL Filtering**.<br>2. Select the default profile and then click **Clone**. The new profile will be named *default-1*.<br>3. Select the new profile and rename it. |

| Configure URL Filtering (Continued) | |
|---|---|
| Step 4 Define how to control access to web content.<br><br>If you are not sure what traffic you want to control, consider setting the categories (except for those blocked by default) to alert. You can then use the visibility tools on the firewall, such as the ACC and App Scope, to determine which web categories to restrict to specific groups or to block entirely. You can then go back and modify the profile to block and allow categories as desired.<br><br>You can also define specific sites to always allow or always block regardless of category and enable the safe search option to filter search results when defining the URL Filtering profile. | 1. For each category that you want visibility into or control over, select a value from the **Action** column as follows:<br>• If you do not care about traffic to a particular category (that is you neither want to block it nor log it), select **Allow**.<br>• For visibility into traffic to sites in a category, select **Alert**<br>• To prevent access to traffic that matches the associated policy, select **Block** (this also generates a log entry).<br>  <br>2. Click **OK** to save the URL filtering profile. |
| Step 5 Attach the URL filtering profile to a security policy. | 1. Select **Policies > Security**.<br>2. Select the desired policy to modify it and then click the **Actions** tab.<br>3. If this is the first time you are defining a security profile, select **Profiles** from the **Profile Type** drop-down.<br>4. In the **Profile Settings** list, select the profile you just created from the **URL Filtering** drop-down. (If you don't see drop-downs for selecting profiles, select **Profiles** from the **Profile Type** drop-down.)<br>5. Click **OK** to save the profile.<br>6. **Commit** the configuration. |
| Step 6 Enable Response Pages in the management profile for each interface on which you are filtering web traffic. | 1. Select **Network > Network Profiles > Interface Mgmt** and then select an interface profile to edit or click **Add** to create a new profile.<br>2. Select **Response Pages**, as well as any other management services required on the interface.<br>3. Click **OK** to save the interface management profile.<br>4. Select **Network > Interfaces** and select the interface to which to attach the profile.<br>5. On the **Advanced > Other Info** tab, select the interface management profile you just created.<br>6. Click **OK** to save the interface settings. |

 © Palo Alto Networks, Inc.

| Configure URL Filtering (Continued) | | |
|---|---|---|
| Step 7 | Save the configuration. | Click **Commit**. |
| Step 8 | To test URL filtering, access a client PC from the zone where the security policy is applied and attempt to access a site in a blocked category. You should see a URL Filtering response page that indicates that the page has been blocked: | |

## For More Information

For more detailed information on how to protect your enterprise from threats, see Threat Prevention. For details on how to scan encrypted (SSH or SSL) traffic for threats, see Decryption.

For information about the threats and applications that Palo Alto Networks products can identify, visit the following links:

- Applipedia—Provides details on the applications that Palo Alto Networks can identify.
- Threat Vault—Lists threats that Palo Alto Networks products can identify. You can search by Vulnerability, Spyware, or Virus. Click the Details icon next to the ID number for more information about a threat.

# Best Practices for Completing the Firewall Deployment

Now that you have integrated the firewall into your network and enabled the basic security features, you can begin configuring more advanced features. Here are some things to consider next:

- Learn about the different Management Interfaces that are available to you and how to access and use them.
- Set up High Availability—High availability (HA) is a configuration in which two firewalls are placed in a group and their configuration is synchronized to prevent a single point to failure on your network. A heartbeat connection between the firewall peers ensures seamless failover in the event that a peer goes down. Setting up the firewalls in a two-device cluster provides redundancy and allows you to ensure business continuity.
- Configure the Master Key—Every Palo Alto Networks firewall has a default master key that encrypts private keys that are used to authenticate administrators when they access management interfaces on the firewall. As a best practice to safeguard the keys, configure the master key on each firewall to be unique.
- Manage Firewall Administrators—Every Palo Alto Networks firewall and appliance is preconfigured with a default administrative account (admin) that provides full read-write access (also known as superuser access) to the device. As a best practice, create a separate administrative account for each person who needs access to the administrative or reporting functions of the firewall. This allows you to better protect the device from unauthorized configuration (or modification) and to enable logging of the actions of each individual administrator.
- Enable User Identification (User-ID)—User-ID is a Palo Alto Networks next-generation firewall feature that allows you to create policies and perform reporting based on users and groups rather than individual IP addresses.
- Enable Decryption—Palo Alto Networks firewalls provide the capability to decrypt and inspect traffic for visibility, control, and granular security. Use decryption on a firewall to prevent malicious content from entering your network or sensitive content from leaving your network concealed as encrypted or tunneled traffic.
- Passive DNS Collection—Enable this opt-in feature to enable the firewall to act as a passive DNS sensor and send select DNS information to Palo Alto Networks for analysis in order to improve threat intelligence and threat prevention capabilities.
- Follow the Best Practices for Securing Your Network from Layer 4 and Layer 7 Evasions.

 © Palo Alto Networks, Inc.

# Device Management

Administrators can configure, manage, and monitor the Palo Alto Networks' firewalls using the web interface, the CLI, and the API management interfaces. Role-based administrative access to the management interfaces can be customized in order to delegate specific tasks or permissions to certain administrators. See the following topics for information on device management options, including how to begin using the management interfaces and how to customize administrator roles:

- Management Interfaces
- Manage Firewall Administrators
- Reference: Web Interface Administrator Access

# Management Interfaces

PAN-OS firewalls and Panorama provide three user interfaces: a web interface, a command line interface (CLI), and a REST management API. See the following topics for how to access and begin using each of the device management interfaces:

- Use the Web Interface to complete administrative tasks and generate reports from the web interface with relative ease. This graphical interface allows you to access the firewall using HTTPS and it is the best way to perform administrative tasks.
- Use the Command Line Interface (CLI) to type through the commands in rapid succession to complete a series of tasks. The CLI is a no-frills interface that supports two command modes and each mode has its own hierarchy of commands and statements. When you get familiar with the nesting structure and the syntax of the commands, the CLI allows quick response times and offers administrative efficiency.
- Use the XML API to streamline your operations and integrate with existing, internally developed applications and repositories. The XML API is provided as a web service that is implemented using HTTP/HTTPS requests and responses.

 © Palo Alto Networks, Inc.

# Use the Web Interface

The following topics describes how to begin using the firewall web interface:

- Launch the Web Interface
- Navigate the Web Interface
- Commit Changes
- Use Configuration Pages
- Required Fields
- Lock Transactions

## Launch the Web Interface

The following web browsers are supported for access to the web interface for PAN-OS firewalls and Panorama:

- Internet Explorer 7+
- Firefox 3.6+
- Safari 5+
- Chrome 11+

Launch an Internet browser and enter the firewall's IP address. Enter your user credentials. If logging in to the firewall for the first time, type the default **admin** into both the **Name** and **Password** fields.

To view information on how to use a specific page and an explanation of the fields and options on the page, click the **Help** icon

in the upper right area of the page to open the online help system. In addition to displaying context-sensitive help for a page, clicking the **Help** icon displays a help navigation pane with options to browse and search all help content.

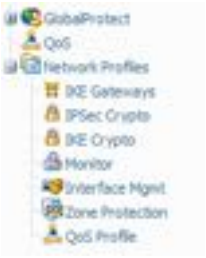
## Navigate the Web Interface

The following conventions apply when using the web interface.

- To display the menu items for a general functional category, click the tab, such as **Objects** or **Device**, near the top of the browser window.

- Click an item on the side menu to display a panel.

- To display submenu items, click the ⊞ icon to the left of an item. To hide submenu items, click the ⊟ icon to the left of the item.

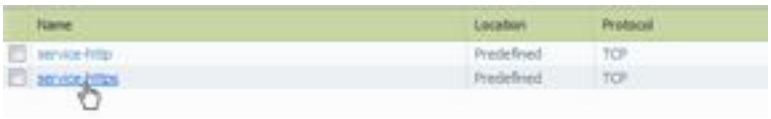


- On most configuration pages, you can click **Add** to create a new item.

- To delete one or more items, select their check boxes and click **Delete**. In most cases, the system prompts you to confirm by clicking **OK** or to cancel the deletion by clicking **Cancel**.

- On some configuration pages, you can select the check box for an item and click **Clone** to create a new item with the same information as the selected item.

- To modify an item, click its underlined link.

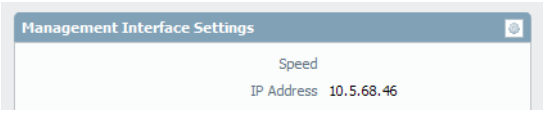


- To view the current list of tasks, click the **Tasks** icon in the lower right corner of the page. The Task Manager window opens to show the list of tasks, along with status, start times, associated messages, and actions. Use the **Show** drop-down list to filter the list of tasks.

 © Palo Alto Networks, Inc.

- The web interface language is controlled by the current language of the computer that is managing the device if a specific language preference has not been defined. For example, if the computer you use to manage the firewall has a locale of Spanish, when you log in to the firewall, the web interface will be in Spanish.
- To specify a language that will always be used for a given account regardless of the locale of the computer, click the **Language** icon in the lower right corner of the page and the Language Preference window opens. Click the drop-down list to select the desired language and then click **OK** to save your change.

- On pages that list information you can modify (for example, the **Setup** page on the **Devices** tab), click the icon in the upper right corner of a section to edit the settings.



- After you configure settings, you must click **OK** or **Save** to store the changes. When you click **OK**, the current "candidate" configuration is updated.

## Commit Changes

Click **Commit** at the top of the web interface to open the Commit dialog box, which displays the following options. Certain options only display if you click **Advanced**.

- **Include Device and Network configuration**—Include the device and network configuration changes in the commit operation.
- **Include Shared Object configuration**—(Multi-virtual system firewalls only) Include the shared object configuration changes in the commit operation.

- **Include Policy and Objects**—(Non-multi-virtual system firewalls only) Include the policy and object configuration changes in the commit operation.
- **Include virtual system configuration**—Include all virtual systems or choose **Select one or more virtual systems**.
- **Preview Changes**—Click this button to bring up a two-pane window that shows proposed changes in the candidate configuration compared to the current running configuration. You can choose the number of lines of context to display, or show all lines. Changes are color coded based on items that you and other administrators added (green), modified (yellow), or deleted (red) since the last commit.

Because the preview results display in a new window, your browser must allow pop-ups. If the preview window does not open, refer to your browser documentation for the steps to unblock pop-ups.

## Use Configuration Pages

The tables on configuration pages include sorting and column chooser options. Click a column header to sort on that column, and click again to change the sort order. Click the arrow to the right of any column and select check boxes to choose the columns to display.

## Required Fields

Required fields are shown with a light yellow background. A message indicating that the field is required appears when you hover over or click in the field entry area.

## Lock Transactions

The web interface provides support for multiple administrators by allowing an administrator to lock a current set of transactions, thereby preventing configuration changes or commit operations by another administrator until the lock is removed. The following types of locks are supported:

- **Config lock**—Blocks other administrators from making changes to the configuration. This type of lock can be set globally or for a virtual system. It can be removed only by the administrator who set it or by a superuser on the system.

 © Palo Alto Networks, Inc.

- **Commit Lock**—Blocks other administrators from committing changes until all of the locks have been released. This type of lock prevents collisions that can occur when two administrators are making changes at the same time and the first administrator finishes and commits changes before the second administrator has finished. The lock is released when the current changes are committed by the administrator who applied the lock, or it can be released manually.

Any administrator can open the lock window to view the current transactions that are locked, along with a time stamp for each.

To lock a transaction, click the unlocked icon on the top bar to open the Locks dialog box. Click **Take a Lock**, select the scope of the lock from the drop-down list, and click **OK**. Add additional locks as needed, and then click **Close** to close the Lock dialog box.

The transaction is locked, and the icon on the top bar changes to a locked icon that shows the number of locked items in parentheses.

To unlock a transaction, click the locked icon on the top bar to open the Locks window. Click the icon for the lock that you want to remove, and click **Yes** to confirm. Click **Close** to close the Lock dialog box.

You can arrange to automatically acquire a commit lock by selecting the **Automatically acquire commit lock** check box in the Management area of the **Device Setup** page.

# Use the Command Line Interface (CLI)

The PAN-OS CLI allows you to access Firewall and Panorama devices, view status and configuration information, and modify configurations. Access to the PAN-OS CLI is provided through SSH, Telnet, or direct console access.

The following topics describe how to access and begin using the PAN-OS CLI:

- Access the PAN-OS CLI
- Operational and Configuration Modes

For more information on the CLI, refer to the *PAN-OS Command Line Interface Reference Guide*.

## Access the PAN-OS CLI

Before you begin, verify that the firewall is installed and that a SSH, Telnet, or direct console connection is established.

Use the following settings for direct console connection:

- Data rate: 9600
- Data bits: 8
- Parity: none
- Stop bits: 1
- Flow control: None

| **Access the PAN-OS CLI** | |
|---|---|
| Step 1 | Open the console connection |
| Step 2 | Enter the administrative username. The default is admin. |
| Step 3 | Enter the administrative password. The default is admin. |
| Step 4 | The PAN-OS CLI opens in Operational mode, and the CLI prompt is displayed:<br>username@hostname> |

## Operational and Configuration Modes

When you log in, the PAN-OS CLI opens in Operational mode. You can move between Operational and Configuration modes at any time. Use Operational mode to view the state of the system, navigate the PAN-OS CLI, and enter configuration mode. Use Configuration mode to view and modify the configuration hierarchy.

- To enter Configuration mode from Operational mode, use the `configure` command:

```
username@hostname> configure
Entering configuration mode
[edit]
```

 © Palo Alto Networks, Inc.

```
username@hostname#
```

- To leave Configuration mode and return to Operational mode, use the `quit` or `exit` command:

```
username@hostname# quit
Exiting configuration mode
username@hostname>
```

- To enter an Operational mode command while in Configuration mode, use the **run** command, for example:

```
username@hostname# run ping host 1.1.1.2
PING 1.1.1.1 (1.1.1.1) 56(84) bytes of data
...
username@hostname#
```

- To direct an Operational mode command to a particular VSYS, specify the target VSYS with the following command:

```
username@hostname# set system setting target-vsys <vsys_name>
```

# Use the XML API

Palo Alto Networks XML API uses standard HTTP requests to send and receive data, allowing access to several types of data on the device so the data can be easily integrated with and used in other systems. Use the REST Management API to view a firewall or Panorama's configuration, extract report data in XML format, and execute operational commands. API calls can be made directly from command line utilities such as cURL or wget, or using any scripting or application framework that supports RESTful services. When using the API with command lines tools, both HTTP GET and POST methods are supported.

You must generate an API key in order to being using the XML API. The API key authenticates the user to the firewall, application, or Panorama. After you have generated an API key, you can use the key to perform device configuration and operational tasks, retrieve reports and logs, and import and export files. See Generate an API Key for steps to generate an API key.

The following table shows the URL structure for API requests:

| XML API URL Structure | |
|---|---|
| Prior to PAN-OS 4.1.0 | http(s)://hostname/esp/restapi.esp?request-parameters-values |
| PAN-OS 4.1.0 and later | http(s)://hostname/api/?request-parameters-values |

URL structure item definitions:

- **hostname**—Device's IP address or Domain name.
- **request-parameters-values**—A series of multiple 'parameter=value' pairs separated by the ampersand character (&). These values can either be keywords or data-values in standard or XML format (response data is always in XML format).

There are APIs for PAN-OS, User-ID, and WildFire products. For more information on how to use the API interface, refer to the PAN-OS XML API Usage Guide. To access the online community for developing scripts, visit: https://live.paloaltonetworks.com/community/devcenter.

## Generate an API Key

In order to use the API to manage a firewall or application, an API key is required to authenticate all API calls. Admin account credentials are used to generate API keys.

As a best practice, create a separate admin account for XML-based administration.

| Generate an API key | |
|---|---|
| Step 1 Create an administrator account. | 1. In the web interface, on the **Device > Administrators** tab, click **Add.**<br>2. Enter a login **Name** for the admin.<br>3. Enter and confirm a **Password** for the admin.<br>4. Click **OK** and **Commit**. |

 © Palo Alto Networks, Inc.

| Generate an API key (Continued) | | |
|---|---|---|
| Step 2 | Request an API key. | Replace the hostname, username and password parameters in the following URL with the appropriate values from your administrator account credentials:<br>http(s)://hostname/api/?type=keygen&user=username&password=password<br>The API key is displayed in an XML block. For example:<br><response status="success"><br><result><br><key>0RgWc42Oi0vDx2WRUIUM6A</key><br></result><br></response> |
| Step 3 | (Optional) Revoke or change an API key.<br>For PAN-OS 4.1.0 and later releases, generating an API key using the same administrator account credentials returns unique API keys every time, and all of the keys are valid.<br>You can choose to revoke and then change an API key associated with an administrator account by changing the password associated with the administrator account. Any API keys that were generated using the previous credentials would no longer be valid. | 1. On the **Device > Adminstrators** tab, open the administrator account associated with the API key.<br>2. Enter and confirm a new **Password** for the administrator account.<br>3. Click **OK** and **Commit**.<br>Any API keys associated with the admin account prior to the password change are revoked upon Commit.<br>4. (Optional) Use the updated administrator account credentials to generate a new API key. See Step 2. |

Example work flow using an API key:

Request an API key by entering the URL with the appropriate values in a web browser:

```
https://10.xx.10.50/esp/restapi.esp?type=keygen&user=admin&password=admin
```

Entering the URL displays an XML block that contains the API key:

```
<response status="success">
  <result>
    <key>0RgWc42Oi0vDx2WRUIUM6A</key>
  </result>
</response>
```

Continue to use the API key to create API requests. For example, to generate a report:

```
https://10.xx.10.50/esp/restapi.esp?type=report&reporttype=dynamic&reportname
=top-app-summary&period=last-hour&topn=5&key=0RgWc42Oi0vDx2WRUIUM6A=
```

# Manage Firewall Administrators

Every Palo Alto Networks firewall and appliance is preconfigured with a default administrative account (admin) that provides full read-write access (also known as superuser access) to the device.

As a best practice, create a separate administrative account for each person who needs access to the administrative or reporting functions of the firewall. This allows you to better protect the device from unauthorized configuration (or modification) and to enable logging of the actions of each individual administrator.

The following topics describe the various ways you can set up administrative accounts and provides procedures for setting up basic administrative access:

- Administrative Roles
- Administrative Authentication
- Create an Administrative Account

## Administrative Roles

The way you configure administrator accounts depends on the security requirements within your organization, whether you have existing authentication services you want to integrate with, and how many different administrative roles you require. A *role* defines the type of access the associated administrator has to the system. There are two types of roles you can assign:

- **Dynamic Roles**—These are built-in roles that provide access to the firewall. When new features are added, the firewall automatically updates the definitions of dynamic roles; you never need to manually update them. The following table lists the access privileges associated with dynamic roles.

| Dynamic Role | Privileges |
|---|---|
| Superuser | Full access to the firewall, including defining new administrator accounts and virtual systems. You must have superuser privileges to create an administrative user with superuser privileges. |
| Superuser (read-only) | Read-only access to the firewall. |
| Virtual system administrator | Full access to a selected virtual system (vsys) on the firewall. |
| Virtual system administrator (read-only) | Read-only access to a selected vsys on the firewall. |
| Device administrator | Full access to all firewall settings except for defining new accounts or virtual systems. |
| Device administrator (read-only) | Read-only access to all firewall settings except password profiles (no access) and administrator accounts (only the logged in account is visible). |

- **Admin Role Profiles**—Allow you to create your own role definitions in order to provide more granular access control to the various functional areas of the web interface, CLI and/or XML API. For example, you could create an Admin Role Profile for your operations staff that provides access to the device and network

 © Palo Alto Networks, Inc.

configuration areas of the web interface and a separate profile for your security administrators that provides access to security policy definition, logs, and reports. Keep in mind that with Admin Role Profiles you must update the profiles to explicitly assign privileges for new features/components that are added to the product.

## Administrative Authentication

There are four ways you can authenticate administrative users:

- **Local administrator account with local authentication**—Both the administrator account credentials and the authentication mechanisms are local to the firewall. You can further secure the local administrator account by creating a password profile that defines a validity period for passwords and by setting device-wide password complexity settings.
- **Local administrator account with SSL-based authentication**—With this option, you create the administrator accounts on the firewall, but authentication is based on SSH certificates (for CLI access) or client certificates/common access cards (for the web interface). Refer to the article How to Configure Certificate-based Authentication for the WebUI for details on how to configure this type of administrative access.
- **Local administrator account with external authentication**—The administrator accounts are managed on the local firewall, but the authentication functions are offloaded to an existing LDAP, Kerberos, or RADIUS service. To configure this type of account, you must first create an authentication profile that defines how to access the external authentication service and then create an account for each administrator that references the profile.
- **External administrator account and authentication**—Account administration and authentication are handled by an external RADIUS server. To use this option, you must define Vendor Specific Attributes (VSAs) on your RADIUS server that map to the admin role and, optionally, the virtual system objects you have defined on the Palo Alto Networks device. Refer to the Radius Vendor Specific Attributes (VSA) article for details on how to configure this type of administrative access.

## Create an Administrative Account

Create administrative accounts to define access and administrative privileges for firewall administrators. Because it is common to delegate specific administrative tasks to specific administrators with varying roles, Palo Alto Networks recommends that you create admin role profiles that allow administrators access only to the areas of the management interface that are required to perform their jobs. You can assign the various roles you create to individual administrator accounts and specify access privileges to each management interface: the web interface, the Command Line Interface (CLI), and the REST Management API. By creating admin roles with very granular access privileges, you can ensure that sensitive company data is protected and end user privacy is ensured.

The following procedure describes how to create a local administrator account with local authentication, including how to set administrator access for each management interface.

| Create a Local Administrator | |
|---|---|
| Step 1 Create the Admin Role Profiles that you plan to assign to your administrators (this does not apply if you plan to use Dynamic Roles). The Admin Role Profiles define what type of access to give to the different sections of the web interface, CLI, and XML API for each administrator that you assign a role to.<br><br>You can use this step to set particularly granular access privileges for web interface users. For details on what a specific option enables on the **Web UI** tab, see Web Interface Access Privileges. | Complete the following steps for each role you want to create:<br>1. Select **Device > Admin Roles** and then click **Add**.<br>2. Enter a **Name** and optionally a **Description** for the role.<br>3. On the Web UI, Command Line and/or XML API tabs, specify the access to allow for each management interface:<br>• On the **Web UI** and/or **XML API** tabs, set the access levels for each functional area of the interface by clicking the icon to toggle it to the desired setting: Enable, Read Only, or Disable.<br>• On the **Command Line** tab, specify the type of access to allow to the CLI: **superreader**, **deviceadmin**, or **devicereader** (for Device roles); **vsysadmin** or **vsysreader** (for Virtual System roles); or **None** to disable CLI access entirely.<br>4. Click **OK** to save the profile.<br><br>For example, allow an admin full access to a device using the XML API, with the exception of importing or exporting files:<br> |

 © Palo Alto Networks, Inc.

| Create a Local Administrator (Continued) | | |
|---|---|---|
| Step 2 | (Optional) Set requirements for local user-defined passwords. | • **Create Password Profiles**—Define how often administrators must change their passwords. You can create multiple password profiles and apply them to administrator accounts as needed to enforce the desired security. To create a password profile, select **Device > Password Profiles** and then click the **Add**.<br>• **Configure minimum password complexity settings**—Define rules that govern password complexity, allowing you to force administrators to create passwords that are harder to guess, crack, or compromise. Unlike password profiles, which can be applied to individual accounts, these rules are device wide and apply to all passwords. To configure the settings, select **Device > Setup** and edit the Minimum Password Complexity section. |
| Step 3 | Create an account for each administrator. | 1. Select **Device > Administrators** and then click **Add**.<br>2. Enter a user **Name** and **Password** for the administrator, or create an **Authentication Profile** to use for validating an administrative user's credentials to an external authentication server. See Step 4 for details on setting up an authentication profile.<br>3. Select the **Role** to assign to this administrator. You can either select one of the predefined Dynamic roles or a custom Role Based profile if you created one in Step 1.<br>4. (Optional) Select a **Password Profile**.<br>5. Click **OK** to save the account. |

| Create a Local Administrator (Continued) | | |
|---|---|---|
| Step 4 | (Optional) Set up authentication to an external server—LDAP, RADIUS or Kerberos.<br><br>The server profile specifies how the firewall can connect to the authentication service you plan to use. | 1. Select **Device > Authentication Profile** and then click **Add**.<br>2. Enter a user **Name** to identify the authentication profile.<br>3. Define the conditions for locking out the administrative user.<br>a. Enter the **Lockout Time**. This is the number of minutes that a user is locked out upon reaching the maximum number of failed attempts (0-60 minutes; default 0). 0 means that the lockout is in effect until it is manually unlocked.<br>b. Enter the **Failed Attempts** count. This is the number of failed login attempts that are allowed before the account is locked out (1-10; default 0). By default, the failed attempt count is 0 and the user is not locked out despite repeated failure to authenticate.<br>4. Specify the users and groups that are explicitly allowed to authenticate. By adding an **Allow List** to an authentication profile, you can limit access to specific users in a user group/directory.<br>• Select the **All** check box to allow all users.<br>• Click **Add** and enter the first few characters of a name in the field to list all the users and user groups that start with those characters. Repeat to add as many users/user groups as required.<br>5. In the **Authentication** drop-down, select the type of authentication you plan to use on your network.<br>If you plan to use local database authentication, you must create the local database. Select **Device > Local User Database** and add the users and groups to be authenticated.<br>6. For access to an external authentication server (not local database), select the appropriate server profile in the **Server Profile** drop-down. To create a new server profile, click the link next to New and continue with configuring access to the **LDAP**, **RADIUS** or **Kerberos** server.<br>7. Click **OK**. |
| Step 5 | Commit your changes. | 1. Click **Commit**. |

# Reference: Web Interface Administrator Access

See the following topics for details on the options to set particularly granular access privileges for PAN-OS and Panorama web interface administrators.

- Web Interface Access Privileges
- Panorama Web Interface Access

## Web Interface Access Privileges

If you want to prevent a role-based administrator from accessing specific tabs on the web interface, you can disable the tab and the administrator will not even see it when logging in using the associated role-based administrative account. For example, you could create an Admin Role Profile for your operations staff that provides access to the **Device** and **Network** tabs only and a separate profile for your security administrators that provides access to the **Object**, **Policy**, and **Monitor** tabs.

The following table describes the tab-level access privileges you can assign to the admin role profile. It also provides cross-references to additional tables that detail granular privileges within a tab. For specific information on how to set the admin role profile to protect end user privacy, see Define User Privacy Settings in the Admin Role Profile.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Dashboard | Controls access to the **Dashboard** tab. If you disable this privilege, the administrator will not see the tab and will not have access to any of the Dashboard widgets. | Yes | No | Yes |
| ACC | Controls access to the Application Command Center (ACC). If you disable this privilege, the **ACC** tab will not display in the web interface. Keep in mind that if you want to protect the privacy of your users while still providing access to the ACC, you can disable the **Privacy > Show Full Ip Addresses** option and/or the **Show User Names In Logs And Reports** option. | Yes | No | Yes |
| Monitor | Controls access to the **Monitor** tab. If you disable this privilege, the administrator will not see the **Monitor** tab and will not have access to any of the logs, packet captures, session information, reports or to App Scope. For more granular control over what monitoring information the admin can see, leave the Monitor option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Monitor Tab. | Yes | No | Yes |

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Policies | Controls access to the **Policies** tab. If you disable this privilege, the administrator will not see the **Policies** tab and will not have access to any policy information. For more granular control over what policy information the admin can see, for example to enable access to a specific type of policy or to enable read-only access to policy information, leave the **Policies** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Policy Tab. | Yes | No | Yes |
| Objects | Controls access to the **Objects** tab. If you disable this privilege, the administrator will not see the **Objects** tab and will not have access to any objects, security profiles, log forwarding profiles, decryption profiles, or schedules. For more granular control over what objects the admin can see, leave the **Objects** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Objects Tab. | Yes | No | Yes |
| Network | Controls access to the **Network** tab. If you disable this privilege, the administrator will not see the **Network** tab and will not have access to any interface, zone, VLAN, virtual wire, virtual router, IPsec tunnel, DHCP, DNS Proxy, GlobalProtect, or QoS configuration information or to the network profiles. For more granular control over what objects the admin can see, leave the **Network** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Network Tab. | Yes | No | Yes |
| Device | Controls access to the **Device** tab. If you disable this privilege, the administrator will not see the **Device** tab and will not have access to any device-wide configuration information, such as User-ID, High Availability, server profile or certificate configuration information. For more granular control over what objects the admin can see, leave the **Objects** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Device Tab.<br> You cannot enable access to the **Admin Roles** or **Administrators** nodes for a role-based administrator even if you enable full access to the **Device** tab. | Yes | No | Yes |

© Palo Alto Networks, Inc.

## Provide Granular Access to the Monitor Tab

In some cases you might want to enable the administrator to view some but not all areas of the Monitor tab. For example, you may want to restrict operations admins to the configuration and system logs only, because they do not contain sensitive user data. Although this section of the admin role definition specifies what areas of the Monitor tab the admin can see, you can also couple privileges in this section with privacy privileges, such as disabling the ability to see user names in logs and reports. One thing to keep in mind, however, is that any system generated reports will still show user names and IP addresses even if you disable that functionality in the role. For this reason, if you do not want the admin to see any of the private user information, you should disable access to the specific reports as detailed in the following table.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Monitor | Enables or disables access to the **Monitor** tab. If disabled, the admin will not see this tab or any of the associated logs or reports. | Yes | No | Yes |
| Logs | Enables or disables access to all log files. You can also leave this privilege enabled and then disable specific logs that you do not want the admin to see. Keep in mind that if you want to protect the privacy of your users while still providing access to one or more of the logs, you can disable the **Privacy > Show Full Ip Addresses** option and/or the **Show User Names In Logs And Reports** option. | Yes | No | Yes |
| Traffic | Specifies whether the admin can see the traffic logs. | Yes | No | Yes |
| Threat | Specifies whether the admin can see the threat logs. | Yes | No | Yes |
| URL Filtering | Specifies whether the admin can see the URL filtering logs. | Yes | No | Yes |
| WildFire Submissions | Specifies whether the admin can see the WildFire logs. These logs are only available if you have a WildFire subscription. | Yes | No | Yes |
| Data Filtering | Specifies whether the admin can see the data filtering logs. | Yes | No | Yes |
| HIP Match | Specifies whether the admin can see the HIP Match logs. HIP Match logs are only available if you have a GlobalProtect portal license and gateway subscription. | Yes | No | Yes |
| Configuration | Specifies whether the admin can see the configuration logs. | Yes | No | Yes |
| System | Specifies whether the admin can see the system logs. | Yes | No | Yes |

© Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Alarms | Specifies whether the admin can see system generated alarms. | Yes | No | Yes |
| Packet Capture | Specifies whether the admin can see packet captures (pcaps) from the **Monitor** tab. Keep in mind that packet captures are raw flow data and as such may contain user IP addresses. Disabling the **Show Full IP Addresses** privileges will not obfuscate the IP address in the pcap and you should therefore disable the Packet Capture privilege if you are concerned about user privacy. | Yes | Yes | Yes |
| App Scope | Specifies whether the admin can see the App Scope visibility and analysis tools. Enabling App Scope enables access to all of the **App Scope** charts. | Yes | No | Yes |
| Session Browser | Specifies whether the admin can browse and filter current running sessions on the firewall. Keep in mind that the session browser shows raw flow data and as such may contain user IP addresses. Disabling the **Show Full IP Addresses** privileges will not obfuscate the IP address in the session browser and you should therefore disable the **Session Browser** privilege if you are concerned about user privacy. | Yes | No | Yes |
| Botnet | Specifies whether the admin can generate and view botnet analysis reports or view botnet reports in read-only mode. Disabling the **Show Full IP Addresses** privileges will not obfuscate the IP address in scheduled botnet reports and you should therefore disable the **Botnet** privilege if you are concerned about user privacy. | Yes | Yes | Yes |
| PDF Reports | Enables or disables access to all PDF reports. You can also leave this privilege enabled and then disable specific PDF reports that you do not want the admin to see. Keep in mind that if you want to protect the privacy of your users while still providing access to one or more of the reports, you can disable the **Privacy > Show Full Ip Addresses** option and/or the **Show User Names In Logs And Reports** option. | Yes | No | Yes |
| Manage PDF Summary | Specifies whether the admin can view, add or delete PDF summary report definitions. With read-only access, the admin can see PDF summary report definitions, but not add or delete them. If you disable this option, the admin can neither view the report definitions or add/delete them. | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| PDF Summary Reports | Specifies whether the admin can see the generated PDF Summary reports in **Monitor > Reports**. If you disable this option, the **PDF Summary Reports** category will not display in the **Reports** node. | Yes | No | Yes |
| User Activity Report | Specifies whether the admin can view, add or delete User Activity report definitions and download the reports. With read-only access, the admin can see User Activity report definitions, but not add, delete, or download them. If you disable this option, the admin cannot see this category of PDF report. | Yes | Yes | Yes |
| Report Groups | Specifies whether the admin can view, add or delete report group definitions. With read-only access, the admin can see report group definitions, but not add or delete them. If you disable this option, the admin cannot see this category of PDF report. | Yes | Yes | Yes |
| Email Scheduler | Specifies whether the admin can schedule report groups for email. Because the generated reports that get emailed may contain sensitive user data that is not removed by disabling the **Privacy > Show Full Ip Addresses** option and/or the **Show User Names In Logs And Reports** options and because they may also show log data to which the admin does not have access, you should disable the **Email Scheduler** option if you have user privacy requirements. | Yes | Yes | Yes |
| Manage Custom Reports | Enables or disables access to all Custom report functionality. You can also leave this privilege enabled and then disable specific custom report categories that you do not want the admin to be able to access. Keep in mind that if you want to protect the privacy of your users while still providing access to one or more of the reports, you can disable the **Privacy > Show Full Ip Addresses** option and/or the **Show User Names In Logs And Reports** option.<br> Reports that are scheduled to run rather than run on demand will show IP address and user information. In this case, be sure to restrict access to the corresponding report areas. In addition, the custom report feature does not restrict the ability to generate reports that contain log data contained in logs that are excluded from the admin role. | Yes | No | Yes |

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Application Statistics | Specifies whether the admin can create a custom report that includes data from the application statistics database. | Yes | No | Yes |
| Data Filtering Log | Specifies whether the admin can create a custom report that includes data from the data filtering log. | Yes | No | Yes |
| Threat Log | Specifies whether the admin can create a custom report that includes data from the threat log. | Yes | No | Yes |
| Threat Summary | Specifies whether the admin can create a custom report that includes data from the threat summary database. | Yes | No | Yes |
| Traffic Log | Specifies whether the admin can create a custom report that includes data from the traffic log. | Yes | No | Yes |
| Traffic Summary | Specifies whether the admin can create a custom report that includes data from the traffic summary database. | Yes | No | Yes |
| Url Log | Specifies whether the admin can create a custom report that includes data from the URL filtering log. | Yes | No | Yes |
| Hipmatch | Specifies whether the admin can create a custom report that includes data from the HIP match log. | Yes | No | Yes |
| View Scheduled Custom Reports | Specifies whether the admin can view a custom report that has been scheduled to generate. | Yes | No | Yes |
| View Predefined Application Reports | Specifies whether the admin can view Application Reports. Privacy privileges do not impact reports available on the **Monitor > Reports** node and you should therefore disable access to the reports if you have user privacy requirements. | Yes | No | Yes |
| View Predefined Threat Reports | Specifies whether the admin can view Threat Reports. Privacy privileges do not impact reports available on the **Monitor > Reports** node and you should therefore disable access to the reports if you have user privacy requirements. | Yes | No | Yes |
| View Predefined URL Filtering Reports | Specifies whether the admin can view URL Filtering Reports. Privacy privileges do not impact reports available on the **Monitor > Reports** node and you should therefore disable access to the reports if you have user privacy requirements. | Yes | No | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| View Predefined Traffic Reports | Specifies whether the admin can view Traffic Reports. Privacy privileges do not impact reports available on the **Monitor > Reports** node and you should therefore disable access to the reports if you have user privacy requirements. | Yes | No | Yes |

## Provide Granular Access to the Policy Tab

If you enable the Policy option in the admin role profile, you can then enable, disable, or provide read-only access to specific nodes within the tab as necessary for the admin role you are defining. By enabling access to a specific policy type, you enable the ability to view, add, or delete policy rules. By enabling read-only access to a specific policy, you enable the admin to view the corresponding policy rule base, but not add or delete rules. Disabling access to a specific type of policy prevents the admin from seeing the policy rule base.

Because policy that is based on specific users (by user name or IP address) must be explicitly defined, privacy settings that disable the ability to see full IP addresses or user names do not apply to the Policy tab. Therefore, you should only allow access to the Policy tab to administrators that are excluded from user privacy restrictions.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Security | Enable this privilege to allow the admin to view, add, and/or delete security policy rules. Set the privilege to read only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the security policy rule base, disable this privilege. | Yes | Yes | Yes |
| NAT | Enable this privilege to allow the admin to view, add, and/or delete NAT policy rules. Set the privilege to read only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the NAT policy rule base, disable this privilege. | Yes | Yes | Yes |
| QoS | Enable this privilege to allow the admin to view, add, and/or delete QoS policy rules. Set the privilege to read only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the QoS policy rule base, disable this privilege. | Yes | Yes | Yes |
| Policy Based Forwarding | Enable this privilege to allow the admin to view, add, and/or delete Policy Based Forwarding (PBF) policy rules. Set the privilege to read only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the PBF policy rule base, disable this privilege. | Yes | Yes | Yes |

© Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Decryption | Enable this privilege to allow the admin to view, add, and/or delete decryption policy rules. Set the privilege to read only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the decryption policy rule base, disable this privilege. | Yes | Yes | Yes |
| Application Override | Enable this privilege to allow the admin to view, add, and/or delete application override policy rules. Set the privilege to read only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the application override policy rule base, disable this privilege. | Yes | Yes | Yes |
| Captive Portal | Enable this privilege to allow the admin to view, add, and/or delete captive portal policy rules. Set the privilege to read only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the captive portal policy rule base, disable this privilege. | Yes | Yes | Yes |
| DoS Protection | Enable this privilege to allow the admin to view, add, and/or delete DoS protection policy rules. Set the privilege to read only if you want the admin to be able to see the rules, but not modify them. To prevent the admin from seeing the DoS protection policy rule base, disable this privilege. | Yes | Yes | Yes |

## Provide Granular Access to the Objects Tab

An *object* is a container that groups specific policy filter values—such as IP addresses, URLs, applications, or services—for simplified rule definition. For example, an address object might contain specific IP address definitions for the web and application servers in your DMZ zone.

When deciding whether to allow access to the objects tab as a whole, determine whether the admin will have policy definition responsibilities. If not, the admin probably does not need access to the tab. If, however, the admin will need to create policy, you can enable access to the tab and then provide granular access privileges at the node level.

By enabling access to a specific node, you give the admin the privilege to view, add, and delete the corresponding object type. Giving read-only access allows the admin to view the already defined objects, but not create or delete any. Disabling a node prevents the admin from seeing the node in the web interface.

| Access Level | | Enable | Read Only | Disable |
|---|---|---|---|---|
| Addresses | Specifies whether the admin can view, add, or delete address objects for use in security policy. | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | | Enable | Read Only | Disable |
|---|---|---|---|---|
| Address Groups | Specifies whether the admin can view, add, or delete address group objects for use in security policy. | Yes | Yes | Yes |
| Regions | Specifies whether the admin can view, add, or delete regions objects for use in security, decryption, or DoS policy. | Yes | Yes | Yes |
| Applications | Specifies whether the admin can view, add, or delete application objects for use in policy. | Yes | Yes | Yes |
| Application Groups | Specifies whether the admin can view, add, or delete application group objects for use in policy. | Yes | Yes | Yes |
| Application Filters | Specifies whether the admin can view, add, or delete application filters for simplification of repeated searches. | Yes | Yes | Yes |
| Services | Specifies whether the admin can view, add, or delete service objects for use in creating policies that limit the port numbers an application can use. | Yes | Yes | Yes |
| Service Groups | Specifies whether the admin can view, add, or delete service group objects for use in security policy. | Yes | Yes | Yes |
| Tags (Panorama only) | Specifies whether the admin can view, add, or delete tags that have been defined on the device. | Yes | Yes | Yes |
| GlobalProtect | Specifies whether the admin can view, add, or delete HIP objects and profiles. You can restrict access to both types of objects at the GlobalProtect level, or provide more granular control by enabling the GlobalProtect privilege and restricting HIP Object or HIP Profile access. | Yes | No | Yes |
| HIP Objects | Specifies whether the admin can view, add, or delete HIP objects, which are used to define HIP profiles. HIP Objects also generate HIP Match logs. | Yes | Yes | Yes |
| HIP Profiles | Specifies whether the admin can view, add, or delete HIP Profiles for use in security policy and/or for generating HIP Match logs. | Yes | Yes | Yes |
| Dynamic Block Lists | Specifies whether the admin can view, add, or delete dynamic block lists for use in security policy. | Yes | Yes | Yes |

© Palo Alto Networks, Inc.

| Access Level | | Enable | Read Only | Disable |
|---|---|---|---|---|
| Custom Objects | Specifies whether the admin can see the custom spyware and vulnerability signatures. You can restrict access to either enable or disable access to all custom signatures at this level, or provide more granular control by enabling the Custom Objects privilege and then restricting access to each type of signature. | Yes | No | Yes |
| Data Patterns | Specifies whether the admin can view, add, or delete custom data pattern signatures for use in creating custom vulnerability protection profiles. | Yes | Yes | Yes |
| Spyware | Specifies whether the admin can view, add, or delete custom spyware signatures for use in creating custom vulnerability protection profiles. | Yes | Yes | Yes |
| Vulnerability | Specifies whether the admin can view, add, or delete custom vulnerability signatures for use in creating custom vulnerability protection profiles. | Yes | Yes | Yes |
| URL Category | Specifies whether the admin can view, add, or delete custom URL categories for use in policy. | Yes | Yes | Yes |
| Security Profiles | Specifies whether the admin can see security profiles. You can restrict access to either enable or disable access to all security profiles at this level, or provide more granular control by enabling the Security Profiles privilege and then restricting access to each type of profile. | Yes | No | Yes |
| Antivirus | Specifies whether the admin can view, add, or delete antivirus profiles. | Yes | Yes | Yes |
| Anti-Spyware | Specifies whether the admin can view, add, or delete anti-spyware profiles. | Yes | Yes | Yes |
| Vulnerability Protection | Specifies whether the admin can view, add, or delete vulnerability protection profiles. | Yes | Yes | Yes |
| URL Filtering | Specifies whether the admin can view, add, or delete URL filtering profiles. | Yes | Yes | Yes |
| File Blocking | Specifies whether the admin can view, add, or delete file blocking profiles. | Yes | Yes | Yes |
| Data Filtering | Specifies whether the admin can view, add, or delete data filtering profiles. | Yes | Yes | Yes |
| DoS Protection | Specifies whether the admin can view, add, or delete DoS protection profiles. | Yes | Yes | Yes |
| Security Profile Groups | Specifies whether the admin can view, add, or delete security profile groups. | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | | Enable | Read Only | Disable |
|---|---|---|---|---|
| Log Forwarding | Specifies whether the admin can view, add, or delete log forwarding profiles. | Yes | Yes | Yes |
| Decryption Profile | Specifies whether the admin can view, add, or delete decryption profiles. | Yes | Yes | Yes |
| Schedules | Specifies whether the admin can view, add, or delete schedules for limiting a security policy to a specific date and/or time range. | Yes | Yes | Yes |

## Provide Granular Access to the Network Tab

When deciding whether to allow access to the **Network** tab as a whole, determine whether the admin will have network administration responsibilities, including GlobalProtect administration. If not, the admin probably does not need access to the tab.

You can also define access to the **Network** tab at the node level. By enabling access to a specific node, you give the admin the privilege to view, add, and delete the corresponding network configurations. Giving read-only access allows the admin to view the already defined configuration, but not create or delete any. Disabling a node prevents the admin from seeing the node in the web interface.

| Access Level | | Enable | Read Only | Disable |
|---|---|---|---|---|
| Interfaces | Specifies whether the admin can view, add, or delete interface configurations. | Yes | Yes | Yes |
| Zones | Specifies whether the admin can view, add, or delete zones. | Yes | Yes | Yes |
| VLANs | Specifies whether the admin can view, add, or delete VLANs. | Yes | Yes | Yes |
| Virtual Wires | Specifies whether the admin can view, add, or delete virtual wires. | Yes | Yes | Yes |
| Virtual Routers | Specifies whether the admin can view, add, modify or delete virtual routers. | Yes | Yes | Yes |
| IPSec Tunnels | Specifies whether the admin can view, add, modify, or delete IPSec Tunnel configurations. | Yes | Yes | Yes |
| DHCP | Specifies whether the admin can view, add, modify, or delete DHCP server and DHCP relay configurations. | Yes | Yes | Yes |
| DNS Proxy | Specifies whether the admin can view, add, modify, or delete DNS proxy configurations. | Yes | Yes | Yes |

© Palo Alto Networks, Inc.

| Access Level | | Enable | Read Only | Disable |
|---|---|---|---|---|
| GlobalProtect | Specifies whether the admin can view, add, modify GlobalProtect portal and gateway configurations. You can disable access to the GlobalProtect functions entirely, or you can enable the GlobalProtect privilege and then restrict the role to either the portal or gateway configuration areas. | Yes | No | Yes |
| Portals | Specifies whether the admin can view, add, modify, or delete GlobalProtect portal configurations. | Yes | Yes | Yes |
| Gateways | Specifies whether the admin can view, add, modify, or delete GlobalProtect gateway configurations. | Yes | Yes | Yes |
| MDM | Specifies whether the admin can view add, modify, or delete GlobalProtect MDM server configurations. | Yes | Yes | Yes |
| QoS | | Yes | Yes | Yes |
| Network Profiles | Sets the default state to enable or disable for all of the Network settings described below. | Yes | No | Yes |
| IKE Gateways | Controls access to the **Network Profiles > IKE Gateways** node. If you disable this privilege, the administrator will not see the **IKE Gateways** node or define gateways that include the configuration information necessary to perform IKE protocol negotiation with peer gateway.<br>If the privilege state is set to read only, you can view the currently configured IKE Gateways but cannot add or edit gateways. | Yes | Yes | Yes |
| IPSec Crypto | Controls access to the **Network Profiles > IPSec Crypto** node. If you disable this privilege, the administrator will not see the **Network Profiles > IPSec Crypto** node or specify protocols and algorithms for identification, authentication, and encryption in VPN tunnels based on IPSec SA negotiation.<br>If the privilege state is set to read only, you can view the currently configured IPSec Crypto configuration but cannot add or edit a configuration. | Yes | Yes | Yes |
| IKE Crypto | Controls how devices exchange information to ensure secure communication. Specify the protocols and algorithms for identification, authentication, and encryption in VPN tunnels based on IPsec SA negotiation (IKEv1 Phase-1). | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | | Enable | Read Only | Disable |
|---|---|---|---|---|
| Monitor | Controls access to the **Network Profiles > Monitor** node. If you disable this privilege, the administrator will not see the **Network Profiles > Monitor** node or be able to create or edit a monitor profile that is used to monitor IPSec tunnels and monitor a next-hop device for policy-based forwarding (PBF) rules.<br>If the privilege state is set to read only, you can view the currently configured monitor profile configuration but cannot add or edit a configuration. | Yes | Yes | Yes |
| Interface Mgmt | Controls access to the **Network Profiles > Interface Mgmt** node. If you disable this privilege, the administrator will not see the **Network Profiles > Interface Mgmt** node or be able to specify the protocols that are used to manage the firewall.<br>If the privilege state is set to read only, you can view the currently configured Interface management profile configuration but cannot add or edit a configuration. | Yes | Yes | Yes |
| Zone Protection | Controls access to the **Network Profiles > Zone Protection** node. If you disable this privilege, the administrator will not see the **Network Profiles > Zone Protection** node or be able to configure a profile that determines how the firewall responds to attacks from specified security zones.<br>If the privilege state is set to read only, you can view the currently configured Zone Protection profile configuration but cannot add or edit a configuration. | Yes | Yes | Yes |
| QoS Profile | Controls access to the **Network Profiles > QoS** node. If you disable this privilege, the administrator will not see the **Network Profiles > QoS** node or be able to configure a profile QoS profile that determines how QoS traffic classes are treated.<br>If the privilege state is set to read only, you can view the currently configured QoS profile configuration but cannot add or edit a configuration. | Yes | Yes | Yes |

## Provide Granular Access to the Device Tab

| Access Level | | Enable | Read Only | Disable |
|---|---|---|---|---|
| Setup | Controls access to the **Setup** node. If you disable this privilege, the administrator will not see the **Setup** node or have access to device-wide setup configuration information, such as Management, Operations, Service, Content-ID, Wildfire or Session setup information.<br>If the privilege state is set to read only, you can view the current configuration but cannot make any changes. | Yes | Yes | Yes |
| Config Audit | Controls access to the **Config Audit** node. If you disable this privilege, the administrator will not see the **Config Audit** node or have access to any device-wide configuration information. | Yes | No | Yes |
| Admin Roles | Controls access to the **Admin Roles** node. This function can only be allowed for read only access.<br>If you disable this privilege, the administrator will not see the **Admin Roles** node or have access to any device-wide information concerning admin roles configuration.<br>If you set this privilege to read only, you can view the configuration information for all admin roles configured on the device. | No | Yes | Yes |
| Administrators | Controls access to the **Administrators** node. This function can only be allowed for read only access.<br>If you disable this privilege, the administrator will not see the **Administrators** node or have access to information about their own admin account.<br>If you set this privilege to read only, the administrator can view the configuration information for their own admin account. They will not see any information about other admin accounts configured on the device. | No | Yes | Yes |
| Virtual Systems | Controls access to the **Virtual Systems** node. If you disable this privilege, the administrator will not see or be able to configure virtual systems.<br>If the privilege state is set to read only, you can view the currently configured virtual systems but cannot add or edit a configuration. | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | | Enable | Read Only | Disable |
|---|---|---|---|---|
| Shared Gateways | Controls access to the **Shared Gateways** node. Shared gateways allow virtual systems to share a common interface for external communications.<br>If you disable this privilege, the administrator will not see or be able to configure shared gateways.<br>If the privilege state is set to read only, you can view the currently configured shared gateways but cannot add or edit a configuration. | Yes | Yes | Yes |
| User Identification | Controls access to the **User Identification** node. If you disable this privilege, the administrator will not see the **User Identification** node or have access to device-wide User Identification configuration information, such as User Mapping, User-ID Agents, Service, Terminal Services Agents, Group Mappings Settings or Captive Portal Settings.<br>If you set this privilege to read only, the administrator can view configuration information for the device but is not allowed to perform any configuration procedures. | Yes | Yes | Yes |
| VM Information Source | Controls access to the **VM Information Source** node that allows you to configure the firewall/Windows User-ID agent to collect VM inventory automatically. If you disable this privilege, the administrator will not see the **VM Information Source** node.<br>If you set this privilege to read only, the administrator can view the VM information sources configured but cannot add, edit, or delete any sources. | Yes | Yes | Yes |
| High Availability | Controls access to the **High Availability** node. If you disable this privilege, the administrator will not see the **High Availability** node or have access to device-wide high availability configuration information such as General setup information or Link and Path Monitoring.<br>If you set this privilege to read only, the administrator can view High Availability configuration information for the device but is not allowed to perform any configuration procedures. | Yes | Yes | Yes |
| Certificate Management | Sets the default state to enable or disable for all of the Certificate settings described below. | Yes | No | Yes |

| Access Level | | Enable | Read Only | Disable |
|---|---|---|---|---|
| Certificates | Controls access to the **Certificates** node. If you disable this privilege, the administrator will not see the **Certificates** node or be able to configure or access information regarding Device Certificates or Default Trusted Certificate Authorities.<br>If you set this privilege to read only, the administrator can view Certificate configuration information for the device but is not allowed to perform any configuration procedures. | Yes | Yes | Yes |
| Certificate Profile | Controls access to the **Certificate Profile** node. If you disable this privilege, the administrator will not see the **Certificate Profile** node or be able to create certificate profiles.<br>If you set this privilege to read only, the administrator can view Certificate Profiles that are currently configured for the device but is not allowed to create or edit a certificate profile. | Yes | Yes | Yes |
| OCSP Responder | Controls access to the **OCSP Responder** node. If you disable this privilege, the administrator will not see the **OCSP Responder** node or be able to define a server that will be used to verify the revocation status of certificates issues by the PAN-OS device.<br>If you set this privilege to read only, the administrator can view the **OCSP Responder** configuration for the device but is not allowed to create or edit an OCSP responder configuration. | Yes | Yes | Yes |
| Response Pages | Controls access to the **Response Pages** node. If you disable this privilege, the administrator will not see the **Response Page** node or be able to define a custom HTML message that is downloaded and displayed instead of a requested web page or file.<br>If you set this privilege to read only, the administrator can view the **Response Page** configuration for the device but is not allowed to create or edit a response page configuration. | Yes | Yes | Yes |
| Log Settings | Sets the default state to enable or disable for all of the Log settings described below. | Yes | No | Yes |

 © Palo Alto Networks, Inc.

| Access Level | | Enable | Read Only | Disable |
|---|---|---|---|---|
| System | Controls access to the **Log Settings > System** node. If you disable this privilege, the administrator will not see the **Log Settings > System** node or be able to specify the severity levels of the system log entries that are logged remotely with Panorama and sent as SNMP traps, syslog messages, and/or email notifications.<br>If you set this privilege to read only, the administrator can view the **Log Settings > System** configuration for the device but is not allowed to create or edit a configuration. | Yes | Yes | Yes |
| Config | Controls access to the **Log Settings > Config** node. If you disable this privilege, the administrator will not see the **Log Settings > Config** node or be able to specify the configuration log entries that are logged remotely with Panorama, and sent as syslog messages and/or email notification.<br>If you set this privilege to read only, the administrator can view the **Log Settings > Config** configuration for the device but is not allowed to create or edit a configuration. | Yes | Yes | Yes |
| HIP Match | Controls access to the **Log Settings > HIP Match** node. If you disable this privilege, the administrator will not see the **Log Settings > HIP Match** node or be able to specify the Host Information Profile (HIP) match log settings that are used to provide information on security policies that apply to GlobalProtect clients<br>If you set this privilege to read only, the administrator can view the **Log Settings > HIP** configuration for the device but is not allowed to create or edit a configuration. | Yes | Yes | Yes |
| Alarms | Controls access to the **Log Settings > Alarms** node. If you disable this privilege, the administrator will not see the **Log Settings > Alarms** node or be able to configure notifications that are generated when a security rule (or group of rules) has been hit repeatedly in a set period of time.<br>If you set this privilege to read only, the administrator can view the **Log Settings > Alarms** configuration for the device but is not allowed to create or edit a configuration. | Yes | Yes | Yes |

| Access Level | | Enable | Read Only | Disable |
|---|---|---|---|---|
| Manage Logs | Controls access to the **Log Settings > Manage Logs** node. If you disable this privilege, the administrator will not see the **Log Settings > Manage Logs** node or be able to clear the indicated logs.<br>If you set this privilege to read only, the administrator can view the **Log Settings > Manage Logs** information but cannot clear any of the logs. | Yes | Yes | Yes |
| Server Profiles | Sets the default state to enable or disable for all of the Server Profiles settings described below. | Yes | No | Yes |
| SNMP Trap | Controls access to the **Server Profiles> SNMP Trap** node. If you disable this privilege, the administrator will not see the **Server Profiles> SNMP Trap** node or be able to specify one or more SNMP trap destinations to be used for system log entries.<br>If you set this privilege to read only, the administrator can view the **Server Profiles> SNMP Trap Logs** information but cannot specify SNMP trap destinations. | Yes | Yes | Yes |
| Syslog | Controls access to the **Server Profiles> Syslog** node. If you disable this privilege, the administrator will not see the **Server Profiles> Syslog** node or be able to specify one or more syslog servers.<br>If you set this privilege to read only, the administrator can view the **Server Profiles> Syslog** information but cannot specify syslog servers. | Yes | Yes | Yes |
| Email | Controls access to the **Server Profiles> Email** node. If you disable this privilege, the administrator will not see the **Server Profiles> Email** node or be able to configure an email profile that can be used to enable email notification for system and configuration log entries<br>If you set this privilege to read only, the administrator can view the **Server Profiles> Email** information but cannot configure and email profile. | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | | Enable | Read Only | Disable |
|---|---|---|---|---|
| Netflow | Controls access to the **Server Profiles> Netflow** node. If you disable this privilege, the administrator will not see the **Server Profiles> Netflow** node or be able to define a NetFlow server profile, which specifies the frequency of the export along with the NetFlow servers that will receive the exported data.<br>If you set this privilege to read only, the administrator can view the **Server Profiles> Netflow** information but cannot define a Netflow profile. | Yes | Yes | Yes |
| RADIUS | Controls access to the **Server Profiles> RADIUS** node. If you disable this privilege, the administrator will not see the **Server Profiles> RADIUS** node or be able to configure settings for the RADIUS servers that are identified in authentication profiles.<br>If you set this privilege to read only, the administrator can view the **Server Profiles> RADIUS** information but cannot configure settings for the RADIUS servers. | Yes | Yes | Yes |
| LDAP | Controls access to the **Server Profiles> LDAP** node. If you disable this privilege, the administrator will not see the **Server Profiles> LDAP** node or be able to configure settings for the LDAP servers to use for authentication by way of authentication profiles.<br>If you set this privilege to read only, the administrator can view the **Server Profiles> LDAP** information but cannot configure settings for the LDAP servers. | Yes | Yes | Yes |
| Kerberos | Controls access to the **Server Profiles> Kerberos** node. If you disable this privilege, the administrator will not see the **Server Profiles> Kerberos** node or configure a Kerberos server that allows users to authenticate natively to a domain controller.<br>If you set this privilege to read only, the administrator can view the **Server Profiles> Kerberos** information but cannot configure settings for Kerberos servers. | Yes | Yes | Yes |
| Local User Database | Sets the default state to enable or disable for all of the Local User Database settings described below. | Yes | No | Yes |

| Access Level | | Enable | Read Only | Disable |
|---|---|---|---|---|
| Users | Controls access to the **Local User Database > Users** node. If you disable this privilege, the administrator will not see the **Local User Database > Users** node or set up a local database on the firewall to store authentication information for remote access users, device administrators, and captive portal users.<br>If you set this privilege to read only, the administrator can view the **Local User Database > Users** information but cannot set up a local database on the firewall to store authentication information. | Yes | Yes | Yes |
| User Groups | Controls access to the **Local User Database > Users** node. If you disable this privilege, the administrator will not see the **Local User Database > Users** node or be able to add user group information to the local database.<br>If you set this privilege to read only, the administrator can view the **Local User Database > Users** information but cannot add user group information to the local database. | Yes | Yes | Yes |
| Authentication Profile | Controls access to the **Authentication Profile** node. If you disable this privilege, the administrator will not see the **Authentication Profile** node or be able to create or edit authentication profiles that specify local database, RADIUS, LDAP, or Kerberos settings that can be assigned to administrator accounts.<br>If you set this privilege to read only, the administrator can view the **Authentication Profile** information but cannot create or edit an authentication profile. | Yes | Yes | Yes |
| Authentication Sequence | Controls access to the **Authentication Sequence** node. If you disable this privilege, the administrator will not see the **Authentication Sequence** node or be able to create or edit an authentication sequence.<br>If you set this privilege to read only, the administrator can view the **Authentication Profile** information but cannot create or edit an authentication sequence. | Yes | Yes | Yes |

 © Palo Alto Networks, Inc.

| Access Level | | Enable | Read Only | Disable |
|---|---|---|---|---|
| Access Domain | Controls access to the **Authentication Sequence** node. If you disable this privilege, the administrator will not see the **Authentication Sequence** node or be able to create or edit an authentication sequence.<br>If you set this privilege to read only, the administrator can view the **Authentication Profile** information but cannot create or edit an authentication sequence. | Yes | Yes | Yes |
| Scheduled Log Export | Controls access to the **Scheduled Log Export** node. If you disable this privilege, the administrator will not see the **Scheduled Log Export** node or be able schedule exports of logs and save them to a File Transfer Protocol (FTP) server in CSV format or use Secure Copy (SCP) to securely transfer data between the device and a remote host.<br>If you set this privilege to read only, the administrator can view the **Scheduled Log Export Profile** information but cannot schedule the export of logs. | Yes | No | Yes |
| Software | Controls access to the **Software** node. If you disable this privilege, the administrator will not see the **Software** node or view the latest versions of the PAN-OS software available from Palo Alto Networks, read the release notes for each version, and select a release to download and install.<br>If you set this privilege to read only, the administrator can view the **Software** information but cannot download or install software. | Yes | Yes | Yes |
| GlobalProtect Client | Controls access to the **GlobalProtect Client** node. If you disable this privilege, the administrator will not see the **GlobalProtect Client** node or view available GlobalProtect releases, download the code or activate the GlobalProtect agent.<br>If you set this privilege to read only, the administrator can view the available **GlobalProtect Client** releases but cannot download or install the agent software. | Yes | Yes | Yes |

| Access Level | | Enable | Read Only | Disable |
|---|---|---|---|---|
| Dynamic Updates | Controls access to the **Dynamic Updates** node. If you disable this privilege, the administrator will not see the **Dynamic Updates** node or be able to view the latest updates, read the release notes for each update, or select an update to upload and install.<br>If you set this privilege to read only, the administrator can view the available **Dynamic Updates** releases, read the release notes but cannot upload or install the software. | Yes | Yes | Yes |
| Licenses | Controls access to the **Licenses** node. If you disable this privilege, the administrator will not see the **Licenses** node or be able to view the licenses installed or activate licenses.<br>If you set this privilege to read only, the administrator can view the installed **Licenses**, but cannot perform license management functions. | Yes | Yes | Yes |
| Support | Controls access to the **Support** node. If you disable this privilege, the administrator will not see the **Support** node or be able to access product and security alerts from Palo Alto Networks or generate tech support or stats dump files.<br>If you set this privilege to read only, the administrator can view the **Support** node and access product and security alerts but cannot generate tech support or stats dump files. | Yes | Yes | Yes |
| Master Key and Diagnostics | Controls access to the **Master Key and Diagnostics** node. If you disable this privilege, the administrator will not see the **Master Key and Diagnostics** node or be able to specify a master key to encrypt private keys on the firewall.<br>If you set this privilege to read only, the administrator can view the **Master Key and Diagnostics** node and view information about master keys that have been specified but cannot add or edit a new master key configuration. | Yes | Yes | Yes |

## Define User Privacy Settings in the Admin Role Profile

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Privacy | Sets the default state to enable or disable for all of the privacy settings described below. | Yes | N/A | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Show Full IP addresses | When set to disable, full IP addresses obtained by traffic running through the Palo Alto firewall are not shown in logs or reports. In place of the IP addresses that are normally displayed, the relevant subnet is displayed.<br> Scheduled reports that are displayed in the interface through **Monitor> Reports** and reports that are sent via scheduled emails will still display full IP addresses. Because of this exception, we recommend that the following settings within the **Monitor** tab be set to disable: Custom Reports, Application Reports, Threat Reports, URL Filtering Reports, Traffic Reports and Email Scheduler. | Yes | N/A | Yes |
| Show User Names in Logs and Reports | When set to disable, user names obtained by traffic running through the Palo Alto Networks firewall are not shown in logs or reports. Columns where the user names would normally be displayed are empty.<br> Scheduled reports that are displayed in the interface through **Monitor> Reports** or reports that are sent via the email scheduler will still display user names. Because of this exception, we recommend that the following settings within the Monitor tab be set to disable: Custom Reports, Application Reports, Threat Reports, URL Filtering Reports, Traffic Reports and Email Scheduler. | Yes | N/A | Yes |
| View Pcap Files | When set to disable, packet capture files that are normally available within the Traffic, Threat and Data Filtering logs are not displayed. | Yes | N/A | Yes |

## Restrict Admin Access to Commit Functions

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Commit | When set to disable, an admin cannot commit any changes to a configuration. | Yes | N/A | Yes |

### Provide Granular Access to Global Settings

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Global | Sets the default state to enable or disable for all of the global settings described below. In effect, this setting is only for System Alarms at this time. | Yes | N/A | Yes |
| System Alarms | When set to disable, an admin cannot view or acknowledge alarms that are generated. | Yes | N/A | Yes |

## Panorama Web Interface Access

On Panorama the Admin Roles allow you to define access to the options on Panorama and the ability to only allow access to Device Group and Template (**Policies**, **Objects**, **Network**, **Device** tabs).

The admin roles that you can create are: **Panorama** and **Device Group and Template**. The **Device Group and Template** admin role does not provide CLI access privileges.

If an administrator is given superuser privileges on the CLI, the administrator has complete access to all features regardless of the privileges given from the web interface.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Dashboard | Controls access to the **Dashboard** tab. If you disable this privilege, the administrator will not see the tab and will not have access to any of the Dashboard widgets. | Yes | No | Yes |
| ACC | Controls access to the Application Command Center (ACC). If you disable this privilege, the **ACC** tab will not display in the web interface. Keep in mind that if you want to protect the privacy of your users while still providing access to the ACC, you can disable the **Privacy > Show Full Ip Addresses** option and/or the **Show User Names In Logs And Reports** option. | Yes | No | Yes |
| Monitor | Controls access to the **Monitor** tab. If you disable this privilege, the administrator will not see the **Monitor** tab and will not have access to any of the logs, packet captures, session information, reports or to App Scope. For more granular control over what monitoring information the admin can see, leave the Monitor option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Monitor Tab. | Yes | No | Yes |

 © Palo Alto Networks, Inc.

| Access Level | Description | Enable | Read Only | Disable |
|---|---|---|---|---|
| Policies | Controls access to the **Policies** tab. If you disable this privilege, the administrator will not see the **Policies** tab and will not have access to any policy information. For more granular control over what policy information the admin can see, for example to enable access to a specific type of policy or to enable read-only access to policy information, leave the **Policies** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Policy Tab. | Yes | No | Yes |
| Objects | Controls access to the **Objects** tab. If you disable this privilege, the administrator will not see the **Objects** tab and will not have access to any objects, security profiles, log forwarding profiles, decryption profiles, or schedules. For more granular control over what objects the admin can see, leave the **Objects** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Objects Tab. | Yes | No | Yes |
| Network | Controls access to the **Network** tab. If you disable this privilege, the administrator will not see the **Network** tab and will not have access to any interface, zone, VLAN, virtual wire, virtual router, IPsec tunnel, DHCP, DNS Proxy, GlobalProtect, or QoS configuration information or to the network profiles. For more granular control over what objects the admin can see, leave the **Network** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Network Tab. | Yes | No | Yes |
| Device | Controls access to the **Device** tab. If you disable this privilege, the administrator will not see the **Device** tab and will not have access to any device-wide configuration information, such as User-ID, High Availability, server profile or certificate configuration information. For more granular control over what objects the admin can see, leave the **Objects** option enabled and then enable or disable specific nodes on the tab as described in Provide Granular Access to the Device Tab.<br> You cannot enable access to the **Admin Roles** or **Administrators** nodes for a role-based administrator even if you enable full access to the **Device** tab. | Yes | No | Yes |

# Certificate Management

The following topics describe the different keys and certificates that Palo Alto Networks devices use, and how to obtain and manage them:

- Keys and Certificates
- Certificate Revocation
- Certificate Deployment
- Set Up Verification for Certificate Revocation Status
- Configure the Master Key
- Obtain Certificates
- Configure a Certificate Profile
- Revoke and Renew Certificates
- Secure Keys with a Hardware Security Module

© Palo Alto Networks, Inc.

# Keys and Certificates

To ensure trust between parties in a secure communication session, Palo Alto Networks devices use digital certificates. Each certificate contains a cryptographic key to encrypt plaintext or decrypt cyphertext. Each certificate also includes a digital signature to authenticate the identity of the issuer. The issuer must be in the list of trusted certificate authorities (CAs) of the authenticating party. Optionally, the authenticating party verifies the issuer did not revoke the certificate (see Certificate Revocation).

Palo Alto Networks devices use certificates in the following applications:

- User authentication for Captive Portal, GlobalProtect, Mobile Security Manager, and firewall/Panorama web interface access.
- Device authentication for GlobalProtect VPN (remote user-to-site or large scale).
- Device authentication for IPSec site-to-site VPN with Internet Key Exchange (IKE).
- Decrypting inbound and outbound SSL traffic. A firewall decrypts the traffic to apply security policies and rules, then re-encrypts it before forwarding the traffic to the final destination. For outbound traffic, the firewall acts as a forward proxy server, establishing an SSL/TLS connection to the destination server. To secure a connection between itself and the client, the firewall uses a *signing certificate* to automatically generate a copy of the destination server certificate.

The following table describes the keys and certificates that Palo Alto Networks devices use. As a best practice, use different keys/certificates for each usage.

**Table: Palo Alto Networks Device Keys/Certificates**

| Key/Certificate Usage | Description |
|---|---|
| Administrative Access | Secure access to device administration interfaces (HTTPS access to the web interface) requires a server certificate for the MGT interface (or a designated interface on the dataplane if the device does not use MGT) and, optionally, a certificate to authenticate the administrator. |
| Captive Portal | In deployments where Captive Portal identifies users who access HTTPS resources, designate a server certificate for the Captive Portal interface. If you configure Captive Portal to use certificates (instead of, or in addition to, username/password credentials) for user identification, designate a user certificate also. For more information on Captive Portal, see Map IP Addresses to User Names Using Captive Portal. |
| Forward Trust | For outbound SSL/TLS traffic, if a firewall acting as a forward proxy trusts the CA that signed the certificate of the destination server, the firewall uses the forward trust CA certificate to generate a copy of the destination server certificate to present to the client. The firewall uses the same decryption key for all forward trust certificates. For added security, store the key on a hardware security module (for details, see Secure Keys with a Hardware Security Module). |
| Forward Untrust | For outbound SSL/TLS traffic, if a firewall acting as a forward proxy does not trust the CA that signed the certificate of the destination server, the firewall uses the forward untrust CA certificate to generate a copy of the destination server certificate to present to the client. |

 © Palo Alto Networks, Inc.

| Key/Certificate Usage | Description |
|---|---|
| SSL Inbound Inspection | The keys that decrypt inbound SSL/TLS traffic for inspection and policy enforcement. For this application, import onto the firewall a private key for each server that is subject to SSL/TLS inbound inspection. See Configure SSL Inbound Inspection. |
| SSL Exclude Certificate | Certificates for servers to exclude from SSL/TLS decryption. For example, if you enable SSL decryption but your network includes servers for which the firewall should not decrypt traffic (for example, web services for your HR systems), import the corresponding certificates onto the firewall and configure them as SSL Exclude Certificates. See Decryption Exceptions. |
| GlobalProtect | All interaction among GlobalProtect components occurs over SSL/TLS connections. Therefore, as part of the GlobalProtect deployment, deploy server certificates for all GlobalProtect portals, gateways, and Mobile Security Managers. Optionally, deploy certificates for authenticating users also.<br>Note that the GlobalProtect Large Scale VPN (LSVPN) feature requires a CA signing certificate. |
| Site-to-Site VPNs (IKE) | In a site-to-site IPSec VPN deployment, peer devices use Internet Key Exchange (IKE) gateways to establish a secure channel. IKE gateways use certificates or preshared keys to authenticate the peers to each other. You configure and assign the certificates or keys when defining an IKE gateway on a firewall. See Site-to-Site VPN Overview. |
| Master Key | The firewall uses a master key to encrypt all private keys and passwords. If your network requires a secure location for storing private keys, you can use an encryption (wrapping) key stored on a hardware security module (HSM) to encrypt the master key. For details, see Encrypt a Master Key Using an HSM. |
| Secure Syslog | The certificate to enable secure connections between the firewall and a syslog server. See Configure the Firewall to Authenticate to the Syslog Server. |
| Trusted Root CA | The designation for a root certificate issued by a CA that the firewall trusts. The firewall can use a self-signed root CA certificate to automatically issue certificates for other applications (for example, SSL Forward Proxy).<br>Also, if a firewall must establish secure connections with other firewalls, the root CA that issues their certificates must be in the list of trusted root CAs on the firewall. |

© Palo Alto Networks, Inc.

# Certificate Revocation

Palo Alto Networks devices use digital certificates to ensure trust between parties in a secure communication session. Configuring a device to check the revocation status of certificates provides additional security. A party that presents a revoked certificate is not trustworthy. When a certificate is part of a chain, the device checks the status of every certificate in the chain except the root CA certificate, for which the device cannot verify revocation status.

Various circumstances can invalidate a certificate before the expiration date. Some examples are a change of name, change of association between subject and certificate authority (for example, an employee terminates employment), and compromise (known or suspected) of the private key. Under such circumstances, the certificate authority that issued the certificate must revoke it.

Palo Alto Networks devices support the following methods for verifying certificate revocation status. If you configure both, the devices first try the OCSP method; if the OCSP server is unavailable, the devices use the CRL method.

- Certificate Revocation List (CRL)
- Open Certificate Status Protocol (OCSP)

In PAN-OS, certificate revocation status verification is an optional feature. It is a best practice to enable it for certificate profiles, which define user and device authentication for Captive Portal, GlobalProtect, site-to-site IPsec VPN, and firewall/Panorama web interface access.

## Certificate Revocation List (CRL)

Each certificate authority (CA) periodically issues a certificate revocation list (CRL) to a public repository. The CRL identifies revoked certificates by serial number. After the CA revokes a certificate, the next CRL update will include the serial number of that certificate.

The Palo Alto Networks firewall downloads and caches the last-issued CRL for every CA listed in the trusted CA list of the firewall. Caching only applies to validated certificates; if a firewall never validated a certificate, the firewall cache does not store the CRL for the issuing CA. Also, the cache only stores a CRL until it expires.

To use CRLs for verifying the revocation status of certificates when the firewall functions as an SSL forward proxy, Configure Revocation Status Verification of Certificates Used for SSL/TLS Decryption.

To use CRLs for verifying the revocation status of certificates that authenticate users and devices, configure a certificate profile and assign it to the interfaces that are specific to the application: Captive Portal, GlobalProtect (remote user-to-site or large scale), site-to-site IPSec VPN, or firewall/Panorama web interface access. For details, see Configure Revocation Status Verification of Certificates Used for User/Device Authentication.

## Open Certificate Status Protocol (OCSP)

When establishing an SSL/TLS session, clients can use Online Certificate Status Protocol (OCSP) to check the revocation status of the authentication certificate. The authenticating client sends a request containing the serial number of the certificate to the OCSP responder (server). The responder searches the database of the certificate

 © Palo Alto Networks, Inc.

authority (CA) that issued the certificate and returns a response containing the status (*good*, *revoked* or *unknown*) to the client. The advantage of the OCSP method is that it can verify status in real-time, instead of depending on the issue frequency (hourly, daily, or weekly) of CRLs.

The Palo Alto Networks firewall downloads and caches OCSP status information for every CA listed in the trusted CA list of the firewall. Caching only applies to validated certificates; if a firewall never validated a certificate, the firewall cache does not store the OCSP information for the issuing CA. If your enterprise has its own public key infrastructure (PKI), you can configure the firewall as an OCSP responder (see Configure an OCSP Responder).

To use OCSP for verifying the revocation status of certificates when the firewall functions as an SSL forward proxy, perform the steps under Configure Revocation Status Verification of Certificates Used for SSL/TLS Decryption.

The following applications use certificates to authenticate users and/or devices: Captive Portal, GlobalProtect (remote user-to-site or large scale), site-to-site IPSec VPN, and firewall/Panorama web interface access. To use OCSP for verifying the revocation status of the certificates:

- Configure an OCSP responder.
- Enable the HTTP OCSP service on the firewall.
- Create or obtain a certificate for each application.
- Configure a certificate profile for each application.
- Assign the certificate profile to the relevant application.

To cover situations where the OCSP responder is unavailable, configure CRL as a fall-back method. For details, see Configure Revocation Status Verification of Certificates Used for User/Device Authentication.

# Certificate Deployment

The basic approaches to deploy certificates for Palo Alto Networks devices are:

- **Obtain certificates from a trusted third-party CA**—The benefit of obtaining a certificate from a trusted third-party certificate authority (CA) such as VeriSign or GoDaddy is that end clients will already trust the certificate because common browsers include root CA certificates from well-known CAs in their trusted root certificate stores. Therefore, for applications that require end clients to establish secure connections with a Palo Alto Network device, purchase a certificate from a CA that the end clients trust to avoid having to pre-deploy root CA certificates to the end clients. (Some such applications are a GlobalProtect portal or GlobalProtect Mobile Security Manager.) However, note that most third-party CAs cannot issue signing certificates. Therefore, this type of certificate is not appropriate for applications (for example, SSL/TLS decryption and large-scale VPN) that require the firewall to issue certificates.
- **Obtain certificates from an enterprise CA**—Enterprises that have their own internal CA can use it to issue certificates for firewall applications and import them onto the firewall. The benefit is that end clients probably already trust the enterprise CA. You can either generate the needed certificates and import them onto the firewall, or generate a certificate signing request (CSR) on the firewall and send it to the enterprise CA for signing. The benefit of this method is that the private key does not leave the firewall. An enterprise CA can also issue a signing certificate, which the firewall uses to automatically generate certificates (for example, for GlobalProtect large-scale VPN or sites requiring SSL/TLS decryption).
- **Generate self-signed certificates**—You can generate a self-signed root CA certificate on the firewall and use it to automatically issue certificates for other firewall applications. Note that if you use this method to generate certificates for an application that requires an end client to trust the certificate, end users will see a certificate error because the root CA certificate is not in their trusted root certificate store. To prevent this, deploy the self-signed root CA certificate to all end user systems. You can deploy the certificates manually or use a centralized deployment method such as an Active Directory Group Policy Object (GPO).

 © Palo Alto Networks, Inc.

# Set Up Verification for Certificate Revocation Status

To verify the revocation status of certificates, the firewall uses Open Certificate Status Protocol (OCSP) and/or certificate revocation lists (CRLs). For details on these methods, see Certificate Revocation If you configure both methods, the firewall first tries OCSP and only falls back to the CRL method if the OCSP responder is unavailable. If your enterprise has its own public key infrastructure (PKI), you can configure the firewall to function as the OCSP responder.

The following topics describe how to configure the firewall to verify certificate revocation status:

- Configure an OCSP Responder
- Configure Revocation Status Verification of Certificates Used for User/Device Authentication
- Configure Revocation Status Verification of Certificates Used for SSL/TLS Decryption

## Configure an OCSP Responder

To use Open Certificate Status Protocol (OCSP) for verifying the revocation status of certificates, you must configure the firewall to access an OCSP responder (server). The entity that manages the OCSP responder can be a third-party certificate authority (CA) or, if your enterprise has its own public key infrastructure (PKI), the firewall itself. For details on OCSP, see Certificate Revocation

| **Configure an OCSP Responder** | |
|---|---|
| Step 1 Define an OCSP responder. | 1. In a firewall, select **Device > Certificate Management > OCSP Responder** and click **Add**.<br>In Panorama, select **Device > Certificate Management > OCSP Responder**, select a **Template** and click **Add**.<br>2. Enter a **Name** to identify the responder (up to 31 characters). The name is case-sensitive. It must be unique and use only letters, numbers, spaces, hyphens, and underscores.<br>3. If the firewall supports multiple virtual systems, the dialog displays a **Location** drop-down. Select the virtual system where the responder will be available or select **Shared** to enable availability on all the virtual systems.<br>4. In the **Host Name** field, enter the host name (recommended) or IP address of the OCSP responder. From this value, PAN-OS automatically derives a URL and adds it to the certificate being verified.<br>If you configure the firewall itself as an OCSP responder, the host name must resolve to an IP address in the interface that the firewall uses for OCSP services (specified in Step 3).<br>5. Click **OK**. |

| Configure an OCSP Responder | | |
|---|---|---|
| Step 2 | Enable OCSP communication on the firewall. | 1. In a firewall, select **Device > Setup > Management**.<br>In Panorama, select **Device > Setup > Management** and select a **Template**.<br>2. In the Management Interface Settings section, click the Edit icon, select the **HTTP OCSP** check box, then click **OK**. |
| Step 3 | Optionally, to configure the firewall itself as an OCSP responder, add an Interface Management Profile to the interface used for OCSP services. | 1. Select **Network > Network Profiles > Interface Mgmt**.<br>2. Click **Add** to create a new profile or click the name of an existing profile.<br>3. Select the **HTTP OCSP** check box and click **OK**.<br>4. Select **Network > Interfaces** and click the name of the interface that the firewall will use for OCSP services. The OCSP **Host Name** specified in Step 1 must resolve to an IP address in this interface.<br>5. Select **Advanced > Other info** and select the Interface Management Profile you configured.<br>6. Click **OK** and **Commit**. |

## Configure Revocation Status Verification of Certificates Used for User/Device Authentication

The firewall uses certificates to authenticate users and devices for such applications as Captive Portal, GlobalProtect, site-to-site IPSec VPN, and firewall/Panorama web interface access. To improve security, it is a best practice to configure the firewall to verify the revocation status of certificates that it uses for device/user authentication.

| Configure Revocation Status Verification of Certificates Used for User/Device Authentication | | |
|---|---|---|
| Step 1 | Configure a Certificate Profile for each application. | Assign one or more root CA certificates to the profile and select how the firewall verifies certificate revocation status. The common name (FQDN or IP address) of a certificate must match an interface to which you apply the profile in Step 2.<br>For details on the certificates that various applications use, see Keys and Certificates |
| Step 2 | Assign the certificate profiles to the relevant applications. | The steps to assign a certificate profile depend on the application that requires it. |

 © Palo Alto Networks, Inc.

# Configure Revocation Status Verification of Certificates Used for SSL/TLS Decryption

The firewall decrypts outbound SSL/TLS traffic to apply security policies and rules, then re-encrypts the traffic before forwarding it. During this process, the firewall acts as a forward proxy server, maintaining separate connections with the client and destination server. For the client connection, the firewall uses a CA certificate to automatically generate a decryption certificate that is a copy of the destination server certificate. You can configure the firewall to verify the revocation status of destination server certificates as follows.

Enabling revocation status verification for SSL/TLS decryption certificates will add time to the process of establishing the session. The first attempt to access a site might fail if the verification does not finish before the session times out. For these reasons, verification is disabled by default.

| **Configure Revocation Status Verification of Certificates Used for SSL/TLS Decryption** | | |
|---|---|---|
| Step 1 | Access the Decryption Certificate Revocation Settings page. | In a firewall, select **Device > Setup > Session** and, in the Session Features section, select **Decryption Certificate Revocation Settings**.<br>In Panorama, select **Device > Setup > Session**, select a **Template** and, in the Session Features section, select **Decryption Certificate Revocation Settings**. |
| Step 2 | Define the service-specific timeout intervals for revocation status requests. | Perform one or both of the following steps, depending on whether the firewall will use Open Certificate Status Protocol (OCSP) or the certificate revocation list (CRL) method to verify the revocation status of certificates. If the firewall will use both, it first tries OCSP; if the OCSP responder is unavailable, the firewall then tries the CRL method.<br>1. In the CRL section, select the **Enable** check box and enter the **Receive Timeout**. This is the interval (1-60 seconds) after which the firewall stops waiting for a response from the CRL service.<br>2. In the OCSP section, select the **Enable** check box and enter the **Receive Timeout**. This is the interval (1-60 seconds) after which the firewall stops waiting for a response from the OCSP responder.<br>Depending on the **Certificate Status Timeout** value you specify in Step 3, the firewall might register a timeout before either or both of the **Receive Timeout** intervals pass. |

| Configure Revocation Status Verification of Certificates Used for SSL/TLS Decryption | | |
|---|---|---|
| Step 3 | Define the total timeout interval for revocation status requests. | Enter the **Certificate Status Timeout**. This is the interval (1-60 seconds) after which the firewall stops waiting for a response from any certificate status service and applies the session blocking logic you optionally define in Step 4. The **Certificate Status Timeout** relates to the OCSP/CRL **Receive Timeout** as follows:<br>• If you enable both OCSP and CRL—The firewall registers a request timeout after the lesser of two intervals passes: the **Certificate Status Timeout** value or the aggregate of the two **Receive Timeout** values.<br>• If you enable only OCSP—The firewall registers a request timeout after the lesser of two intervals passes: the **Certificate Status Timeout** value or the OCSP **Receive Timeout** value.<br>• If you enable only CRL—The firewall registers a request timeout after the lesser of two intervals passes: the **Certificate Status Timeout** value or the CRL **Receive Timeout** value. |
| Step 4 | Define the blocking behavior for *unknown* certificate status or a revocation status request timeout. | If you want the firewall to block SSL/TLS sessions when the OCSP or CRL service returns a certificate revocation status of *unknown*, select the **Block Session With Unknown Certificate Status** check box. Otherwise, the firewall proceeds with the session.<br>If you want the firewall to block SSL/TLS sessions after it registers a request timeout, select the **Block Session On Certificate Status Check Timeout** check box. Otherwise, the firewall proceeds with the session. |
| Step 5 | Save and apply your entries. | Click **OK** and **Commit**. |

© Palo Alto Networks, Inc.

# Configure the Master Key

Every firewall has a default master key that encrypts private keys and other secrets (such as passwords and shared keys). The private keys authenticate users when they access administrative interfaces on the firewall. As a best practice to safeguard the keys, configure the master key on each firewall to be unique and periodically change it. For added security, use a *wrapping key* stored on a hardware security module (HSM) to encrypt the master key. For details, see Encrypt a Master Key Using an HSM.

In a high availability (HA) configuration, ensure both devices in the pair use the same master key to encrypt private keys and certificates. If the master keys differ, HA configuration synchronization will not work properly.

When you export a firewall configuration, the master key encrypts the passwords of users managed on external servers. For locally managed users, the firewall hashes the passwords but the master key does not encrypt them.

| Configure a Master Key |
|---|
| 1. In a firewall, select **Device > Master Key and Diagnostics** and, in the Master Key section, click the Edit icon.<br>In Panorama, select **Panorama > Master Key and Diagnostics** and, in the Master Key section, click the Edit icon. |
| 2. Enter the **Current Master Key** if one exists. |
| 3. Define a new **New Master Key** and then **Confirm New Master Key**. The key must contain exactly 16 characters. |
| 4. (Optional) To specify the master key **Life Time**, enter the number of **Days** and/or **Hours** after which the key will expire. If you set a life time, create a new master key before the old key expires. |
| 5. (Optional) If you set a key life time, enter a **Time for Reminder** that specifies the number of **Days** and **Hours** preceding master key expiration when the firewall emails you a reminder. |
| 6. (Optional) Select whether to use an **HSM** to encrypt the master key. For details, see Encrypt a Master Key Using an HSM. |
| 7. Click **OK** and **Commit**. |

© Palo Alto Networks, Inc.

# Obtain Certificates

- Create a Self-Signed Root CA Certificate
- Generate a Certificate on the Firewall
- Import a Certificate and Private Key
- Obtain a Certificate from an External CA

## Create a Self-Signed Root CA Certificate

A self-signed root certificate authority (CA) certificate is the top-most certificate in a certificate chain. A firewall can use this certificate to automatically issue certificates for other uses. For example, the firewall issues certificates for SSL/TLS decryption and for satellite devices in a GlobalProtect large-scale VPN.

When establishing a secure connection with the firewall, the remote client must trust the root CA that issued the certificate. Otherwise, the client browser will display a warning that the certificate is invalid and might (depending on security settings) block the connection. To prevent this, after generating the self-signed root CA certificate, import it into the client systems.

| **Generate a Self-signed Root CA Certificate** |
|---|
| 1. In a firewall, select **Device > Certificate Management > Certificates > Device Certificates**.<br>In Panorama, select **Device > Certificate Management > Certificates > Device Certificates** and select a **Template**. |
| 2. If the device supports multiple virtual systems, the tab displays a **Location** drop-down. Select a virtual system for the certificate. To make the certificate available to all virtual systems, select the shared option described in Step 6. |
| 3. Click **Generate**. |
| 4. Enter a **Certificate Name**, such as *GlobalProtect_CA*. The name is case-sensitive and can have up to 31 characters. It must be unique and use only letters, numbers, hyphens, and underscores. |
| 5. In the **Common Name** field, enter the FQDN (recommended) or IP address of the interface where you will configure the service that will use this certificate. |
| 6. To make the certificate available to all virtual systems, select the **Shared** check box. This check box only appears if the device supports multiple virtual systems. |
| 7. Leave the **Signed By** field blank to designate the certificate as self-signed. |
| 8. Select the **Certificate Authority** check box. |
| 9. Do *not* select an **OCSP Responder**. Certificate revocation status verification does not apply to root CA certificates. |
| 10. Click **Generate** and **Commit**. |

 © Palo Alto Networks, Inc.

## Generate a Certificate on the Firewall

The firewall uses certificates to authenticate clients, servers, users and devices in several applications, including SSL/TLS decryption, Captive Portal, GlobalProtect, site-to-site IPSec VPN, and firewall/Panorama web interface access. Generate certificates for each usage. For details on application-specific certificates, see Keys and Certificates

To generate a certificate, you must first create or import a root CA certificate to sign it. For details, see Create a Self-Signed Root CA Certificate or Import a Certificate and Private Key.

To use Open Certificate Status Protocol (OCSP) for verifying certificate revocation status, Configure an OCSP Responder *before* generating the certificate. For details on status verification, see Certificate Revocation

**Generate a Certificate on the Firewall**

1. In a firewall, select **Device > Certificate Management > Certificates > Device Certificates**.
   In Panorama, select **Device > Certificate Management > Certificates > Device Certificates** and select a **Template**.
2. If the device supports multiple virtual systems, the tab displays a **Location** drop-down. Select a virtual system for the certificate. To make the certificate available to all virtual systems, select the shared option described in Step 6.
3. Click **Generate**.
4. Enter a **Certificate Name**. The name is case-sensitive and can have up to 31 characters. It must be unique and use only letters, numbers, hyphens, and underscores.
5. In the **Common Name** field, enter the FQDN (recommended) or IP address of the interface where you will configure the service that will use this certificate.
6. To make the certificate available to all virtual systems, select the **Shared** check box. This check box only appears if the device supports multiple virtual systems.
7. In the **Signed By** field, select the root CA certificate that will issue the certificate.
8. If applicable, select an **OCSP Responder**.
9. (Optional) Define the **Cryptographic Settings** as necessary to create a certificate that will work with the devices that must authenticate to it. The default and recommended key size (**Number of Bits**) is 2048 bits. The default and recommended encryption algorithm (**Digest**) is SHA256.
10. (Optional) **Add** the **Certificate Attributes** to uniquely identify the firewall and the service that will use the certificate.

    If you add a **Host Name** (DNS name) attribute, it is a best practice for it to match the **Common Name**. The host name populates the Subject Alternative Name field of the certificate.
11. Click **Generate** and, in the Device Certificates tab, click the certificate **Name**.

    Regardless of the time zone on the firewall, it always displays the corresponding Greenwich Mean Time (GMT) for certificate validity and expiration dates/times.
12. Select the check boxes that correspond to the intended use of the certificate on the firewall. For example, if the firewall will use this certificate to authenticate user access to its web interface, select the **Certificate for Secure Web GUI** check box.
13. Click **OK** and **Commit**.

## Import a Certificate and Private Key

If your enterprise has its own public key infrastructure (PKI), you can import a certificate and private key into the firewall from your enterprise certificate authority (CA). Enterprise CA certificates (unlike most certificates purchased from a trusted, third-party CA) can automatically issue CA certificates for applications such as SSL/TLS decryption or large-scale VPN.

Instead of importing a self-signed root CA certificate into all the client systems, it is a best practice to import a certificate from the enterprise CA because the clients will already have a trust relationship with the enterprise CA, which simplifies the deployment.

If the certificate you will import is part of a certificate chain, it is a best practice to import the entire chain.

**Import a Certificate and Private Key**

1. From the enterprise CA, export the certificate and private key that the firewall will use for authentication.

   When exporting a private key, you must enter a passphrase to encrypt the key for transport. Ensure the management system can access the certificate and key files. When importing the key onto the firewall, you must enter the same passphrase to decrypt it.

2. In a firewall, select **Device > Certificate Management > Certificates > Device Certificates**.

   In Panorama, select **Device > Certificate Management > Certificates > Device Certificates** and select a **Template**.

3. If the device supports multiple virtual systems, the tab displays a **Location** drop-down. Select a virtual system for the certificate. To make the certificate available to all virtual systems, select the shared option described in Step 6.

4. Click **Import**.

5. Enter a **Certificate Name**. The name is case-sensitive and can have up to 31 characters. It must be unique and use only letters, numbers, hyphens, and underscores.

6. To make the certificate available to all virtual systems, select the **Shared** check box. This check box only appears if the device supports multiple virtual systems.

7. Enter the path and name of the **Certificate File** received from the CA, or **Browse** to find the file.

8. Select a **File Format**:
   - **Encrypted Private Key and Certificate (PKCS12)**—This is the default and most common format, in which the key and certificate are in a single container (**Certificate File**). If a hardware security module (HSM) will store the private key for this certificate, select the **Private key resides on Hardware Security Module** check box.
   - **Base64 Encoded Certificate (PEM)**—You must import the key separately from the certificate. If a hardware security module (HSM) stores the private key for this certificate, select the **Private key resides on Hardware Security Module** check box and skip Step 9. Otherwise, select the **Import Private Key** checkbox, enter the **Key File** or **Browse** to it, then perform Step 9.

9. Enter and re-enter (confirm) the **Passphrase** used to encrypt the private key.

10. Click **OK**. The Device Certificates tab displays the imported certificate.

 © Palo Alto Networks, Inc.

## Obtain a Certificate from an External CA

The advantage of obtaining a certificate from an external certificate authority (CA) is that the private key does not leave the firewall. To obtain a certificate from an external CA, generate a certificate signing request (CSR) and submit it to the CA. After the CA issues a certificate with the specified attributes, import it onto the firewall. The CA can be a well-known, public CA or an enterprise CA.

To use Open Certificate Status Protocol (OCSP) for verifying the revocation status of the certificate, Configure an OCSP Responder *before* generating the CSR.

| **Obtain a Certificate from an External CA** | | |
|---|---|---|
| Step 1 | Request the certificate from an external CA. | 1. In a firewall, select **Device > Certificate Management > Certificates > Device Certificates**.<br>In Panorama, select **Device > Certificate Management > Certificates > Device Certificates** and select a **Template**.<br>2. If the device supports multiple virtual systems, the tab displays a **Location** drop-down. Select a virtual system for the certificate. To make the certificate available to all virtual systems, select the shared option described in sub-step 6.<br>3. Click **Generate**.<br>4. Enter a **Certificate Name**. The name is case-sensitive and can have up to 31 characters. It must be unique and use only letters, numbers, hyphens, and underscores.<br>5. In the **Common Name** field, enter the FQDN (recommended) or IP address of the interface where you will configure the service that will use this certificate.<br>6. To make the certificate available to all virtual systems, select the **Shared** check box. This check box only appears if the device supports multiple virtual systems.<br>7. In the **Signed By** field, select **External Authority (CSR)**.<br>8. If applicable, select an **OCSP Responder**.<br>9. (Optional) **Add** the **Certificate Attributes** to uniquely identify the firewall and the service that will use the certificate.<br>If you add a **Host Name** attribute, it is a best practice for it to match the **Common Name** (this is mandatory for GlobalProtect). The host name populates the Subject Alternative Name field of the certificate.<br>10. Click **Generate**. The Device Certificates tab displays the CSR with a Status of *pending*. |
| Step 2 | Submit the CSR to the CA. | 1. Select the CSR and click **Export** to save the .csr file to a local computer.<br>2. Upload the .csr file to the CA. |

| Obtain a Certificate from an External CA | |
|---|---|
| Step 3 Import the certificate. | 1. After the CA sends a signed certificate in response to the CSR, return to the Device Certificates tab and click **Import**.<br>2. Enter the **Certificate Name** used to generate the CSR in Step 1-4.<br>3. Enter the path and name of the PEM **Certificate File** that the CA sent, or **Browse** to it.<br>4. Click **OK**. The Device Certificates tab displays the certificate with a Status of *valid*. |
| Step 4 Configure the certificate. | 1. Click the certificate **Name**.<br>2. Select the check boxes that correspond to the intended use of the certificate on the firewall. For example, if the firewall will use this certificate to authenticate administrators who access the web interface, select the **Certificate for Secure Web GUI** check box.<br>3. Click **OK** and **Commit**. |

 © Palo Alto Networks, Inc.

# Configure a Certificate Profile

Certificate profiles define user and device authentication for Captive Portal, GlobalProtect, site-to-site IPSec VPN, Mobile Security Manager, and firewall/Panorama web interface access. The profiles specify which certificates to use, how to verify certificate revocation status, and how that status constrains access. Configure a certificate profile for each application.

It is a best practice to enable Open Certificate Status Protocol (OCSP) and/or Certificate Revocation List (CRL) status verification for certificate profiles. For details on these methods, see Certificate Revocation

| Configure a Certificate Profile | | |
|---|---|---|
| Step 1 | Obtain the certificate authority (CA) certificates you will assign. | Perform one of the following steps to obtain the CA certificates you will assign to the profile. You must assign at least one.<br>• Create a Self-Signed Root CA Certificate.<br>• Export a certificate from your enterprise CA and then import it onto the firewall (see Step 3). |
| Step 2 | Identify the certificate profile. | 1. In a firewall, select **Device > Certificate Management > Certificates Profile** and click **Add**.<br>In Panorama, select **Device > Certificate Management > Certificates Profile**, select a **Template** and click **Add**.<br>2. Enter a **Name** to identify the profile. The name is case-sensitive. It must be unique and use only letters, numbers, spaces, hyphens, and underscores. It can have up to 31 characters.<br>3. If the firewall supports multiple virtual systems, the dialog displays a **Location** drop-down. Select the virtual system where the profile will be available or select **Shared** to enable availability on all the virtual systems. |

| Configure a Certificate Profile | |
|---|---|
| Step 3 Assign one or more certificates. | Perform the following steps for each certificate:<br>1. In the CA Certificates table, click **Add**.<br>2. Select a **CA Certificate** from Step 1, or click **Import** and perform the following sub-steps:<br>a. Enter a **Certificate Name**.<br>b. Enter the path and name of the **Certificate File** you exported from your enterprise CA, or **Browse** to find the file.<br>c. Click **OK**.<br>3. Optionally, if the firewall uses OCSP to verify certificate revocation status, configure the following fields to override the default behavior. For most deployments, these fields do not apply.<br>• By default, the firewall uses the OCSP responder URL that you set in the procedure Configure an OCSP Responder. To override that setting, enter a **Default OCSP URL** (starting with *http://* or *https://*).<br>• By default, the firewall uses the certificate selected in the **CA Certificate** field to validate OCSP responses. To use a different certificate for validation, select it in the **OCSP Verify CA Certificate** field.<br>4. Click **OK**. The CA Certificates table displays the assigned certificate. |

© Palo Alto Networks, Inc.

| Configure a Certificate Profile | | |
|---|---|---|
| Step 4 | Define the methods for verifying certificate revocation status and the associated blocking behavior. | 1. Select **Use CRL** and/or **Use OCSP**. If you select both, the firewall first tries OCSP and only falls back to the CRL method if the OCSP responder is unavailable.<br>2. Depending on the verification method, enter the **CRL Receive Timeout** and/or **OCSP Receive Timeout**. These are the intervals (1-60 seconds) after which the firewall stops waiting for a response from the CRL/OCSP service.<br>3. Enter the **Certificate Status Timeout**. This is the interval (1-60 seconds) after which the firewall stops waiting for a response from any certificate status service and applies any session blocking logic you define. The **Certificate Status Timeout** relates to the OCSP/CRL **Receive Timeout** as follows:<br>• If you enable both OCSP and CRL—The firewall registers a request timeout after the lesser of two intervals passes: the **Certificate Status Timeout** value or the aggregate of the two **Receive Timeout** values.<br>• If you enable only OCSP—The firewall registers a request timeout after the lesser of two intervals passes: the **Certificate Status Timeout** value or the OCSP **Receive Timeout** value.<br>• If you enable only CRL—The firewall registers a request timeout after the lesser of two intervals passes: the **Certificate Status Timeout** value or the CRL **Receive Timeout** value.<br>4. If you want the firewall to block sessions when the OCSP or CRL service returns a certificate revocation status of *unknown*, select the **Block session if certificate status is unknown** check box. Otherwise, the firewall proceeds with the session.<br>5. If you want the firewall to block sessions after it registers an OCSP or CRL request timeout, select the **Block session if certificate status cannot be retrieved within timeout** check box. Otherwise, the firewall proceeds with the session. |
| Step 5 | Save and apply your entries. | Click **OK** and **Commit**. |

# Revoke and Renew Certificates

▲ Revoke a Certificate
▲ Renew a Certificate

## Revoke a Certificate

Various circumstances can invalidate a certificate before the expiration date. Some examples are a change of name, change of association between subject and certificate authority (for example, an employee terminates employment), and compromise (known or suspected) of the private key. Under such circumstances, the certificate authority (CA) that issued the certificate must revoke it. The following task describes how to revoke a certificate for which the firewall is the CA.

| **Revoke a Certificate** |
|---|
| 1. Select **Device > Certificate Management > Certificates > Device Certificates**. |
| 2. If the device supports multiple virtual systems, the tab displays a **Location** drop-down. Select the virtual system to which the certificate belongs. |
| 3. Select the certificate to revoke. |
| 4. Click **Revoke**. PAN-OS immediately sets the status of the certificate to revoked and adds the serial number to the Open Certificate Status Protocol (OCSP) responder cache or certificate revocation list (CRL). You need not perform a commit. |

## Renew a Certificate

If a certificate expires, or soon will, you can reset the validity period. If an external certificate authority (CA) signed the certificate and the firewall uses the Open Certificate Status Protocol (OCSP) to verify certificate revocation status, the firewall uses the OCSP responder information to update the certificate status (see Configure an OCSP Responder). If the firewall is the CA that issued the certificate, the firewall replaces it with a new certificate that has a different serial number but the same attributes as the old certificate.

| **Renew a Certificate** |
|---|
| 1. In a firewall, select **Device > Certificate Management > Certificates > Device Certificates**.<br>In Panorama, select **Device > Certificate Management > Certificates > Device Certificates** and select a **Template**. |
| 2. If the device supports multiple virtual systems, the tab displays a **Location** drop-down. Select the virtual system to which the certificate belongs. |
| 3. Select a certificate to renew and click **Renew**. |
| 4. Enter a **New Expiration Interval** (in days). |
| 5. Click **OK** and **Commit**. |

 © Palo Alto Networks, Inc.

# Secure Keys with a Hardware Security Module

A hardware security module (HSM) is a physical device that manages digital keys. An HSM provides secure storage and generation of digital keys. It provides both logical and physical protection of these materials from non-authorized use and potential adversaries.

HSM clients integrated with Palo Alto Networks devices enable enhanced security for the private keys used in SSL/TLS decryption (both SSL forward proxy and SSL inbound inspection). In addition, you can use the HSM to encrypt device master keys.

The following topics describe how to integrate an HSM with your Palo Alto Networks devices:

- Set up Connectivity with an HSM
- Encrypt a Master Key Using an HSM
- Store Private Keys on an HSM
- Manage the HSM Deployment

# Set up Connectivity with an HSM

HSM clients are integrated with PA-3000 Series, PA-4000 Series, PA-5000 Series, PA-7050, and VM-Series firewalls and on Panorama (virtual appliance and M-100 appliance) for use with the following HSMs:

- SafeNet Luna SA 5.2.1 or later
- Thales Nshield Connect 11.62 or later

The HSM server version must be compatible with these client versions. Refer to the HSM vendor documentation for the client-server version compatibility matrix.

The following topics describe how to set up connectivity between the firewall/Panorama and one of the supported HSMs:

▲ Set Up Connectivity with a SafeNet Luna SA HSM

▲ Set Up Connectivity with a Thales Nshield Connect HSM

## Set Up Connectivity with a SafeNet Luna SA HSM

To set up connectivity between the Palo Alto Networks device and a SafeNet Luna SA HSM, you must specify the address of the HSM server and the password for connecting to it in the firewall configuration. In addition, you must register the firewall with the HSM server. Prior to beginning the configuration, make sure you have created a partition for the Palo Alto Networks devices on the HSM server.

HSM configuration is not synced between high availability firewall peers. Consequently, you must configure the HSM module separately on each of the peers.

In Active-Passive HA deployments, you must manually perform one failover to configure and authenticate each HA peer individually to the HSM. After this manual failover has been performed, user interaction is not required for the failover function.

| **Set up a Connectivity with a SafeNet Luna SA HSM** | |
|---|---|
| Step 1 Configure the firewall to communicate with the SafeNet Luna SA HSM. | 1. Log in to the firewall web interface and select **Device > Setup > HSM**.<br>2. Edit the Hardware Security Module Provider section and select **Safenet Luna SA** as the **Provider Configured**.<br>3. Click **Add** and enter a **Module Name**. This can be any ASCII string up to 31 characters in length.<br>4. Enter the IPv4 address of the HSM module as the **Server Address**.<br>If you are configuring a high availability HSM configuration, enter module names and IP addresses for the additional HSM devices.<br>5. (Optional) If configuring a high availability HSM configuration, select the **High Availability** check box and add the following: a value for **Auto Recovery Retry** and a **High Availability Group Name**.<br>If two HSM servers are configured, you should configure high availability. Otherwise the second HSM server is not used.<br>6. Click **OK** and **Commit.** |

 © Palo Alto Networks, Inc.

| Set up a Connectivity with a SafeNet Luna SA HSM (Continued) | | |
|---|---|---|
| Step 2 | (Optional) Configure a service route to enable the firewall to connect to the HSM.<br><br>By default, the firewall uses the Management Interface to communicate with the HSM. To use a different interface, you must configure a service route. | 1. Select **Device > Setup > Services.**<br>2. Select **Service Route Configuration** from the Services Features area.<br>3. Select **Customize** from the Service Route Configuration area.<br>4. Select the **IPv4** tab.<br>5. Select **HSM** from the **Service** column.<br>6. Select an interface to use for HSM from the **Source Interface** drop-down.<br><br>If you select a dataplane connected port for HSM, issuing the `clear session all` CLI command, will clear all existing HSM sessions causing all HSM states to be brought down and then up. During the several seconds required for HSM to recover, all SSL/TLS operations will fail.<br><br>7. Click **OK** and **Commit.** |
| Step 3 | Configure the firewall to authenticate to the HSM. | 1. Select **Device > Setup > HSM**.<br>2. Select **Setup Hardware Security Module** in the Hardware Security Operations area.<br>3. Select the HSM **Server Name** from the drop-down.<br>4. Enter the **Administrator Password** to authenticate the firewall to the HSM.<br>5. Click **OK.**<br><br>The firewall attempts to perform an authentication with the HSM and displays a status message.<br><br>6. Click **OK.** |
| Step 4 | Register the firewall (the HSM client) with the HSM and assign it to a partition on the HSM.<br><br>If the HSM already has a firewall with the same `<cl-name>` registered, you must remove the duplicate registration using the following command before registration will succeed:<br><br>`client delete -client <cl-name>`<br><br>where `<cl-name>` is the name of the client (firewall) registration you want to delete. | 1. Log in to the HSM from a remote system.<br>2. Register the firewall using the following command:<br><br>`client register -c <cl-name> -ip <fw-ip-addr>`<br><br>where `<cl-name>` is a name that you assign to the firewall for use on the HSM and `<fw-ip-addr>` is the IP address of the firewall that is being configured as an HSM client.<br><br>3. Assign a partition to the firewall using the following command:<br><br>`client assignpartition -c <cl-name> -p <partition-name>`<br><br>where `<cl-name>` is the name assigned to the firewall in the `client register` command and `<partition-name>` is the name of a previously configured partition that you want to assign to the firewall. |

| Set up a Connectivity with a SafeNet Luna SA HSM (Continued) | | |
|---|---|---|
| Step 5 | Configure the firewall to connect to the HSM partition. | 1. Select **Device > Setup > HSM**.<br>2. Click the **Refresh** icon.<br>3. Select the **Setup HSM Partition** in the Hardware Security Operations area.<br>4. Enter the **Partition Password** to authenticate the firewall to the partition on the HSM.<br>5. Click **OK**. |
| Step 6 | (Optional) Configure an additional HSM for high availability (HA). | 1. Follow Step 1 through Step 5 to add an additional HSM for high availability (HA).<br>This process adds a new HSM to the existing HA group.<br>2. If you remove an HSM from your configuration, repeat Step 5.<br>This will remove the deleted HSM from the HA group. |
| Step 7 | Verify connectivity with the HSM. | 1. Select **Device > Setup > HSM**.<br>2. Check the **Status** of the HSM connection:<br>Green = HSM is authenticated and connected<br>Red = HSM was not authenticated or network connectivity to the HSM is down.<br>3. View the following columns in Hardware Security Module Status area to determine authentication status:<br>**Serial Number** —The serial number of the HSM partition if the HSM was successfully authenticated.<br>**Partition**—The partition name on the HSM that was assigned on the firewall.<br>**Module State**—The current operating state of the HSM. It always has the value Authenticated if the HSM is displayed in this table. |

## Set Up Connectivity with a Thales Nshield Connect HSM

The following workflow describes how to configure the firewall to communicate with a Thales Nshield Connect HSM. This configuration requires that you set up a remote filesystem (RFS) to use as a *hub* to sync key data for all firewalls in your organization that are using the HSM.

HSM configuration is not synced between high availability firewall peers. Consequently, you must configure the HSM module separately on each of the peers.

If the high availability firewall configuration is in Active-Passive mode, you must manually perform one failover to configure and authenticate each HA peer individually to the HSM. After this manual failover has been performed, user interaction is not required for the failover function.

 © Palo Alto Networks, Inc.

| Set up Connectivity with a Thales Nshield Connect HSM | | |
|---|---|---|
| Step 1 | Configure the Thales Nshield Connect server as the firewall's HSM provider. | 1. From the firewall web interface, select **Device > Setup > HSM** and edit the Hardware Security Module Provider section.<br>2. Select **Thales Nshield Connect** as the **Provider Configured**.<br>3. Click **Add** and enter a **Module Name**. This can be any ASCII string up to 31 characters in length.<br>4. Enter the IPv4 address as the **Server Address** of the HSM module.<br>If you are configuring a high availability HSM configuration, enter module names and IP addresses for the additional HSM devices.<br>5. Enter the IPv4 address of the **Remote Filesystem Address**.<br>6. Click **OK** and **Commit**. |
| Step 2 | (Optional) Configure a service route to enable the firewall to connect to the HSM.<br>By default, the firewall uses the Management Interface to communicate with the HSM. To use a different interface, you must configure a service route. | 1. Select **Device > Setup > Services.**<br>2. Select **Service Route Configuration** from the Services Features area.<br>3. Select **Customize** from the Service Route Configuration area.<br>4. Select the **IPv4** tab.<br>5. Select **HSM** from the **Service** column.<br>6. Select an interface to use for HSM from the **Source Interface** drop-down.<br>If you select a dataplane connected port for HSM, issuing the `clear session all` CLI command, will clear all existing HSM sessions causing all HSM states to be brought down and then up. During the several seconds required for HSM to recover, all SSL/TLS operations will fail.<br>7. Click **OK** and **Commit.** |
| Step 3 | Register the firewall (the HSM client) with the HSM server.<br>This step briefly describes the procedure for using the front panel interface of the Thales Nshield Connect HSM. For more details, consult the Thales documentation. | 1. Log in to the front panel display of the Thales Nshield Connect HSM unit.<br>2. On the unit front panel, use the right-hand navigation button to select **System > System configuration > Client config > New client**.<br>3. Enter the IP address of the firewall.<br>4. Select **System > System configuration > Client config > Remote file system** and enter the IP address of the client computer where you set up the remote file system. |

| Set up Connectivity with a Thales Nshield Connect HSM (Continued) | | |
|---|---|---|
| Step 4 | Set up the remote filesystem to accept connections from the firewall. | 1. Log in to the remote filesystem (RFS) from a Linux client.<br>2. Obtain the electronic serial number (ESN) and the hash of the $K_{NETI}$ key. The $K_{NETI}$ key authenticates the module to clients:<br>`anonkneti <ip-address>`<br>where `<ip-address>` is the IP address of the HSM.<br>The following is an example:<br>`anonkneti 192.0.2.1 B1E2-2D4C-E6A2 5a2e5107e70d525615a903f6391ad72b1c03352c`<br>In this example, **`B1E2-2D4C-E6A2`** is the ESM and 5a2e5107e70d525615a903f6391ad72b1c03352c is the hash of the $K_{NETI}$ key.<br>3. Use the following command from a superuser account to perform the remote filesystem setup:<br>`rfs-setup --force <ip-address> <ESN> <hash-Kneti-key>`<br>where `<ip-address>` is the IP address of the HSM,<br>`<ESN>` is the electronic serial number (ESN) and<br>`<hash-Kneti-key>` is the hash of the KNETI key.<br>The following example uses the values obtained in this procedure:<br>`rfs-setup --force <192.0.2.1> <B1E2-2D4C-E6A2> <5a2e5107e70d525615a903f6391ad72b1c03352c>`<br>4. Use the following command to permit client submit on the Remote Filesystem:<br>`rfs-setup --gang-client --write-noauth <FW-IPaddress>`<br>where `<FW-IPaddress>` is the IP address of the firewall. |
| Step 5 | Configure the firewall to authenticate to the HSM. | 1. From the firewall web interface, select **Device > Setup > HSM**.<br>2. Select **Setup Hardware Security Module** in the Hardware Security Operations area.<br>3. Click **OK.**<br>The firewall attempts to perform an authentication with the HSM and displays a status message.<br>4. Click **OK.** |
| Step 6 | Synchronize the firewall with the remote filesystem. | 1. Select the **Device > Setup > HSM**.<br>2. Select **Synchronize with Remote Filesystem** in the Hardware Security Operations section. |

 © Palo Alto Networks, Inc.

| Set up Connectivity with a Thales Nshield Connect HSM (Continued) | | |
|---|---|---|
| Step 7 | Verify that the firewall can connect to the HSM. | 1. Select **Device > Setup > HSM**.<br>2. Check the Status indicator to verify that the firewall is connected to the HSM:<br>Green = HSM is authenticated and connected.<br>Red = HSM was not authenticated or network connectivity to the HSM is down.<br>3. View the following columns in Hardware Security Module Status section to determine authentication status.<br>**Name**: The name of the HSM attempting to be authenticated.<br>**IP address:** The IP address of the HSM that was assigned on the firewall.<br>**Module State**: The current operating state of the HSM: **Authenticated** or **Not Authenticated**. |

# Encrypt a Master Key Using an HSM

A master key is configured on a Palo Alto Networks firewall to encrypt all private keys and passwords. If you have security requirements to store your private keys in a secure location, you can encrypt the master key using an encryption key that is stored on an HSM. The firewall then requests the HSM to decrypt the master key whenever it is required to decrypt a password or private key on the firewall. Typically, the HSM is located in a highly secure location that is separate from the firewall for greater security.

The HSM encrypts the master key using a wrapping key. To maintain security, this encryption key must occasionally be changed. For this reason, a command is provided on the firewall to rotate the wrapping key which changes the master key encryption. The frequency of this wrapping key rotation depends on your application.

Master key encryption using an HSM is not supported on firewalls configured in FIPS of CC mode.

The following topics describe how to encrypt the master key initially and how to refresh the master key encryption:

- Encrypt the Master Key
- Refresh the Master Key Encryption

## Encrypt the Master Key

If you have not previously encrypted the master key on a device, use the following procedure to encrypt it. Use this procedure for first time encryption of a key, or if you define a new master key and you want to encrypt it. If you want to refresh the encryption on a previously encrypted key, see Refresh the Master Key Encryption.

| Encrypt a Master Key Using an HSM | |
|---|---|
| 1. | Select **Device > Master Key and Diagnostics.** |
| Step 8 | Specify the key that is currently used to encrypt all of the private keys and passwords on the firewall in the **Master Key** field. |
| Step 9 | If changing the master key, enter the new master key and confirm. |
| Step 10 | Select the **HSM** check box.<br>**Life Time:** The number of days and hours after which the master key expires (range 1-730 days).<br>**Time for Reminder:** The number of days and hours before expiration when the user is notified of the impending expiration (range 1-365 days). |
| Step 11 | Click **OK**. |

## Refresh the Master Key Encryption

As a best practice, refresh the master key encryption on a regular basis by rotating the master key wrapping key on the HSM. This command is the same for both the SafeNet Luna SA and Thales Nshield Connect HSMs.

 © Palo Alto Networks, Inc.

**Refresh the Master Key Encryption**

1. Use the following CLI command to rotate the wrapping key for the master key on an HSM:

   ```
   > request hsm mkey-wrapping-key-rotation
   ```

   If the master key is encrypted on the HSM, the CLI command will generate a new wrapping key on the HSM and encrypt the master key with the new wrapping key.

   If the master key is not encrypted on the HSM, the CLI command will generate new wrapping key on the HSM for future use.

   The old wrapping key is not deleted by this command.

## Store Private Keys on an HSM

For added security, the private keys used to enable SSL/TLS decryption—both SSL forward proxy and SSL inbound inspection—can be secured with an HSM as follows:

- **SSL forward proxy**—The private key in the CA certificate that is used to sign certificates in SSL/TLS forward proxy operations can be stored on the HSM. The firewall will then send the certificates it generates during SSL/TLS forward proxy operations to the HSM for signing before forwarding them on to the client.
- **SSL inbound inspection**—The private keys for the internal servers for which you are doing SSL/TLS inbound inspection can be stored on the HSM.

For instructions on importing the private keys onto the HSM, refer to the documentation from your HSM provider. After the required keys are on the HSM, you can configure the firewall to locate the keys as follows:

| **Store Private Keys on an HSM** | | |
|---|---|---|
| Step 1 | Import the private keys used in your SSL forward proxy and/or SSL inbound inspection deployments onto the HSM. | For instructions on importing the private keys onto the HSM, refer to the documentation from your HSM provider. |
| Step 2 | (Thales Nshield Connect only) Sync the key data from the HSM remote file system to the firewall. | 1. From the firewall web interface, select **Device > Setup > HSM**.<br>2. Select **Synchronize with Remote Filesystem** in the Hardware Security Operations section. |
| Step 3 | Import the certificate(s) that correspond to the private key(s) you are storing on the HSM onto the firewall. | 1. From the firewall web interface, select **Device > Certificate Management > Certificates > Device Certificates**.<br>2. Click **Import**.<br>3. Enter the **Certificate Name**.<br>4. Enter filename of the **Certificate File** you imported to the HSM.<br>5. Select the appropriate **File Format** from the drop-down.<br>6. Select the **Private Key resides on Hardware Security Module** check box.<br>7. Click **OK** and **Commit**. |
| Step 4 | (Forward trust certificates only) Enable the certificate for use in SSL/TLS Forward Proxy. | 1. Select the **Device > Certificate Management > Certificates > Device Certificates**.<br>2. Locate the certificate you imported in Step 3.<br>3. Select the **Forward Trust Certificate** check box.<br>4. Click **OK** and **Commit**. |

 © Palo Alto Networks, Inc.

| Store Private Keys on an HSM (Continued) | | |
|---|---|---|
| Step 5 | Verify that the certificate has been successfully imported to the firewall. | 1. Select **Device > Certificate Management > Certificates > Device Certificates**.<br>2. Locate the certificate you imported in Step 3.<br>3. In the Key column notice the following:<br>If a Lock icon is displayed, the private key for the certificate can be found on the HSM.<br>If an Error icon is displayed, the private key is not imported to the HSM or the HSM is not properly authenticated or connected. |

## Manage the HSM Deployment

| Manage HSM | |
|---|---|
| • View the HSM configuration settings. | Select **Device > Setup > HSM**. |
| • Display detailed HSM information. | Select **Show Detailed Information** from the Hardware Security Operations section.<br>Information regarding the HSM servers, HSM HA status, and HSM hardware is displayed. |
| • Export Support file | Select **Export Support File** from the Hardware Security Operations section.<br>A test file is created to help customer support when addressing a problem with an HSM configuration on the firewall. |
| • Reset HSM configuration. | Select **Reset HSM Configuration** from the Hardware Security Operations section.<br>Selecting this option removes all HSM connections. All authentication procedures must be repeated after using this option. |

 © Palo Alto Networks, Inc.

# High Availability

High availability (HA) is a configuration in which two firewalls are placed in a group and their configuration is synchronized to prevent a single point to failure on your network. A heartbeat connection between the firewall peers ensures seamless failover in the event that a peer goes down. Setting up the firewalls in a two-device cluster provides redundancy and allows you to ensure business continuity.

The Palo Alto Networks firewalls support stateful active/passive or active/active high availability with session and configuration synchronization. Some models of the firewall, such as the VM-Series firewall and the PA-200, only support HA lite without session synchronization capability. The following topics provide more information about high availability and how to configure it in your environment.

- HA Overview
- HA Concepts
- Set Up Active/Passive HA
- HA Resources

# HA Overview

On Palo Alto Networks firewalls, you can set up two devices as an HA pair. HA allows you to minimize downtime by making sure that an alternate device is available in the event that the primary device fails. The devices use dedicated or in-band HA ports on the firewall to synchronize data—network, object, and policy configurations—and to maintain state information. Device specific configuration such as management port IP address or administrator profiles, HA specific configuration, log data, and the Application Command Center (ACC) information is not shared between devices. For a consolidated application and log view across the HA pair, you must use Panorama, the Palo Alto Networks centralized management system.

When a failure occurs on the active device and the passive device takes over the task of securing traffic, the event is called a failover. The conditions that trigger a failover are:

- One or more of the monitored interfaces fail. (Link Monitoring)
- One or more of the destinations specified on the device cannot be reached. (Path Monitoring)
- The device does not respond to heartbeat polls. (Heartbeat Polling and Hello messages)

After you understand the HA Concepts, continue to Set Up Active/Passive HA.

 © Palo Alto Networks, Inc.

# HA Concepts

The following topics provide conceptual information about how HA works on a Palo Alto Networks firewall:

- HA Modes
- HA Links and Backup Links
- Device Priority and Preemption
- Failover Triggers
- HA Timers

## HA Modes

You can set up the firewalls for HA in two modes:

- **Active/Passive**— One device actively manages traffic while the other is synchronized and ready to transition to the active state, should a failure occur. In this configuration, both devices share the same configuration settings, and one actively manages traffic until a path, link, system, or network failure occurs. When the active device fails, the passive device takes over seamlessly and enforces the same policies to maintain network security. Active/passive HA is supported in the virtual wire, Layer 2 and Layer 3 deployments. For information on setting up your devices in an active/passive configuration, see Configure Active/Passive HA.

The PA-200 and the VM-Series firewalls support a lite version of active/passive HA. HA lite provides configuration synchronization and some runtime data synchronization such as IPSec security associations. It does not support any session synchronization, and therefore, HA Lite does not offer stateful failover.

- **Active/Active**— Both the devices in the pair are active and processing traffic, and work synchronously to handle session setup and session ownership. The active/active deployment is supported in virtual wire and Layer 3 deployments, and is only recommended for networks with asymmetric routing. For information on setting up the devices in an active/active configuration, refer to the Active/Active High Availability Tech Note.

## HA Links and Backup Links

The devices in an HA pair use HA links to synchronize data and maintain state information. Some models of the firewall have dedicated HA ports—Control link (HA1) and Data link (HA2), while others require you to use the in-band ports as HA links.

On devices with dedicated HA ports such as the PA-3000 Series, PA-4000 Series, PA-5000 Series, and PA-7050 firewalls (see HA Ports on the PA-7050 Firewall), use the dedicated HA ports to manage communication and synchronization between the devices. For devices without dedicated HA ports such as the PA-200, PA-500, and PA-2000 Series firewalls, as a best practice use the management port for the HA1 link to allow for a direct connection between the management planes on the devices, and an in-band port for the HA2 link.

The HA1 and HA2 links provide synchronization for functions that reside on the management plane. Using the dedicated HA interfaces on the management plane is more efficient than using the in-band ports as this eliminates the need to pass the synchronization packets over the dataplane.

- **Control Link**: The HA1 link is used to exchange hellos, heartbeats, and HA state information, and management plane sync for routing, and User-ID information. This link is also used to synchronize configuration changes on either the active or passive device with its peer. The HA1 link is a Layer 3 link and requires an IP address.
  **Ports used for HA1**: TCP port 28769 and 28260 for clear text communication; port 28 for encrypted communication (SSH over TCP).

- **Data Link**: The HA2 link is used to synchronize sessions, forwarding tables, IPSec security associations and ARP tables between devices in an HA pair. Data flow on the HA2 link is always unidirectional (except for the HA2 keep-alive); it flows from the active device to the passive device. The HA2 link is a Layer 2 link, and it uses ether type 0x7261 by default.
  **Ports used for HA2:** The HA data link can be configured to use either IP (protocol number 99) or UDP (port 29281) as the transport, and thereby allow the HA data link to span subnets.
  Additionally, an HA3 link is used in Active/Active HA deployments. When there is an asymmetric route, the HA3 link is used for forwarding packets to the HA peer that owns the session. The HA3 link is a Layer 2 link and it does not support Layer 3 addressing or encryption.

- **Backup Links**: Provide redundancy for the HA1 and the HA2 links. In-band ports are used as backup links for both HA1 and HA2. Consider the following guidelines when configuring backup HA links:
  - The IP addresses of the primary and backup HA links must not overlap each other.
  - HA backup links must be on a different subnet than the primary HA links.
  - HA1-backup and HA2-backup ports must be configured on separate physical ports. The HA1-backup link uses port 28770 and 28260.

Palo Alto Networks recommends enabling heartbeat backup (uses port 28771 on the MGT interface) if you use an in-band port for the HA1 or the HA1 backup links.

## HA Ports on the PA-7050 Firewall

For HA connectivity on the PA-7050, refer to the following table for details on which ports on the Switch Management Card (SMC) are mandated and where ports on the Network Processing Card (NPC) are suitable. For an overview of the Modules and Interface cards on the PA-7050 firewall, refer to the PA-7050 Hardware Reference Guide.

The following ports on the SMC are designed for HA connectivity:

 © Palo Alto Networks, Inc.

| HA Links and Backup Links | Ports on the SMC | Description |
|---|---|---|
| **Control Link** | HA1-A<br>Speed: Ethernet 10/100/1000 | Used for HA control and synchronization. Connect this port directly from the HA1-A port on the first device to the HA1-A on the second device in the pair, or connect them together through a switch or router.<br>HA1 cannot be configured on NPC data ports or the MGT port. |
| **Control Link Backup** | HA1-B<br>Speed: Ethernet 10/100/1000 port | Used for HA control and synchronization as a backup for HA1-A. Connect this port directly from the HA1-B port on the first device to the HA1-B on the second device in the pair, or connect them together through a switch or router.<br>HA1 Backup cannot be configured on NPC data ports or the MGT port. |
| **Data Link** | HSCI-A<br>(High Speed Chassis Interconnect) | Quad Port SFP (QSFP) interfaces used to connect two PA-7050 firewalls in an HA configuration. Each port is comprised of four 10 gigabit links internally for a combined speed of 40 gigabits and is used for HA2 data link in an active/passive configuration. When in active/active mode, the port is also used for HA3 packet forwarding for asymmetrically routed sessions that require Layer 7 inspection for App-ID and Content-ID.<br>In a typical installation, HSCI-A on the first chassis connects directly to HSCI-A on the second chassis and HSCI-B on the first chassis connects to HSCI-B on the second chassis. This will provide full 80 gigabit transfer rates. In software, both ports (HSCI-A and HSCI-B) are treated as one HA interface.<br>The HSCI ports are not routable and must be connected directly to each other.<br>Palo Alto Networks recommends using the dedicated HSCI ports for both HA2 and HA3 connections. However, the HA2 and HA3 links can be configured on NPC data ports, if needed. |
| **Data Link Backup** | HSCI-B<br>(High Speed Chassis Interconnect) | The Quad Port SFP (QSFP) interfaces (see description above) in the HSCI-B port is used to increase the bandwidth for HA2/HA3 purposes.<br>The HSCI ports are not routable and must be connected directly to each other.<br>Palo Alto Networks recommends using the dedicated HSCI-B ports for both HA2 and HA3 backup connections. The HA2/HA3 backup link can be configured on the NPC data ports, if needed. |

## Device Priority and Preemption

The devices in an HA pair can be assigned a *device priority* value to indicate a preference for which device should assume the active role and manage traffic. If you need to use a specific device in the HA pair for actively securing traffic, you must enable the preemptive behavior on both the firewalls and assign a device priority value for each

device. The device with the lower numerical value, and therefore *higher priority*, is designated as active and manages all traffic on the network. The other device is in a passive state, and synchronizes configuration and state information with the active device so that it is ready to transition to an active state should a failure occur.

By default, preemption is disabled on the firewalls and must be enabled on both devices. When enabled, the preemptive behavior allows the firewall with the *higher priority* (lower numerical value) to resume as active after it recovers from a failure. When preemption occurs, the event is logged in the system logs.

## Failover Triggers

When a failure occurs on the active device and the passive device takes over the task of securing traffic, the event is called a failover. A failover is triggered when a monitored metric on the active device fails. The metrics that are monitored for detecting a device failure are:

- **Heartbeat Polling and Hello messages**

  The firewalls use hello message and heartbeats to verify that the peer device is responsive and operational. Hello messages are sent from one peer to the other at the configured *Hello Interval* to verify the state of the device. The heartbeat is an ICMP ping to the HA peer over the control link, and the peer responds to the ping to establish that the devices are connected and responsive. By default, the interval for the heartbeat is 1000 milliseconds. For details on the HA timers that trigger a failover, see HA Timers.

- **Link Monitoring**

  The physical interfaces to be monitored are grouped into a link group and their state (link up or link down) is monitored. A link group can contain one or more physical interfaces. A device failure is triggered when any or all of the interfaces in the group fail. The default behavior is failure of any one link in the link group will cause the device to change the HA state to non-functional to indicate a failure of a monitored object.

- **Path Monitoring**

  Monitors the full path through the network to mission-critical IP addresses. ICMP pings are used to verify reachability of the IP address. The default interval for pings is 200ms. An IP address is considered unreachable when 10 consecutive pings (the default value) fail, and a device failure is triggered when any or all of the IP addresses monitored become unreachable. The default behavior is any one of the IP addresses becoming unreachable will cause the device to change the HA state to non-functional to indicate a failure of a monitored object.

In addition to the failover triggers listed above, a failover also occurs when the administrator places the device is a suspended state or if preemption occurs.

On the PA-3000 Series, PA-5000 Series, and PA-7050 firewalls, a failover can occur when an internal health check fails. This health check is not configurable and is enabled to verify the operational status for all the components within the firewall.

 © Palo Alto Networks, Inc.

## HA Timers

High Availability (HA) timers are used to detect a firewall failure and trigger a failover. To reduce the complexity in configuring HA timers, you can select from three profiles have been added: **Recommended**, **Aggressive** and **Advanced**. These profiles auto-populate the optimum HA timer values for the specific firewall platform to enable a speedier HA deployment.

Use the **Recommended** profile for typical failover timer settings and the **Aggressive** profile for faster failover timer settings. The **Advanced** profile allows you to customize the timer values to suit your network requirements.

The following table describes each timer included in the profiles and the current preset values across the different hardware models; these values are for current reference only and can change in a subsequent release.

**Recommended/Aggressive HA Timer Values by Platform**

| Timers | Description | PA-7050<br>PA-5000 Series<br>PA-4000 Series<br>PA-3000 Series | PA-2000 Series<br>PA-500 Series<br>PA-200 Series<br>VM-Series | Panorama VM<br>M-100 |
|---|---|---|---|---|
| Monitor fail hold up time | The interval during which the firewall will remain active following a path monitor or link monitor failure. This setting is recommended to avoid an HA failover due to the occasional flapping of neighboring devices. | 0/0 | 0/0 | 0/0 |
| Preemption hold time | Time a passive or active-secondary device will wait before taking over as the active or active-primary device. | 1/1 | 1/1 | 1/1 |
| Heartbeat interval | The frequency at which the HA peers exchange heartbeat messages in the form of an ICMP ping. | 1000/1000 | 2000/1000 | 2000/1000 |
| Promotion hold time | Time that the passive device (in active/passive mode) or the active-secondary device (in active/active mode) will wait before taking over as the active or active-primary device after communications with the HA peer have been lost. This hold time will begin only after the peer failure declaration has been made. | 2000/500 | 2000/500 | 2000/500 |

| Timers | Description | PA-7050<br>PA-5000 Series<br>PA-4000 Series<br>PA-3000 Series | PA-2000 Series<br>PA-500 Series<br>PA-200 Series<br>VM-Series | Panorama VM<br>M-100 |
|---|---|---|---|---|
| Additional master hold up time | This time interval is applied to the same event as Monitor Fail Hold Up Time (range 0-60000 ms, default 500 ms). The additional time interval is applied only to the active device in active/passive mode and to the active-primary device in active/active mode. This timer is recommended to avoid a failover when both devices experience the same link/path monitor failure simultaneously. | 500/500 | 500/500 | 7000/5000 |
| Hello interval | The time interval in milliseconds between the hello packets that are sent to verify that the HA functionality on the other firewall is operational. The range is 8000-60000 ms with a default of 8000 ms for all platforms. | 8000/8000 | 8000/8000 | 8000/8000 |
| Maximum no. of flaps | A flap is counted when the firewall leaves the active state within 15 minutes after it last left the active state. This value indicates the maximum number of flaps that are permitted before the firewall is determined to be suspended and the passive firewall takes over (range 0-16, default 3). | 3/3 | 3/3 | Not Applicable |

# Set Up Active/Passive HA

- Prerequisites for Active/Passive HA
- Configuration Guidelines for Active/Passive HA
- Configure Active/Passive HA
- Define HA Failover Conditions
- Verify Failover

© Palo Alto Networks, Inc.

## Prerequisites for Active/Passive HA

To set up high availability on your Palo Alto Networks firewalls, you need a pair of firewalls that meet the following requirements:

- **The same model**—both the devices in the pair must be of the same hardware model or virtual machine model.
- **The same PAN-OS version**—both the devices should be running the same PAN-OS version and must each be up-to-date on the application, URL, and threat databases. They must also both have the same multiple virtual systems capability (single or multi vsys).
- **The same type of interfaces**—dedicated HA links, or a combination of the management port and in-band ports that are set to *interface type* HA.
  - Determine the IP address for the HA1 (control) connection between the device pair. The HA1 IP address for both peers must be on the same subnet if they are directly connected or are connected to the same switch.

    For devices without dedicated HA ports, you can use the management port for the control connection. Using the management port provides a direct communication link between the management planes on both devices. However, because the management ports will not be directly cabled between the devices, make sure that you have a route that connects these two interfaces across your network.
  - If you use Layer 3 as the transport method for the HA2 (data) connection, determine the IP address for the HA2 link. Use Layer 3 *only* if the HA2 connection must communicate over a routed network. The IP subnet for the HA2 links must not overlap with that of the HA1 links or with any other subnet assigned to the data ports on the firewall.
- **The same set of licenses**—Licenses are unique to each device and cannot be shared between the devices. Therefore, you must license both devices identically. If both devices do not have an identical set of licenses, they cannot synchronize configuration information and maintain parity for a seamless failover.

If you have an existing firewall and you want to add a new firewall for HA purposes and the new firewall has an existing configuration, it is recommended that you perform a factory reset on the new firewall. This will ensure that the new firewall has a clean configuration. After HA is configured, you will then sync the configuration on the primary device to the newly introduced device with the clean config.

 © Palo Alto Networks, Inc.

## Configuration Guidelines for Active/Passive HA

To set up an active (PeerA) passive (PeerB) pair in HA, you must configure some options identically on both devices and some independently (non-matching) on each device. These HA settings are not synchronized between the devices. For details on what is/is not synchronized, refer to HA Synchronization.

To proceed with the instructions on configuring the devices in HA, see Configure Active/Passive HA.

The following table lists the settings that you must configure identically on both devices:

| Identical Configuration Settings on PeerA and PeerB |
|---|
| • HA must be enabled on both devices.<br>• Both device must have the same Group ID value. The Group ID value is used to create a virtual MAC address for all the configured interfaces. The format of the virtual MAC is 00-1B-17:00: xx: yy where<br>00-1B-17: vendor ID; 00: fixed; xx: HA group ID; yy: interface ID.<br>When a new active device takes over, Gratuitous ARPs are sent from each of the connected interfaces of the new active member to inform the connected Layer 2 switches of the virtual MAC address' new location.<br>• If using in-band ports, the interfaces for the HA1 and HA2 links must be set to type HA.<br>• The HA mode must be set to Active Passive.<br>• If required, preemption must be enabled on both devices. The device priority value, however, must not be identical.<br>• If required, encryption on the HA1 link (for communication between the HA peers) must be configured on both devices.<br>• Based on the combination of HA1 and HA1 Backup ports you are using, use the following recommendations to decide whether you should enable heartbeat backup:<br>  • HA1: Dedicated HA1 port<br>HA1 Backup: In-band port<br>Recommendation: Enable Heartbeat Backup<br>  • HA1: Dedicated HA1 port<br>HA1 Backup: Management port<br>Recommendation: Do not enable Heartbeat Backup<br>  • HA1: In-band port<br>HA1 Backup: In-band port<br>Recommendation: Enable Heartbeat Backup<br>  • HA1: Management port<br>HA1 Backup: In-band port<br>Recommendation: Do not enable Heartbeat Backup |

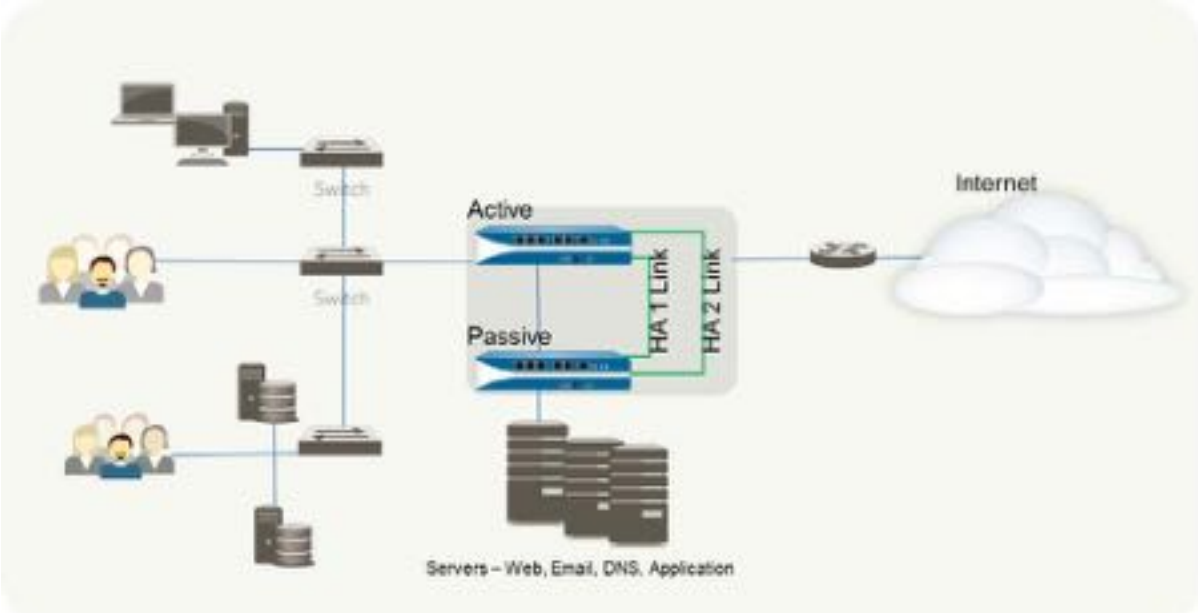
The following table lists the settings that must be configured independently on each device:

| Independent Configuration Settings | PeerA | PeerB |
|---|---|---|
| Control Link | IP address of the HA1 link configured on this device (PeerA). | IP address of the HA1 link configured on this device (PeerB). |
| | For devices without dedicated HA ports, use the management port IP address for the control link. | |
| Data Link<br>The data link information is synchronized between the devices after HA is enabled and the control link is established between the devices. | By default, the HA2 link uses Ethernet/Layer 2.<br>If using a Layer 3 connection, configure the IP address for the data link on this device (PeerA). | By default, the HA2 link uses Ethernet/Layer 2.<br>If using a Layer 3 connection, configure the IP address for the data link on this device (PeerB). |
| Device Priority (required, if preemption is enabled) | The device you plan to make active must have a lower numerical value than its peer. So, if Peer A is to function as the active device, keep the default value of 100 and increment the value on PeerB. | If PeerB is passive, set the device priority value to a number larger than that on PeerA. For example, set the value to 110. |
| Link Monitoring—Monitor one or more physical interfaces that handle vital traffic on this device and define the failure condition. | Select the physical interfaces on the firewall that you would like to monitor and define the failure condition (all or any) to trigger a failover. | Pick a similar set of physical interfaces that you would like to monitor on this firewall and define the failure condition (all or any) to trigger a failover. |
| Path Monitoring—Monitor one or more destination IP addresses that the firewall can use ICMP pings to ascertain responsiveness. | Define the failure condition (all or any), ping interval and the ping count. This is particularly useful for monitoring the availability of other interconnected networking devices. For example, monitor the availability of a router that connects to a server, connectivity to the server itself, or some other vital device that is in the flow of traffic.<br>Make sure that the node/device that you are monitoring is not likely to be unresponsive, especially when it comes under load, as this could cause a a path monitoring failure and trigger a failover. | Pick a similar set of devices or destination IP addresses that can be monitored for determining the failover trigger for PeerB. Define the failure condition (all or any), ping interval and the ping count. |

 © Palo Alto Networks, Inc.

## Configure Active/Passive HA

The following procedure shows how to configure a pair of firewalls in an active/passive deployment as depicted in the following example topology.



| Connect and Configure the Devices | |
|---|---|
| Step 1 Connect the HA ports to set up a physical connection between the devices. | • For devices with dedicated HA ports, use an Ethernet cable to connect the dedicated HA1 ports and the HA2 ports on the device pair. Use a crossover cable if the devices are directly connected to each other.<br>• For devices without dedicated HA ports, select two data interfaces for the HA2 link and the backup HA1 link. Then, use an Ethernet cable to connect these in-band HA interfaces across both devices. Use the management port for the HA1 link and ensure that the management ports can connect to each other across your network. |
| Pick a device in the pair and complete these tasks: | |
| Step 2 Enable ping on the management port. Enabling ping allows the management port to exchange heartbeat backup information. | 1. Select **Device > Setup > Management** and then click the Edit icon in the Management Interface Settings section of the screen.<br>2. Select **Ping** as a service that is permitted on the interface. |
| Step 3 If the device does not have dedicated HA ports, set up the data ports to function as HA ports.<br>For devices with dedicated HA ports continue to Step 4. | 1. Select **Network > Interfaces.**<br>2. Confirm that the link is up on the ports that you want to use.<br>3. Select the interface and set the interface type to HA.<br>  <br>4. Set the **Link Speed** and **Link Duplex** settings, as appropriate. |

| Connect and Configure the Devices (Continued) | | |
|---|---|---|
| Step 4 | Set up the control link connection.<br><br>This example shows an in-band port that is set to interface type HA.<br><br>For devices that use the management port as the control link, the IP address information is automatically pre-populated. | 1. In **Device > High Availability > General**, edit the **Control Link (HA1)** section.<br>2. Select the interface that you have cabled for use as the HA1 link in the **Port** drop down menu. Set the IP address and netmask. Enter a Gateway IP address only if the HA1 interfaces are on separate subnets. Do not add a gateway if the devices are directly connected.<br> |
| Step 5 | (Optional) Enable encryption for the control link connection.<br><br>This is typically used to secure the link if the two devices are not directly connected, that is if the ports are connected to a switch or a router. | 1. Export the HA key from a device and import it into the peer device.<br>a. Select **Device > Certificate Management > Certificates.**<br>b. Select **Export HA key.** Save the HA key to a network location that the peer device can access.<br>c. On the peer device, navigate to **Device > Certificate Management > Certificates,** and select **Import HA key** to browse to the location that you saved the key and import it in to the peer device.<br>2. Select **Device > High Availability > General**, edit the **Control Link (HA1)** section.<br>3. Select **Encryption Enabled.** |
| Step 6 | Set up the backup control link connection. | 1. In **Device > High Availability > General**, edit the **Control Link (HA1 Backup)** section.<br>2. Select the HA1 backup interface and set the IP address and netmask.<br> |

 © Palo Alto Networks, Inc.

| Connect and Configure the Devices (Continued) | | |
|---|---|---|
| Step 7 | Set up the data link connection (HA2) and the backup HA2 connection between the devices. | 1. In **Device > High Availability > General**, edit the **Data Link (HA2)** section.<br>2. Select the interface for the data link connection.<br>3. Select the **Transport** method. The default is **ethernet**, and will work when the HA pair is connected directly or through a switch. If you need to route the data link traffic through the network, select **IP** or **UDP** as the transport mode.<br>4. If you use IP or UDP as the transport method, enter the IP address and netmask.<br>  <br>5. Verify that **Enable Session Synchronization** is selected.<br>6. Select **HA2 Keep-alive** to enable monitoring on the HA2 data link between the HA peers. If a failure occurs based on the threshold that is set (default is 10000 ms), the defined action will occur. For active/passive configuration, a critical system log message is generated when an HA2 keep-alive failure occurs.<br>You can configure the HA2 keep-alive option on both devices, or just one device in the HA pair. If the option is only enabled on one device, only that device will send the keep-alive messages. The other device will be notified if a failure occurs.<br>7. Edit the **Data Link (HA2 Backup)** section, select the interface, and add the IP address and netmask. |
| Step 8 | Enable heartbeat backup if your control link uses a dedicated HA port or an in-band port.<br><br>You do not need to enable heartbeat backup if you are using the management port for the control link. | 1. In **Device > High Availability > General**, edit the **Election Settings** section.<br>2. Select **Heartbeat Backup**.<br>The heartbeat backup link is used for transmitting redundant heartbeats and hello messages. To allow the heartbeats to be transmitted between the devices, you must verify that the management port across both peers can route to each other. |

| Connect and Configure the Devices (Continued) | |
|---|---|
| Step 9 Set the device priority and enable preemption.<br><br>This setting is only required if you wish to make sure that a specific device is the preferred active device. For information, see Device Priority and Preemption. | 1. In **Device > High Availability > General**, edit the **Election Settings** section.<br>2. Set the numerical value in **Device Priority**. Make sure to set a lower numerical value on the device that you want to assign a higher priority to.<br><br>If both firewalls have the same device priority value, the firewall with the lowest MAC address on the HA1 control link will become the active device.<br>3. Select **Preemptive**.<br><br>You must enable preemptive on both the active and the passive device. |
| Step 10 (Optional) Modify the failover timers.<br><br>By default, the HA timer profile is set to the **Recommended** profile and is suited for most HA deployments. | 1. In **Device > High Availability > General**, edit the **Election Settings** section.<br>2. Select the **Aggressive** profile for triggering failover faster; select **Advanced** to define custom values for triggering failover in your set up.<br><br>To view the preset value for an individual timer included in a profile, select **Advanced** and click **Load Recommended** or **Load Aggressive**. The preset values for your hardware model will be displayed on screen. |
| Step 11 (Optional, only configured on the passive device) Modify the link status of the HA ports on the passive device.<br><br>The passive link state is **shutdown**, by default. After you enable HA, the link state for the HA ports on the active device will be green and those on the passive device will be down and display as red. | Setting the link state to **Auto** allows for reducing the amount of time it takes for the passive device to take over when a failover occurs and it allows you to monitor the link state.<br><br>To enable the link status on the passive device to stay up and reflect the cabling status on the physical interface:<br>1. In **Device > High Availability > General**, edit the **Active Passive Settings** section.<br>2. Set the **Passive Link State** to **Auto**.<br><br>The auto option decreases the amount of time it takes for the passive device to take over when a failover occurs.<br><br>Although the interface displays green (as cabled and up) it continues to discard all traffic until a failover is triggered.<br><br>When you modify the passive link state, make sure that the adjacent devices do not forward traffic to the passive firewall based only on the link status of the device. |

 © Palo Alto Networks, Inc.

| Connect and Configure the Devices (Continued) | |
|---|---|
| Step 12 Enable HA. | 1. Select **Device > High Availability > General,** edit the **Setup** section.<br>2. Select **Enable HA.**<br>3. Set a **Group ID**. This ID uniquely identifies each HA pair on your network, and is essential if you have multiple HA pairs that share the same broadcast domain on your network.<br>4. Set the mode to **Active Passive**.<br>5. Select **Enable Config Sync.** This setting enables the synchronization of the configuration settings between the active and the passive device.<br>6. Enter the IP address assigned to the control link of the peer device in **Peer HA1 IP Address**.<br>  <br>For devices without dedicated HA ports, if the peer uses the management port for the HA1 link, enter the management port IP address of the peer.<br>7. Enter the **Backup HA1 IP Address**. |
| Step 13 Save your configuration changes. | Click **Commit**. |
| Step 14 Complete Step 2 through Step 13 on the other device in the HA pair. | |
| Step 15 After you finish configuring both devices, verify that the devices are paired in active/passive HA. | 1. Access the **Dashboard** on both devices, and view the **High Availability** widget.<br>2. On the active device, click the **Sync to peer** link.<br>3. Confirm that the devices are paired and synced, as shown below: |

**Connect and Configure the Devices (Continued)**

On the passive device: The state of the local device should display **passive** and the configuration is **synchronized.**

On the active device: The state of the local device should display **active** and the configuration is **synchronized**.

 © Palo Alto Networks, Inc.

# Define HA Failover Conditions

| Configure the Failover Triggers | | |
|---|---|---|
| Step 1 | To configure link monitoring, define the interfaces that you would like to monitor. A change in the link state of these interface will trigger a failover. | 1. Select **Device > High Availability > Link and Path Monitoring.**<br>2. In the **Link Group** section, click **Add.**<br>3. Name the **Link Group, Add** the interfaces to monitor, and select the **Failure Condition** for the group. The Link group you define is added to the **Link Group** section.<br> |
| Step 2 | (Optional) Modify the failure condition for the Link Groups that you configured (in the preceding step) on the device.<br><br>By default, the device will trigger a failover when any monitored link fails. | 1. Select the **Link Monitoring** section.<br>2. Set the **Failure Condition** to **All.**<br>The default setting is **Any**. |
| Step 3 | To configure path monitoring, define the destination IP addresses that the firewall should ping to verify network connectivity. | 1. In the **Path Group** section of the **Device > High Availability > Link and Path Monitoring** tab, pick the **Add option for your set up:** Virtual Wire, VLAN, or Virtual Router.<br>2. Select the appropriate item from the drop-down list for the **Name** and **Add** the IP addresses (source and/or destination, as prompted) that you wish to monitor. Then select the **Failure Condition** for the group. The path group you define is added to the **Path Group** section.<br> |
| Step 4 | (Optional) Modify the failure condition for all Path Groups configured on the device.<br><br>By default, the device will trigger a failover when any monitored path fails. | Set the **Failure Condition** to **All.**<br><br>The default setting is **Any**. |
| Step 5 | Save your changes. | Click **Commit**. |

If you are using SNMPv3 to monitor the firewalls, note that the SNMPv3 Engine ID is unique to each device; the EngineID is not synchronized between the HA pair and therefore, allows you to independently monitor each device in the HA pair. For information on setting up SNMP, see Set Up SNMP Trap Destinations.

Because the EngineID is generated using the device's unique serial number, on the VM-Series firewall you must apply a valid license in order to obtain a unique EngineID for each firewall.

## Verify Failover

To test that your HA configuration works properly trigger a manual failover and verify that the devices transition states successfully.

| Verify Failover | |
|---|---|
| Step 1 Suspend the active device. | Click the **Suspend local device** link on the **Device > High Availability > Operational Commands** tab.<br>  |
| Step 2 Verify that the passive device has taken over as active. | On the **Dashboard**, verify that the state of the passive device changes to **active** in the **High Availability** widget.<br> |
| Step 3 Restore the suspended device to a functional state. Wait for a couple minutes, and then verify that preemption has occurred, if preemptive is enabled. | 1. On the device you previously suspended, select the **Make local device functional** link on the **Device > High Availability > Operational Commands** tab.<br>  <br>2. In the **High Availability** widget on the **Dashboard,** confirm that the device has taken over as the active device and that the peer is now in a passive state.<br> |

 © Palo Alto Networks, Inc.

# HA Resources

For more information on HA, refer to the following sources:

- Active/Active HA
- High Availability Synchronization
- High Availability Failover Optimization
- Upgrading an HA pair
- Examples: Deploying HA

© Palo Alto Networks, Inc.

 © Palo Alto Networks, Inc.

# Reports and Logging

The firewall provides reports and logs that are useful for monitoring activity on your network. You can monitor the logs and filter the information to generate reports with predefined or customized views. You can for example, use the predefined templates to generate reports on a user's activity or analyze the reports and logs to interpret unusual behavior on your network and generate a custom report on the traffic pattern. The following topics describe how to view, manage, customize, and generate the reports and logs on the firewall:

- Use the Dashboard
- Use the Application Command Center
- Use App-Scope
- Take Packet Captures
- Monitor the Firewall
- Forward Logs to External Services
- Monitor the Firewall Using SNMP
- Manage Reporting
- Identify Firewall Interfaces in External Monitoring Systems
- Manage Reporting
- Syslog Field Descriptions

# Use the Dashboard

The **Dashboard** tab widgets show general device information, such as the software version, the operational status of each interface, resource utilization, and up to 10 of the most recent entries in the threat, configuration, and system logs. All of the available widgets are displayed by default, but each administrator can remove and add individual widgets, as needed.

Click the refresh icon to update the Dashboard or an individual widget. To change the automatic refresh interval, select an interval from the drop-down (**1 min**, **2 mins**, **5 mins**, or **Manual**). To add a widget to the Dashboard, click the widget drop-down, select a category and then the widget name. To delete a widget, click in the title bar.

The following table describes the Dashboard widgets.

| Dashboard Charts | Descriptions |
|---|---|
| Top Applications | Displays the applications with the most sessions. The block size indicates the relative number of sessions (mouse-over the block to view the number), and the color indicates the security risk—from green (lowest) to red (highest). Click an application to view its application profile. |
| Top High Risk Applications | Similar to Top Applications, except that it displays the highest-risk applications with the most sessions. |
| General Information | Displays the device name, model, PAN-OS software version, the application, threat, and URL filtering definition versions, the current date and time, and the length of time since the last restart. |
| Interface Status | Indicates whether each interface is up (green), down (red), or in an unknown state (gray). |
| Threat Logs | Displays the threat ID, application, and date and time for the last 10 entries in the Threat log. The threat ID is a malware description or URL that violates the URL filtering profile. |
| Config Logs | Displays the administrator username, client (Web or CLI), and date and time for the last 10 entries in the Configuration log. |
| Data Filtering Logs | Displays the description and date and time for the last 60 minutes in the Data Filtering log. |
| URL Filtering Logs | Displays the description and date and time for the last 60 minutes in the URL Filtering log. |
| System Logs | Displays the description and date and time for the last 10 entries in the System log.<br>A **`Config installed`** entry indicates configuration changes were committed successfully. |
| System Resources | Displays the Management CPU usage, Data Plane usage, and the Session Count, which displays the number of sessions established through the firewall. |
| Logged In Admins | Displays the source IP address, session type (Web or CLI), and session start time for each administrator who is currently logged in. |
| ACC Risk Factor | Displays the average risk factor (1 to 5) for the network traffic processed over the past week. Higher values indicate higher risk. |

 © Palo Alto Networks, Inc.

| Dashboard Charts | Descriptions |
|---|---|
| High Availability | If high availability (HA) is enabled, indicates the HA status of the local and peer device—green (active), yellow (passive), or black (other). For more information about HA, see High Availability. |
| Locks | Shows configuration locks taken by administrators. |

# Use the Application Command Center

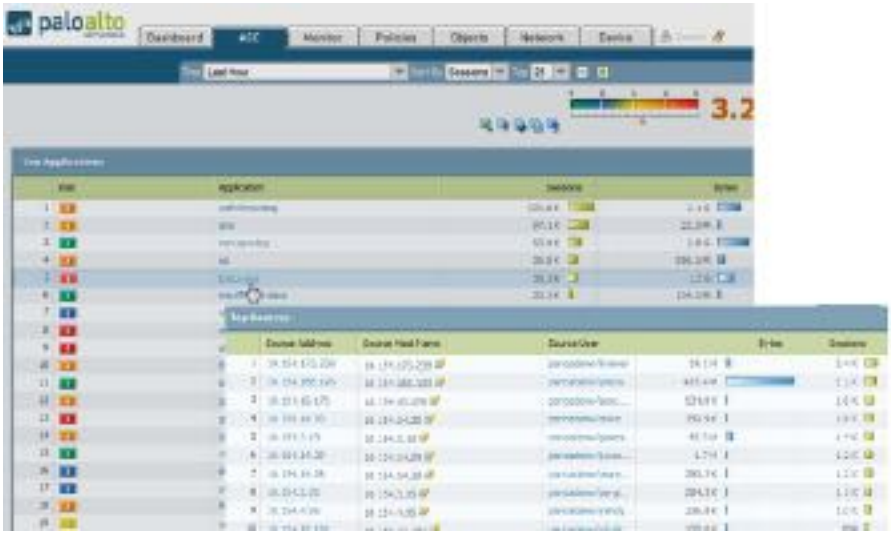
The **ACC** tab visually depicts trends and historic view of traffic on your network.

- ACC Risk Level
- ACC Charts
- ACC Detail Pages
- Use the ACC

 © Palo Alto Networks, Inc.

## ACC Risk Level

The **ACC** tab displays the overall risk level for all network traffic, the risk levels and number of threats detected for the most active and highest-risk applications on your network, and the number of threats detected from the busiest application categories and from all applications at each risk level. Use the ACC to view application data for the past hour, day, week, month, or any custom-defined time frame. **Risk** levels (1=lowest to 5=highest) indicate the application's relative security risk based on criteria such as whether the application can share files, is prone to misuse, or tries to evade firewalls.



## ACC Charts

There are five charts displayed on the **Application Command Center (ACC)** tab:

- Application
- URL Filtering
- Threat Prevention
- Data Filtering
- HIP Matches

The following table describes the charts displayed on the **ACC** tab:

| ACC Chart | Description |
|---|---|
| Application | Displays application information grouped by the following attributes:<br>• Applications<br>• High risk applications<br>• Categories<br>• Sub Categories<br>• Technology<br>• Risk<br>Each chart can include the number of sessions, bytes transmitted and received, number of threats, application category, application subcategories, application technology, and risk level, as applicable. |
| URL Filtering | Displays URL/category information grouped by the following attributes:<br>• URL Categories<br>• URLs<br>• Blocked URL Categories<br>• Blocked URLs<br>Each chart can include the URL, URL category, repeat count (number of times access was attempted, as applicable). |
| Threat Prevention | Displays threat information grouped by the following attributes:<br>• Threats<br>• Types<br>• Spyware<br>• Spyware Phone Home<br>• Spyware Downloads<br>• Vulnerability<br>• Virus<br>Each chart can include the threat ID, count (number of occurrences), number of sessions, and subtype (such as vulnerability), as applicable |

 © Palo Alto Networks, Inc.

| ACC Chart | Description |
|---|---|
| Data Filtering | Displays information on data filtered by the firewall grouped by the following attributes:<br>• Content/File Types<br>• Types<br>• File Names |
| HIP Matches | Displays the host information collected by the firewall grouped by:<br>• HIP Objects<br>• HIP Profiles |

## ACC Detail Pages

To view additional details, click any of the links on the ACC charts. A details page opens to show information about the item at the top and additional lists for related items. For example, click on the web-browsing link on the Application chart opens the Application Information page for web-browsing:

 © Palo Alto Networks, Inc.

## Use the ACC

The following procedure describes how to use the **ACC** tab and how to customize your view:

| Use the ACC | |
|---|---|
| Step 1 | On the **ACC**, change one or more of the settings at the top of the page.<br>• Use the drop-down to select Applications, URL Categories, Threats, Content/File Types, and HIP Objects to view.<br>• Select a virtual system, if virtual systems are defined.<br>• Select a time period from the **Time** drop-down. The default is Last Hour.<br>• Select a sorting method from the **Sort By** drop-down. You can sort the charts in descending order by number of sessions, bytes, or threats. The default is by number of sessions.<br>• For the selected sorting method, select the top number of applications and application categories shown in each chart from the **Top** drop-down.<br>Click the submit icon to apply the selected settings. |
| Step 2 | To open log pages associated with the information on the page, use the log links in the upper-right corner of the page, as shown here. The context for the logs matches the information on the page.<br> |
| Step 3 | To filter the list, click an item in one of the columns, this will add that item to the filter bar located above the log column names. After adding the desired filters, click the Apply Filter icon .<br>  |

# Use App-Scope

The App-Scope reports provide visibility and analysis tools to help pinpoint problematic behavior, helping you understand changes in application usage and user activity, users and applications that take up most of the network bandwidth, and identify network threats.

With the App-Scope reports, you can quickly see if any behavior is unusual or unexpected. Each report provides a dynamic, user-customizable window into the network; hovering the mouse over and clicking either the lines or bars on the charts opens detailed information about the specific application, application category, user, or source on the ACC.

The following App-Scope reports are available:

- Summary Report
- Change Monitor Report
- Threat Monitor Report
- Threat Map Report
- Network Monitor Report
- Traffic Map Report

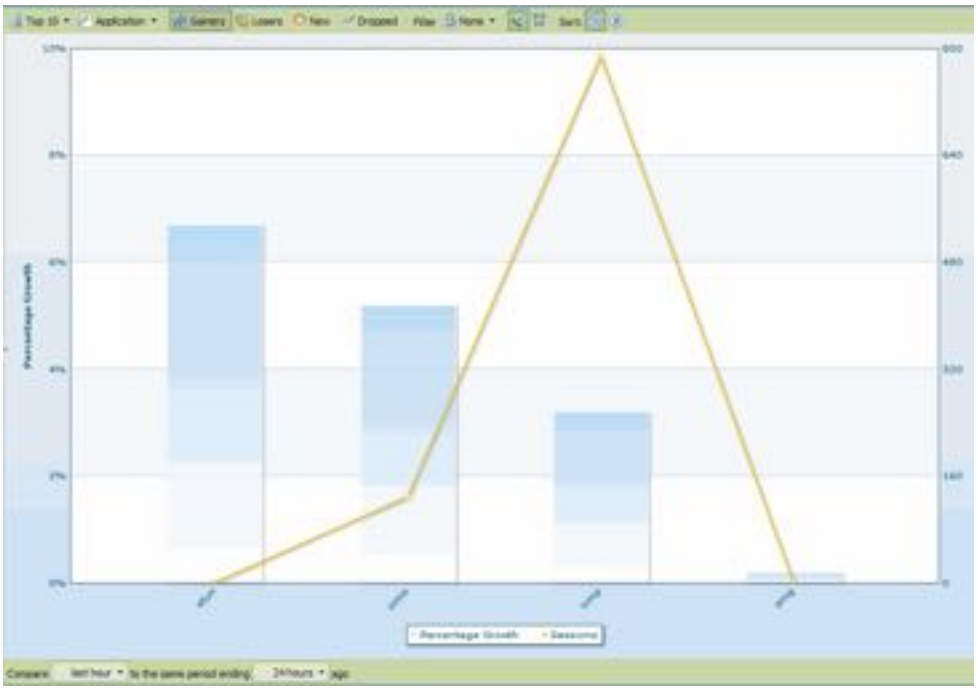
© Palo Alto Networks, Inc.

## Summary Report

The App-Scope Summary report displays charts for the top five gainers, losers, and bandwidth consuming applications, application categories, users, and sources.

## Change Monitor Report

The App-Scope Change Monitor report displays changes over a specified time period. For example, the following chart displays the top applications that gained in use over the last hour as compared with the last 24-hour period. The top applications are determined by session count and sorted by percent.



The Change Monitor Report contains the following buttons and options.

| Button | Description |
|---|---|
| Top 10 | Determines the number of records with the highest measurement included in the chart. |
| Application | Determines the type of item reported: Application, Application Category, Source, or Destination. |
| Gainers | Displays measurements of items that have increased over the measured period. |
| Losers | Displays measurements of items that have decreased over the measured period. |
| New | Displays measurements of items that were added over the measured period. |
| Dropped | Displays measurements of items that were discontinued over the measured period. |
| Filter None | Applies a filter to display only the selected item. **None** displays all entries. |

© Palo Alto Networks, Inc.

| Button | Description |
|---|---|
| | Determines whether to display session or byte information. |
|  | Determines whether to sort entries by percentage or raw growth. |
|  | Specifies the period over which the change measurements are taken. |

## Threat Monitor Report

The App-Scope Threat Monitor report displays a count of the top threats over the selected time period. For example, the following figure shows the top 10 threat types over the last 6 hours.

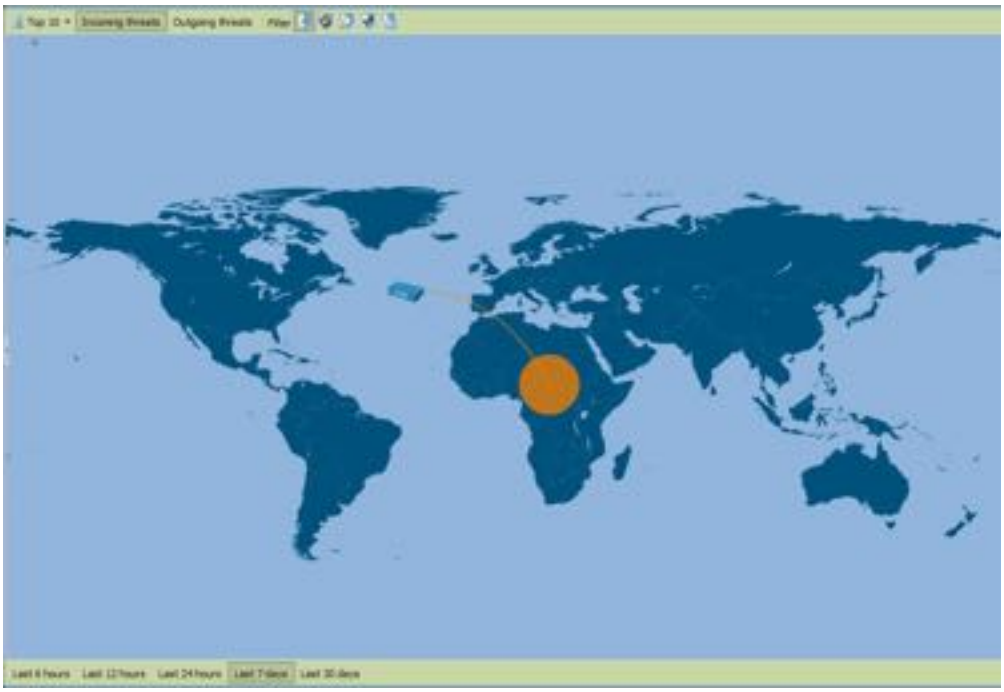
Each threat type is color-coded as indicated in the legend below the chart. The Threat Monitor report contains the following buttons and options.

| Button | Description |
|---|---|
| | Determines the number of records with the highest measurement included in the chart. |
| | Determines the type of item measured: Threat, Threat Category, Source, or Destination. |
| | Applies a filter to display only the selected type of items. |
| | Determines whether the information is presented in a stacked column chart or a stacked area chart. |
|  | Specifies the period over which the measurements are taken. |

 © Palo Alto Networks, Inc.

## Threat Map Report

The App-Scope Threat Map report shows a geographical view of threats, including severity. Each threat type is color-coded as indicated in the legend below the chart.

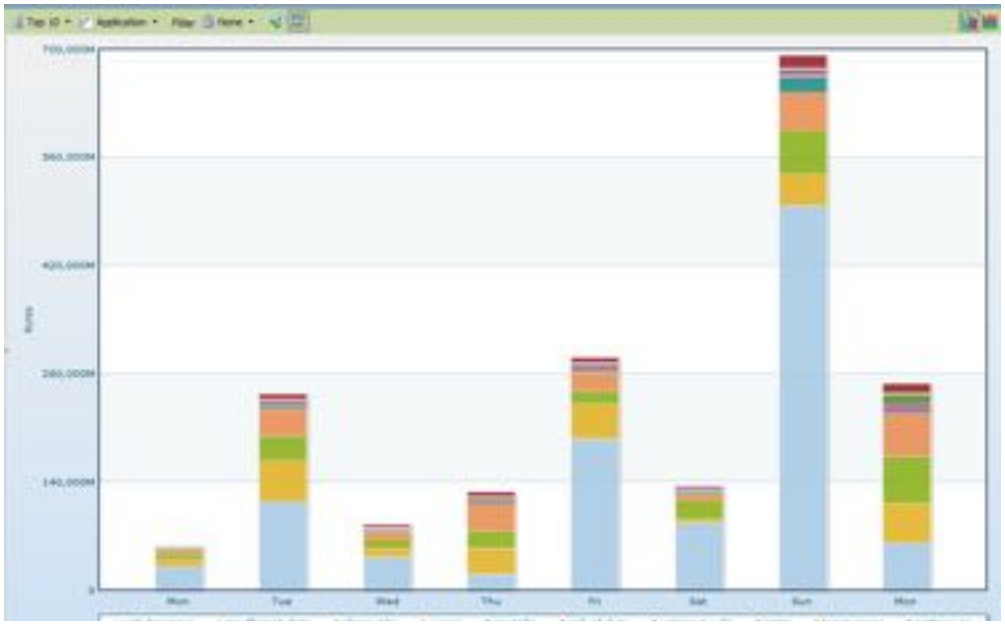


Click a country on the map to zoom in. Click the **Zoom Out** button in the lower right corner of the screen to zoom out. The Threat Map report contains the following buttons and options.

| Button | Description |
|---|---|
| | Determines the number of records with the highest measurement included in the chart. |
|   | Displays incoming threats. |
|   | Displays outgoing threats. |
| | Applies a filter to display only the selected type of items. |
| | Indicates the period over which the measurements are taken. |

## Network Monitor Report

The App-Scope Network Monitor report displays the bandwidth dedicated to different network functions over the specified period of time. Each network function is color-coded as indicated in the legend below the chart. For example, the image below shows application bandwidth for the past 7 days based on session information.



The Network Monitor report contains the following buttons and options.

| Button | Description |
|---|---|
| | Determines the number of records with the highest measurement included in the chart. |
|  | Determines the type of item reported: Application, Application Category, Source, or Destination. |
|  | Applies a filter to display only the selected item. **None** displays all entries. |
| | Determines whether to display session or byte information. |
| | Determines whether the information is presented in a stacked column chart or a stacked area chart. |
|  | Indicates the period over which the change measurements are taken. |

 © Palo Alto Networks, Inc.

## Traffic Map Report

The App-Scope Traffic Map report shows a geographical view of traffic flows according to sessions or flows.

Each traffic type is color-coded as indicated in the legend below the chart. The Traffic Map report contains the following buttons and options.

| Buttons | Description |
|---|---|
| Top 10 | Determines the number of records with the highest measurement included in the chart. |
| Incoming threats | Displays incoming threats. |
| Outgoing threats | Displays outgoing threats. |
| 010 101 | Determines whether to display session or byte information. |
| Last 6 hours Last 12 hours Last 24 hours Last 7 days Last 30 days | Indicates the period over which the change measurements are taken. |

# Take Packet Captures

PAN-OS supports packet capture for troubleshooting or detecting unknown applications. You can define filters such that only the packets that match the filters are captured. The packet captures are locally stored on the device and are available for download to your local computer.

Packet Capture is for troubleshooting only. This feature can cause the system performance to degrade and should be used only when necessary. Remember to disable the feature after you complete the packet capture.

The following table describes the packet capture settings on **Monitor > Packet Capture**.

| Field | Description |
|---|---|
| **Configure Filtering** | |
| **Manage Filters** | Click **Manage Filters**, click **Add** to add a new filter, and specify the following information:<br>• **Id**—Enter or select an identifier for the filter.<br>• **Ingress Interface**—Select the firewall interface.<br>• **Source**—Specify the source IP address.<br>• **Destination**—Specify the destination IP address.<br>• **Src Port**—Specify the source port.<br>• **Dest Port**—Specify the destination port.<br>• **Proto**—Specify the protocol to filter.<br>• **Non-IP**—Choose how to treat non-IP traffic (exclude all IP traffic, include all IP traffic, include only IP traffic, or do not include an IP filter).<br>• **IPv6**—Select the check box to include IPv6 packets in the filter. |
| **Filtering** | Click to toggle the filtering selections on or off. |
| **Pre-Parse Match** | Click to toggle the pre-parse match option on or off.<br>The pre-parse-match option is added for advanced troubleshooting purposes. After a packet enters the ingress port, it proceeds through several processing steps before it is parsed for matches against pre-configured filters.<br>It is possible for a packet, due to a failure, to not reach the filtering stage. This can occur, for example, if a route lookup fails.<br>Set the pre-parse-match setting to **ON** to emulate a positive match for every packet entering the system. This allows the firewall to capture even the packets that do not reach the filtering process. If a packet is able to reach the filtering stage, it is then processed according to the filter configuration and discarded if it fails to meet filtering criteria. |

 © Palo Alto Networks, Inc.

| Field | Description |
|---|---|
| **Configure Capturing** | |
| **Packet Capture** | Click to toggle packet capturing on or off.<br>For anti-spyware and vulnerability protection profiles, you can enable extended packet captures for rules and exceptions defined in the profile. This functionality allows the firewall to capture from 1 to 50 packets and provides more context when analyzing the threat logs.<br>To define the extended packet capture length:<br>1. Select **Device > Setup > Content-ID.**<br>2. Edit the Threat Detection Settings section to specify the **Capture Length** for the number of packets to capture.<br>  <br>3. View the packet capture in **Monitor > Logs > Threat**.<br>Locate the threat log entry and click the green arrow (Packet Capture) icon in the corresponding row to view the capture. |
| **Packet Capture Stage** | Select **Add** and specify the following:<br>• **Stage**—Indicate the point at which to capture the packet:<br>• **drop**—When packet processing encounters an error and the packet is to be dropped.<br>• **firewall**—When the packet has a session match or a first packet with a session is successfully created.<br>• **receive**—When the packet is received on the dataplane processor.<br>• **transmit**—When the packet is to be transmitted on the dataplane processor.<br>• **File**—Specify the capture file name. The file name should begin with a letter and can include letters, digits, periods, underscores, or hyphens.<br>• **Packet Count**—Specify the number of packets after which capturing stops.<br>• **Byte Count**—Specify the number of bytes after which capturing stops. |
| **Captured Files** | |
| **Captured Files** | Select **Delete** to remove a packet capture file from the list displaying captured files. |
| **Settings** | |
| **Clear All Settings** | Select **Clear All Settings** to clear all packet capture settings. |

# Monitor the Firewall

The following sections describe the methods you can use to monitor the firewall and provide basic setup instructions:

- Monitor Applications and Threats
- Monitor Log Data
- Monitor the Dashboard
- View Reports

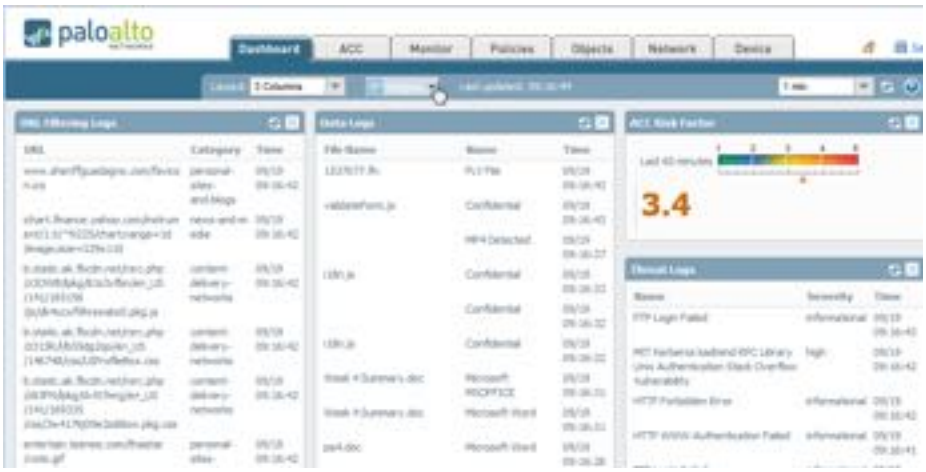
You can also configure the firewall (excluding PA-4000 Series and PA-7050 firewalls) to export flow data to a NetFlow collector for analysis and reporting. To configure NetFlow Settings, refer to the PAN-OS-6.0 Web Interface Reference Guide.

© Palo Alto Networks, Inc.

## Monitor Applications and Threats

All Palo Alto Networks next-generation firewalls come equipped with the App-ID technology, which identifies the applications traversing your network, irrespective of protocol, encryption, or evasive tactic. You can then Use the Application Command Center to monitor the applications. ACC graphically summarizes the log database to highlight the applications traversing your network, who is using them, and their potential security impact. ACC is dynamically updated, using the continuous traffic classification that App-ID performs; if an application changes ports or behavior, App-ID continues to see the traffic, displaying the results in ACC.

You can quickly investigate new, risky, or unfamiliar applications that appear in ACC with a single click that displays a description of the application, its key features, its behavioral characteristics, and who is using it. Additional visibility into URL categories, threats, and data provides a complete and well-rounded picture of network activity. With ACC, you can very quickly learn more about the traffic traversing the network and then translate that information into a more informed security policy.



# Monitor Log Data

All Palo Alto Networks next-generation firewalls can generate log files that provide an audit trail of the activities and events on the firewall. There are separate logs for separate types of activities and events. For example, the Threat logs record all traffic that causes the firewall to generate a security alarm, whereas URL Filtering logs record all traffic that matches a URL Filtering profile attached to a security policy, and Config logs record all changes to the firewall configuration.

You can either Forward Logs to External Services or you can view logs locally on the device as follows:

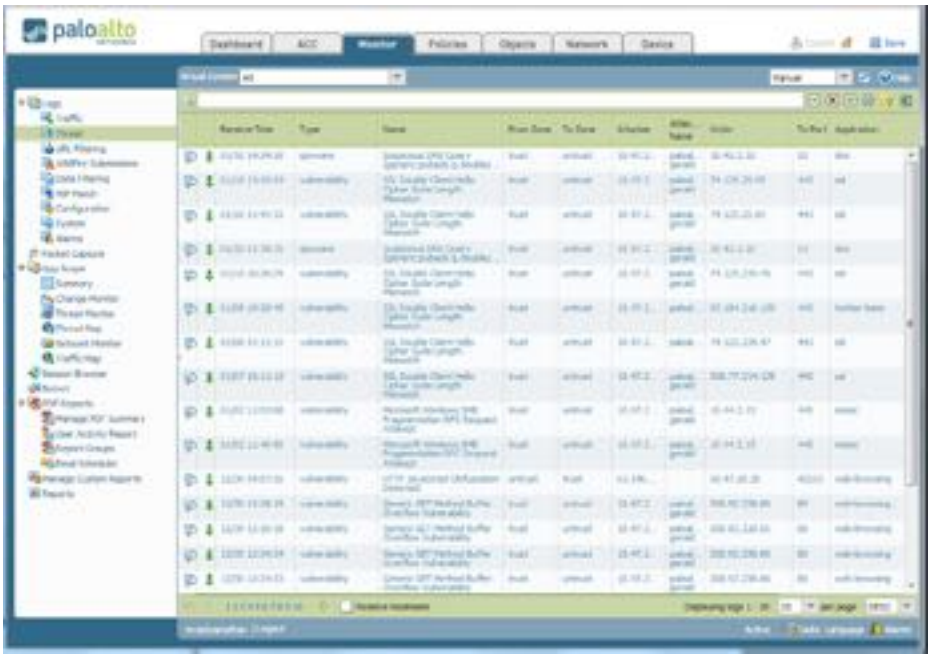
- View the Log Files
- Filter Log Data

## View the Log Files

The firewall maintains logs for WildFire, configurations, system, alarms, traffic flows, threats, URL filtering, data filtering, and Host Information Profile (HIP) matches. You can view the current logs at any time. To locate specific entries, you can apply filters to most of the log fields.

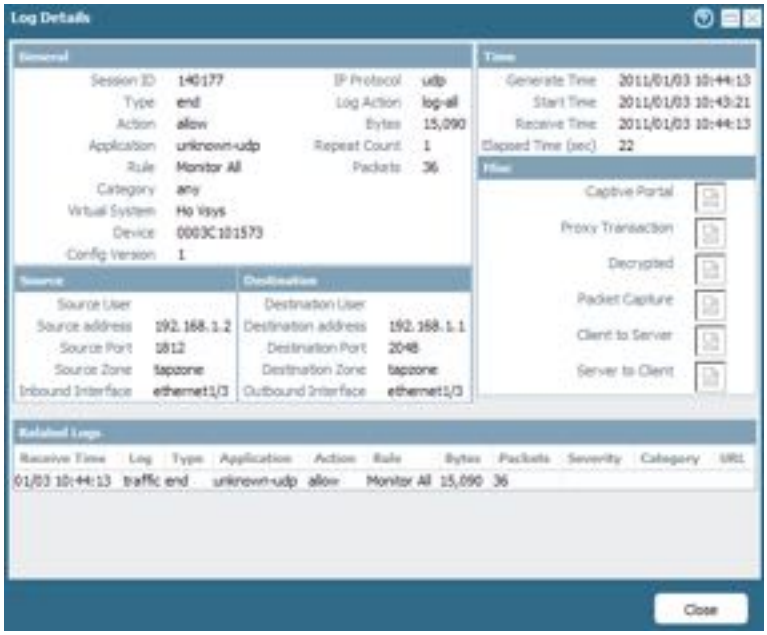
The firewall displays the information in logs so that role-based administration permissions are respected. When you display logs, only the information that you have permission to see is included. For information on administrator permissions, see Administrative Roles.

By default all log files are generated and stored locally on the firewall. You can view these log files directly (**Monitor > Logs**):



To display additional details, click the spyglass icon for an entry.

 © Palo Alto Networks, Inc.



The following table includes information on each log type:

| Log Description Charts | Description |
|---|---|
| Traffic | Displays an entry for the start and end of each session. Each entry includes the date and time, the source and destination zones, addresses, and ports, the application name, the security rule name applied to the flow, the rule action (**allow, deny, or drop**), the ingress and egress interface, and the number of bytes.<br>Click next to an entry to view additional details about the session, such as whether an ICMP entry aggregates multiple sessions between the same source and destination (the **Count** value will be greater than one).<br>The **Type** column indicates whether the entry is for the start or end of the session, or whether the session was denied or dropped. A **drop** indicates that the security rule that blocked the traffic specified **any** application, while a **deny** indicates the rule identified a specific application.<br>If traffic is dropped before the application is identified, such as when a rule drops all traffic for a specific service, the application is shown as **not-applicable**. |

| Log Description Charts | Description |
|---|---|
| Threat | Displays an entry when traffic matches a Security Profile (Antivirus, Anti-spyware, Vulnerability, URL Filtering, File Blocking, Data Filtering, or DoS Protection) that is attached to a security policy on the firewall. Each entry includes the date and time, a threat name or URL, the source and destination zones, addresses, and ports, the application name, and the alarm action (**allow** or **block**) and severity.<br>Click next to an entry to view additional details about the threat, such as whether the entry aggregates multiple threats of the same type between the same source and destination (the **Count** value will be greater than one).<br>The **Type** column indicates the type of threat, such as "virus" or "spyware." The **Name** column is the threat description or URL, and the **Category** column is the threat category (such as "keylogger") or URL category.<br>If local packet captures are enabled, click next to an entry to access the captured packets. To enable local packet captures, see Take Packet Captures. |
| URL Filtering | Displays logs for all traffic that matches a URL Filtering profile attached to a security policy. For example, if policy blocks access to specific web sites and web site categories or if policy is configured to generate an alert when a web site is accessed. For information on defining URL filtering profiles, see URL Filtering. |
| WildFire Submissions | Displays logs for files that are uploaded and analyzed by the WildFire cloud, log data is sent back to the device after analysis, along with the analysis results. |
| Data Filtering | Displays logs for the security policies that help prevent sensitive information such as credit card or social security numbers from leaving the area protected by the firewall. See Set Up Data Filtering for information on defining data filtering profiles.<br>This log also shows information for file blocking profiles. For example, if you are blocking *.exe* files, the log will show the files that were blocked. If you forward files to WildFire, you will see the results of that action. In this case, if you are forwarding PE files to WildFire, for example, the log will show that the file was forwarded and will also show the status on whether or not it was uploaded to WildFire successfully or not. |
| Configuration | Displays an entry for each configuration change. Each entry includes the date and time, the administrator username, the IP address from where the change was made, the type of client (XML, Web or CLI), the type of command executed, whether the command succeeded or failed, the configuration path, and the values before and after the change. |
| System | Displays an entry for each system event. Each entry includes the date and time, the event severity, and an event description. |
| HIP Match | Displays traffic flows that match a HIP Object or HIP Profile that you have configured. |

## Filter Log Data

Each log page has a filter area at the top of the page.

Use the filter area as follows:

 © Palo Alto Networks, Inc.

- Click any of the underlined links in the log listing to add that item as a log filter option. For example, if you click the **Host** link in the log entry for 10.0.0.252 and **Web Browsing** in both items are added, and the search will find entries that match both (AND search).
- To define other search criteria, click **Add Log Filter**. Select the type of search (and/or), the attribute to include in the search, the matching operator, and the values for the match, if appropriate. Click **Add** to add the criterion to the filter area on the log page, and then click **Close** to close the pop-up window. Click **Apply Filter** to display the filtered list.

If the **Value** string matches an **Operator** (such as **has** or **in**), enclose the string in quotation marks to avoid a syntax error. For example, if you filter by destination country and use `IN` as a **Value** to specify INDIA, enter the filter as `( dstloc eq "IN" )`.

You can combine filter expressions added on the log page with those you define in the Add Log Filter dialog. The filter field on the log page displays each filter as an entry.

If you add a **Receive Time** filter with the **Operator** set to **in** and the **Value** set to **Last 60 seconds**, some of the page links on the log viewer might not show results because the number of pages might grow or shrink due to the dynamic nature of the selected time.

- To clear filters and redisplay the unfiltered list, click **Clear Filter**.
- To save your selections as a new filter, click **Save Filter**, enter a name for the filter, and click **OK**.
- To export the current log listing (as shown on the page, including any applied filters) click **Save Filter**. Select whether to open the file or save it to disk, and select the check box if you want to always use the same option. Click **OK**.
- To export the current log listing in CSV Format, select the **Export to CSV** icon. By default, exporting the log listing to CSV format generates a CSV report with up to 2,000 rows of logs. To change the limit for rows displayed in CSV reports, use the **Max Rows in CSV Export** field on the **Log Export and Reporting** subtab (select **Device > Setup > Management > Logging and Reporting Settings**).

To change the automatic refresh interval, select an interval from the drop-down list (**1 min**, **30 seconds**, **10 seconds**, or **Manual**).

To change the number of log entries per page, select the number of rows from the **Rows** drop-down.

Log entries are retrieved in blocks of 10 pages. Use the paging controls at the bottom of the page to navigate through the log list. Select the **Resolve Hostname** check box to begin resolving external IP addresses to domain names.

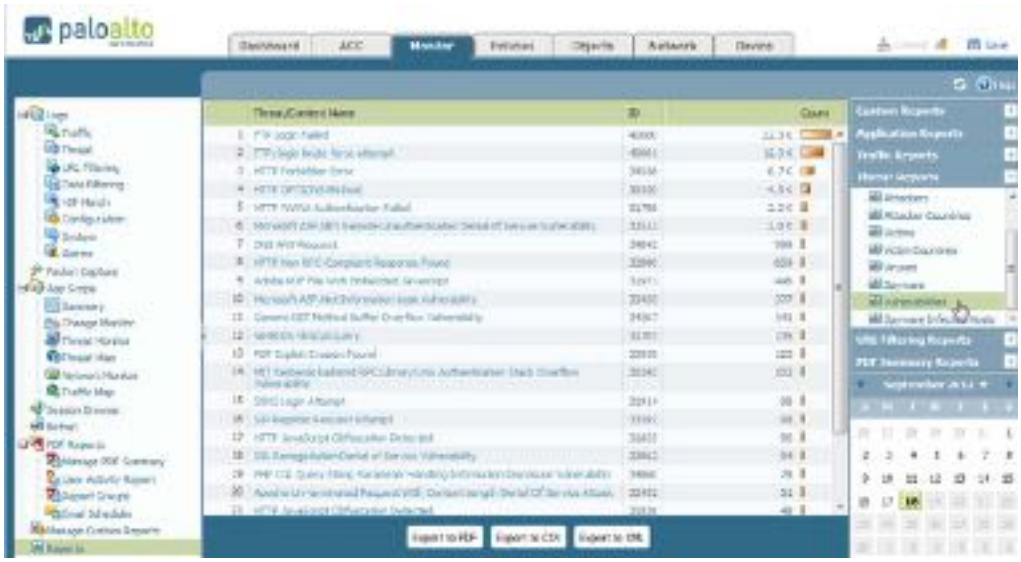
## Monitor the Dashboard

You can also monitor the local log data directly from the **Dashboard** by adding the associated widgets:

 © Palo Alto Networks, Inc.

## View Reports

The firewall also uses the log data to generate reports (**Monitor > Reports**) that display the log data in a tabular or graphical format. See About Reports for more details on the predefined and custom reports available on the firewall.



# Forward Logs to External Services

Depending on the type and severity of the data in the log files, you may want to be alerted to critical events that require your attention, or you may have policies that require you to archive the data for longer than it can be stored on the firewall. In these cases you will want to forward your log data to an external service for archive, notification, and/or analysis.

To forward log data to an external service you must complete the following tasks:

- Configure the firewall to access the remote services that will be receiving the logs. See Define Remote Logging Destinations.
- Configure each log type for forwarding. See Enable Log Forwarding.

 © Palo Alto Networks, Inc.

## Define Remote Logging Destinations

In order to reach an external service—such as a Syslog server or SNMP trap manager—the firewall must know the details of how to access and, if necessary, authenticate to the service. On the firewall, you define this information in a Server Profile. You must create a Server Profile for each external service you want the firewall to interact with. The type of logging destinations you need to set up and which logs you forward will depend on your needs. Some common log forwarding scenarios include the following:

- For immediate notification about critical system events or threats that require your attention, you can generate SNMP traps or send email alerts. See Set Up Email Alerts and/or Set Up SNMP Trap Destinations.
- For long-term storage and archival of data and for centralized device monitoring, you can send the log data to a Syslog server. See Define Syslog Servers. This enables integration with third-party security monitoring tools, such as Splunk! or ArcSight. You can also secure the channel between the firewall and the Syslog server. See Configure the Firewall to Authenticate to the Syslog Server.
- For aggregation and reporting of log data from multiple Palo Alto Networks firewalls, you can forward logs to a Panorama Manager or Panorama Log Collector. See Enable Log Forwarding.

You can define as many Server Profiles as you need. For example, you could use separate Server Profiles to send traffic logs to one Syslog server and system logs to a different one. Or, you could include multiple server entries in a single Server Profile to enable you to log to multiple Syslog servers for redundancy.

By default, all log data is forwarded over the MGT interface. If you plan to use an interface other than MGT, you will need to configure a Service Route for each service to which you plan to forward logs as described in Step 5 in the procedure to Set Up Network Access for External Services.

## Set Up Email Alerts

| Set Up Email Alerts | | |
|---|---|---|
| Step 1 | Create a Server Profile for your email server. | 1. Select **Device > Server Profiles > Email**.<br>2. Click **Add** and then enter a **Name** for the profile.<br>3. (Optional) Select the virtual system to which this profile applies from the **Location** drop-down.<br>4. Click **Add** to add a new email server entry and enter the information required to connect to the Simple Mail Transport Protocol (SMTP) server and send email (you can add up to four email servers to the profile):<br>• **Server**—Name to identify the mail server (1-31 characters). This field is just a label and does not have to be the host name of an existing SMTP server.<br>• **Display Name**—The name to show in the From field of the email.<br>• **From**—The email address where notification emails will be sent from.<br>• **To**—The email address to which notification emails will be sent.<br>• **Additional Recipient**—If you want the notifications sent to a second account, enter the additional address here. You can only add one additional recipient. To add multiple recipients, add the email address of a distribution list.<br>• **Gateway**—The IP address or host name of the SMTP gateway to use to send the emails.<br>5. Click **OK** to save the server profile. |
| Step 2 | (Optional) Customize the format of the email messages the firewall sends. | Select the **Custom Log Format** tab. For details on how to create custom formats for the various log types, refer to the Common Event Format Configuration Guide. |
| Step 3 | Save the server profile and commit your changes. | 1. Click **OK** to save the profile.<br>2. Click **Commit** to save the changes to the running configuration. |

## Set Up SNMP Trap Destinations

Simple Network Management Protocol (SNMP) is a standard facility for monitoring the devices on your network. You can configure the firewall to send SNMP traps to your SNMP management software to alert you to critical system events or threats that require your immediate attention.

You can also use SNMP to monitor the firewall. In this case, your SNMP manager must be configured to get statistics from the firewall rather than (or in addition to) having the firewall send traps to the manager. For more information, see Configure the Firewall to Authenticate to the Syslog Server.

 © Palo Alto Networks, Inc.

**Set Up SNMP Trap Destinations**

Step 1 (SNMP v3 only) Get the engine ID for the firewall.

In many cases, the MIB browser or SNMP manager will automatically discover the engine ID upon successful connection to the SNMP agent on the firewall. You can usually find this information in the agent settings section of the interface. Refer to the documentation for your specific product for instructions on finding the agent information.

In order to find out the firewall's engine ID, you must configure the firewall for SNMP v3 and send a GET message from your SNMP manager or MIB browser as follows:

1. Enable the interface to allow inbound SNMP requests:
   - If you will be receiving SNMP GET messages on the MGT interface, select **Device > Setup > Management** and click the Edit icon in the Management Interface Settings section of the screen. In the **Services** section, select the **SNMP** check box and then click **OK**.
   - If you will be receiving SNMP GET messages on a different interface, you must associate a management profile with the interface and enable SNMP management.
2. Configure the firewall for SNMP v3 as described in Step 2 in Set Up SNMP Monitoring. If you do not configure the firewall for SNMP v3 your MIB browser will not allow you to GET the engine ID.
3. Connect your MIB browser or SNMP manager to the firewall and run a GET for OID 1.3.6.1.6.3.10.2.1.1.0. The value that is returned is the unique engine ID for the firewall.

Step 2 Create a Server Profile that contains the information for connecting and authenticating to the SNMP manager(s).

1. Select **Device > Server Profiles > SNMP Trap**.
2. Click **Add** and then enter a **Name** for the profile.
3. (Optional) Select the virtual system to which this profile applies from the **Location** drop-down.
4. Specify the version of SNMP you are using (V2c or V3).
5. Click **Add** to add a new **SNMP Trap Receiver** entry (you can add up to four trap receivers per server profile). The required values depend on whether you are using SNMP V2c or V3 as follows:

   SNMP V2c

   - **Server**—Name to identify the SNMP manager (1-31 characters). This field is just a label and does not have to be the host name of an existing SNMP server.
   - **Manager**—The IP address of the SNMP manager to which you want to send traps.
   - **Community**—The community string required to authenticate to the SNMP manager.

   SNMP V3

   - **Server**—Name to identify the SNMP manager (1-31 characters). This field is just a label and does not have to be the host name of an existing SNMP server.
   - **Manager**—The IP address of the SNMP manager to which you want to sent traps.
   - **User**—The username required to authenticate to the SNMP manager.
   - **EngineID**—The engine ID of the firewall, as identified in Step 1. This is a hexadecimal value from 5 to 64 bytes with a 0x prefix. Each firewall has a unique engine ID.
   - **Auth Password**—The password to be used for authNoPriv level messages to the SNMP manager. This password will be hashed using Secure Hash Algorithm (SHA-1), but will not be encrypted.
   - **Priv Password**—The password to be used for authPriv level messages to the SNMP manager. This password be hashed using SHA and will be encrypted using Advanced Encryption Standard (AES 128).
6. Click **OK** to save the server profile.

| Set Up SNMP Trap Destinations (Continued) | | |
|---|---|---|
| Step 3 | (Optional) Set up a service route for SNMP traps. | By default, SNMP traps are sent over the MGT interface. If you want to use a different interface for SNMP traps, you must edit the service route to enable the firewall to reach your SNMP manager. See Set Up Network Access for External Services for instructions. |
| Step 4 | Commit your changes. | Click **Commit**. The device may take up to 90 seconds to save your changes. |
| Step 5 | Enable the SNMP manager to interpret the traps it receives from the firewall. | Load the PAN-OS MIB files into your SNMP management software and compile them. Refer to the documentation for your SNMP manager for specific instructions on how to do this. |

## Define Syslog Servers

Syslog is a standard log transport mechanism that enables the aggregation of log data from different network devices—such as routers, firewalls, printers—from different vendors into a central repository for archive, analysis, and reporting.

The firewall generates five types of logs that can be forwarded to an external syslog server: traffic, threat, WildFire, host information profile (HIP) match, config, and system. If you want to forward all or some of these logs to an external service for log-term storage and analysis, you can use TCP or SSL for reliable and secure transport of logs, or UDP for non-secure transport.

 © Palo Alto Networks, Inc.

| Set Up Syslog Forwarding | |
|---|---|
| Step 1 Create a Server Profile that contains the information for connecting to the Syslog server(s). | 1. Select **Device > Server Profiles > Syslog**.<br>2. Click **Add** and then enter a **Name** for the profile.<br>3. (Optional) Select the virtual system to which this profile applies from the **Location** drop-down.<br>4. Click **Add** to add a new Syslog server entry and enter the information required to connect to the Syslog server (you can add up to four Syslog servers to the same profile):<br>• **Name**—Unique name for the server profile.<br>• **Server**—IP address or fully qualified domain name (FQDN) of the Syslog server.<br>• **Transport**—Select TCP, UDP, or SSL as the method of communication with the syslog server.<br>• **Port**—The port number on which to send Syslog messages (default is UDP on port 514); you must use the same port number on the firewall and the Syslog server.<br>• **Format**—Select the Syslog message format to use, BSD or IETF. Traditionally, BSD format is over UDP and IETF format is over TCP/SSL. For setting up secure syslog forwarding with client authentication, see Configure the Firewall to Authenticate to the Syslog Server.<br>• **Facility**—Select one of the Syslog standard values, which is used to calculate the priority (PRI) field in your Syslog server implementation. You should select the value that maps to how you use the PRI field to manage your Syslog messages.<br>5. (Optional) To customize the format of the Syslog messages the firewall sends, select the **Custom Log Format** tab. For details on how to create custom formats for the various log types, refer to the Common Event Format Configuration Guide.<br>6. Click **OK** to save the server profile. |

| Set Up Syslog Forwarding (Continued) | |
|---|---|
| Step 2 (Optional) Configure the header format used in Syslog messages. Choosing the header format offers more flexibility in filtering and reporting on the log data for some SIEMs.<br>  <br><br>This is a global setting and applies to all syslog server profiles configured on the appliance. | 1. Select **Device > Setup > Management** and click the Edit icon in the Logging and Reporting Settings section.<br>2. Select **Log Export and Reporting**.<br>3. Select one of the following options from the **Send Hostname in Syslog** drop-down:<br>• **FQDN**— (the default) Concatenates the hostname and domain name defined on the sending device.<br>• **hostname**— Uses the hostname defined on the sending device.<br>• **ipv4-address**—Uses theIPv4 address of the interface used to send logs on the device. By default, this is the MGT interface of the device.<br>• **ipv6-address**—Uses the IPv6 address of the interface used to send logs on the device. By default, this is the MGT interface of the device.<br>• **none**—Leaves the hostname field unconfigured on the device. There is no identifier for the device that sent the logs.<br>4. Click **OK** and **Commit**. |
| Step 3 Commit your changes. | Click **Commit**. The device may take up to 90 seconds to save your changes. |
| Step 4 Enable log forwarding. | See Enable Log Forwarding.<br>You must configure each log type for forwarding and specify the severity for which the event is logged.<br>WildFire logs are a type of threat log, but they are not logged and forwarded along with threat logs. While WildFire logs use the same syslog format as threat logs, the threat subtype is preset to WildFire. Therefore, you must enable logging/forwarding for WildFire logs distinctly from threat logs. |
| Step 5 Review the logs on the syslog server. | To parse the logs, see Syslog Field Descriptions. |

## Configure the Firewall to Authenticate to the Syslog Server

To enable client authentication for syslog over SSL, you can use a trusted CA or a self-signed CA for generating certificates that can be used for secure syslog communication. Check for the following when generating a certificate for secure syslog communication:

- The private key must be available on the sending device; the keys cannot be stored on a Hardware Security Module (HSM).
- The subject and the issuer for the certificate must not be identical.

 © Palo Alto Networks, Inc.

- The certificate is neither a trusted CA nor a certificate signing request (CSR). Neither of these types of certificates can be enabled for secure syslog communication.

**Configure the Firewall to Authenticate to the Syslog Server**

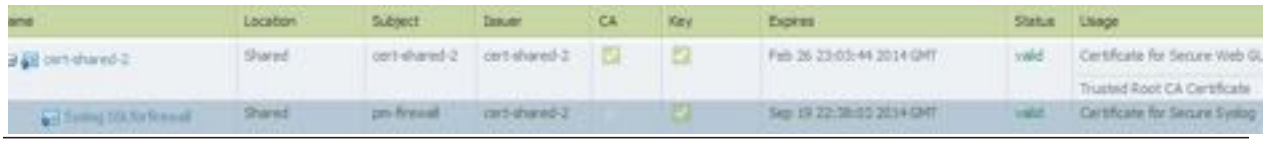
Step 1 If the syslog server requires client authentication, generate the certificate for secure communication. For details on certificates, see Certificate Management.

To verify that the sending device is authorized to communicate with the syslog server, you must enable the following:

- The server and the sending device must have certificates that are signed by the Enterprise CA; or you can generate a self-signed certificate on the firewall, export the CA root certificate from the firewall and import it in to the syslog server.
- Use the Enterprise CA or the self-signed certificate to generate a certificate with the IP address of the sending device (as the Common Name) and enabled for use in secure syslog communication. The syslog server uses this certificate to verify that the firewall is authorized to communicate with the syslog server.

  Use the following steps to generate the certificate on the firewall or Panorama:

1. Select **Device > Certificate Management > Certificates > Device Certificates**.
2. Click **Generate** to create a new certificate that will be signed by a trusted CA or the self-signed CA.
3. Enter a **Name** for the certificate.
4. In **Common Name**, enter the IP address of the device sending logs to the syslog server.
5. Select **Shared** if you want the certificate to be a shared certificate on Panorama or to be shared by all virtual systems in a multiple virtual system firewall.
6. In **Signed by**, select the trusted CA or the self-signed CA that is trusted by both the syslog server and the sending device.
7. Click **Generate**. The certificate and the keypair will be generated.
8. Click the link with name of the certificate and enable the option Certificate for Secure Syslog for secure access to the syslog server.
9. **Commit** the changes.
10. Verify the certificate details and that it is marked for **Usage** as **Certificate for Secure Syslog**.



## Enable Log Forwarding

After you create the Server Profiles that define where to send your logs (see Define Remote Logging Destinations), you must enable log forwarding. For each log type, you can specify whether to forward it to Syslog, email, SNMP trap receiver, and/or Panorama.

Before you can forward log files to a Panorama Manager or a Panorama Log Collector, the firewall must be configured as a managed device. You can then enable log forwarding to Panorama for each type of log. For logs forwarded to Panorama, support for centralized log forwarding to an external syslog server is available.

You can use Secure Copy (SCP) commands from the CLI to export the entire log database (logdb) to an SCP server and import it to another firewall: refer to the PAN-OS Command Line Interface (CLI) Reference Guide. Because the log database is too large for an export or import to be practical on the following platforms, they do not support these options: PA-7050 firewall (all PAN-OS releases), Panorama virtual appliance running Panorama 6.0 or later releases, and Panorama M-Series appliances (all Panorama releases).

The way you enable forwarding depends on the log type:

- **Traffic Logs**—You enable forwarding of Traffic logs by creating a Log Forwarding Profile (**Objects > Log Forwarding**) and adding it to the security policies you want to trigger the log forwarding. Only traffic that matches a specific rule within the security policy will be logged and forwarded.
- **Threat Logs**—You enable forwarding of Threat logs by creating a Log Forwarding Profile (**Objects > Log Forwarding**) that specifies which severity levels you want to forward and then adding it to the security policies for which you want to trigger the log forwarding. A Threat log entry will only be created (and therefore forwarded) if the associated traffic matches a Security Profile (Antivirus, Anti-spyware, Vulnerability, URL Filtering, File Blocking, Data Filtering, or DoS Protection). The following table summarizes the threat severity levels:

| Severity | Description |
|---|---|
| **Critical** | Serious threats such as those that affect default installations of widely deployed software, result in root compromise of servers, and the exploit code is widely available to attackers. The attacker usually does not need any special authentication credentials or knowledge about the individual victims and the target does not need to be manipulated into performing any special functions. |
| **High** | Threats that have the ability to become critical but have mitigating factors; for example, they may be difficult to exploit, do not result in elevated privileges, or do not have a large victim pool. |
| **Medium** | Minor threats in which impact is minimized, such as DoS attacks that do not compromise the target or exploits that require an attacker to reside on the same LAN as the victim, affect only non-standard configurations or obscure applications, or provide very limited access. In addition, WildFire Submissions log entries with a malware verdict are logged as Medium. |
| **Low** | Warning-level threats that have very little impact on an organization's infrastructure. They usually require local or physical system access and may often result in victim privacy or DoS issues and information leakage. Data Filtering profile matches are logged as Low. |

 © Palo Alto Networks, Inc.

| Severity | Description |
|---|---|
| **Informational** | Suspicious events that do not pose an immediate threat, but that are reported to call attention to deeper problems that could possibly exist. URL Filtering log entries and WildFire Submissions log entries with a benign verdict are logged as Informational. |

- **Config Logs**—You enable forwarding of Config logs by specifying a Server Profile in the log settings configuration. (**Device > Log Settings > Config Logs**).
- **System Logs**—You enable forwarding of System logs by specifying a Server Profile in the log settings configuration. (**Device > Log Settings > System Logs**). You must select a Server Profile for each severity level you want to forward. For a partial list of system log messages and their corresponding severity levels, refer to the System Log Reference. The following table summarizes the system log severity levels:

| Severity | Description |
|---|---|
| **Critical** | Hardware failures, including HA failover and link failures. |
| **High** | Serious issues, including dropped connections with external devices, such as LDAP and RADIUS servers. |
| **Medium** | Mid-level notifications, such as antivirus package upgrades. |
| **Low** | Minor severity notifications, such as user password changes. |
| **Informational** | Log in/log off, administrator name or password change, any configuration change, and all other events not covered by the other severity levels. |

# Monitor the Firewall Using SNMP

All Palo Alto Networks firewalls support standard networking SNMP management information base (MIB) modules as well as proprietary Enterprise MIB modules. You can configure an SNMP manager to get statistics from the firewall. For example, you could configure your SNMP manager to monitor the interfaces, active sessions, concurrent sessions, session utilization percentage, temperature, and/or system uptime on the firewall.

Palo Alto Networks firewalls support SNMP GET requests only; SNMP SET requests are not supported.

| Set Up SNMP Monitoring | | |
|---|---|---|
| Step 1 | Enable the interface to allow inbound SNMP requests. | • If you will be receiving SNMP GET messages on the MGT interface, select **Device > Setup > Management** and click the Edit icon in the Management Interface Settings section of the screen. In the **Services** section, select the **SNMP** check box and then click **OK**.<br>• If you will be receiving SNMP GET messages on a different interface, you must associate a management profile with the interface and enable SNMP management. |
| Step 2 | From the web interface on the firewall, configure the settings to allow the SNMP agent on the firewall to respond to incoming GET requests from the SNMP manager. | 1. Select **Device > Setup > Operations > SNMP Setup**.<br>2. Specify the **Physical Location** of the firewall and the name or email address of an administrative **Contact**.<br>3. Select the SNMP **Version** and then enter the configuration details as follows (depending on which SNMP version you are using) and then click **OK**:<br>• **V2c**—Enter the **SNMP Community String** that will allow the SNMP manager access to the SNMP agent on the firewall. The default value is **public**, however because this is a well-known community string, it is a best practice to use a value that is not easily guessed.<br>• **V3**—You must create at least one View and one User in order to use SNMPv3. The view specifies which management information the manager has access to. If you want to allow access to all management information, just enter the top-level **OID** of .1.3.6.1 and specify the **Option** as **include** (you can also create views that exclude certain objects). Use **0xf0** as the **Mask**. Then when you create a user, select the **View** you just created and specify the **Auth Password** and **Priv Password**.<br>The authentication settings (the community string for V2c or the username and passwords for V3) configured on the firewall must match the value configured on the SNMP manager.<br>4. Click **OK** to save the settings.<br>5. Click **Commit** to save the SNMP settings. |
| Step 3 | Enable the SNMP manager to interpret firewall statistics. | Load the PAN-OS MIB files into your SNMP management software and, if necessary, compile them. Refer to the documentation for your SNMP manager for specific instructions on how to do this. |

© Palo Alto Networks, Inc.

| Set Up SNMP Monitoring (Continued) | | |
|---|---|---|
| Step 4 | Identify the statistics you want to monitor. | Using a MIB browser, walk the PAN-OS MIB files to identify the object identifiers (OIDs) that correspond to the statistics you want to monitor. For example, suppose you want to monitor Session Utilization Percentage on the firewall. Using a MIB browser you will see that this statistic corresponds to OID 1.3.6.1.4.1.25461.2.1.2.3.1.0 in the PAN-COMMON-MIB. |
| Step 5 | Configure the SNMP management software to monitor the OIDs you are interested in. | Refer to the documentation for your SNMP manager for specific instructions on how to do this. |
| Step 6 | After you complete the configuration on both the firewall and the SNMP manager, you can begin monitoring the firewall from your SNMP management software. | The following is an example of how an SNMP manager displays real-time session utilization percentage statistics for a monitored PA-500 firewall:<br>  |

# Monitor the Firewall Using NetFlow

NetFlow is an industry-standard protocol that enables the firewall to record statistics on the IP traffic that traverses its interfaces. The firewall exports the statistics as NetFlow fields to a NetFlow collector. The NetFlow collector is a server you use to analyze network traffic for security, administration, accounting and troubleshooting purposes. All firewalls support NetFlow Version 9 except the PA-4000 Series and PA-7050 firewalls. The firewalls support only unidirectional NetFlow, not bidirectional. You can enable NetFlow exports on all interface types except HA, log card, or decrypt mirror. To identify firewall interfaces in a NetFlow collector, see Identify Firewall Interfaces in External Monitoring Systems.

The firewall supports standard and enterprise (PAN-OS specific) NetFlow templates. NetFlow collectors require templates to decipher the exported fields. The firewall selects a template based on the type of data it exports: IPv4 or IPv6 traffic, with or without NAT, and with standard or enterprise-specific fields. The firewall periodically refreshes templates to apply any changes to them. You configure the refresh frequency according to the requirements of the particular NetFlow collector you use.

| **Monitor the Firewall Using NetFlow** | | |
|---|---|---|
| Step 1 | Create a NetFlow server profile. | 1. Select **Device > Server Profiles > NetFlow** and click **Add**.<br>2. Enter a **Name** for the profile.<br>3. Specify the frequency at which the firewall refreshes templates (in **Minutes** or **Packets**) and exports records (**Active Timeout** in minutes).<br>4. Select the **PAN-OS Field Types** check box if you want the firewall to export App-ID and User-ID fields.<br>5. For each NetFlow collector that will receive fields (up to two per profile), click **Add** and enter an identifying server **Name**, hostname or IP address (**NetFlow Server**), and access **Port** (default 2055).<br>6. Click **OK** to save the profile. |
| Step 2 | Assign the NetFlow server profile to the interfaces that carry the traffic you want to analyze.<br>In this example, you assign the profile to an existing Layer 3 interface. | 1. Select **Network > Interfaces > Ethernet**.<br>2. Click an **Interface** name to edit it.<br>3. In the **NetFlow Profile** drop-down, select the NetFlow server profile.<br>4. Click **OK** and **Commit** your changes. |

© Palo Alto Networks, Inc.

# Identify Firewall Interfaces in External Monitoring Systems

When you use a NetFlow collector (see Monitor the Firewall Using NetFlow) or SNMP manager (see Monitor the Firewall Using SNMP) to monitor traffic flows, an interface index (SNMP ifindex object) identifies the firewall interface that carried a particular flow. The formula that the Palo Alto Networks firewall uses to calculate interface indexes varies by platform and whether the interface is physical or logical.

You cannot use SNMP to monitor logical interfaces, only physical interfaces. You can use NetFlow to monitor logical or physical interfaces.

Most NetFlow collectors use SNMP to determine the name of a physical interface based on the SNMP interface index.

Physical interface indexes have a range of 1-9999, which the firewall calculates as follows:

| Firewall Platform | Calculation | Example Interface Index |
|---|---|---|
| Non-chassis based:<br>VM-Series, PA-200, PA-500, PA-3000 Series, PA-4000 Series, PA-5000 Series<br> The PA-4000 Series platform supports SNMP but not NetFlow. | MGT port + physical port offset<br>• MGT port—This is a constant that depends on the platform:<br>  • 2 for hardware-based firewalls (for example, the PA-5000 Series firewall)<br>  • 1 for the VM-Series firewall<br>• Physical port offset—This is the physical port number. | PA-5000 Series firewall, Eth1/4 =<br>2 (MGT port) + 4 (physical port) = **6** |
| Chassis based:<br>PA-7050 firewalls<br> This platform supports SNMP but not NetFlow. | (Max. ports * slot) + physical port offset + MGT port<br>• Maximum ports—This is a constant of 64.<br>• Slot—This is the chassis slot number of the network interface card.<br>• Physical port offset—This is the physical port number.<br>• MGT port—This is a constant of 5 for PA-7050 firewalls. | PA-7050 firewall, Eth3/9 =<br>[64 (max. ports) * 3 (slot)] + 9 (phyical port) + 5 (MGT port) = **206** |

Logical interface indexes for all platforms are nine-digit numbers that the firewall calculates as follows:

| Interface Type | Range | Digit 9 | Digits 7-8 | Digits 5-6 | Digits 1-4 | Example Interface Index |
|---|---|---|---|---|---|---|
| Layer 3 subinterface | 101010001-199999999 | Type: 1 | Interface slot: 1-9 (01-09) | Interface port: 1-9 (01-09) | Subinterface: suffix 1-9999 (0001-9999) | Eth1/5.22 = 100000000 (type) + 100000 (slot) + 50000 (port) + 22 (suffix) = **101050022** |
| Layer 2 subinterface | 101010001-199999999 | Type: 1 | Interface slot: 1-9 (01-09) | Interface port: 1-9 (01-09) | Subinterface: suffix 1-9999 (0001-9999) | Eth2/3.6 = 100000000 (type) + 200000 (slot) + 30000 (port) + 6 (suffix) = **102030006** |

| Interface Type | Range | Digit 9 | Digits 7-8 | Digits 5-6 | Digits 1-4 | Example Interface Index |
|---|---|---|---|---|---|---|
| Vwire subinterface | 101010001-199999999 | Type: 1 | Interface slot: 1-9 (01-09) | Interface port: 1-9 (01-09) | Subinterface: suffix 1-9999 (0001-9999) | Eth4/2.312 = 100000000 (type) + 400000 (slot) + 20000 (port) + 312 (suffix) = **104020312** |
| VLAN | 200000001-200009999 | Type: 2 | 00 | 00 | VLAN suffix: 1-9999 (0001-9999) | VLAN.55 = 200000000 (type) + 55 (suffix) = **200000055** |
| Loopback | 300000001-300009999 | Type: 3 | 00 | 00 | Loopback suffix: 1-9999 (0001-9999) | Loopback.55 = 300000000 (type) + 55 (suffix) = **300000055** |
| Tunnel | 400000001-400009999 | Type: 4 | 00 | 00 | Tunnel suffix: 1-9999 (0001-9999) | Tunnel.55 = 400000000 (type) + 55 (suffix) = **400000055** |
| Aggregate group | 500010001-500089999 | Type: 5 | 00 | AE suffix: 1-8 (01-08) | Subinterface: suffix 1-9999 (0001-9999) | AE5.99 = 500000000 (type) + 50000 (AE Suffix) + 99 (suffix) = **500050099** |

© Palo Alto Networks, Inc.

# Manage Reporting

The reporting capabilities on the firewall allow you to keep a pulse on your network, validate your policies, and focus your efforts on maintaining network security for keeping your users safe and productive.

- About Reports
- View Reports
- Disable Predefined Reports
- Generate Custom Reports
- Generate Botnet Reports
- Manage PDF Summary Reports
- Generate User/Group Activity Reports
- Manage Report Groups
- Schedule Reports for Email Delivery

© Palo Alto Networks, Inc.

## About Reports

The firewall includes predefined reports that you can use as-is, build custom reports that meet your needs for specific data and actionable tasks, or combine predefined and custom reports to compile information you need. The firewall provides the following types of reports:

- **Predefined Reports—**Allow you to view a quick summary of the traffic on your network. A suite of predefined reports are available in four categories —Applications, Traffic, Threat, and URL Filtering. See View Reports.
- **User or Group Activity Reports—**Allow you to schedule or create an on-demand report on the application use and URL activity for a specific user or for a user group; the report includes the URL categories and an estimated browse time calculation for individual users. See Generate User/Group Activity Reports.
- **Custom Reports**—Create and schedule custom reports that show exactly the information you want to see by filtering on conditions and columns to include. You can also include query builders for more specific drill down on report data. See Generate Custom Reports.
- **PDF Summary Reports—**Aggregate up to 18 predefined or custom reports/graphs from Threat, Application, Trend, Traffic, URL Filtering categories into one PDF document. See Manage PDF Summary Reports.
- **Botnet Reports**—Allow you to use behavior-based mechanisms to identify potential botnet-infected hosts in the network. See Generate Botnet Reports.
- **Report Groups**—Combine custom and predefined reports into report groups and compile a single PDF that is emailed to one or more recipients. See Manage Report Groups.

Reports can be generated on demand, on a recurring schedule, and can be scheduled for email delivery.

 © Palo Alto Networks, Inc.

# View Reports

The firewall provides an assortment of over 40 predefined reports that are generated everyday; these reports can be viewed directly on the firewall. In addition to these reports, you can view *scheduled* custom reports and summary reports.

About 200 MB of storage is allocated for saving reports on the firewall. This storage space is not user configurable, and older reports are purged to store recent reports. Therefore, for long term retention of reports, you can either export the reports or schedule the reports for email delivery. To disable selected reports and conserve system resources on the firewall, see Disable Predefined Reports.

User/group activity reports must be generated on demand or scheduled for email delivery. Unlike the other reports, these reports cannot be saved on the firewall.

**View Reports**

Step 1 Select **Monitor > Reports**.

The reports are chunked into sections on the right-hand side of the window: **Custom Reports**, **Application Reports**, **Traffic Reports**, **Threat Reports**, **URL Filtering Reports**, and **PDF Summary Reports**.

Step 2 Select a report to view. When you select a report, the previous day's report is displayed on screen.

To view reports for any of the previous days, select an available date from the calendar at the bottom of the page and select a report within the same section. If you change sections, the time selection is reset.

Step 3 To view a report offline, you can export the report to PDF, CSV or to XML formats. Click **Export to PDF**, **Export to CSV**, or **Export to XML** at the bottom of the page. Then print or save the file.

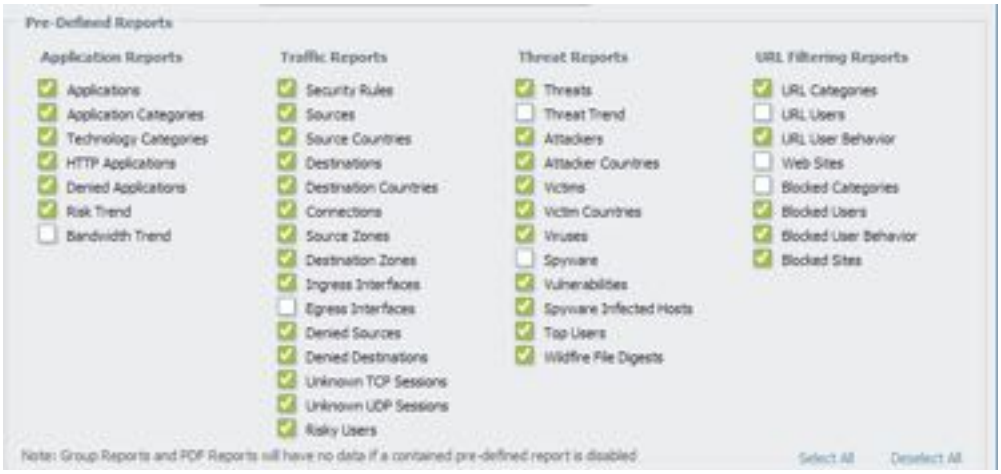
## Disable Predefined Reports

The firewall includes about 40 predefined reports that are automatically generated each day. If you do not use some or all of these predefined reports, you can disable selected reports and conserve system resources on the firewall.

Before disabling one or more predefined reports, make sure that the report is not included in a Group Report or a PDF Report. If the disabled predefined report is included in a group or PDF report, the Group/PDF report will be rendered without any data.

### Disable Predefined Reports

1. Select **Device > Setup > Management** on the firewall.
2. Click the Edit icon in the Logging and Reporting Settings section and select the **Log Export and Reporting** tab.
3. To disable reports:
   - Clear the check box corresponding to each report that you want to disable.
   - Select **Deselect All** to disable all predefined reports.



4. Click **OK**, and **Commit** the changes.

 © Palo Alto Networks, Inc.

## Generate Custom Reports

In order to create purposeful custom reports, you must consider the attributes or key pieces of information that you want to retrieve and analyze. This consideration guides you in making the following selections in a custom report:

| Selection | Description |
|---|---|
| Data Source | The data file that is used to generate the report. The firewall offers two types of data sources—Summary databases and Detailed logs.<br>• Summary databases are available for traffic, threat, and application statistics. The firewall aggregates the detailed logs on traffic, application, and threat at 15-minute intervals. The data is condensed—duplicate sessions are grouped together and incremented with a repeat counter, and some attributes (or columns) are not included in the summary—to allow faster response time when generating reports.<br>• Detailed logs are itemized and are a complete listing of all the attributes (or columns) that pertain to the log entry. Reports based on detailed logs take much longer to run and are not recommended unless absolutely necessary. |
| Attributes | The columns that you want to use as the match criteria. The attributes are the columns that are available for selection in a report. From the list of **Available Columns**, you can add the selection criteria for matching data and for aggregating the details (the **Selected Columns**). |
| Sort By/ Group By | The **Sort By** and the **Group By** criteria allow you to organize/segment the data in the report; the sorting and grouping attributes available vary based on the selected data source.<br>The Sort By option specifies the attribute that is used for aggregation. If you do not select an attribute to sort by, the report will return the first N number of results without any aggregation.<br>The Group By option allows you to select an attribute and use it as an anchor for grouping data; all the data in the report is then presented in a set of top 5, 10, 25 or 50 groups. For example, when you select Hour as the group by selection and want the top 25 groups for a 24-hr time period. The results of the report will be generated on an hourly basis over a 24-hr period. The first column in the report will be the hour and then the next set of columns will be the rest of your selected report columns. |

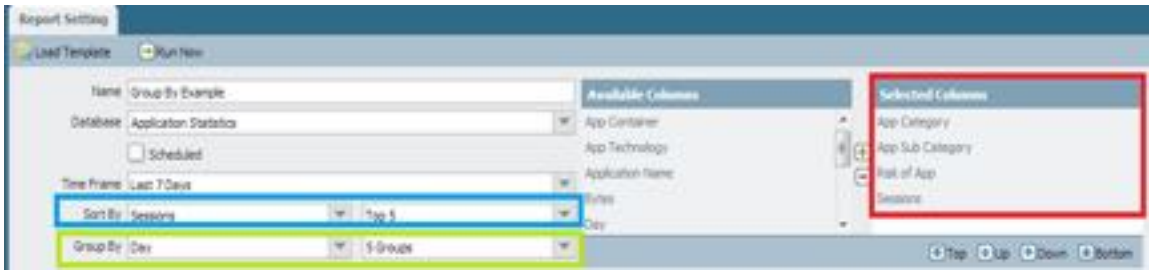
© Palo Alto Networks, Inc.

| Selection | Description |
|---|---|
| | The following example illustrates how the **Selected Columns** and **Sort By**/**Group By** criteria work together when generating reports:<br>  <br>The columns circled in red (above) depict the columns selected, which are the attributes that you match against for generating the report. Each log entry from the data source is parsed and these columns are matched on. If multiple sessions have the same values for the selected columns, the sessions are aggregated and the repeat count (or sessions) is incremented.<br>The column circled in blue indicates the chosen sort order. When the sort order (**Sort By**) is specified, the data is sorted (and aggregated) by the selected attribute.<br>The column circled in green indicates the **Group By** selection, which serves as an anchor for the report. The **Group By** column is used as a match criteria to filter for the top N groups. Then, for each of the top N groups the report enumerates the values for all the other selected columns. |

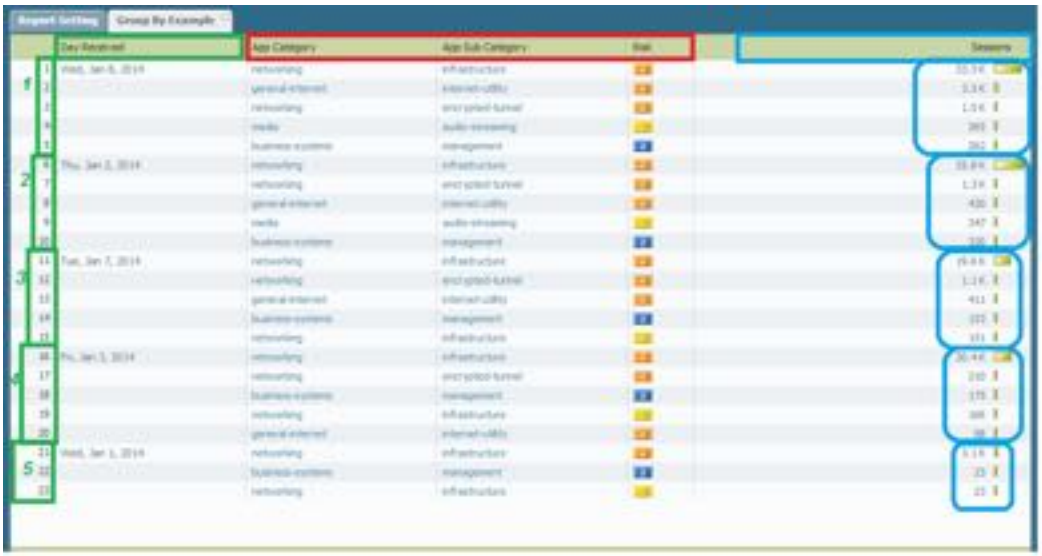
 © Palo Alto Networks, Inc.

| Selection | Description |
|---|---|

For example, if a report has the following selections



The output will display as follows:



The report is anchored by **Day** and sorted by **Sessions**. It lists the 5 days (**5 Groups**) with maximum traffic in the **Last 7 Days** time frame. The data is enumerated by the **Top 5** sessions for each day for the selected columns—**App Category**, **App Subcategory** and **Risk**.

| | |
|---|---|
| Time Period | The date range for which you want to analyze data. You can define a custom range or select a time period ranging from last 15 minutes to the last 30 days. The reports can be run on demand or scheduled to run at a daily or weekly cadence. |
| Query Builder | The query builder allows you to define specific queries to further refine the selected attributes. It allows you see just what you want in your report using **and** and **or** operators and a match criteria, and then include or exclude data that matches or negates the query in the report. Queries enable you to generate a more focused collation of information in a report. |

## Generate Custom Reports

1. Select **Monitor > Manage Custom Reports**.
2. Click **Add** and then enter a **Name** for the report.

   To base a report on an predefined template, click **Load Template** and choose the template. You can then edit the template and save it as a custom report.
3. Select the database to use for the report.

Each time you create a custom report, a **Log View** report is automatically created. This report show the logs that were used to build the custom report. The log view report uses the same name as the custom report, but appends the phrase (Log View) to the report name.

When creating a report group, you can include the log view report with the custom report. For more information, see Manage Report Groups.

4. Select the **Scheduled** check box to run the report each night. The report is then available for viewing in the **Reports** column on the side.
5. Define the filtering criteria. Select the **Time Frame**, the **Sort By** order, **Group By** preference, and select the columns that must display in the report.
6. (Optional) Select the **Query Builder** attributes, if you want to further refine the selection criteria. To build a report query, specify the following and click **Add**. Repeat as needed to construct the full query.
   - **Connector**—Choose the connector (and/or) to precede the expression you are adding.
   - **Negate**—Select the check box to interpret the query as a negation. If for example, you choose to match entries in the last 24 hours and/or are originating from the untrust zone, the negate option causes a match on entries that are not in the past 24 hours and/or are not from the untrust zone.
   - **Attribute**—Choose a data element. The available options depend on the choice of database.
   - **Operator**—Choose the criterion to determine whether the attribute applies (such as =). The available options depend on the choice of database.
   - **Value**—Specify the attribute value to match.

     For example, the following figure (based on the Traffic Log database) shows a query that matches if the traffic log entry was received in the past 24 hours and is from the "untrust" zone.

7. To test the report settings, select **Run Now**. Modify the settings as required to change the information that is displayed in the report.
8. Click **OK** to save the custom report.

© Palo Alto Networks, Inc.

**Generate Custom Reports (Continued)**

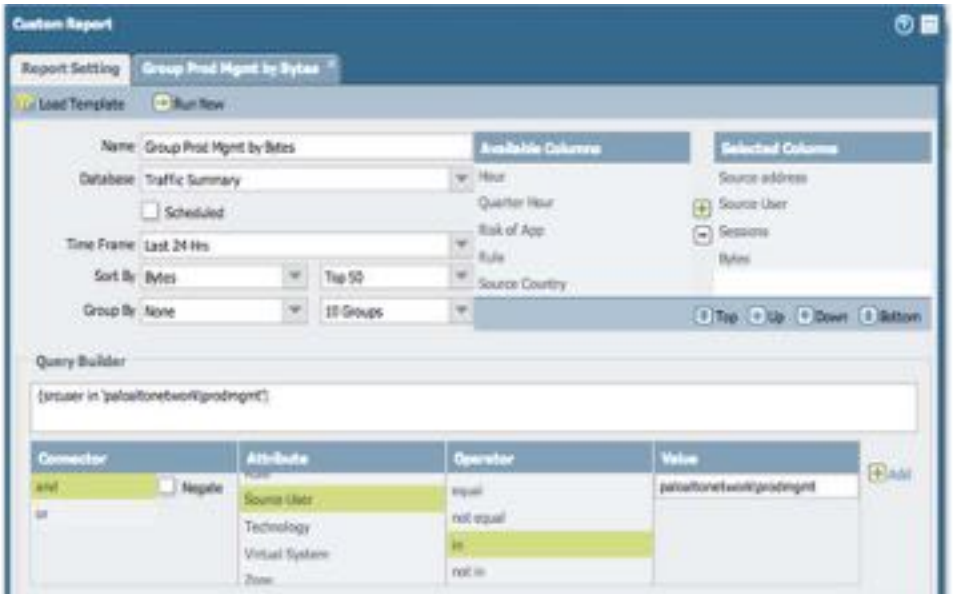
**Examples of Custom Reports**

If we now set up a simple report in which we use the traffic summary database from the last 30 days, and sort the data by the top 10 sessions and these sessions are grouped into 5 groups by day of the week. You would set up the custom report to look like this:

And the PDF output for the report would look as follows:

**Generate Custom Reports (Continued)**

Now, if you want to use the query builder to generate a custom report that represents the top consumers of network resources within a user group, you would set up the report to look like this:



The report would display the top users in the product management user group sorted by bytes, as follows:

 © Palo Alto Networks, Inc.

# Generate Botnet Reports

The botnet report enables you to use heuristic and behavior-based mechanisms to identify potential malware- or botnet-infected hosts in your network. To evaluate botnet activity and infected hosts, the firewall correlates user and network activity data in Threat, URL, and Data Filtering logs with the list of malware URLs in PAN-DB, known dynamic DNS domain providers, and domains registered within the last 30 days. You can configure the report to identify hosts that visited those sites, as well as hosts that communicated with Internet Relay Chat (IRC) servers or that used unknown applications. Malware often use dynamic DNS to avoid IP blacklisting, while IRC servers often use bots for automated functions.

The firewall requires Threat Prevention and URL Filtering licenses to use the botnet report.

- Configure a Botnet Report
- Interpret Botnet Report Output

## Configure a Botnet Report

You can schedule a botnet report or run it on demand. The firewall generates scheduled botnet reports every 24 hours because behavior-based detection requires correlating traffic across multiple logs over that timeframe.

| Configure a Botnet Report | |
|---|---|
| Step 1 Define the types of traffic that indicate possible botnet activity. | 1. Select **Monitor > Botnet** and click **Configuration** on the right side of the page.<br>2. **Enable** and define the **Count** for each type of HTTP Traffic that the report will include.<br>The **Count** values represent the minimum number of events of each traffic type that must occur for the report to list the associated host with a higher confidence score (higher likelihood of botnet infection). If the number of events is less than the **Count**, the report will display a lower confidence score or (for certain traffic types) won't display an entry for the host. For example, if you set the **Count** to three for **Malware URL visit**, then hosts that visit three or more known malware URLs will have higher scores than hosts that visit less than three. For details, see Interpret Botnet Report Output.<br>3. Define the thresholds that determine whether the report will include hosts associated with traffic involving Unknown TCP or Unknown UDP applications.<br>4. Select the **IRC** check box to include traffic involving IRC servers.<br>5. Click **OK** to save the report configuration. |

| Configure a Botnet Report (Continued) | |
|---|---|
| Step 2 Schedule the report or run it on demand. | 1. Click **Report Setting** on the right side of the page.<br>2. Select a time interval for the report in the **Test Run Time Frame** drop-down.<br>3. Select the **No. of Rows** to include in the report.<br>4. (Optional) **Add** queries to the Query Builder to filter the report output by attributes such as source/destination IP addresses, users, or zones.<br>For example, if you know in advance that traffic initiated from the IP address 10.3.3.15 contains no potential botnet activity, you can add `not (addr.src in 10.0.1.35)` as a query to exclude that host from the report output. For details, see Interpret Botnet Report Output.<br>5. Select **Scheduled** to run the report daily or click **Run Now** to run the report immediately.<br>6. Click **OK** and **Commit**. |

## Interpret Botnet Report Output

The botnet report displays a line for each host that is associated with traffic you defined as suspicious when configuring the report. For each host, the report displays a confidence score of 1 to 5 to indicate the likelihood of botnet infection, where 5 indicates the highest likelihood. The scores correspond to threat severity levels: 1 is informational, 2 is low, 3 is medium, 4 is high, and 5 is critical. The firewall bases the scores on:

- **Traffic type**—Certain HTTP traffic types are more likely to involve botnet activity. For example, the report assigns a higher confidence to hosts that visit known malware URLs than to hosts that browse to IP domains instead of URLs, assuming you defined both those activities as suspicious.
- **Number of events**—Hosts that are associated with a higher number of suspicious events will have higher confidence scores based on the thresholds (**Count** values) you define when you Configure a Botnet Report.
- **Executable downloads**—The report assigns a higher confidence to hosts that download executable files. Executable files are a part of many infections and, when combined with the other types of suspicious traffic, can help you prioritize your investigations of compromised hosts.

When reviewing the report output, you might find that the sources the firewall uses to evaluate botnet activity (for example, the list of malware URLs in PAN-DB) have gaps. You might also find that these sources identify traffic that you consider safe. To compensate in both cases, you can add query filters when you Configure a Botnet Report.

 © Palo Alto Networks, Inc.

# Manage PDF Summary Reports

PDF summary reports contain information compiled from existing reports, based on data for the top 5 in each category (instead of top 50). They also contain trend charts that are not available in other reports.

| **Generate PDF Summary Reports** | |
|---|---|
| Step 1 Set up a **PDF Summary Report**. | 1. Select **Monitor > PDF Reports > Manage PDF Summary**.<br>2. Click **Add** and then enter a **Name** for the report.<br>3. Use the drop-down list for each report group and select one or more of the elements to design the PDF Summary Report. You can include a maximum of 18 report elements.<br>  <br>• To remove an element from the report, click the **x** icon or clear the selection from the drop-down for the appropriate report group.<br>• To rearrange the reports, drag and drop the icons to another area of the report.<br>4. Click **OK t**o save the report.<br>5. **Commit** the changes. |

| Generate PDF Summary Reports | |
|---|---|
| Step 2 View the report. | To download and view the PDF Summary Report, see View Reports.   |

 © Palo Alto Networks, Inc.

## Generate User/Group Activity Reports

User/Group activity reports summarize the web activity of individual users or user groups. Both reports include the same information with a couple exceptions—**Browsing Summary by URL Category** and **Browse time calculations** are included in User Activity Reports, but are not included in Group Activity Reports.

User-ID must be configured on the firewall, in order to access the list of user/user groups.

**Generate User/Group Activity Reports**

1. Select **Monitor > PDF Reports > User Activity Report**.
2. Click **Add** and then enter a **Name** for the report.
3. Create the report:
   - For a User Activity Report: Select **User** and enter the **Username** or **IP address** (IPv4 or IPv6) of the user who will be the subject of the report.
   - For Group Activity Report: Select **Group** and select the **Group Name** for which to retrieve user group information in the report.
4. Select the time frame for the report from the drop-down.

   The number of logs that are analyzed in a user activity report is determined by the number of rows defined on the **Max Rows in User Activity Report** on the Logging and Reporting Settings section on **Device >Setup > Management**.
5. Select **Include Detailed Browsing** to include detailed URL logs in the report.

   The detailed browsing information can include a large volume of logs (thousands of logs) for the selected user or user group and can make the report very large.
6. To run the report on demand, click **Run Now**.
7. To save the report, click **OK**. User/Group activity reports cannot be saved on the firewall; to schedule the report for email delivery, see Schedule Reports for Email Delivery.

# Manage Report Groups

Report groups allow you to create sets of reports that the system can compile and send as a single aggregate PDF report with an optional title page and all the constituent reports included.

| Set up Report Groups | |
|---|---|
| Step 1 Set up report groups.<br><br>You must set up a **Report Group** to email report(s). | 1. Create a Server Profile for your email server.<br>2. Define the **Report Group**. A report group can compile predefined reports, PDF Summary reports, custom reports, and Log View report into a single PDF.<br>a. Select **Monitor > Report Group**.<br>b. Click **Add** and then enter a **Name** for the report group.<br>c. (Optional) Select **Title Page** and add a **Title** for the PDF output.<br>d. Select reports from the left column and click **Add** to move each report to the report group on the right.<br><br>  <br><br>The **Log View** report is a report type that is automatically created each time you create a custom report and uses the same name as the custom report. This report will show the logs that were used to build the contents of the custom report.<br><br>To include the log view data, when creating a report group, add your custom report under the **Custom Reports** list and then add the log view report by selecting the matching report name from the **Log View** list. The report will include the custom report data and the log data that was used to create the custom report.<br>e. Click **OK** to save the settings.<br>f. To use the report group, see Schedule Reports for Email Delivery. |

© Palo Alto Networks, Inc.

## Schedule Reports for Email Delivery

Reports can be scheduled for daily delivery or delivered weekly on a specified day. Scheduled reports are executed starting at 2:00 AM, and email delivery starts after all scheduled reports have been generated.

**Schedule Reports for Email Delivery**

1. Select **Monitor > PDF Reports > Email Scheduler**.
2. Select the **Report Group** for email delivery. To set up a report group; see Manage Report Groups.
3. Select the frequency at which to generate and send the report in **Recurrence**.
4. Select the email server profile to use for delivering the reports. To set up an email server profile, see Create a Server Profile for your email server.
5. The **Override Recipient email(s)** allows you to send this report exclusively to the recipients specified in this field. When you add recipients to the **Override Recipient email(s)**, the report is not sent to the recipients configured in the email server profile. Use this option for those occasions when the report is for the attention of someone other than the administrators or recipients defined in the email server profile.

# Syslog Field Descriptions

This is a list of the standard fields for each of the five log types that are forwarded to an external server. For ease of parsing, the comma is the delimiter; each field is a comma-separated value (CSV) string. Fields that are not currently implemented/reserved for future use as tagged as FUTURE_USE.

- Traffic Logs

## Traffic Logs

**Format:** FUTURE_USE, Receive Time, Serial Number, Type, Subtype, FUTURE_USE, Generated Time, Source IP, Destination IP, NAT Source IP, NAT Destination IP, Rule Name, Source User, Destination User, Application, Virtual System, Source Zone, Destination Zone, Ingress Interface, Egress Interface, Log Forwarding Profile, FUTURE_USE, Session ID, Repeat Count, Source Port, Destination Port, NAT Source Port, NAT Destination Port, Flags, Protocol, Action, Bytes, Bytes Sent, Bytes Received, Packets, Start Time, Elapsed Time, Category, FUTURE_USE, Sequence Number, Action Flags, Source Location, Destination Location, FUTURE_USE, Packets Sent, Packets Received.

| Field Name | Description |
|---|---|
| Receive Time (receive_time) | Time the log was received at the management plane |
| Serial Number (serial) | Serial number of the device that generated the log |
| Type (type) | Specifies type of log; values are traffic, threat, config, system and hip-match |
| Subtype (subtype) | Subtype of traffic log; values are start, end, drop, and deny<br>• Start—session started<br>• End—session ended<br>• Drop—session dropped before the application is identified and there is no rule that allows the session.<br>• Deny—session dropped after the application is identified and there is a rule to block or no rule that allows the session. |
| Generated Time (time_generated) | Time the log was generated on the dataplane |
| Source IP (src) | Original session source IP address |
| Destination IP (dst) | Original session destination IP address |
| NAT Source IP (natsrc) | If Source NAT performed, the post-NAT Source IP address |
| NAT Destination IP (natdst) | If Destination NAT performed, the post-NAT Destination IP address |
| Rule Name (rule) | Name of the rule that the session matched |

 © Palo Alto Networks, Inc.

| Field Name | Description |
|---|---|
| Source User (srcuser) | Username of the user who initiated the session |
| Destination User (dstuser) | Username of the user to which the session was destined |
| Application (app) | Application associated with the session |
| Virtual System (vsys) | Virtual System associated with the session |
| Source Zone (from) | Zone the session was sourced from |
| Destination Zone (to) | Zone the session was destined to |
| Ingress Interface (inbound_if) | Interface that the session was sourced form |
| Egress Interface (outbound_if) | Interface that the session was destined to |
| Log Forwarding Profile (logset) | Log Forwarding Profile that was applied to the session |
| Session ID (sessionid) | An internal numerical identifier applied to each session |
| Repeat Count (repeatcnt) | Number of sessions with same Source IP, Destination IP, Application, and Subtype seen within 5 seconds; used for ICMP only |
| Source Port (sport) | Source port utilized by the session |
| Destination Port (dport) | Destination port utilized by the session |
| NAT Source Port (natsport) | Post-NAT source port |
| NAT Destination Port (natdport) | Post-NAT destination port |
| Flags (flags) | 32-bit field that provides details on session; this field can be decoded by AND-ing the values with the logged value:<br>• 0x80000000—session has a packet capture (PCAP)<br>• 0x02000000—IPv6 session<br>• 0x01000000—SSL session was decrypted (SSL Proxy)<br>• 0x00800000—session was denied via URL filtering<br>• 0x00400000—session has a NAT translation performed (NAT)<br>• 0x00200000—user information for the session was captured via the captive portal (Captive Portal)<br>• 0x00080000—X-Forwarded-For value from a proxy is in the source user field<br>• 0x00040000—log corresponds to a transaction within a http proxy session (Proxy Transaction)<br>• 0x00008000—session is a container page access (Container Page)<br>• 0x00002000—session has a temporary match on a rule for implicit application dependency handling. Available in PAN-OS 5.0.0 and above<br>• 0x00000800—symmetric return was used to forward traffic for this session |
| Protocol (proto) | IP protocol associated with the session |

| Field Name | Description |
|---|---|
| Action (action) | Action taken for the session; values are allow or deny:<br>• Allow—session was allowed by policy<br>• Deny—session was denied by policy |
| Bytes (bytes) | Number of total bytes (transmit and receive) for the session |
| Bytes Sent (bytes_sent) | Number of bytes in the client-to-server direction of the session<br>Available on all models except the PA-4000 Series |
| Bytes Received (bytes_received) | Number of bytes in the server-to-client direction of the session<br>Available on all models except the PA-4000 Series |
| Packets (packets) | Number of total packets (transmit and receive) for the session |
| Start Time (start) | Time of session start |
| Elapsed Time (elapsed) | Elapsed time of the session |
| Category (category) | URL category associated with the session (if applicable) |
| Sequence Number (seqno) | A 64-bit log entry identifier incremented sequentially; each log type has a unique number space. This field is not supported on PA-7050 firewalls. |
| Action Flags (actionflags) | A bit field indicating if the log was forwarded to Panorama |
| Source Location (srcloc) | Source country or Internal region for private addresses; maximum length is 32 bytes |
| Destination Location (dstloc) | Destination country or Internal region for private addresses. Maximum length is 32 bytes |
| Packets Sent (pkts_sent) | Number of client-to-server packets for the session<br>Available on all models except the PA-4000 Series |
| Packets Received (pkts_received) | Number of server-to-client packets for the session<br>Available on all models except the PA-4000 Series |

## Threat Logs

**Format**: FUTURE_USE, Receive Time, Serial Number, Type, Subtype, FUTURE_USE, Generated Time, Source IP, Destination IP, NAT Source IP, NAT Destination IP, Rule Name, Source User, Destination User, Application, Virtual System, Source Zone, Destination Zone, Ingress Interface, Egress Interface, Log Forwarding Profile, FUTURE_USE, Session ID, Repeat Count, Source Port, Destination Port, NAT Source Port, NAT Destination Port, Flags, Protocol, Action, Miscellaneous, Threat ID, Category, Severity, Direction, Sequence Number, Action Flags, Source Location, Destination Location, FUTURE_USE, Content Type, PCAP_id*, Filedigest*, Cloud*

 © Palo Alto Networks, Inc.

| Field Name | Description |
|---|---|
| Receive Time (receive_time) | Time the log was received at the management plane |
| Serial Number (serial) | Serial number of the device that generated the log |
| Type (type) | Specifies type of log; values are traffic, threat, config, system and hip-match |
| Subtype (subtype) | Subtype of threat log; values are URL, virus, spyware, vulnerability, file, scan, flood, data, and WildFire:<br>• url—URL filtering log<br>• virus—virus detection<br>• spyware—spyware detection<br>• vulnerability—vulnerability exploit detection<br>• file—file type log<br>• scan—scan detected via Zone Protection Profile<br>• flood—flood detected via Zone Protection Profile<br>• data—data pattern detected from Data Filtering Profile<br>• wildfire—WildFire log |
| Generated Time (time_generated) | Time the log was generated on the dataplane |
| Source IP (src) | Original session source IP address |
| Destination IP (dst) | Original session destination IP address |
| NAT Source IP (natsrc) | If source NAT performed, the post-NAT source IP address |
| NAT Destination IP (natdst) | If destination NAT performed, the post-NAT destination IP address |
| Rule Name (rule) | Name of the rule that the session matched |
| Source User (srcuser) | Username of the user who initiated the session |
| Destination User (dstuser) | Username of the user to which the session was destined |
| Application (app) | Application associated with the session |
| Virtual System (vsys) | Virtual System associated with the session |
| Source Zone (from) | Zone the session was sourced from |
| Destination Zone (to) | Zone the session was destined to |
| Ingress Interface (inbound_if) | Interface that the session was sourced from |
| Egress Interface (outbound_if) | Interface that the session was destined to |
| Log Forwarding Profile (logset) | Log Forwarding Profile that was applied to the session |

© Palo Alto Networks, Inc.

| Field Name | Description |
|---|---|
| Session ID (sessionid) | An internal numerical identifier applied to each session |
| Repeat Count (repeatcnt) | Number of sessions with same Source IP, Destination IP, Application, and Subtype seen within 5 seconds; used for ICMP only |
| Source Port (sport) | Source port utilized by the session |
| Destination Port (dport) | Destination port utilized by the session |
| NAT Source Port (natsport) | Post-NAT source port |
| NAT Destination Port (natdport) | Post-NAT destination port |
| Flags (flags) | 32-bit field that provides details on session; this field can be decoded by AND-ing the values with the logged value:<br>• 0x80000000—session has a packet capture (PCAP)<br>• 0x02000000—IPv6 session<br>• 0x01000000—SSL session was decrypted (SSL Proxy)<br>• 0x00800000—session was denied via URL filtering<br>• 0x00400000—session has a NAT translation performed (NAT)<br>• 0x00200000—user information for the session was captured via the captive portal (Captive Portal)<br>• 0x00080000—X-Forwarded-For value from a proxy is in the source user field<br>• 0x00040000—log corresponds to a transaction within a http proxy session (Proxy Transaction)<br>• 0x00008000—session is a container page access (Container Page)<br>• 0x00002000—session has a temporary match on a rule for implicit application dependency handling. Available in PAN-OS 5.0.0 and above<br>• 0x00000800—symmetric return was used to forward traffic for this session |
| Protocol (proto) | IP protocol associated with the session |

 © Palo Alto Networks, Inc.

| Field Name | Description |
|---|---|
| Action (action) | Action taken for the session; values are alert, allow, deny, drop, drop-all-packets, reset-client, reset-server, reset-both, block-url.<br>• Alert—threat or URL detected but not blocked<br>• Allow—flood detection alert<br>• Deny—flood detection mechanism activated and deny traffic based on configuration<br>• Drop—threat detected and associated session was dropped<br>• Drop-all-packets—threat detected and session remains, but drops all packets<br>• Reset-client—threat detected and a TCP RST is sent to the client<br>• Reset-server—threat detected and a TCP RST is sent to the server<br>• Reset-both—threat detected and a TCP RST is sent to both the client and the server<br>• Block-url—URL request was blocked because it matched a URL category that was set to be blocked |
| Miscellaneous (misc) | Field with variable length with a maximum of 1023 characters<br>The actual URI when the subtype is URL<br>File name or file type when the subtype is file<br>File name when the subtype is virus<br>File name when the subtype is WildFire |
| Threat ID (threatid) | Palo Alto Networks identifier for the threat. It is a description string followed by a 64-bit numerical identifier in parenthesis for some Subtypes:<br>• 8000 – 8099—scan detection<br>• 8500 – 8599—flood detection<br>• 9999—URL filtering log<br>• 10000 – 19999—sypware phone home detection<br>• 20000 – 29999—spyware download detection<br>• 30000 – 44999—vulnerability exploit detection<br>• 52000 – 52999—filetype detection<br>• 60000 – 69999—data filtering detection<br>• 100000 – 2999999—virus detection<br>• 3000000 – 3999999—WildFire signature feed<br>• 4000000-4999999—DNS Botnet signatures |
| Category (category) | For URL Subtype, it is the URL Category; For WildFire subtype, it is the verdict on the file and is either ‘malicious’ or ‘benign’; For other subtypes the value is ‘any’ |
| Severity (severity) | Severity associated with the threat; Values are informational, low, medium, high, critical |

| Field Name | Description |
|---|---|
| Direction (direction) | Indicates the direction of the attack, *client-to-server* or *server-to-client*<br>• 0—direction of the threat is client to server<br>• 1—direction of the threat is server to client |
| Sequence Number (seqno) | A 64-bit log entry identifier incremented sequentially. Each log type has a unique number space. This field is not supported on PA-7050 firewalls. |
| Action Flags (actionflags) | A bit field indicating if the log was forwarded to Panorama. |
| Source Location (srcloc) | Source country or Internal region for private addresses. Maximum length is 32 bytes. |
| Destination Location (dstloc) | Destination country or Internal region for private addresses. Maximum length is 32 bytes. |
| Content Type (contenttype) | Applicable only when Subtype is URL.<br>Content type of the HTTP response data. Maximum length 32 bytes. |
| New in v6.0!PCAP ID (pcap_id) | Pcap-ID is a 64 bit unsigned integral denoting an ID to correlate threat pcap files with extended pcaps taken as a part of that flow. All threat logs will contain either a pcap_id of 0 (no associated pcap), or an ID referencing the extended pcap file. |
| New in v6.0! File Digest (filedigest) | Only for WildFire subtype; all other types do not use this field<br>The filedigest string shows the binary hash of the file sent to be analyzed by the WildFire service. |
| New in v6.0! Cloud (cloud) | Only for WildFire subtype; all other types do not use this field<br>The cloud string displays the FQDN of either the WildFire appliance (private) or the WildFire cloud (public) from where the file was uploaded for analysis. |

## HIP Match Logs

**Format:** FUTURE_USE, Receive Time, Serial Number, Type, Subtype, FUTURE_USE, Generated Time, Source User, Virtual System, Machine name, OS*, Source Address, HIP, Repeat Count, HIP Type, FUTURE_USE, FUTURE_USE, Sequence Number, Action Flags

| Field Name | Description |
|---|---|
| Receive Time (receive_time) | Time the log was received at the management plane |
| Serial Number (serial) | Serial number of the device that generated the log |
| Type (type) | Type of log; values are traffic, threat, config, system and hip-match |
| Subtype (subtype) | Subtype of HIP match log; unused |
| Generated Time (time_generated) | Time the log was generated on the dataplane |
| Source User (srcuser) | Username of the user who initiated the session |

 © Palo Alto Networks, Inc.

| Field Name | Description |
|---|---|
| Virtual System (vsys) | Virtual System associated with the HIP match log |
| Machine Name (machinename) | Name of the user's machine |
| New in v6.0! OS | The operating system installed on the user's machine or device (or on the client system) |
| Source Address (src) | IP address of the source user |
| HIP (matchname) | Name of the HIP object or profile |
| Repeat Count (repeatcnt) | Number of times the HIP profile matched |
| HIP Type (matchtype) | Whether the hip field represents a HIP object or a HIP profile |
| Sequence Number (seqno) | A 64-bit log entry identifier incremented sequentially; each log type has a unique number space. This field is not supported on PA-7050 firewalls. |
| Action Flags (actionflags) | A bit field indicating if the log was forwarded to Panorama |

## Config Logs

**Format:** FUTURE_USE, Receive Time, Serial Number, Type, Subtype, FUTURE_USE, Generated Time, Host, Virtual System, Command, Admin, Client, Result, Configuration Path, Sequence Number, Action Flags

| Field Name | Description |
|---|---|
| Receive Time (receive_time) | Time the log was received at the management plane |
| Serial Number (serial) | Serial number of the device that generated the log |
| Type (type) | Type of log; values are traffic, threat, config, system and hip-match |
| Subtype (subtype) | Subtype of configuration log; unused |
| Generated Time (time_generated) | Time the log was generated on the dataplane |
| Host (host) | Host name or IP address of the client machine |
| Virtual System (vsys) | Virtual System associated with the configuration log |
| Command (cmd) | Command performed by the Admin; values are add, clone, commit, delete, edit, move, rename, set, validate. |
| Admin (admin) | Username of the Administrator performing the configuration |
| Client (client) | Client used by the Administrator; values are Web and CLI |
| Result (result) | Result of the configuration action; values are Submitted, Succeeded, Failed, and Unauthorized |

| Field Name | Description |
|---|---|
| Configuration Path (path) | The path of the configuration command issued; up to 512 bytes in length |
| Sequance Number (seqno) | A 64bit log entry identifier incremented sequentially; each log type has a unique number space. This field is not supported on PA-7050 firewalls. |
| Action Flags (actionflags) | A bit field indicating if the log was forwarded to Panorama. |

## System Logs

**Format:** FUTURE_USE, Receive Time, Serial Number, Type, Subtype, FUTURE_USE, Generated Time, Virtual System, Event ID, Object, FUTURE_USE, FUTURE_USE, Module, Severity, Description, Sequence Number, Action Flags

| Field Name | Description |
|---|---|
| Receive Time (receive_time) | Time the log was received at the management plane |
| Serial Number (serial) | Serial number of the device that generated the log |
| Type (type) | Type of log; values are traffic, threat, config, system and hip-match |
| Subtype (subtype) | Subtype of the system log; refers to the system daemon generating the log; values are crypto, dhcp, dnsproxy, dos, general, global-protect, ha, hw, nat, ntpd, pbf, port, pppoe, ras, routing, satd, sslmgr, sslvpn, userid, url-filtering, vpn |
| Generated Time (time_generated) | Time the log was generated on the dataplane |
| Virtual System (vsys) | Virtual System associated with the configuration log |
| Event ID (eventid) | String showing the name of the event |
| Object (object) | Name of the object associated with the system event |
| Module (module) | This field is valid only when the value of the Subtype field is general. It provides additional information about the sub-system generating the log; values are general, management, auth, ha, upgrade, chassis |
| Severity (severity) | Severiry associated with the event; values are informational, low, medium, high, critical |
| Description (opaque) | Detailed description of the event, up to a maximum of 512 bytes |
| Sequence Number (seqno) | A 64bit log entry identifier incremented sequentially; each log type has a unique number space. This field is not supported on PA-7050 firewalls. |
| Action Flags (actionflags) | A bit field indicating if the log was forwarded to Panorama |

 © Palo Alto Networks, Inc.

## Syslog Severity

The syslog severity is set based on the log type and contents.

| Log Type/Severity | Syslog Severity |
|---|---|
| Traffic | Info |
| Config | Info |
| Threat/System—Informational | Info |
| Threat/System—Low | Notice |
| Threat/System—Medium | Warning |
| Threat/System—High | Error |
| Threat/System—Critical | Critical |

## Custom Log/Event Format

To facilitate the integration with external log parsing systems, the firewall allows you to customize the log format; it also allows you to add custom *Key: Value* attribute pairs. Custom message formats can be configured under **Device > Server Profiles > Syslog > Syslog Server Profile > Custom Log Format**.

To achieve ArcSight Common Event Format (CEF) compliant log formatting, refer to the CEF Configuration Guide.

## Escape Sequences

Any field that contains a comma or a double-quote is enclosed in double quotes. Furthermore, if a double-quote appears inside a field it is escaped by preceding it with another double-quote. To maintain backward compatibility, the Misc field in threat log is always enclosed in double-quotes.

 © Palo Alto Networks, Inc.

# User-ID

User Identification (User-ID) is a Palo Alto Networks next-generation firewall feature that allows you to create policies and perform reporting based on users and groups rather than individual IP addresses. The following sections describe the Palo Alto Networks User-ID feature and provide instructions on setting up user- and group-based access:

- User-ID Overview
- User-ID Concepts
- Enable User-ID
- Map Users to Groups
- Map IP Addresses to Users
- Enable User- and Group-Based Policy
- Verify the User-ID Configuration

© Palo Alto Networks, Inc.

# User-ID Overview

User-ID seamlessly integrates Palo Alto Networks firewalls with a range of enterprise directory and terminal services offerings, enabling you to tie application activity and security policies to users and groups—not just IP addresses. In addition, with User-ID enabled, the Application Command Center (ACC), App-Scope, reports, and logs all include usernames in addition to user IP addresses.

The Palo Alto Networks next-generation firewall supports monitoring of the following enterprise services:

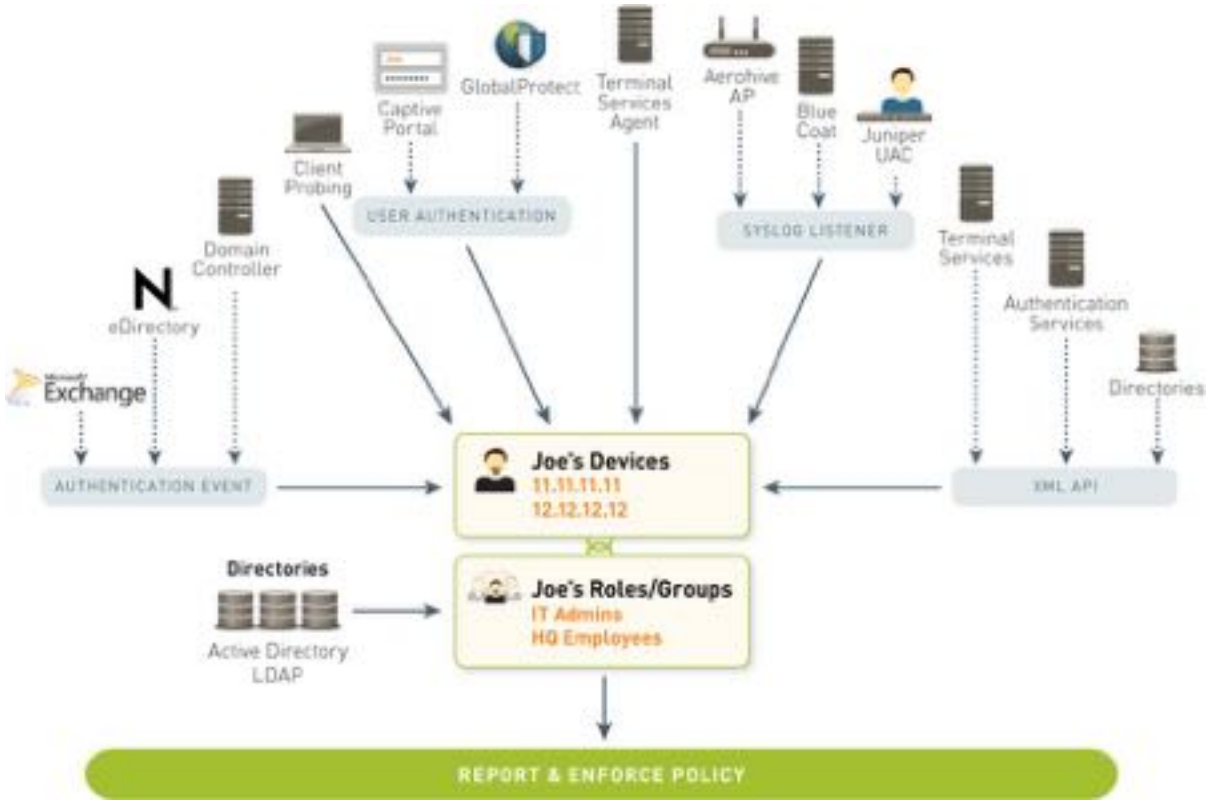
- Microsoft Active Directory
- LDAP
- Novell eDirectory
- Citrix Metaframe Presentation Server or XenApp
- Microsoft Terminal Services

To be able to create policy based on user and group, the firewall must have a list of all available users and their corresponding group mappings that you can select from when defining your policies. It gets this Group Mapping information by connecting directly to your LDAP directory server.

To be able to enforce the user- and group-based policies, the firewall must be able to map the IP addresses in the packets it receives to usernames. User-ID provides many mechanisms to get these IP address to username mappings. For example, it uses agents to monitor server logs for login events and/or probe clients, and/or listen for syslog messages from authenticating services. To identify mappings for IP addresses were not mapped using one of the agent mechanisms, you can configure the firewall to redirect HTTP requests to a captive portal login. You can tailor the mechanisms you use for User Mapping to suit your environment, and you can even use different mechanisms at different sites.

 © Palo Alto Networks, Inc.

**Figure: User-ID**



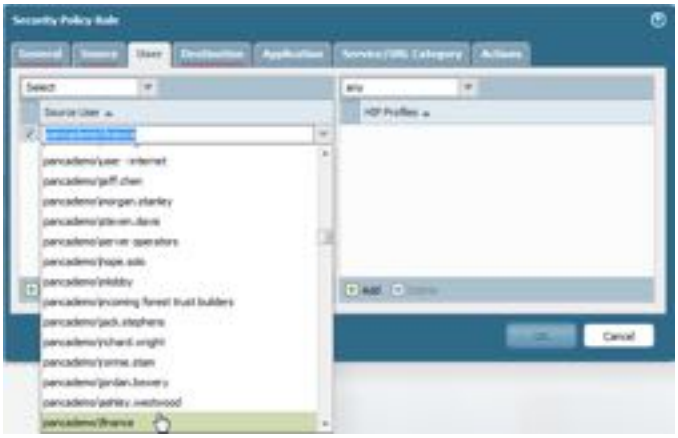
Proceed to User-ID Concepts for information on how User-ID works and Enable User-ID for instructions on setting up User-ID on the firewall.

# User-ID Concepts

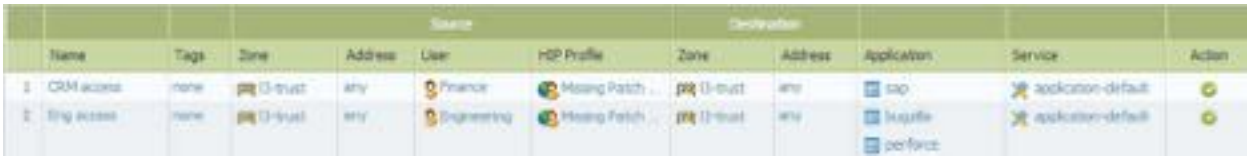
▲ Group Mapping
▲ User Mapping

## Group Mapping

In order to define security policies based on user or group, the firewall must retrieve the list of groups and the corresponding list of members from your directory server. To enable this functionality, you must create an LDAP server profile that instructs the firewall how to connect and authenticate to the server and how to search the directory for the user and group information. After you connect to the LDAP server and configure the group mapping functionality for user identification, you will be able to select users or groups when defining your security policies. The firewall supports a variety of LDAP directory servers, including Microsoft Active Directory (AD), Novell eDirectory, and Sun ONE Directory Server.



You can then define policies based on group membership rather than on individual users for simplified administration. For example, the following security policy allows access to specific internal applications based on group membership:



## User Mapping

Having the names of the users and groups is only one piece of the puzzle. The firewall also needs to know which IP addresses map to which users so that security policies can be enforced appropriately. Figure: User-ID illustrates the different methods that are used to identify users and groups on your network and shows how user mapping and group mapping work together to enable user- and group-based security enforcement and visibility.

The following topics describe the different methods of user mapping:

 © Palo Alto Networks, Inc.

- Server Monitoring
- Client Probing
- Port Mapping
- Syslog
- Captive Portal
- GlobalProtect
- User-ID XML API

## Server Monitoring

With server monitoring a User-ID agent—either a Windows-based agent running on a domain server in your network, or the integrated PAN-OS User-ID agent running on the firewall—monitors the security event logs for specified Microsoft Exchange Servers, domain controllers, or Novell eDirectory servers for login events. For example, in an AD environment, you can configure the User-ID agent to monitor the security logs for Kerberos ticket grants or renewals, Exchange server access (if configured), and file and print service connections. Keep in mind that in order for these events to be recorded in the security log, the AD domain must be configured to log successful account login events. In addition, because users can log in to any of the servers in the domain, you must set up server monitoring for all servers in order to capture all user login events.

Because server monitoring requires very little overhead and because the majority of users can generally be mapped using this method, it is recommended as the base user mapping method for most User-ID deployments. See Configure User Mapping Using the Windows User-ID Agent or Configure User Mapping Using the PAN-OS Integrated User-ID Agent for details.

## Client Probing

In a Microsoft Windows environment, you can configure the User-ID agent to probe client systems using Windows Management Instrumentation (WMI). The Windows-based User-ID agent can also perform NetBIOS probing (not supported on the PAN-OS integrated User-ID agent). Probing is particularly useful in environments with a high IP address turnover because changes will be reflected on the firewall more quickly, enabling more accurate enforcement of user-based policies. However, if the correlation between IP addresses and users is fairly static, you probably do not need to enable client probing. Because probing can generate a large amount of network traffic (based on the total number of mapped IP addresses), the agent that will be initiating the probes should be located as close as possible to the end clients.

If probing is enabled, the agent will probe each learned IP address periodically (every 20 minutes by default, but this is configurable) to verify that the same user is still logged in. In addition, when the firewall encounters an IP address for which it has no user mapping it will send the address to the agent for an immediate probe.

See Configure User Mapping Using the Windows User-ID Agent or Configure User Mapping Using the PAN-OS Integrated User-ID Agent for details.

© Palo Alto Networks, Inc.

## Port Mapping

In environments with multi-user systems—such as Microsoft Terminal Server or Citrix environments—many users share the same IP address. In this case, the user-to-IP address mapping process requires knowledge of the source port of each client. To perform this type of mapping, you must install the Palo Alto Networks Terminal Services Agent on the Windows/Citrix terminal server itself to intermediate the assignment of source ports to the various user processes. For terminal servers that do not support the Terminal Services Agent, such as Linux terminal servers, you can use the XML API to send user mapping information from login and logout events to User-ID. See Configure User Mapping for Terminal Server Users for configuration details.

## Syslog

In environments with existing network services that authenticate users—such as wireless controllers, 802.1x devices, Apple Open Directory servers, proxy servers, or other Network Access Control (NAC) mechanisms—the firewall User-ID agent (either the Windows agent or the PAN-OS integrated agent on the firewall) can listen for authentication syslog messages from those services. Syslog filters, which are provided by a content update (integrated User-ID agent only) or configured manually, allow the User-ID agent to parse and extract usernames and IP addresses from authentication syslog events generated by the external service, and add the information to the User-ID IP address to username mappings maintained by the firewall. See Configure User-ID to Receive User Mappings from a Syslog Sender for configuration details.

**Figure: User-ID Integration with Syslog**

 © Palo Alto Networks, Inc.

## Captive Portal

If the firewall or the User-ID agent are unable to map an IP address to a user—for example if the user is not logged in or is using an operating system such as Linux that is not supported by your domain servers—you can configure Captive Portal. When configured, any web traffic (HTTP or HTTS) matching your Captive Portal policy requires user authentication, either transparently via an NT LAN Manager (NTLM) challenge to the browser, or actively by redirecting the user to a web authentication form for authentication against a RADIUS, LDAP, Kerberos, or local authentication database or using client certificate authentication. See Map IP Addresses to User Names Using Captive Portal for details.

## GlobalProtect

For mobile or roaming users, the GlobalProtect client provides the user mapping information to the firewall directly. In this case, every GlobalProtect user has an agent or app running on the client that requires the user to enter login credentials for VPN access to the firewall. This login information is then added to the User-ID user mapping table on the firewall for visibility and user-based security policy enforcement. Because GlobalProtect users must authenticate to gain access to the network, the IP address to username mapping is explicitly known. This is the best solution in sensitive environments where you must be certain of who a user is in order to allow access to an application or service. For more information on setting up GlobalProtect, refer to the GlobalProtect Administrator's Guide.

## User-ID XML API

For other types of user access that cannot be mapped using any of the standard user mapping methods or Captive Portal—for example, to add mappings of users connecting from a third-party VPN solution or users connecting to a 802.1x enabled wireless network—you can use the User-ID XML API to capture login events and send them to the User-ID agent or directly to the firewall. See Send User Mappings to User-ID Using the XML API for details.

© Palo Alto Networks, Inc.

# Enable User-ID

You must complete the following tasks to set up the firewall to user users and groups in policy enforcement, logging, and reporting:

- Map Users to Groups
- Map IP Addresses to Users
- Enable User- and Group-Based Policy
- Verify the User-ID Configuration

 © Palo Alto Networks, Inc.

# Map Users to Groups

Use the following procedure to connect to your LDAP directory to enable the firewall to retrieve user-to-group mapping information:

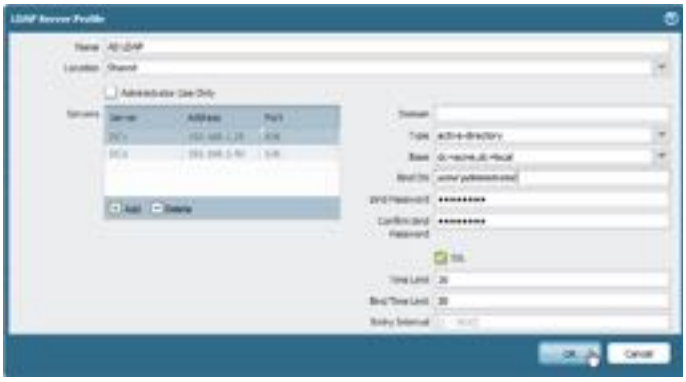
Best practices for group mapping in an Active Directory environment:

- If you have a single domain, you only need one LDAP server profile that connects the firewall to the domain controller with the best connectivity. You can add additional domain controllers for fault tolerance.
- If you have multiple domains and/or multiple forests, you must create a server profile to connect to a domain server in each domain/forest. Take steps to ensure unique usernames in separate forests.
- If you have Universal Groups, create a server profile to connect to the Global Catalogue server.

## Map Users to Groups

Step 1 Create an LDAP Server Profile that specifies how to connect to the directory servers you want the firewall to use to obtain group mapping information.

1. Select **Device > Server Profiles > LDAP**.
2. Click **Add** and then enter a **Name** for the profile.
3. (Optional) Select the virtual system to which this profile applies from the **Location** drop-down.
4. Click **Add** to add a new LDAP server entry and then enter a **Server** name to identify the server (1-31 characters) and the IP **Address** and **Port** number the firewall should use to connect to the LDAP server (default=389 for LDAP; 636 for LDAP over SSL). You can add up to four LDAP servers to the profile, however, all the servers you add to a profile must be of the same type. For redundancy you should add at least two servers.

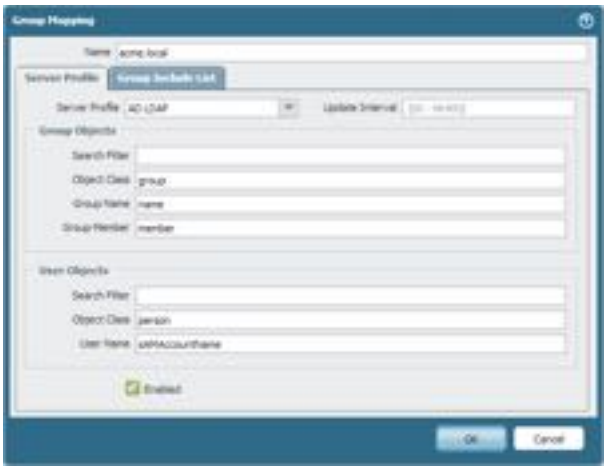


5. Enter the LDAP **Domain** name to prepend to all objects learned from the server. The value you enter here depends on your deployment:
   - If you are using Active Directory, you must enter the NetBIOS domain name; NOT a FQDN (for example, enter `acme`, not `acme.com`). Note that if you need to collect data from multiple domains you will need to create separate server profiles.
   - If you are using a global catalog server, leave this field blank.
6. Select the **Type** of LDAP server you are connecting to. The correct LDAP attributes in the group mapping settings will automatically be populated based on your selection. However, if you have customized your LDAP schema you may need to modify the default settings.
7. In the **Base** field, select the DN that corresponds to the point in the LDAP tree where you want the firewall to begin its search for user and group information.
8. Enter the authentication credentials for binding to the LDAP tree in the **Bind DN**, **Bind Password**, and **Confirm Bind Password** fields. The Bind DN can be in either User Principal Name (UPN) format (for example, `administrator@acme.local`) or it can be a fully qualified LDAP name (for example, `cn=administrator,cn=users,dc=acme,dc=local`).
9. If you want the firewall to communicate with the LDAP server(s) over a secure connection, select the SSL check box. If you enable SSL, make sure that you have also specified the appropriate port number.
10. Click **OK** to save the profile.

**Map Users to Groups (Continued)**

Step 2 Add the LDAP server profile to the User-ID Group Mapping configuration.

1. Select **Device > User Identification > Group Mapping Settings** and click **Add**.
2. Select the **Server Profile** you created in Step 1.
3. Make sure the **Enabled** check box is selected.
4. (Optional) If you want to limit which groups are displayed within security policy, select the **Group Include List** tab and then browse through the LDAP tree to locate the groups you want to be able to use in policy. For each group you want to include, select it in the **Available Groups** list and click the add icon to move it to the **Included Groups** list. Repeat this step for every group you want to be able to use in your policies.
5. Click **OK** to save the settings.



Step 3 **Commit** the configuration.

© Palo Alto Networks, Inc.

# Map IP Addresses to Users

The tasks you need to perform to map IP addresses to usernames depends on the type and location of the client systems on your network. Complete as many of the following tasks as necessary to enable mapping of your client systems:

- To map users as they log in to your Exchange servers, domain controllers, or eDirectory servers, or Windows clients that can be directly probed you must configure a User-ID agent to monitor the server logs and/or probe client systems. You can either install the standalone Windows User-ID agent on one or more member servers in the domain that contains the servers and clients to be monitored (see Configure User Mapping Using the Windows User-ID Agent) or you can configure the on-firewall User-ID agent that is integrated with PAN-OS (Configure User Mapping Using the PAN-OS Integrated User-ID Agent). For guidance as to which agent configuration is appropriate for your network and the number and placements of agents that are required, refer to Architecting User Identification Deployments.
- If you have clients running multi-user systems such as Microsoft Terminal Server or Citrix Metaframe Presentation Server or XenApp, see Configure the Palo Alto Networks Terminal Server Agent for User Mapping for instructions on how to install and configure the agent on a Windows server. If you have a multi-user system that is not running on Windows, you can use the User-ID XML API to send IP address to username mappings directly to the firewall. See Retrieve User Mappings from a Terminal Server Using the User-ID XML API.
- To obtain user mappings from existing network services that authenticate users, such as wireless controllers, 802.1x devices, Apple Open Directory servers, proxy servers, or other Network Access Control (NAC) mechanisms, configure the User-ID agent (either the Windows agent or the agentless user mapping feature on the firewall) to listen for authentication syslog messages from those services. See Configure User-ID to Receive User Mappings from a Syslog Sender.
- If you have users with client systems that are not logged into your domain servers—for example, users running Linux clients that do not log in to the domain—see Map IP Addresses to User Names Using Captive Portal.
- For other clients that you are unable to map using the previous methods, you can use the User-ID XML API to add user mappings directly to the firewall. See Send User Mappings to User-ID Using the XML API.
- Because policy is local to each firewall, each firewall must have a current list of IP address to username mappings in order to accurately enforce security policy by group or user. However, you can configure one firewall to collect all the user mappings and distribute them to the other firewalls. For details, see Configure a Firewall to Share User Mapping Data with Other Firewalls.

© Palo Alto Networks, Inc.

# Configure User Mapping Using the Windows User-ID Agent

In most cases, the majority of your network users will have logins to your monitored domain services. For these users, the Palo Alto Networks User-ID agent monitors the servers for login events and performs the IP address to user mapping. The way you configure the User-ID agent depends on the size of your environment and the location of your domain servers. As a best practice, you should locate your User-ID agents near your monitored servers (that is, the monitored servers and the Windows User-ID agent should not be across a WAN link from each other). This is because most of the traffic for user mapping occurs between the agent and the monitored server, with only a small amount of traffic—the delta of IP address mappings since the last update—from the agent to the firewall.

The following topics describe how to install and configure the User-ID Agent and how to configure the firewall to retrieve user mapping information from the agent:

- Install the User-ID Agent
- Configure the User-ID Agent for User Mapping

## Install the User-ID Agent

The following procedure shows how to install the User-ID agent on a member server in the domain and set up the service account with the required permissions. If you are upgrading, the installer will automatically remove the older version, however, it is a good idea to back up the config.xml file before running the installer.

For information about the system requirements for installing the Windows-based User-ID agent and for information on the supported server OS versions are supported, refer to "Operating System (OS) Compatibility User-ID Agent" in the User-ID Agent Release Notes, which are available on the Palo Alto Networks Software Updates page.

| Install the Windows User-ID Agent | |
|---|---|
| Step 1 Decide where to install the User-ID agent(s).<br><br>The User-ID agent queries the Domain Controller and Exchange server logs using Microsoft Remote Procedure Calls (MSRPCs), which require a complete transfer of the entire log at each query. Therefore, you should always install one or more User-ID agents at each site that has servers to be monitored.<br><br> For more detailed information on where to install User-ID agents, refer to Architecting User Identification (User-ID) Deployments. | • You must install the User-ID agent on a system running one of the following OS versions (32-bit and 64-bit are both supported):<br>  • Microsoft Windows XP/Vista/7<br>  • Microsoft Windows Server 2003/2008<br>• Make sure the system you plan to install the User-ID agent on is a member of the domain that the servers it will be monitoring belong to.<br>• As a best practice, install the User-ID agent close to the servers it will be monitoring (there is more traffic between the User-ID agent and the monitored servers than there is between the User-ID agent and the firewall, so locating the agent close to the monitored servers optimizes bandwidth usage).<br>• To ensure the most comprehensive mapping of users, you must monitor all servers that contain user login information. You may need to install multiple User-ID agents to efficiently monitor all of your resources. |

 © Palo Alto Networks, Inc.

**Install the Windows User-ID Agent (Continued)**

| | |
|---|---|
| Step 2 Download the User-ID agent installer.<br><br>As a best practice, install the User-ID agent version that is the same as the PAN-OS version running on the firewalls. | 1. Log in to Palo Alto Networks Support site.<br>2. Select **Software Updates** from the Manage Devices section.<br>3. Scroll to the User Identification Agent section of the screen and **Download** the version of the User-ID agent you want to install.<br>4. Save the `UaInstall-x.x.x-xx.msi` file on the system(s) where you plan to install the agent. |
| Step 3 Run the installer as an administrator.<br> | 1. To launch a command prompt as an administrator, click Start and right-click **Command Prompt** and then select **Run as administrator**.<br>2. From the command line, run the .msi file you downloaded. For example, if you saved the .msi file to the Desktop you would enter the following:<br>`C:\Users\administrator.acme>cd Desktop`<br>`C:\Users\administrator.acme\Desktop>UaInstall-6.0.0-1.msi`<br>3. Follow the setup prompts to install the agent using the default settings. By default, the agent gets installed to the `C:\Program Files (x86)\Palo Alto Networks\User-ID Agent` folder, but you can **Browse** to a different location.<br>4. When the installation completes, **Close** the setup window. |
| Step 4 Launch the User-ID Agent application.<br>  | 1. Click Start and select **User-ID Agent**. |
| Step 5 (Optional) Change the service account that the User-ID agent uses to log in.<br> | By default, the agent uses the administrator account used to install the .msi file. However, you may want to switch this to a restricted account as follows:<br>1. Select **User Identification > Setup** and click **Edit**.<br>2. Select the **Authentication** tab and enter the service account name that you want the User-ID agent to use in the **User name for Active Directory** field.<br>3. Enter the **Password** for the specified account. |

| Install the Windows User-ID Agent (Continued) | |
|---|---|
| Step 6 (Optional) Assign account permissions to the installation folder.<br><br>You only need to perform this step if the service account you configured for the User-ID agent is not a member of the administrators group for the domain or a member of both the Server Operators and the Event Log Readers groups. | 1. Give the service account permissions to the installation folder:<br>a. From the Windows Explorer, navigate to `C:\Program Files\Palo Alto Networks` and right-click the folder and select **Properties**.<br>b. On the **Security** tab, **Add** the User-ID agent service account and assign it permissions to **Modify**, **Read & execute**, **List folder contents**, and **Read** and then click **OK** to save the account settings.<br>2. Give the service account permissions to the User-ID Agent registry sub-tree:<br>a. Run `regedit32` and navigate to the Palo Alto Networks sub-tree in one of the following locations:<br>– **32-bit systems**—`HKEY_LOCAL_MACHINE\Software\Palo Alto Networks`<br>– **64-bit systems**—`HKEY_LOCAL_MACHINE\Software\WOW6432Node\Palo Alto Networks`<br>b. Right-click the Palo Alto Networks node and select **Permissions**.<br>c. Assign the User-ID service account **Full Control** and then click **OK** to save the setting.<br>3. On the domain controller, add the service account to the builtin groups to enable privileges to read the security log events (Event Log Reader group) and open sessions (Server Operator group):<br>a. Run the MMC and Launch the Active Directory Users and Computers snap-in.<br>b. Navigate to the Builtin folder for the domain and then right-click each group you need to edit (Event Log Reader and Server Operator) and select **Add to Group** to open the properties dialog.<br>c. Click **Add** and enter the name of the service account that you configured the User-ID service to use and then click **Check Names** to validate that you have the proper object name.<br>d. Click **OK** twice to save the settings. |

## Configure the User-ID Agent for User Mapping

The Palo Alto Networks User-ID agent is a Windows service that connects to servers on your network—for example, Active Directory servers, Microsoft Exchange servers, and Novell eDirectory servers—and monitors the logs for login events. The agent uses this information to map IP addresses to usernames. Palo Alto Networks firewalls connect to the User-ID agent to retrieve this user mapping information, enabling visibility into user activity by username rather than IP address and enables user- and group-based security enforcement.

 © Palo Alto Networks, Inc.

For information about the server OS versions supported by the User-ID agent, refer to "Operating System (OS) Compatibility User-ID Agent" in the *User-ID Agent Release Notes*, which are available on the Palo Alto Networks Software Updates page.

| Map IP Addresses to Users Using the User-ID Agent | | |
|---|---|---|
| Step 1 | Launch the User-ID Agent application. | 1. Select **User-ID Agent** from the Windows Start menu.<br> |
| Step 2 | Define the servers the User-ID agent should monitor to collect IP address to user mapping information.<br>The User-ID agent can monitor up to 100 servers and listen for syslog messages from up to 100 syslog senders.<br>Keep in mind that in order to collect all of the required mappings, you must connect to all servers that your users log in to in order to monitor the security log files on all servers that contain login events. | 1. Select **User Identification > Discovery**.<br>2. In the **Servers** section of the screen, click **Add**.<br>3. Enter a **Name** and **Server Address** for the server to be monitored. The network address can be a FQDN or an IP address.<br>4. Select the **Server Type** (**Microsoft Active Directory**, **Microsoft Exchange**, **Novell eDirectory**, or **Syslog Sender**) and then click **OK** to save the server entry. Repeat this step for each server to be monitored.<br>5. (Optional) To enable the firewall to automatically discover domain controllers on your network using DNS lookups, click **Auto Discover**.<br>The auto-discovery locates domain controllers in the local domain only; you must manually add Exchange servers, eDirectory servers, and syslog senders.<br>6. (Optional) To tune the frequency at which the firewall polls configured servers for mapping information, select **User Identification > Setup** and **Edit** the Setup section. On the **Server Monitor** tab, modify the value in the **Server Log Monitor Frequency (seconds)** field. As a best practice, you should increase the value in this field to 5 seconds in environments with older Domain Controllers or high-latency links. Click **OK** to save the changes. |

| Map IP Addresses to Users Using the User-ID Agent (Continued) | | |
|---|---|---|
| Step 3 | (Optional) If you configured the agent to connect to a Novell eDirectory server, you must specify how the agent should search the directory. | 1. Select **User Identification > Setup** and click **Edit** in the Setup section of the window.<br>2. Select the **eDirectory** tab and then complete the following fields:<br>• **Search Base**—The starting point or root context for agent queries, for example: `dc=domain1, dc=example, dc=com`.<br>• **Bind Distinguished Name**—The account to use to bind to the directory, for example: `cn=admin, ou=IT, dc=domain1, dc=example, dc=com`.<br>• **Bind Password**—The bind account password. The agent saves the encrypted password in the configuration file.<br>• **Search Filter**—The search query for user entries (default is `objectClass=Person`).<br>• **Server Domain Prefix**—A prefix to uniquely identify the user. This is only required if there are overlapping name spaces, such as different users with the same name from two different directories.<br>• **Use SSL**—Select the check box to use SSL for eDirectory binding.<br>• **Verify Server Certificate**—Select the check box to verify the eDirectory server certificate when using SSL. |
| Step 4 | (Optional) Enable client probing.<br>Client probing is useful in environments where IP addresses are not tightly bound to users because it ensures that previously mapped addresses are still valid. However, as the total number of learned IP addresses grows, so does the amount of traffic generated. As a best practice, only enable probing on network segments where IP address turnover is high.<br>For more details on the placement of User-ID agents using client probing, refer to Architecting User Identification (User-ID) Deployments. | 1. On the **Client Probing** tab, select the **Enable WMI Probing** check box and/or the **Enable NetBIOS Probing** check box.<br>2. Make sure the Windows firewall will allow client probing by adding a remote administration exception to the Windows firewall for each probed client.<br> For NetBIOS probing to work effectively, each probed client PC must allow port 139 in the Windows firewall and must also have file and printer sharing services enabled. WMI probing is always preferred over NetBIOS whenever possible. |
| Step 5 | Save the configuration. | Click **OK** to save the User-ID agent setup settings and then click **Commit** to restart the User-ID agent and load the new settings. |

 © Palo Alto Networks, Inc.

| Map IP Addresses to Users Using the User-ID Agent (Continued) | | |
|---|---|---|
| Step 6 | (Optional) Define the set of users for which you do not need to provide IP address to user name mappings, such as kiosk accounts.<br><br>You can also use the `ignore-user` list to identify users whom you want to force to authenticate using Captive Portal. | Create an `ignore_user_list.txt` file and save it to the User-ID Agent folder on the domain server where the agent is installed.<br><br>List of the user accounts to ignore; there is no limit to the number of accounts you can add to the list. Each user account name must be on a separate line. For example:<br>`SPAdmin`<br>`SPInstall`<br>`TFSReport` |
| Step 7 | Configure the firewalls to connect to the User-ID agent. | Complete the following steps on each firewall you want to connect to the User-ID agent to receive user mappings:<br>1. Select **Device > User Identification > User-ID Agents** and click **Add**.<br>2. Enter a **Name** for the User-ID agent.<br>3. Enter the IP address of the Windows **Host** on which the User-ID Agent is installed.<br>4. Enter the **Port** number on which the agent will be listening for user mapping requests. This value must match the value configured on the User-ID agent. By default, the port is set to 5007 on the firewall and on newer versions of the User-ID agent. However, some older User-ID agent versions use port 2010 as the default.<br>5. Make sure that the configuration is **Enabled** and then click **OK**.<br>6. **Commit** the changes.<br>7. Verify that the **Connected status** displays as connected. |
| Step 8 | Verify that the User-ID agent is successfully mapping IP addresses to usernames and that the firewalls can connect to the agent. | 1. Launch the User-ID agent and select **User Identification**.<br>2. Verify that the agent status shows **Agent is running**. If the Agent is not running, click **Start**.<br>3. To verify that the User-ID agent can connect to monitored servers, make sure the Status for each Server is **Connected**.<br>4. To verify that the firewalls can connect to the User-ID agent, make sure the Status for each of the Connected Devices is **Connected**.<br>5. To verify that the User-ID agent is mapping IP addresses to usernames, select **Monitoring** and make sure that the mapping table is populated. You can also **Search** for specific users, or **Delete** user mappings from the list. |

## Configure User Mapping Using the PAN-OS Integrated User-ID Agent

The following procedure shows how to configure the PAN-OS integrated agent on the firewall for user mapping. The integrated User-ID agent performs the same tasks as the Windows-based agent with the exception of NetBIOS client probing (WMI probing is supported).

| Map IP Addresses to Users Using the Integrated User-ID Agent | | |
|---|---|---|
| Step 1 | Create an Active Directory (AD) account for the firewall agent that has the privilege levels required to log in to each service or host you plan to monitor to collect user mapping data. | • **Windows 2008 or later domain servers**—Add the account to the Event Log Readers group. If you are using the on-device User-ID agent, the account must also be a member of the Distributed COM Users Group.<br>• **Windows 2003 domain servers**—Assign Manage Auditing and Security Logs permissions through group policy.<br>• **WMI probing**—Make sure the account has rights to read the CIMV2 namespace; by default, Domain Administrator and Server Operator accounts have this permission.<br>• **NTLM authentication**—Because the firewall must join the domain if you are using Captive Portal NTLM authentication with an on-device User-ID agent, the Windows account you create for NTLM access must have administrative privileges. Note that due to AD restrictions on virtual systems running on the same host, if you have configured multiple virtual systems, only vsys1 will be able to join the domain. |

 © Palo Alto Networks, Inc.

**Map IP Addresses to Users Using the Integrated User-ID Agent (Continued)**

| | |
|---|---|
| Step 2 Define the servers the firewall should monitor to collect IP address to user mapping information. You can define entries for up to 100 Microsoft Active Directory, Microsoft Exchange, or Novell eDirectory servers on your network.<br><br>Keep in mind that in order to collect all of the required mappings, you must connect to all servers that your users log in to so that the firewall can monitor the security log files on all servers that contain login events. | 1. Select **Device > User Identification > User Mapping**.<br>2. In the Server Monitoring section of the screen, click **Add**.<br>3. Enter a **Name** and **Network Address** for the server. The network address can be a FQDN or an IP address.<br>4. Select the **Type** of server.<br>5. Make sure the **Enabled** check box is selected and then click **OK**<br>6. (Optional) To enable the firewall to automatically discover domain controllers on your network using DNS lookups, click **Discover**.<br> <br>The auto-discovery feature is for domain controllers only; you must manually add any Exchange servers or eDirectory servers you want to monitor.<br>7. (Optional) Specify the frequency at which the firewall polls Windows servers for mapping information. This is the interval between the end of the last query and the start of the next query.<br>If the query load is high, the observed delay between queries might significantly exceed the specified frequency.<br>a. In the **Palo Alto Networks User ID Agent Setup** section, click the Edit icon.<br>b. Select the **Server Monitor** tab and specify the **Server Log Monitor Frequency** in seconds (default is 2, range is 1-3600).<br>As a best practice, increase the value in this field to 5 seconds in environments with older domain controllers or high-latency links.<br>c. Click **OK** to save the changes. |
| Step 3 Set the domain credentials for the account the firewall will use to access Windows resources. This is required for monitoring Exchange servers and domain controllers as well as for WMI probing. | 1. Click the Edit icon in the **Palo Alto Networks User ID Agent Setup** section of the screen.<br>2. On the **WMI Authentication** tab, enter the **User Name** and **Password** for the account that will be used to probe the clients and monitor servers. Enter the user name using the domain\username syntax.<br> |

| Map IP Addresses to Users Using the Integrated User-ID Agent (Continued) | | |
|---|---|---|
| Step 4 | (Optional) Enable WMI probing.<br> The on-device agent does not support NetBIOS probing; it is supported on the Windows-based User-ID agent only. | 1. On the **Client Probing** tab, select the **Enable Probing** check box.<br>2. (Optional) If necessary, modify the **Probe Interval** (in minutes) to ensure it is long enough for the User-ID agent to probe all the learned IP addresses (default is 20, range is 1-1440). This is the interval between the end of the last probe request and the start of the next request.<br> If the request load is high, the observed delay between requests might significantly exceed the specified interval.<br>3. Make sure the Windows firewall will allow client probing by adding a a remote administration exception to the Windows firewall for each probed client. |
| Step 5 | Save the configuration. | 1. Click **OK** to save the User-ID agent setup settings.<br>2. Click **Commit** to save the configuration. |
| Step 6 | (Optional) Define the set of users for which you do not need to provide IP address to user name mappings, such as kiosk accounts.<br> You can also use the `ignore-user` list to identify users whom you want to force to authenticate using Captive Portal. | 1. Open a CLI session to the firewall.<br>2. To add the list of user accounts for which you do not want the firewall to perform mapping, run the following command:<br>**set user-id-collector ignore-user <value>**<br>Where <value> is a list of the user accounts to ignore; there is no limit to the number of accounts you can add to the list. Separate entries with a space and do not include the domain name with the username. For example:<br>`set user-id-collector ignore-user SPAdmin SPInstall TFSReport`<br>3. **Commit** your changes. |
| Step 7 | Verify the configuration. | 1. From the CLI, enter the following command:<br>`show user server-monitor state all`<br>2. On the **Device > User Identification > User Mapping** tab in the web interface, verify that the **Status** of each server you configured for server monitoring is **Connected**. |

# Configure User-ID to Receive User Mappings from a Syslog Sender

The following topics describe how to configure the User-ID agent (either the Windows agent or the integrated agent on the firewall) as a Syslog listener:

- Configure the Integrated User-ID Agent as a Syslog Listener
- Configure the Windows User-ID Agent as a Syslog Listener

## Configure the Integrated User-ID Agent as a Syslog Listener

The following workflow describes how to configure the PAN-OS integrated User-ID agent to receive syslog messages from authenticating services.

The PAN-OS integrated User-ID agent accepts syslogs over SSL and UDP only. However, you must use caution when using UDP to receive syslog messages because it is an unreliable protocol and as such there is no way to verify that a message was sent from a trusted syslog server. Although you can restrict syslog messages to specific source IP addresses, an attacker can still spoof the IP address, potentially allowing the injection of unauthorized syslog messages into the firewall. As a best practice, always use SSL to listen for syslog messages. However, if you must use UDP, make sure that the syslog server and client are both on a dedicated, secure VLAN to prevent untrusted hosts from sending UDP traffic to the firewall.

| **Collect User Mappings from Syslog Senders** | |
|---|---|
| Step 1 Determine whether there is a pre-defined syslog filter for your particular syslog sender(s).<br><br>Palo Alto Networks provides several pre-defined syslog filters, which are delivered as Application content updates and are therefore updated dynamically as new filters are developed. The pre-defined filters are global to the firewall, whereas manually defined filters apply to a single virtual system only.<br><br> Any new syslog filters in a given content release will be documented in the corresponding release note along with the specific regex used to define the filter. | 1. Verify that your Application or Application and Threat database is up to date:<br>a. Select **Device > Dynamic Updates**.<br>b. Click **Check Now** (located in the lower left-hand corner of the window) to check for the latest updates.<br>c. If a new update is available, **Download** and **Install** it.<br>2. Check to see what pre-defined filters are available:<br>a. Select **Device > User Identification > User Mapping**.<br>b. In the Server Monitoring section of the screen, click **Add**.<br>c. Select **Syslog Sender** as the server **Type**.<br>d. Select the **Filter** drop-down and check to see if there is a filter for the manufacturer and product you plan to forward syslogs from. If the filter you need is available, skip to Step 5 for instructions on defining the servers. If the filter you need is not available, continue to Step 2. |

**Collect User Mappings from Syslog Senders (Continued)**

Step 2 Manually define syslog filter(s) for extracting the User-ID IP address to username mapping information from syslog messages.

In order to be parsed by the User-ID agent, syslog messages must meet the following criteria:

- Each syslog message must be a single line text string. Line breaks are delimited by a carriage return and a new line (`\r\n`) or a new line (`\n`).
- The maximum allowed size of an individual syslog message is 2048 bytes.
- Syslog messages sent over UDP must be contained in a single packet; messages sent over SSL can span multiple packets.
- A single packet may contain multiple syslog messages.

1. Review the syslogs generated by the authenticating service to identify the syntax of the login events. This enables you to create the matching patterns that will allow the firewall to identify and extract the authentication events from the syslogs.

   While reviewing the syslogs also determine whether the domain name is included in the log entries. If the authentication logs do not contain domain information, consider defining a default domain name when adding the syslog sender to the monitored servers list in Step 5.
2. Select **Device > User Identification > User Mapping** and edit the Palo Alto Networks User-ID Agent Setup section.
3. On the **Syslog Filters** tab, **Add** a new syslog parse profile.
4. Enter a name for the **Syslog Parse Profile**.
5. Specify the **Type** of parsing to use to filter out the user mapping information by selecting one of the following options:
   - **Regex Identifier**—With this type of parsing, you specify regular expressions to describe search patterns for identifying and extracting user mapping information from syslog messages. Continue to Step 3 for instructions on creating the regex identifiers.
   - **Field Identifier**—With this type of parsing, you specify a string to match the authentication event, and prefix and suffix strings to identify the user mapping information in the syslogs. Continue to Step 4 for instructions on creating the field identifiers.

 © Palo Alto Networks, Inc.

**Collect User Mappings from Syslog Senders (Continued)**

Step 3 If you selected **Regex Identifier** as the parsing **Type**, create the regex matching patterns for identifying the authentication events and extracting the user mapping information.

The example below shows a regex configuration for matching syslog messages with the following format:

```
[Tue Jul 5 13:15:04 2005 CDT] Administrator
authentication success User:johndoe1
Source:192.168.3.212
```

If the syslog contains a standalone space and/or tab as a delimiter you must use an \s (for a space) and/or \t (for a tab) in order for the agent to parse the syslog.

1. Specify how to match successful authentication events in the syslogs by entering a matching pattern in the **Event Regex** field. For example, when matched against the example syslog message, the following regex instructs the firewall to extract the first `{1}` instance of the string `authentication success`. The backslash before the space is a standard regex escape character that instructs the regex engine not to treat the space as a special character: `(authentication\ success){1}`.
2. Enter the regex for identifying the beginning of the username in the authentication success messages in the **Username Regex** field. For example, the regex `User:([a-zA-Z0-9\\\._]+)` would match the string `User:johndoe1` in the example message and extract `acme\johndoe1` as the User-ID.

   If the syslogs do not contain domain information and you require domain names in your user mappings, be sure to enter the **Default Domain Name** when defining the monitored server entry in Step 5.
3. Enter the regex for identifying the IP address portion of the authentication success messages in the **Address Regex** field. For example, the following regular expression `Source:([0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3})` would match an IPv4 address (`Source:192.168.0.212` in the example syslog).
4. Click **OK**.

**Collect User Mappings from Syslog Senders (Continued)**

Step 4 If you selected **Field Identifier** as the parsing **Type**, define the string matching patterns for identifying the authentication events and extracting the user mapping information.

The example below shows a field identifier configuration for matching syslog messages with the following format:

```
[Tue Jul 5 13:15:04 2005 CDT] Administrator
authentication success User:johndoe1
Source:192.168.3.212
```

If the syslog contains a standalone space and/or tab as a delimiter you must use an \s (for a space) and/or \t (for a tab) in order for the agent to parse the syslog.

1. Specify how to match successful authentication events in the syslogs by entering a matching pattern in the **Event String** field. For example, when matched against the sample syslog message, you would enter the string `authentication success` to identify authentication events in the syslog.
2. Enter the matching string for identifying the beginning of the username field within the authentication syslog message in the **Username Prefix** field. For example, the string `User:` identifies the beginning of the username field in the sample syslog.
3. Enter the **Username Delimiter** to mark the end of the username field within an authentication syslog message. For example, if the username is followed by a space, you would enter `\s` to indicate that the username field is delimited by a standalone space in the sample log.
4. Enter the matching string for identifying the beginning of the IP address field within the authentication event log in the **Address Prefix** field. For example, the string `Source:` identifies the beginning of the address field in the example log.
5. Enter the **Address Delimiter** to mark the end of the IP address field within the authentication success message within the field. For example, if the address is followed by a line break, you would enter `\n` to indicate that the address field is delimited by a new line.
6. Click **OK**.

Step 5 Define the servers that will send syslog messages to the firewall for user mapping purposes.

You can define up to 50 syslog senders per virtual system and up to a total of 100 monitored servers, including syslog senders, Microsoft Active Directory, Microsoft Exchange, or Novell eDirectory servers. The firewall will discard any syslog messages received from servers that are not on this list.

A Syslog sender using SSL to connect will only show a **Status** of **Connected** when there is an active SSL connection. Syslog senders using UDP will not show a **Status** value.

1. Select **Device > User Identification > User Mapping**.
2. In the Server Monitoring section of the screen, click **Add**.
3. Enter a **Name** and **Network Address** for the server.
4. Select **Syslog Sender** as the server **Type**.
5. Make sure the **Enabled** check box is selected.
6. (Optional) If the syslogs that the authenticating device sends do not include domain information in the login event logs, enter the **Default Domain Name** to append to the user mappings.
7. Click **OK** to save the settings.

 © Palo Alto Networks, Inc.

**Collect User Mappings from Syslog Senders (Continued)**

| | |
|---|---|
| Step 6 Enable syslog listener services in the management profile associated with the interface used for user mapping.<br><br>Use caution when using UDP to receive syslog messages because it is an unreliable protocol and as such there is no way to verify that a message was sent from a trusted syslog server. Although you can restrict syslog messages to specific source IP addresses, an attacker can still spoof the IP address, potentially allowing the injection of unauthorized syslog messages into the firewall. As a best practice, always use SSL to listen for syslog messages when using agentless User Mapping on a firewall. However, if you must use UDP, make sure that the syslog server and client are both on a dedicated, secure VLAN to prevent untrusted hosts from sending UDP traffic to the firewall.<br><br>  | 1. Select **Network > Network Profiles > Interface Mgmt** and then select an interface profile to edit or click **Add** to create a new profile.<br>2. Select **User-ID Syslog Listener-SSL** and/or **User-ID Syslog Listener-UDP**, depending on the protocols you defined when you set up your Syslog Senders in the Server Monitor list.<br><br>On the Windows User-ID agent, the default listening port for syslog over UDP or TCP is 514, but the port value is configurable. For the agentless User Mapping feature on the firewall only syslog over UDP and SSL are supported and the listening ports (514 for UDP and 6514 for SSL) are not configurable; they are enabled through the management service only.<br><br>3. Click **OK** to save the interface management profile.<br><br>Even after enabling the User-ID Syslog Listener service on the interface, the interface will only accept syslog connections from servers that have a corresponding entry in the User-ID monitored servers configuration. Connections or messages from servers that are not on the list will be discarded. |
| Step 7 Save the configuration. | Click **Commit** to save the configuration. |

**Collect User Mappings from Syslog Senders (Continued)**

Step 8 Verify the configuration by opening an SSH connection to the firewall and then running the following CLI commands:

To see the status of a particular syslog sender:

```
admin@PA-5050> show user server-monitor state Syslog2
        UDP Syslog Listener Service is enabled
        SSL Syslog Listener Service is enabled

Proxy: Syslog2(vsys: vsys1)     Host: Syslog2(10.5.204.41)
        number of log messages                          : 1000
        number of auth. success messages                : 1000
        number of active connections                    : 0
        total connections made                          : 4
```

To see how many log messages came in from syslog senders and how many entries were successfully mapped:

```
admin@PA-5050> show user server-monitor statistics

Directory Servers:
Name                            TYPE     Host            Vsys    Status

------------------------------------------------------------------------------
AD                              AD       10.2.204.43     vsys1   Connected

Syslog Servers:
Name                        Connection Host            Vsys    Status
------------------------------------------------------------------------------
Syslog1                     UDP        10.5.204.40     vsys1   N/A
Syslog2                     SSL        10.5.204.41     vsys1   Not connected
```

To see how many user mappings were discovered through syslog senders:

```
admin@PA-5050> show user ip-user-mapping all type SYSLOG

IP              Vsys   From    User                            IdleTimeout(s) M

## Configure the Windows User-ID Agent as a Syslog Listener

The following workflow describes how to configure a Windows-based User-ID agent to listen for syslogs from authenticating services.

The Windows User-ID agent accepts syslogs over TCP and UDP only. However, you must use caution when using UDP to receive syslog messages because it is an unreliable protocol and as such there is no way to verify that a message was sent from a trusted syslog server. Although you can restrict syslog messages to specific source IP addresses, an attacker can still spoof the IP address, potentially allowing the injection of unauthorized syslog messages into the firewall. As a best practice, use TCP instead of UDP. In either case, make sure that the syslog server and client are both on a dedicated, secure VLAN to prevent untrusted hosts from sending syslogs to the User-ID agent.

| **Configure the Windows User-ID Agent to Collect User Mappings from Syslog Senders** | |
|---|---|
| Step 1 Launch the User-ID Agent application.<br> | 1. Click Start and select **User-ID Agent**. |
| Step 2 Manually define syslog filter(s) for extracting the User-ID IP address to username mapping information from syslog messages.<br>In order to be parsed by the User-ID agent, syslog messages must meet the following criteria:<br>• Each syslog message must be a single line text string. Line breaks are delimited by a carriage return and a new line (`\r\n`) or a new line (`\n`).<br>• The maximum allowed size of an individual syslog message is 2048 bytes.<br>• Syslog messages sent over UDP must be contained in a single packet; messages sent over SSL can span multiple packets.<br>• A single packet may contain multiple syslog messages. | 1. Review the syslogs generated by the authenticating service to identify the syntax of the login events. This enables you to create the matching patterns that will allow the firewall to identify and extract the authentication events from the syslogs.<br>While reviewing the syslogs also determine whether the domain name is included in the log entries. If the authentication logs do not contain domain information, consider defining a default domain name when adding the syslog sender to the monitored servers list in Step 5.<br>2. Select **User Identification > Setup** and click **Edit** in the Setup section of the dialog.<br>3. On the **Syslog** tab, **Add** a new syslog parse profile.<br>4. Enter a **Profile Name** and **Description**.<br>5. Specify the **Type** of parsing to use to filter out the user mapping information by selecting one of the following options:<br>• **Regex**—With this type of parsing, you specify regular expressions to describe search patterns for identifying and extracting user mapping information from syslog messages. Continue to Step 3 for instructions on creating the regex identifiers.<br>• **Field**—With this type of parsing, you specify a sting to match the authentication event, and prefix and suffix strings to identify the user mapping information in the syslogs. Continue to Step 4 for instructions on creating the field identifiers. |

**Configure the Windows User-ID Agent to Collect User Mappings from Syslog Senders (Continued)**

Step 3 If you selected **Regex** as the parsing **Type**, create the regex matching patterns for identifying the authentication events and extracting the user mapping information.

The example below shows a regex configuration for matching syslog messages with the following format:

```
[Tue Jul 5 13:15:04 2005 CDT] Administrator
authentication success User:johndoe1
Source:192.168.3.212
```

If the syslog contains a standalone space and/or tab as a delimiter you must use an \s (for a space) and/or \t (for a tab) in order for the agent to parse the syslog.

1. Specify how to match successful authentication events in the syslogs by entering a matching pattern in the **Event Regex** field. For example, when matched against the example syslog message, the following regex instructs the firewall to extract the first `{1}` instance of the string `authentication success`. The backslash before the space is a standard regex escape character that instructs the regex engine not to treat the space as a special character: `(authentication\ success){1}`.
2. Enter the regex for identifying the beginning of the username in the authentication success messages in the **Username Regex** field. For example, the regex `User:([a-zA-Z0-9\\\._]+)` would match the string `User:johndoe1` in the example message and extract `acme\johndoe1` as the User-ID.

   If the syslogs do not contain domain information and you require domain names in your user mappings, be sure to enter the **Default Domain Name** when defining the monitored server entry in Step 5.
3. Enter the regex for identifying the IP address portion of the authentication success messages in the **Address Regex** field. For example, the following regular expression `Source:([0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3})` would match an IPv4 address (`Source:192.168.0.212` in the example syslog).
4. Click **OK** to save the profile.

 © Palo Alto Networks, Inc.

**Configure the Windows User-ID Agent to Collect User Mappings from Syslog Senders (Continued)**

**Step 4** If you selected **Field Identifier** as the parsing **Type**, define the string matching patterns for identifying the authentication events and extracting the user mapping information.

The example below shows a field identifier configuration for matching syslog messages with the following format:

```
[Tue Jul 5 13:15:04 2005 CDT] Administrator
authentication success User:johndoe1
Source:192.168.3.212
```

If the syslog contains a standalone space and/or tab as a delimiter you must use an \s (for a space) and/or \t (for a tab) in order for the agent to parse the syslog.

1. Specify how to match successful authentication events in the syslogs by entering a matching pattern in the **Event String** field. For example, when matched against the sample syslog message, you would enter the string `authentication success` to identify authentication events in the syslog.
2. Enter the matching string for identifying the beginning of the username field within the authentication syslog message in the **Username Prefix** field. For example, the string `User:` identifies the beginning of the username field in the sample syslog.
3. Enter the **Username Delimiter** to mark the end of the username field within an authentication syslog message. For example, if the username is followed by a space, you would enter `\s` to indicate that the username field is delimited by a standalone space in the sample log.
4. Enter the matching string for identifying the beginning of the IP address field within the authentication event log in the **Address Prefix** field. For example, the string `Source:` identifies the beginning of the address field in the example log.
5. Enter the **Address Delimiter** to mark the end of the IP address field within the authentication success message within the field. For example, if the address is followed by a line break, you would enter `\n` to indicate that the address field is delimited by a new line.
6. Click **OK** to save the profile.

**Step 5** Enable the syslog listening service on the agent.

As a best practice, make sure that the syslog server and client are both on a dedicated, secure VLAN to prevent untrusted hosts from sending syslogs to the User-ID agent.

1. Select the **Enable Syslog Service** check box.
2. (Optional) Modify the **Syslog Service Port** number to match the port number used by the syslog sender (default=514).
3. To save the agent syslog configuration, click **OK**.

**Step 6** Define the servers that will send syslog messages to the User-ID agent.

You can define up to 100 syslog senders. The User-ID agent will discard any syslog messages received from servers that are not on this list.

1. Select **User Identification > Discovery**.
2. In the **Servers** section of the screen, click **Add**.
3. Enter a **Name** and **Server Address** for the server that will send syslogs to the agent.
4. Select **Syslog Sender** as the **Server Type**.
5. Select a **Filter** you defined in Step 2.
6. (Optional) If the syslogs that the authenticating device sends do not include domain information in the login event logs, enter the **Default Domain Name** to append to the user mappings.
7. Click **OK** to save the settings.

**Step 7** Save the configuration.

Click **Commit** to save the configuration.

**Configure the Windows User-ID Agent to Collect User Mappings from Syslog Senders (Continued)**

Step 8 Verify the configuration by opening an SSH connection to the firewall and then running the following CLI commands:

To see the status of a particular syslog sender:

```
admin@PA-5050> show user server-monitor state Syslog2
        UDP Syslog Listener Service is enabled
        SSL Syslog Listener Service is enabled

Proxy: Syslog2(vsys: vsys1)     Host: Syslog2(10.5.204.41)
        number of log messages                          : 1000
        number of auth. success messages                : 1000
        number of active connections                    : 0
        total connections made                          : 4
```

To see how many log messages came in from syslog senders and how many entries were successfully mapped:

```
admin@PA-5050> show user server-monitor statistics

Directory Servers:
Name                          TYPE     Host            Vsys    Status

------------------------------------------------------------------------------
AD                            AD       10.2.204.43     vsys1   Connected

Syslog Servers:
Name                      Connection Host            Vsys    Status
------------------------------------------------------------------------------
Syslog1                   UDP        10.5.204.40     vsys1   N/A
Syslog2                   SSL        10.5.204.41     vsys1   Not connected
```

To see how many user mappings were discovered through syslog senders:

```
admin@PA-5050> show user ip-user-mapping all type SYSLOG

IP              Vsys   From    User                            IdleTimeout(s) M
axTimeout(s)
--------------- ------ ------- ------------------------------- -------------- -

# Map IP Addresses to User Names Using Captive Portal

If the firewall receives a request from a zone that has User-ID enabled and the source IP address does not have any user data associated with it yet, it checks its Captive Portal policy for a match to determine whether to perform authentication. This is useful in environments where you have clients that are not logged in to your domain servers, such as Linux clients. This user mapping method is only triggered for web traffic (HTTP or HTTPS) that matches a security rule/policy, but that has not been mapped using a different method.

- Captive Portal Authentication Methods
- Captive Portal Modes
- Configure Captive Portal

## Captive Portal Authentication Methods

Captive Portal uses the following methods to obtain user data from the client when a request matches a Captive Portal policy:

| Authentication Method | Description |
|---|---|
| NT LAN Manager (NTLM) | The firewall uses an encrypted challenge-response mechanism to obtain the user's credentials from the browser. When configured properly, the browser will provide the credentials to the firewall transparently without prompting the user, but will display a prompt for credentials if necessary. If the browser cannot perform NTLM or if NTLM authentication fails, the firewall falls back to web form or client certificate authentication, depending on your Captive Portal configuration.<br>By default, IE supports NTLM. Firefox and Chrome can be configured to use it. You cannot use NTLM to authenticate non-Windows clients. |
| Web Form | Requests are redirected to a web form for authentication. You can configure Captive Portal to use a local user database, RADIUS, LDAP, or Kerberos to authenticate users. Although users will always be prompted for credentials, this authentication method works with all browsers and operating systems. |
| Client Certificate Authentication | Prompts the browser to present a valid client certificate for authenticating the user. To use this method, you must provision client certificates on each user system and install the trusted CA certificate used to issue those certificates on the firewall. This is the only authentication method that enables transparent authentication for Mac OS and Linux clients. |

## Captive Portal Modes

The Captive Portal mode defines how web requests are captured for authentication:

© Palo Alto Networks, Inc.

| Mode | Description |
|---|---|
| Transparent | The firewall intercepts the browser traffic per the Captive Portal rule and impersonates the original destination URL, issuing an HTTP 401 to invoke authentication. However, because the firewall does not have the real certificate for the destination URL, the browser will display a certificate error to users attempting to access a secure site. Therefore you should only use this mode when absolutely necessary, such as in Layer 2 or virtual wire deployments. |
| Redirect | The firewall intercepts unknown HTTP or HTTPS sessions and redirects them to a Layer 3 interface on the firewall using an HTTP 302 redirect in order to perform authentication. This is the preferred mode because it provides a better end-user experience (no certificate errors). However, it does require additional Layer 3 configuration. Another benefit of the Redirect mode is that it provides for the use of session cookies, which enable the user to continue browsing to authenticated sites without requiring re-mapping each time the time outs expire. This is especially useful for users who roam from one IP address to another (for example, from the corporate LAN to the wireless network) because they will not need to re-authenticate upon IP address change as long as the session stays open. In addition, if you plan to use NTLM authentication, you must use Redirect mode because the browser will only provide credentials to trusted sites. |

## Configure Captive Portal

The following procedure shows how to configure Captive Portal using the PAN-OS integrated User-ID agent to redirect requests that match a Captive Portal policy to a Layer 3 interface on the firewall.

If you plan to use Captive Portal without using the other User-ID functions (user mapping and group mapping), you do not need to configure an agent.

| Configure Captive Portal Using the PAN-OS Integrated User-ID Agent | | |
|---|---|---|
| Step 1 | Make sure the firewall has a route to the servers it will be monitoring to gather user data (for example, your Domain Controllers and your Exchange servers). | In this release of the product, the firewall must be able to communicate with the servers over the MGT interface, so you must make sure that the network your directory servers are on is accessible from this interface. If this configuration does not work in your environment, you must configure Captive Portal using the Window-based User-ID agent. |
| Step 2 | Make sure DNS is configured to resolve your Domain Controller addresses. | To verify proper resolution, ping the server FQDN. For example:<br>`admin@PA-200> ping host dc1.acme.com` |

 © Palo Alto Networks, Inc.

| Configure Captive Portal Using the PAN-OS Integrated User-ID Agent (Continued) | | |
|---|---|---|
| Step 3 | (Redirect mode only) Create a Layer 3 interface to which to redirect Captive Portal requests. | 1. Create a management profile to enable the interface to display Captive Portal response pages:<br>a. Select **Network > Interface Mgmt** and click **Add**.<br>b. Enter a **Name** for the profile, select **Response Pages**, and then click **OK**.<br>2. Create the Layer 3 interface. Be sure to attach the management profile you just created (on the **Advanced > Other Info** tab of the Ethernet Interface dialog).<br>3. Create a DNS "A" record that maps the IP address you configured on the Layer 3 interface to an intranet host name (that is, a hostname that does not have a dot in the name, such as `ntlmhost`). |
| Step 4 | (Redirect mode only) To transparently redirect users without displaying certificate errors, install a certificate that matches the IP address of the interface to which you are redirecting requests.You can either generate a self-signed certificate or import a certificate that is signed by an external CA.<br>When setting up Captive Portal for the first time, imported certificates may not work. If you plan to use an imported certificate, complete the initial configuration without specifying a **Server Certificate**. After you get Captive Portal working, you can go back and switch to the imported certificate. | To use a self-signed certificate, you must first create a root CA certificate and then use that CA to sign the certificate you will use for Captive Portal as follows:<br>1. To create a root CA certificate, select **Device > Certificate Management > Certificates > Device Certificates** and then click **Generate**. Enter a **Certificate Name**, such as RootCA. Do not select a value in the **Signed By** field (this is what indicates that it is self-signed). Make sure you select the **Certificate Authority** check box and then click **Generate** the certificate.<br>2. To create the certificate to use for Captive Portal, click **Generate**. Enter a **Certificate Name** and enter the DNS name of the intranet host for the interface as the **Common Name**. In the **Signed By** field, select the CA you created in the previous step. Add an IP address attribute and specify the IP address of the Layer 3 interface to which you will be redirecting requests. **Generate** the certificate.<br>  <br>3. To configure clients to trust the certificate, select the CA certificate on the **Device Certificates** tab and click **Export**. You must then import the certificate as a trusted root CA into all client browsers, either by manually configuring the browser or by adding the certificate to the trusted roots in an Active Directory Group Policy Object (GPO). |

| Configure Captive Portal Using the PAN-OS Integrated User-ID Agent (Continued) | | |
|---|---|---|
| Step 5 | Set up an authentication mechanism to use when the web form is invoked. Note that even if you plan to use NTLM, you must also set up a secondary authentication mechanism that can be used if NTLM authentication fails or if the user agent does not support it.<br><br>**Best Practices:**<br>•If using RADIUS to authenticate users from the web form, be sure to enter a RADIUS domain. This will be used as the default domain if users don't supply one upon login.<br>•If using AD to authenticate users from the web form, make sure to enter **sAMAccountName** as the **LogonAttribute**. | 1. Configure the firewall to connect to the authentication service you plan to use so that it can access the authentication credentials.<br>• If you plan to authenticate using LDAP, Kerberos, or RADIUS you must create a server profile that instructs the firewall how to connect to the service and access the authentication credentials for your users. Select **Device > Server Profiles** and add a new profile for the specific service you will be accessing.<br>• If you plan to use local database authentication, you must first create the local database. Select **Device > Local User Database** and add the users and groups to be authenticated.<br>2. Create an authentication profile that references the server profile or local user database you just created. Select **Device > Authentication Profile** and add a new profile for use with Captive Portal. For details on creating a specific type of authentication profile, refer to the online help. |
| Step 6 | (Optional) Set up client certificate authentication. Note that you do not need to set up both an authentication profile and a client certificate profile to enable Captive Portal. If you configure both, the user will be required to authenticate using both methods.<br><br>For details on other certificate profile fields, such as whether to use CRL or OCSP, refer to the online help. | 1. Generate certificates for each user who will be authenticating using Captive Portal.<br>2. Download the CA certificate in Base64 format.<br>3. Import the root CA certificate from the CA that generated the client certificates onto the firewall:<br>a. Select **Device > Certificate Management > Certificates > Device Certificates** and click **Import**.<br>b. Enter a **Certificate Name** that identifies the certificate as your client CA certificate.<br>c. **Browse** to the **Certificate File** you downloaded from the CA.<br>d. Select **Base64 Encoded Certificate (PEM)** as the **File Format** and then click **OK**.<br>e. Select the certificate you just imported on the **Device Certificates** tab to open it.<br>f. Select **Trusted Root CA** and then click **OK**.<br>4. Create the client certificate profile that you will use when you configure Captive Portal.<br>a. Select **Device > Certificates > Certificate Management > Certificate Profile** and click **Add** and enter a profile **Name**.<br>b. In the **Username Field** drop-down, select the certificate field that contains the user's identity information.<br>c. In the **CA Certificates** field, click **Add**, select the Trusted Root CA certificate you just imported and then click **OK**. |

| Configure Captive Portal Using the PAN-OS Integrated User-ID Agent (Continued) | |
|---|---|
| Step 7 Enable NTLM authentication.<br> When using the on-device User-ID agent, the firewall must be able to successfully resolve the DNS name of your Domain Controller in order for the firewall to join the domain. The credentials you supply here will be used to join the firewall to the domain upon successful DNS resolution. | 1. Select **Device > User Identification > User Mapping** and click the Edit icon in the **Palo Alto Networks User ID Agent Setup** section of the screen.<br>2. On the **NTLM** tab, select the **Enable NTLM authentication processing** check box.<br>3. Enter the NTLM domain against which the User-ID agent on the firewall should check NTLM credentials.<br>4. Enter the user name and password for the Active Directory account you created in Step 1 in Map IP Addresses to Users Using the Integrated User-ID Agent for NTLM authentication.<br> Do not include the domain in the **Admin User Name** field. Otherwise, the firewall will fail to join the domain. |

| Configure Captive Portal Using the PAN-OS Integrated User-ID Agent (Continued) | |
|---|---|
| Step 8 Configure the Captive Portal settings. | 1. Select **Device > User Identification > Captive Portal Settings** and click the Edit icon in the **Captive Portal** section of the screen.<br>2. Make sure the **Enabled** check box is selected.<br>3. Set the **Mode**. This example shows how to set up **Redirect** mode.<br>4. (Redirect mode only) Select the **Server Certificate** the firewall should use to redirect requests over SSL. This is the certificate you created in Step 4.<br>5. (Redirect mode only) Specify the **Redirect Host**, which is the intranet hostname that resolves to the IP address of the Layer 3 interface to which you are redirecting requests, as specified in Step 3.<br>6. Select the authentication method to use if NTLM fails (or if you are not using NTLM):<br>• If you are using LDAP, Kerberos, RADIUS, or local database authentication, select the **Authentication Profile** you created in Step 5.<br>• If you are using client certificate authentication, select the **Certificate Profile** you created in Step 6.<br>  <br>7. Click **OK** to save your settings.<br>8. Click **Commit** to save the Captive Portal configuration. |

# Configure User Mapping for Terminal Server Users

Individual terminal server users appear to have the same IP address and therefore an IP address to username mapping is not sufficient to identify a specific user. To enable identification of specific users on Windows-based terminal servers, the Palo Alto Networks Terminal Services agent (TS agent) allocates a port range to each user. It then notifies every connected firewall about the allocated port range, which allows the firewall to create an IP address-port-user mapping table and enable user- and group-based security policy enforcement. For non-Windows terminal servers you can configure the User-ID XML API to extract user mapping information.

The following sections describe how to configure user mapping for terminal server users:

- Configure the Palo Alto Networks Terminal Server Agent for User Mapping
- Retrieve User Mappings from a Terminal Server Using the User-ID XML API

## Configure the Palo Alto Networks Terminal Server Agent for User Mapping

Use the following procedure to install the TS agent on the terminal server. You must install the TS agent on all terminal servers that your users log in to in order to successfully map all your users.

For information about the supported terminal servers supported by the TS Agent, refer to "Operating System (OS) Compatibility TS Agent" in the Terminal Services Agent Release Notes, which are available on the Palo Alto Networks Software Updates page.

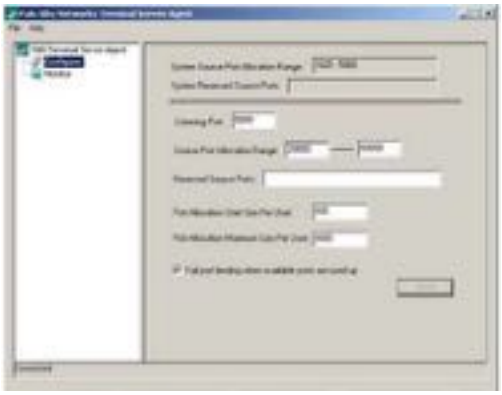
| **Install the Windows Terminal Server Agent** | |
|---|---|
| Step 1 Download the TS Agent installer. | 1. Log in to the Palo Alto Networks Support site.<br>2. Select **Software Updates** from the Manage Devices section.<br>3. Scroll to the **Terminal Services Agent** section and **Download** the version of the agent you want to install.<br>4. Save the `TaInstall64.x64-x.x.x-xx.msi` or `TaInstall-x.x.x-xx.msi` file (be sure to select the appropriate version based on whether the Windows system is running a 32-bit OS or a 64-bit OS) on the system(s) where you plan to install the agent. |

| Install the Windows Terminal Server Agent (Continued) | |
|---|---|
| Step 2 Run the installer as an administrator.<br> | 1. To launch a command prompt as an administrator, click Start and right-click **Command Prompt** and then select **Run as administrator**.<br>2. From the command line, run the .msi file you downloaded. For example, if you saved the .msi file to the Desktop you would enter the following:<br>`C:\Users\administrator.acme>cd Desktop`<br>`C:\Users\administrator.acme\Desktop>TaInstall-6.0.0-1.msi`<br>3. Follow the setup prompts to install the agent using the default settings. By default, the agent gets installed to the `C:\Program Files (x86)\Palo Alto Networks\Terminal Server Agent` folder, but you can **Browse** to a different location.<br>4. When the installation completes, **Close** the setup window.<br>If you are upgrading to a TS Agent version that has a newer driver than the existing installation, the installation wizard prompts you to reboot the system after upgrading in order to use the new driver. |
| Step 3 Launch the Terminal Server Agent application. | Click Start and select **Terminal Server Agent**.<br>  |

 © Palo Alto Networks, Inc.

**Install the Windows Terminal Server Agent (Continued)**

Step 4 Define the range of ports for the TS Agent to allocate to end users.



The **System Source Port Allocation Range** and **System Reserved Source Ports** fields specify the range of ports that will be allocated to non-user sessions. Make sure the values specified in these fields do not overlap with the ports you designate for user traffic. These values can only be changed by editing the corresponding Windows registry settings.

1. Select **Configure**.
2. Set the **Source Port Allocation Range** (default 20000-39999). This is the full range of port numbers that the TS Agent will allocate for user mapping. The port range you specify cannot overlap with the **System Source Port Allocation Range**.
3. (Optional) If there are ports/port ranges within the source port allocation that you do not want the TS Agent to allocate to user sessions, specify them as **Reserved Source Ports**. To include multiple ranges, use commas with no spaces, for example: `2000-3000,3500,4000-5000`.
4. Specify the number of ports to allocate to each individual user upon login to the terminal server in the **Port Allocation Start Size Per User** field (default 200).
5. Specify the **Port Allocation Maximum Size Per User**, which is the maximum number of ports the Terminal Server agent can allocate to an individual user.
6. Specify whether to continue processing traffic from the user if the user runs out of allocated ports. By default, the **Fail port binding when available ports are used up** is selected, which indicates that the application will fail to send traffic when all ports are used. To enable users to continue using applications when they run out of ports, clear this check box. Keep in mind that this traffic may not be identified with User-ID.

Step 5 Configure the firewalls to connect to the Terminal Server agent.

Complete the following steps on each firewall you want to connect to the Terminal Server agent to receive user mappings:

1. Select **Device > User Identification > Terminal Server Agents** and click **Add**.
2. Enter a **Name** for the Terminal Server agent.
3. Enter the IP address of the Windows **Host** on which the Terminal Server agent is installed.
4. Enter the **Port** number on which the agent will listen for user mapping requests. This value must match the value configured on the Terminal Server agent. By default, the port is set to 5009 on the firewall and on the agent. If you change it here you must also change the **Listening Port** field on the Terminal Server agent **Configure** screen.
5. Make sure that the configuration is **Enabled** and then click **OK**.
6. **Commit** the changes.
7. Verify that the **Connected** status displays as connected.

| Install the Windows Terminal Server Agent (Continued) | |
|---|---|
| Step 6 Verify that the Terminal Server agent is successfully mapping IP addresses to usernames and that the firewalls can connect to the agent.<br>  | 1. Launch the Terminal Server agent and verify that the firewalls can connect by making sure the **Connection Status** for each of Device in the Connection List is **Connected**.<br>2. To verify that the Terminal Server agent is successfully mapping port ranges to usernames, select **Monitoring** and make sure that the mapping table is populated. |

## Retrieve User Mappings from a Terminal Server Using the User-ID XML API

The User-ID XML API is a RESTful API that uses standard HTTP requests to send and receive data. API calls can be made directly from command line utilities such as cURL or using any scripting or application framework that supports RESTful services.

To enable a non-Windows terminal server to send user mapping information directly to the firewall, create scripts that extract the user login and logout events and use them for input to the User-ID XML API request format. Then define the mechanisms for submitting the XML API request(s) to the firewall using cURL or wget and providing the firewall's API key for secure communication. Creating user mappings from multi-user systems such as terminal servers requires use of the following API messages:

- **<multiusersystem>**—Sets up the configuration for an XML API Multi-user System on the firewall. This message allows for definition of the terminal server IP address (this will be the source address for all users on that terminal server). In addition, the <multiusersystem> setup message specifies the range of source port numbers to allocate for user mapping and the number of ports to allocate to each individual user upon login (called the *block size*). If you want to use the default source port allocation range (1025-65534) and block size (200), you do not need to send a <multiusersystem> setup event to the firewall. Instead, the firewall will automatically generate the XML API Multi-user System configuration with the default settings upon receipt of the first user login event message.
- **<blockstart>**—Used with the <login> and <logout> messages to indicate the starting source port number allocated to the user. The firewall then uses the block size to determine the actual range of port numbers to map to the IP address and username in the login message. For example, if the <blockstart> value is 13200 and the block size configured for the multi-user system is 300, the actual source port range allocated to the user is 13200 through 13499. Each connection initiated by the user should use a unique source port number within the allocated range, enabling the firewall to identify the user based on its IP address-port-user mappings for enforcement of user- and group-based security policy rules. When a user exhausts all the ports allocated, the terminal server must send a new <login> message allocating a new port range for the user so that the firewall can update the IP address-port-user mapping. In addition, a single

 © Palo Alto Networks, Inc.

username can have multiple blocks of ports mapped simultaneously. When the firewall receives a <logout> message that includes a <blockstart> parameter, it removes the corresponding IP address-port-user mapping from its mapping table. When the firewall receives a <logout> message with a username and IP address, but no <blockstart>, it removes the user from its table. And, if the firewall receives a <logout> message with an IP address only, it removes the multi-user system and all mappings associated with it.

The XML files that the terminal server sends to the firewall can contain multiple message types and the messages do not need to be in any particular order within the file. However, upon receiving an XML file that contains multiple message types, the firewall will process them in the following order: multiusersystem requests first followed by logins then logouts.

The following workflow provides an example of how to use the User-ID XML API to send user mappings from a non-Windows terminal server to the firewall.

**Use the User-ID XML API to Map Non-Windows Terminal Services Users**

Step 1 — Generate the API key that will be used to authenticate the API communication between the firewall and the Terminal server. To generate the key you must provide login credentials for an administrative account; the API is available to all administrators (including role-based administrators with XML API privileges enabled).

Any special characters in the password must be URL/percent-encoded.

From a browser, log in to the firewall. Then, to generate the API key for the firewall, open a new browser window and enter the following URL:

```
https://<Firewall-IPaddress>/api/?type=keygen&user=<username>&
password=<password>
```

Where <Firewall-IPaddress> is the IP address or FQDN of the firewall and <username> and <password> are the credentials for the administrative user account on the firewall. For example:

```
https://10.1.2.5/api/?type=keygen&user=admin&password=admin
```

The firewall responds with a message containing the key, for example:

```
<response status="success">
   <result>
      <key>k7J335J6hI7nBxIqyfa62sZugWx7ot%2BgzEA9UOnlZRg=</key>
   </result>
</response>
```

**Use the User-ID XML API to Map Non-Windows Terminal Services Users (Continued)**

Step 2 (Optional) Generate a setup message that the terminal server will send to specify the port range and block size of ports per user that your terminal services agent uses.

If the terminal services agent does not send a setup message, the firewall will automatically create a terminal server agent configuration using the following default settings upon receipt of the first login message:

- Default port range: 1025 to 65534
- Per user block size: 200
- Maximum number of multi-user systems: 1000

The following shows a sample setup message:

```
<uid-message>
  <payload>
    <multiusersystem>
      <entry ip="10.1.1.23" startport="20000"
        endport="39999" blocksize="100">
    </multiusersystem>
  </payload>
  <type>update</type>
  <version>1.0</version>
</uid-message>
```

where `entry ip` specifies the IP address assigned to terminal server users, `startport` and `endport` specify the port range to use when assigning ports to individual users and `blocksize` specifies the number of ports to assign to each user. The maximum blocksize is 4000 and each multi-user system can allocate a maximum of 1000 blocks.

If you define a custom blocksize and or port range, keep in mind that you must configure the values such that every port in the range gets allocated and that there are no gaps or unused ports. For example, if you set the port range to 1000-1499, you could set the block size to 100, but not to 200. This is because if you set it to 200, there would be unused ports at the end of the range.

Step 3 Create a script that will extract the login events and create the XML input file to send to the firewall.

Make sure the script enforces assignment of port number ranges at fixed boundaries with no port overlaps. For example, if the port range is 1000-1999 and the block size is 200, acceptable blockstart values would be 1000, 1200, 1400, 1600, or 1800. Blockstart values of 1001, 1300, or 1850 would be unacceptable because some of the port numbers in the range would be left unused.

The login event payload that the terminal server sends to the firewall can contain multiple login events.

The following shows the input file format for a user-ID XML login event:

```
<uid-message>
<payload>
<login>
<entry name="acme\jjaso" ip="10.1.1.23" blockstart="20000">
<entry name="acme\jparker" ip="10.1.1.23" blockstart="20100">
<entry name="acme\ccrisp" ip="10.1.1.23" blockstart="21000">
</login>
</payload>
<type>update</type>
<version>1.0</version>
</uid-message>
```

The firewall uses this information to populate its user mapping table. Based on the mappings extracted from the example above, if the firewall received a packet with a source address and port of 10.1.1.23:20101, it would map the request to user jparker for policy enforcement.

Each multi-user system can allocate a maximum of 1000 port blocks.

 © Palo Alto Networks, Inc.

**Use the User-ID XML API to Map Non-Windows Terminal Services Users (Continued)**

| | | |
|---|---|---|
| Step 4 | Create a script that will extract the logout events and create the XML input file to send to the firewall.<br><br>Upon receipt of a `logout` event message with a `blockstart` parameter, the firewall removes the corresponding IP address-port-user mapping. If the `logout` message contains a username and IP address, but no `blockstart` parameter, the firewall removes all mappings for the user. If the `logout` message contains an IP address only, the firewall removes the multi-user system and all associated mappings. | The following shows the input file format for a User-ID XML logout event:<br>`<uid-message>`<br>`  <payload>`<br>`  <logout>`<br>`  <entry name="acme\jjaso" ip="10.1.1.23" blockstart="20000">`<br>`  <entry name="acme\ccrisp" ip="10.1.1.23">`<br>`  <entry ip="10.2.5.4">`<br>`  </logout>`<br>`  </payload>`<br>`  <type>update</type>`<br>`  <version>1.0</version>`<br>`</uid-message>`<br><br>You can also clear the multiuser system entry from the firewall using the following CLI command: **`clear xml-api multiusersystem`** |
| Step 5 | Make sure that the scripts you create include a way to dynamically enforce that the port block range allocated using the XML API matches the actual source port assigned to the user on the terminal server and that the mapping is removed when the user logs out or the port allocation changes. | One way to do this would be to use netfilter NAT rules to hide user sessions behind the specific port ranges allocated via the XML API based on the uid. For example, to ensure that a user with the user ID jjaso is mapped to a source network address translation (SNAT) value of 10.1.1.23:20000-20099 the script you create should include the following:<br>`[root@ts1 ~]# iptables -t nat -A POSTROUTING -m owner --uid-owner jjaso -p tcp -j SNAT --to-source 10.1.1.23:20000-20099`<br>Similarly, the scripts you create should also ensure that the IP table routing configuration dynamically removes the SNAT mapping when the user logs out or the port allocation changes:<br>`[root@ts1 ~]# iptables -t nat -D POSTROUTING 1` |
| Step 6 | Define how to package the XML input files containing the setup, login, and logout events into wget or cURL messages for transmission to the firewall. | **To apply the files to the firewall using wget:**<br>`> wget --post file <filename> "https://<Firewall-IPaddress>/api/?type=user-id&key=<key>&file-name=<input_filename.xml>&client=wget&vsys=<VSYS_name>"`<br>For example, the syntax for sending an input file named login.xml to the firewall at 10.2.5.11 using key `k7J335J6hI7nBxIqyfa62sZugWx7ot%2BgzEA9UOnlZRg` using wget would look as follows:<br>`> wget --post file login.xml "https://10.2.5.11/api/?type=user-id&key=k7J335J6hI7nBxIqyfa62sZugWx7ot%2BgzEA9UOnlZRg&file-name=login.xml&client=wget&vsys=vsys1"`<br><br>**To apply the file to the firewall using cURL:**<br>`> curl --form file=@<filename> https://<Firewall-IPaddress>/api/?type=user-id&key=<key>&vsys=<VSYS_name>`<br>For example, the syntax for sending an input file named login.xml to the firewall at 10.2.5.11 using key `k7J335J6hI7nBxIqyfa62sZugWx7ot%2BgzEA9UOnlZRg` using cURL would look as follows:<br>`> curl --form file@login.xml "https://10.2.5.11/api/?type=user-id&key=k7J335J6hI7nBxIqyfa62sZugWx7ot%2BgzEA9UOnlZRg&vsys=vsys1"` |

| Use the User-ID XML API to Map Non-Windows Terminal Services Users (Continued) | | |
|---|---|---|
| Step 7 | Verify that the firewall is successfully receiving login events from the terminal servers. | Verify the configuration by opening an SSH connection to the firewall and then running the following CLI commands:<br>**To verify if the terminal server is connecting to the firewall over XML:**<br>`admin@PA-5050> show user xml-api multiusersystem`<br>`Host Vsys Users Blocks`<br>`----------`<br>`10.5.204.43 vsys1 5 2`<br>**To verify that the firewall is receiving mappings from a terminal server over XML:**<br>`admin@PA-5050> show user ip-port-user-mapping all`<br>`Global max host index 1, host hash count 1`<br>`XML API Multi-user System 10.5.204.43`<br>`Vsys 1, Flag 3`<br>`Port range: 20000 - 39999`<br>`Port size: start 200; max 2000`<br>`Block count 100, port count 20000`<br>`20000-20199: acme\administrator`<br>`Total host: 1` |

## Send User Mappings to User-ID Using the XML API

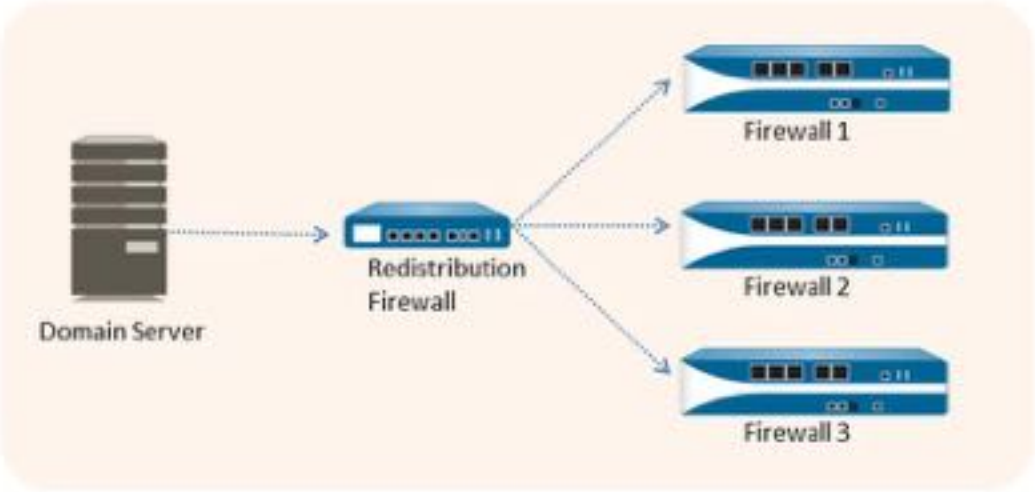
Although the User-ID functionality provides many out-of-the box methods for obtaining user mapping information, you may have some applications or devices that capture user information that cannot be natively integrated with User-ID. In this case you can use the User-ID XML API to create custom scripts that allow you to leverage existing user data and send it to the User-ID agent or directly to the firewall.

The User-ID XML API is a RESTful API that uses standard HTTP requests to send and receive data. API calls can be made directly from command line utilities such as cURL or using any scripting or application framework that supports RESTful services. To leverage user data from an existing system—such as a custom application developed internally or another device that is not supported by one of the existing user mapping mechanisms—you can create custom scripts to extract the data and send it to the firewall or the User-ID agent using the XML API.

To enable an external system to send user mapping information to the User-ID agent or directly to the firewall, you can create scripts that extract the user login and logout events and use them for input to the User-ID XML API request format. Then define the mechanisms for submitting the XML API request(s) to the firewall using cURL or wget using the firewall's API key for secure communication. For more details, refer to the PAN-OS XML API Usage Guide.

## Configure a Firewall to Share User Mapping Data with Other Firewalls

Because policy is local to each firewall, each firewall needs current user mapping and group mapping information to accurately enforce security policy by user and group. However, you can configure one firewall to collect all the mapping information and act as a User-ID agent to share that information with other firewalls. The redistribution firewall can share only the information it collects using local methods (for example, the PAN-OS integrated User-ID agent or Captive Portal), not the information collected from the Windows-based User-ID and Terminal Services agents. You configure the receiving firewalls to retrieve the mapping information from the redistribution firewall; they don't need to communicate directly with domain servers.



The following procedure describes how to set up redistribution of User-ID information.

| Configure a Firewall to Redistribute User Mappings | |
|---|---|
| Step 1 Configure the redistribution firewall.<br>User-ID configurations apply to a single virtual system only. To redistribute User-ID mappings from multiple virtual systems you must configure the user mapping settings on each virtual system separately, using a unique pre-shared key in each configuration. | 1. Select **Device > User Identification > User Mapping** and edit the Palo Alto Networks User-ID Agent Setup section.<br>2. Select **Redistribution**.<br>3. Enter a **Collector Name**.<br>4. Enter and confirm the **Pre-Shared Key** that will enable other firewalls to connect to this firewall to retrieve user mapping information.<br>5. Click **OK** to save the redistribution configuration. |

 © Palo Alto Networks, Inc.

| Configure a Firewall to Redistribute User Mappings (Continued) | | |
|---|---|---|
| Step 2 | Create an interface management profile that enables the User-ID service and attach it to the interface that the other firewalls will connect to in order to retrieve user mappings. | 1. Select **Network > Network Profiles > Interface Mgmt** and click **Add**.<br>2. Enter a **Name** for the profile and then select the Permitted Services. At a minimum, select **User-ID Service** and **HTTPS**.<br>3. Click **OK** to save the profile.<br>4. Select **Network > Interfaces > Ethernet** and select the interface you plan to use for redistribution.<br>5. On the **Advanced > Other Info** tab, select the **Management Profile** you just created.<br>6. Click **OK** and **Commit**. |
| Step 3 | Configure the other firewalls to retrieve user mappings from the redistribution firewall.<br> If the redistribution firewall has multiple virtual systems configured for redistribution, make sure you are using the pre-shared key that corresponds to the virtual system from which you want this firewall to retrieve User-ID mappings. | Perform the following steps on each firewall that you want to be able to retrieve user mappings:<br>1. Select **Device > User Identification > User-ID Agents**.<br>2. Click **Add** and enter a User-ID agent **Name** for the redistribution firewall.<br>3. Enter the hostname or IP address of the firewall interface that you configured for redistribution in the **Host** field.<br>4. Enter 5007 as the **Port** number on which the redistribution firewall will listen for User-ID requests.<br>5. Enter the **Collector Name** that you specified in the redistribution firewall configuration (Step 1-3).<br>6. Enter and confirm the **Collector Pre-Shared Key**. The key value you enter here must match the value configured on the redistribution firewall (Step 1-4).<br>7. (Optional) If you are using the redistribution firewall to retrieve group mappings in addition to user mappings, select the **Use as LDAP Proxy** check box.<br>8. (Optional) If you are using the redistribution firewall for Captive Portal authentication, select the **Use for NTLM Authentication** check box.<br>9. Make sure that the configuration is **Enabled** and then click **OK**.<br>10. **Commit** the changes. |
| Step 4 | Verify the configuration. | On the **User-ID Agents** tab, verify that the redistribution firewall entry you just added shows a green icon in the **Connected** column.<br>If a red icon appears, check traffic logs (**Monitor > Logs > Traffic**) to identify the issue. You can also check to see if any user mapping data has been received by running the following operational commands from the CLI:<br>`show user ip-user-mapping` (to view user mapping information on the dataplane)<br>`show user ip-user-mapping-mp` (to view mappings on the management plane). |

# Enable User- and Group-Based Policy

In order to enable security policy based on user and/or group, you must enable User-ID for each zone that contains users you want to identify. You can then define policies that allow or deny traffic based on user name or group membership. Additionally, you can create Captive Portal policies to enable identification for IP addresses that do not yet have any user data associated with them.

| Enable User- and Group-Based Policy | |
|---|---|
| Step 1 Enable User-ID on the source zones that contain the users that will send requests that require user-based access controls. | 1. Select **Network > Zones**.<br>2. Click the **Name** of the zone in which you want to enable User-ID to open the Zone dialog.<br>3. Select the **Enable User Identification** check box and then click **OK**.<br>  |

 © Palo Alto Networks, Inc.

| Enable User- and Group-Based Policy (Continued) | |
|---|---|
| Step 2 Create security policies based on user and/or group.<br><br> As a best practice, create policies based on group rather than user whenever possible. This prevents you from having to continually update your policies (which requires a commit) whenever your user base changes. | 1. After configuring User-ID, you will be able to choose a user name or group name when defining the source or destination of a security rule:<br>a. Select **Policies > Security** and click **Add** to create a new policy or click on an existing policy rule name to open the Security Policy Rule dialog.<br>b. Specify which users and/or groups to match in the policy in one of the following ways:<br>– If you want to specify specific users/groups as matching criteria, select the **User** tab and click the **Add** button in the Source User section to display a list of users and groups discovered by the firewall group mapping function. Select the users and/or groups to add to the policy.<br>– If you want the policy to match any user who has or has not successfully authenticated and you don't need to know the specific user or group name, select **known-user** or **unknown** from the drop-down list above the **Source User** list.<br>2. Configure the rest of the policy as appropriate and then click **OK** to save it. For details on other fields in the security policy, see Set Up Basic Security Policies. |

| Enable User- and Group-Based Policy (Continued) | |
|---|---|
| Step 3 Create your Captive Portal policies. | 1. Select **Policies > Captive Portal**.<br>2. Click **Add** and enter a **Name** for the policy.<br>3. Define the matching criteria for the rule by completing the **Source**, **Destination**, and **Service/URL Category** tabs as appropriate to match the traffic you want to authenticate. The matching criteria on these tabs is the same as the criteria you define when creating a security policy. See Set Up Basic Security Policies for details.<br>4. Define the **Action** to take on traffic that matches the rule:<br>• **no-captive-portal**—Allow traffic to pass without presenting a Captive Portal page for authentication.<br>• **web-form**—Present a Captive Portal page for the user to explicitly enter authentication credentials or use client certificate authentication.<br>• **browser-challenge**—Open an NTLM authentication request to the web browser of the user. The web browser will respond using the current login credentials of the user. If the login credentials are not available, the user will be prompted to supply them. If you select this action, you must enable NT LAN Manager (NTLM) authentication when you Configure Captive Portal. If NTLM authentication fails, the firewall falls back to **web-form** authentication.<br>5. Click **OK**.<br>The following example shows a Captive Portal policy that instructs the firewall to present a web form to authenticate unknown users who send HTTP requests from the trust zone to the untrust zone.<br>  |
| Step 4 Save your policy settings. | Click **Commit**. |

 © Palo Alto Networks, Inc.

# Verify the User-ID Configuration

After you configure group mapping and user mapping and enable User-ID on your security policies and Captive Portal policies, you should verify that it is working properly.

| Verify the User-ID Configuration | |
|---|---|
| Step 1 Verify that group mapping is working. | From the CLI, enter the following command:<br>**show user group-mapping statistics** |
| Step 2 Verify that user mapping is working. | If you are using the on-device User-ID agent, you can verify this from the CLI using the following command:<br>**show user ip-user-mapping-mp all**<br><br>IP Vsys From User Timeout (sec)<br>---<br>192.168.201.1 vsys1 UIA acme\george 210<br>192.168.201.11 vsys1 UIA acme\duane 210<br>192.168.201.50 vsys1 UIA acme\betsy 210<br>192.168.201.10 vsys1 UIA acme\administrator 210<br>192.168.201.100 vsys1 AD acme\administrator 748<br>Total: 5 users<br>*: WMI probe succeeded |

| Verify the User-ID Configuration (Continued) | |
|---|---|
| Step 3 Test your security policy. | • From a machine in the zone where User-ID is enabled, attempt to access sites and applications to test the rules you defined in your policy and ensure that traffic is allowed and denied as expected.<br>• You can also use the `test security-policy-match` command to determine whether the policy is configured correctly. For example, suppose you have a rule that blocks user duane from playing World of Warcraft, you could test the policy as follows:<br>`test security-policy-match application worldofwarcraft source-user acme\duane source any destination any destination-port any protocol 6`<br><br>`"deny worldofwarcraft" {`<br>`from corporate;`<br>`source any;`<br>`source-region any;`<br>`to internet;`<br>`destination any;`<br>`destination-region any;`<br>`user acme\duane;`<br>`category any;`<br>`application/service worldofwarcraft;`<br>`action deny;`<br>`terminal no;`<br>`}` |

 © Palo Alto Networks, Inc.

**Verify the User-ID Configuration (Continued)**

Step 4 Test your Captive Portal configuration.

1. From the same zone, go to a machine that is not a member of your directory, such as a Mac OS system, and try to ping to a system external to the zone. The ping should work without requiring authentication.
2. From the same machine, open a browser and navigate to a web site in a destination zone that matches a Captive Portal policy you defined. You should see the Captive Portal web form.

3. Log in using the correct credentials and confirm that you are redirected to the requested page.
4. You can also test your Captive Portal policy using the `test cp-policy-match` command as follows:

```
test cp-policy-match from corporate to internet
source 192.168.201.10 destination 8.8.8.8

Matched rule: 'captive portal' action: web-form
```

Step 5 Verify that user names are displayed in the log files (**Monitor > Logs**).

**Verify the User-ID Configuration (Continued)**

Step 6 Verify that user names are displayed in reports (**Monitor > Reports**). For example, when drilling down into the denied applications report, you should see a list of the users who attempted to access the applications as in the following example.

# App-ID

To safely enable applications on your network, the Palo Alto Networks next-generation firewalls provide both an application and web perspective—App-ID and URL Filtering—to protect against a full spectrum of legal, regulatory, productivity, and resource utilization risks.

App-ID enables visibility into the applications on the network, so you can learn how they work, understand their behavioral characteristics and their relative risk. This application knowledge allows you to create and enforce security policies to enable, inspect, and shape desired applications and block undesired applications. When you define policies to begin allowing traffic, App-ID begins to classify traffic without any additional configuration.

- App-ID Overview
- Manage Custom or Unknown Applications
- Best Practices for Using App-ID in Policy
- Applications with Implicit Support
- About Application Level Gateways
- Disable the SIP Application-level Gateway (ALG)

# App-ID Overview

App-ID, a patented traffic classification system only available in Palo Alto Networks firewalls, determines what the application is irrespective of port, protocol, encryption (SSH or SSL) or any other evasive tactic used by the application. It applies multiple classification mechanisms—application signatures, application protocol decoding, and heuristics—to your network traffic stream to accurately identify applications.

Here's how App-ID identifies applications traversing your network:

- Traffic is matched against policy to check whether it is allowed on the network.
- Signatures are then applied to allowed traffic to identify the application based on unique application properties and related transaction characteristics. The signature also determines if the application is being used on its default port or it is using a non-standard port. If the traffic is allowed by policy, the traffic is then scanned for threats and further analyzed for identifying the application more granularly.
- If App-ID determines that encryption (SSL or SSH) is in use, and a decryption policy is in place, the session is decrypted and application signatures are applied again on the decrypted flow.
- Decoders for known protocols are then used to apply additional context-based signatures to detect other applications that may be tunneling inside of the protocol (e.g., Yahoo! Instant Messenger used across HTTP). Decoders validate that the traffic conforms to the protocol specification and provide support for NAT traversal and opening dynamic pinholes for applications such as SIP and FTP.
- For applications that are particularly evasive and cannot be identified through advanced signature and protocol analysis, heuristics or behavioral analysis may be used to determine the identity of the application.

When the application is identified, the policy check determines how to treat the application, for example—block, or allow and scan for threats, inspect for unauthorized file transfer and data patterns, or shape using QoS.

 © Palo Alto Networks, Inc.

# Manage Custom or Unknown Applications

Palo Alto Networks provides weekly App-ID updates to identify new applications. By default, App-ID is always enabled on the firewall, and you don't need to enable a series of signatures to identify well-known applications. Typically, the only applications that are classified as *unknown* traffic—*tcp, udp or non-syn-tcp*—in the ACC and the traffic logs are commercially available applications that have not yet been added to App-ID, internal or custom applications on your network, or potential threats.

On occasion, the firewall may report an application as unknown for the following reasons:

- Incomplete data—A handshake took place, but no data packets were sent prior to the timeout.
- Insufficient data—A handshake took place followed by one or more data packets; however, not enough data packets were exchanged to identify the application.

The following choices are available to handle unknown applications:

- Create security policies to control unknown applications by unknown TCP, unknown UDP or by a combination of source zone, destination zone, and IP addresses.
- Request an App-ID from Palo Alto Networks—If you would like to inspect and control the applications that traverse your network, for any unknown traffic, you can record a packet capture. If the packet capture reveals that the application is a commercial application, you can submit this packet capture to Palo Alto Networks for App-ID development. If it is an internal application, you can create a custom App-ID and/or define an application override policy.
- Create a custom App-ID with a signature and attach it to a security policy, or create a custom App-ID and define an application override policy—A custom App-ID allows you to customize the definition of the internal application—its characteristics, category and sub-category, risk, port, timeout—and exercise granular policy control in order to minimize the range of unidentified traffic on your network. Creating a custom App-ID also allows you to correctly identify the application in the ACC and traffic logs and is useful in auditing/reporting on the applications on your network. For a custom application you can specify a signature and a pattern that uniquely identifies the application and attach it to a security policy that allows or denies the application.

In order to collect the right data to create a custom application signature, you'll need a good understanding of packet captures and how datagrams are formed. If the signature is created too broadly you might inadvertently include other similar traffic; if it is defined too narrowly, the traffic will evade detection if it does not strictly match the pattern.

Custom App-IDs are stored in a separate database on the firewall and this database is not impacted by the weekly App-ID updates.

The supported application protocol decoders that enables the firewall to detect applications that may be tunneling inside of the protocol include the following as of content update 424: HTTP, HTTPS, DNS, FTP, IMAP SMTP, Telnet, IRC (Internet Relay Chat), Oracle, RTMP, RTSP, SSH, GNU-Debugger, GIOP (Global Inter-ORB Protocol), Microsoft RPC, Microsoft SMB (also known as CIFS). Additionally, with the 4.0 release of PAN-OS this custom App-ID capability has been expanded to include unknown TCP and unknown UDP as well.

Alternatively, if you would like the firewall to process the custom application using fast path (Layer-4 inspection instead of using App-ID for Layer-7 inspection), you can reference the custom App-ID in an application override policy. An application override with a custom application will prevent the session from being processed by the App-ID engine, which is a Layer-7 inspection. Instead it forces the firewall to handle the session as a regular stateful inspection firewall at Layer-4, and thereby saves application processing time.

© Palo Alto Networks, Inc.

For example, if you build a custom application that triggers on a host header *www.mywebsite.com*, the packets are first identified as *web-browsing* and then are matched as your custom application (whose parent application is web-browsing). Because the parent application is web-browsing, the custom application is inspected at Layer-7 and scanned for content and vulnerabilities.

If you define an application override, the firewall stops processing at Layer-4. The custom application name is assigned to the session to help identify it in the logs, and the traffic is not scanned for threats.

For more details, refer to the following articles:

- Identifying Unknown Applications
- Video: How to Configure a Custom App-ID
- Custom Application Signatures

 © Palo Alto Networks, Inc.

# Best Practices for Using App-ID in Policy

- Review the ACC for the list of applications on your network, and determine which applications to allow or block. If you are migrating from a firewall where you defined port-based rules, to get a list of applications that run on a given port search by the port number in the application browser (**Objects > Applications**) on the Palo Alto Networks firewall or in Applipedia.
- Use **application-default** for the **Service**. The firewall compares the port used with the list of default ports for that application. If the port used is not a default port for the application, the firewall drops the session and logs the message **appid policy lookup deny**. If you have a application that is accessed on many ports and you would like to limit the ports on which the application is used, specify it in **Service**/**Service Group** objects in policies.
- Use application filters to dynamically include new applications in existing policy rules. See an example.

# Applications with Implicit Support

When creating a policy to allow specific applications, you must also be sure that you are allowing any other applications on which the application depends. In many cases, you do not have to explicitly allow access to the dependent applications in order for the traffic to flow because the firewall is able to determine the dependencies and allow them implicitly. This implicit support also applies to custom applications that are based on HTTP, SSL, MS-RPC, or RTSP. Applications for which the firewall cannot determine dependent applications on time will require that you explicitly allow the dependent applications when defining your policies. You can determine application dependencies in Applipedia.

The following table lists the applications for which the firewall has implicit support (as of Content Update 469).

**Table: Applications with Implicit Support**

| Application | Implicitly Supports |
|---|---|
| 360-safeguard-update | http |

# About Application Level Gateways

The Palo Alto Networks firewall does not classify traffic by port and protocol; instead it identifies the application based on its unique properties and transaction characteristics using the App-ID technology. Some applications, however, require the firewall to dynamically open *pinholes* to establish the connection, determine the parameters for the session and negotiate the ports that will be used for the transfer of data; these applications use the application-layer payload to communicate the dynamic TCP or UDP ports on which the application opens data connections. For such applications, the firewall serves as an Application Level Gateway (ALG), and it opens a pinhole for a limited time and for exclusively transferring data or control traffic. The firewall also performs a NAT rewrite of the payload when necessary.

The Palo Alto Networks firewall functions as an ALG for the following protocols: FTP, SIP, H.323, RTSP, Oracle/SQLNet/TNS, MGCP, Unistim, SCCP, protocols.

When the firewall serves as an ALG for the Session Initiation Protocol (SIP), by default it performs NAT on the payload and opens dynamic pinholes for media ports. In some cases, depending on the SIP applications in use in your environment, the SIP endpoints have NAT intelligence embedded in their clients. In such cases, you might need to disable the SIP ALG functionality to prevent the firewall from modifying the signaling sessions. When SIP ALG is disabled, if App-ID determines that a session is SIP, the payload is not translated and dynamic pinholes are not opened. See Disable the SIP Application-level Gateway (ALG).

# Disable the SIP Application-level Gateway (ALG)

The Palo Alto Networks firewall uses the Session Initiation Protocol (SIP) application-level gateway (ALG) to open dynamic pinholes in the firewall where NAT is enabled. However, some applications—such as VoIP—have NAT intelligence embedded in the client application. In these cases, the SIP ALG on the firewall can interfere with the signaling sessions and cause the client application to stop working.

One solution to this problem is to define an Application Override Policy for SIP, but using this approach disables the App-ID and threat detection functionality. A better approach is to disable the SIP ALG, which does not disable App-ID or threat detection.

The following procedure describes how to disable the SIP ALG.

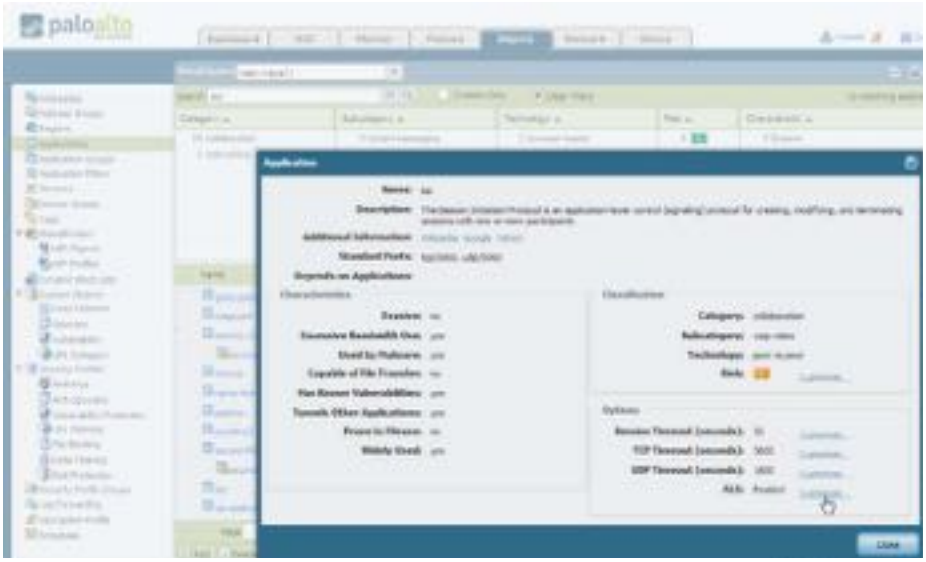
**Disable the SIP ALG**

Step 1 Select **Objects > Applications**.

Step 2 Select the **sip** application.

You can type **sip** in the **Search** box to help find the sip application.

Step 3 Select **Customize...** for **ALG** in the Options section of the Application dialog box.



Step 4 Select the **Disable ALG** check box in the Application - sip dialog box and click **OK**.

Step 5 **Close** the Application dialog box and **Commit** the change.

# Threat Prevention

The Palo Alto Networks next-generation firewall protects and defends your network from commodity threats and advanced persistent threats (APTs). The firewall's multi-pronged detection mechanisms include a signature-based (IPS/Command and Control/Antivirus) approach, heuristics-based (bot detection) approach, sandbox-based (WildFire) approach, and Layer 7 protocol analysis-based (App-ID) approach.

Commodity threats are exploits that are less sophisticated and more easily detected and prevented using a combination of the antivirus, anti-spyware, vulnerability protection and the URL filtering/Application identification capabilities on the firewall.

Advanced threats are perpetuated by organized cyber criminals or malicious groups that use sophisticated attack vectors to target your network, most commonly for intellectual property theft and financial data theft. These threats are more evasive and require intelligent monitoring mechanisms for detailed host and network forensics on malware. The Palo Alto Networks next-generation firewall in conjunction with WildFire and Panorama provides a comprehensive solution that intercepts and break the attack chain and provides visibility to prevent security infringement on your network—including mobile and virtualized—infrastructure.

# License the Threat Prevention Features

The following sections describe the available licenses required to utilize threat prevention features and describes the activation process:

▲ About Threat Prevention Licenses

▲ Obtain and Install Licenses

## About Threat Prevention Licenses

The following is the list of licenses required for enabling all the threat prevention features on the firewall:

- **Threat Prevention**—Provides antivirus, anti-spyware, and vulnerability protection.
- **URL Filtering**—Provides the ability to control access to websites based on URL category. You can purchase and install a subscription for PAN-DB (Palo Alto Networks database) or the BrightCloud URL filtering databases.
- **WildFire**—The WildFire feature is included as part of the base product. This means that anyone can configure a file blocking profile to forward Portable Executable (PE) files to WildFire for analysis. A threat prevention subscription is required in order to receive antivirus signature updates, which include signatures discovered by WildFire.

  The WildFire subscription service provides enhanced services for organizations that require immediate security, enabling sub-hourly WildFire signature updates, advanced file type forwarding (APK, PDF, Microsoft Office, and Java Applet), as well as the ability to upload files using the WildFire API. A WildFire subscription is also required if your firewalls will be forwarding files to a private WF-500 WildFire appliance.
- **Decryption Port Mirror—**Provides the ability to create a copy of decrypted traffic from the firewall and send it to a traffic collection tool that is capable of receiving raw packet captures—such as NetWitness or Solera—for archiving and analysis.Currently this license is available free of charge through the Palo Alto Networks Support Portal; this feature is supported on the PA-7050, PA-5000 Series and PA-3000 Series platforms only. For more information, see Configure Decryption Port Mirroring.

## Obtain and Install Licenses

To purchase licenses, contact the Palo Alto Networks sales department. After you obtain a license, navigate to **Device > Licenses**.

You can perform the following tasks depending on how you receive your licenses:

- **Retrieve license keys from license server**—Use this option if your license has been activated on the support portal.
- **Activate feature using authorization code**—Use this option to enable purchased subscriptions using an authorization code for licenses that have not been previously activated on the support portal.

 © Palo Alto Networks, Inc.

- **Manually upload license key**—Use this option if your device does not have connectivity to the Palo Alto Networks support site. In this case, you must download a license key file from the support site on an Internet connected computer and then upload to the device.

For more details about registering and activating licenses on your firewall, see Activate Licenses.

# About Security Profiles

Security profiles provide threat protection in security policies. For example, you can apply an antivirus profile to a security policy and all traffic that matches the security policy will be scanned for viruses.

For basic configuration examples to help you get started with these features, see Set Up Security Profiles and Policies.

The following table provides an overview of the security profiles that can be applied to security policies as well as a basic description of DoS and Zone Protection profiles:

| Threat Prevention Feature | Description |
|---|---|
| Antivirus | Protects against viruses, worms, and trojans as well as spyware downloads. Using a stream-based malware prevention engine, which inspects traffic the moment the first packet is received, the Palo Alto Networks antivirus solution can provide protection for clients without significantly impacting the performance of the firewall. This feature will scan for a wide variety of malware in executables, PDF files, HTML and JavaScript viruses, including support for scanning inside compressed files and data encoding schemes. Scanning of decrypted content can be performed by enabling decryption on the firewall.<br>The default profile inspects all of the listed protocol decoders for viruses, and generates alerts for SMTP, IMAP, and POP3 protocols while blocking for FTP, HTTP, and SMB protocols. Customized profiles can be used to minimize antivirus inspection for traffic between trusted security zones, and to maximize the inspection of traffic received from untrusted zones, such as the Internet, as well as the traffic sent to highly sensitive destinations, such as server farms.<br>The Palo Alto Networks WildFire system also provides signatures for persistent threats that are more evasive and have not yet been discovered by other antivirus solutions. As threats are discovered by WildFire, signatures are quickly created and then integrated into the standard antivirus signatures that can be downloaded by Threat Prevention subscribers on a daily basis (sub-hourly for WildFire subscribers). |

 © Palo Alto Networks, Inc.

| Threat Prevention Feature | Description |
|---|---|
| Anti-spyware | Blocks attempts from spyware on compromised hosts trying to phone-home or beacon out to external command-and-control (C2) servers. You can apply various levels of protection between zones. For example, you may want to have custom anti-spyware profiles that minimize inspection between trusted zones, while maximizing inspection on traffic received from an untrusted zone, such as Internet facing zones.<br>You can choose between two pre-defined profiles when applying anti-spyware to a security policy.<br>• **Default**—The default profile will use the default action for every signature, as specified by Palo Alto Networks when the signature is created.<br>• **Strict**—The strict profile will override the action of critical, high, and medium severity threats to the block action, regardless of the action defined in the signature file. The default action is taken with medium and informational severity signatures.<br>In PAN-OS 6.0, the DNS sinkhole feature has been added. The DNS sinkhole action that can be enabled in Anti-Spyware profiles enables the firewall to forge a response to a DNS query for a known malicious domain, causing the malicious domain name to resolve to an IP address that you define. This feature can be used to identify infected hosts on the protected network using DNS traffic in situations where the firewall cannot see the infected client's DNS query (That is, the firewall cannot see the originator of the DNS query). In a typical deployment where the firewall is north of the local DNS server, the threat log will identify the local DNS resolver as the source of the traffic rather than the actual infected host. Sinkholing malware DNS queries solves this visibility problem by forging responses to the client host queries directed at malicious domains, so that clients attempting to connect to malicious domains (for command-and-control, for example) will instead attempt to connect to a sinkhole IP address you define. Infected hosts can then be easily identified in the traffic and threat logs because any host that attempts to connect to the sinkhole IP address are most likely infected with malware. Anti-spyware and vulnerability protection profiles are configured similarly. With anti-spyware, the main purpose is to detect malicious traffic leaving the network from infected clients, whereas vulnerability protection protects against threats entering the network. |
| Vulnerability Protection | Stops attempts to exploit system flaws or gain unauthorized access to systems. For example, this feature will protect against buffer overflows, illegal code execution, and other attempts to exploit system vulnerabilities. The default vulnerability protection profile protects clients and servers from all known critical, high, and medium-severity threats. You can also create exceptions, which allow you to change the response to a specific signature.<br>Anti-spyware and vulnerability protection profiles are configured similarly. With vulnerability protection, the main purpose is to detect malicious traffic entering the network from infected clients, whereas anti-spyware protection protects against threats leaving the network. |
| URL Filtering | Provides the ability to control user web traffic based on specific websites and/or website categories such as adult, shopping, gambling, and so on. The Palo Alto Networks PAN-DB URL database, or the BrightCloud database are available for categorization and enforcing URL Filtering policies on the firewall. |

| Threat Prevention Feature | Description |
|---|---|
| Data Filtering | Helps to prevent sensitive information such as credit card or social security numbers from leaving a protected network. You can also filter on key words, such as a sensitive project name and the word confidential. It is important to focus your profile on the desired file types to reduce false positives. For example, you may only want to search Word documents or Excel spreadsheets. You may also only want to scan web-browsing traffic, or FTP.<br><br>You can use default profiles, or create custom data patterns. There are two default profiles:<br>• **CC# (Credit Card)**—Identifies credit card numbers using a hash algorithm. The content must match the hash algorithm in order for data to be detected as a credit card number. This method will reduce false positives.<br>• **SSN# (Social Security Number)**—Uses an algorithm to detect nine digit numbers, regardless of format. There are two fields: **SSN#** and **SSN# (no dash)**.<br><br>Weight and Threshold Values<br><br>It is important to understand how the weight of an object (SSN, CC#, pattern) is calculated in order to set the appropriate threshold for a condition you are trying to filter. Each occurrence multiplied by the weight value will be added together in order to reach an action threshold (alert or block).<br><br>Example 1<br><br>For simplicity, if you only want to filter files with Social Security Numbers (SSN) and you define a weight of 3 for SSN#, you would use the following formula: each instance of a SSN x weight = threshold increment. In this case, if a Word document has 10 social security numbers you multiply that by the weight of 3, so 10 x 3 = 30. In order to take action for a file that contains 10 social security numbers you would set the threshold to 30. You may want to set an alert at 30 and then block at 60. You may also want to set a weight in the field SSN# (no dash) for Social Security Numbers that do not contain dashes. If multiple settings are used, they will accumulate to reach a given threshold.<br><br>Example 2<br><br>In this example, we will filter on files that contain Social Security Numbers and the custom pattern confidential. In other words, if a file has Social Security Numbers in addition to the word confidential and the combined instances of those items hit the threshold, the file will trigger an alert or block, depending on the action setting.<br>`SSN# weight = 3`<br>`Custom Pattern confidential weight = 20`<br> The custom pattern is case sensitive.<br><br>If the file contains 20 Social Security Numbers and a weight of 3 is configured, that is 20 x 3 = 60. If the file also contains one instance of the term confidential and a weight of 20 is configured, that is 1 x 20 = 20 for a total of 80. If your threshold for block is set to 80, this scenario would block the file. The alert or block action will be triggered as soon as the threshold is hit. |

 © Palo Alto Networks, Inc.

| Threat Prevention Feature | Description |
|---|---|
| File Blocking | Blocks specified file types over specified applications and in the specified session flow direction (inbound/outbound/both). You can set the profile to alert or block on upload and/or download and you can specify which applications will be subject to the file blocking profile. You can also configure custom block pages that will appear when a user attempts to download the specified file type. This allows the user to take a moment to consider whether or not they want to download a file.<br>The following actions can be set when the specified file is detected:<br>• **Alert**—When the specified file type is detected, a log is generated in the data filtering log.<br>• **Block**—When the specified file type is detected, the file is blocked and a customizable block page is presented to the user. A log is also generated in the data filtering log.<br>• **Continue**—When the specified file type is detected, a customizable continuation page is presented to the user. The user can click through the page to download the file. A log is also generated in the data filtering log.<br>• **Forward**—When the specified file type is detected, the file is sent to WildFire for analysis. A log is also generated in the data filtering log.<br>• **Continue-and-forward**—When the specified file type is detected, a customizable continuation page is presented to the user. The user can click through the page to download the file. If the user clicks through the continue page to download the file, the file is sent to WildFire for analysis. A log is also generated in the data filtering log. |
| DoS Protection | Provide detailed control for Denial of Service (DoS) protection policies. DoS policies allow you to control the number of sessions between interfaces, zones, addresses, and countries based on aggregate sessions or source and/or destination IP addresses. There are two DoS protection mechanisms that the Palo Alto Networks firewalls support.<br>• **Flood Protection**—Detects and prevents attacks where the network is flooded with packets resulting in too many half-open sessions and/or services being unable to respond to each request. In this case the source address of the attack is usually spoofed.<br>• **Resource Protection**— Detects and prevent session exhaustion attacks. In this type of attack, a large number of hosts (bots) are used to establish as many fully established sessions as possible to consume all of a system's resources.<br>Both of these protection mechanisms can be defined in a single DoS profile.<br>The DoS profile is used to specify the type of action to take and details on matching criteria for the DoS policy. The DoS profile defines settings for SYN, UDP, and ICMP floods, can enable resource protect and defines the maximum number of concurrent connections. After you configure the DoS protection profile, you then attach it to a DoS policy.<br>When configuring DoS protection, it is important to analyze your environment in order to set the correct thresholds and due to some of the complexities of defining DoS protection policies, this guide will not go into detailed examples. For more information, refer to the Threat Prevention Tech Note. |

| Threat Prevention Feature | Description |
|---|---|
| Zone Protection | Provides additional protection between specific network zones in order to protect the zones against attack. The profile must be applied to the entire zone, so it is important to carefully test the profiles in order to prevent issues that may arise with the normal traffic traversing the zones. When defining packets per second (pps) thresholds limits for zone protection profiles, the threshold is based on the packets per second that do not match a previously established session. For more information, refer to the Threat Prevention Tech Note. |

 © Palo Alto Networks, Inc.

# Set Up Security Profiles and Policies

The following sections provide basic threat prevention configuration examples:

- Set Up Antivirus, Anti-spyware, and Vulnerability Protection
- Set Up Data Filtering
- Set Up File Blocking

For information on controlling web access as part of your threat prevention strategy, see URL Filtering.

## Set Up Antivirus, Anti-spyware, and Vulnerability Protection

The following describes the steps needed to set up the default Antivirus, Anti-spyware, and Vulnerability Protection profiles. These features are very similar in purpose, so the following steps are just general steps needed to enable the default profiles.

All Anti-spyware and Vulnerability Protection signatures have a default action defined by Palo Alto Networks. You can view the default action by navigating to **Objects > Security Profiles > Anti-Spyware** or **Objects > Security Profiles >Vulnerability Protection** and then selecting a profile. Click the **Exceptions** tab and then click **Show all signatures** and you will see a list of the signatures with the default action in the Action column. To change the default action, you must create a new profile and then create rules with a non-default action, and/or add individual signature exceptions to **Exceptions** in the profile.

| **Set up Antivirus/Anti-spyware/Vulnerability Protection** | | |
|---|---|---|
| Step 1 | Verify that you have a Threat Prevention license. | • The Threat Prevention license bundles the Antivirus, Anti-spyware, and the Vulnerability Protection features in one license.<br>• Select **Device > Licenses** to verify that the **Threat Prevention** license is installed and check the expiration date. |
| Step 2 | Download the latest antivirus threat signatures. | 1. Select **Device > Dynamic Updates** and click **Check Now** at the bottom of the page to retrieve the latest signatures.<br>In the **Actions** column, click **Download** to install the latest Antivirus and Applications and Threats signatures. |

| Set up Antivirus/Anti-spyware/Vulnerability Protection (Continued) | |
|---|---|
| Step 3 Schedule signature updates. | 1. From **Device > Dynamic Updates**, click the text to the right of **Schedule** to automatically retrieve signature updates for **Antivirus** and **Applications and Threats**.<br>2. Specify the frequency and timing for the updates and whether the update will be downloaded and installed or only downloaded. If you select **Download Only**, you would need to manually go in and click the **Install** link in the **Action** column to install the signature. When you click **OK**, the update is scheduled. No commit is required.<br>3. (Optional) You can also enter the number of hours in the **Threshold** field to indicate the minimum age of a signature before a download will occur. For example, if you entered **10**, the signature must be at least 10 hours old before it will be downloaded, regardless of the schedule.<br>4. In an HA configuration, you can also click the **Sync To Peer** option to synchronize the content update with the HA peer after download/install. This will not push the schedule settings to the peer device, you need to configure the schedule on each device. |

### Best Practices for Antivirus Schedules

The general recommendation for antivirus signature update schedules is to perform a **download-and-install** on a daily basis for antivirus and weekly for applications and vulnerabilities.

#### Recommendations for HA Configurations:

- **Active/Passive HA**—If the MGT port is used for antivirus signature downloads, you should configure a schedule on both devices and both devices will download/install independently. If you are using a data port for downloads, the passive device will not perform downloads while it is in the passive state. In this case you would set a schedule on both devices and then select the **Sync To Peer** option. This will ensure that whichever device is active, the updates will occur and will then push to the passive device.
- **Active/Active HA**—If the MGT port is used for antivirus signature downloads on both devices, then schedule the download/install on both devices, but do not select the **Sync To Peer** option. If you are using a data port, schedule the signature downloads on both devices and select **Sync To Peer**. This will ensure that if one device in the active/active configuration goes into the active-secondary state, the active device will download/install the signature and will then push it to the active-secondary device.

 © Palo Alto Networks, Inc.

| Set up Antivirus/Anti-spyware/Vulnerability Protection (Continued) | |
|---|---|
| Step 4 Attach the security profiles to a security policy. | 1. Select **Policies > Security**, select the desired policy to modify it and then click the **Actions** tab.<br>2. In **Profile Settings**, click the drop-down next to each security profile you would like to enable. In this example we choose default for **Antivirus, Vulnerability Protection,** and **Anti-spyware**.<br>If no security profiles have been previously defined, select **Profiles** from the **Profile Type** drop-down. You will then see the list of options to select the security profiles.<br>  |
| Step 5 Save the configuration. | Click **Commit**. |

## Set Up Data Filtering

The following describes the steps needed to configure a data filtering profile that will detect Social Security Numbers and a custom pattern identified in .doc and .docx documents.

| Data Filtering Configuration Example | | |
|---|---|---|
| Step 1 | Create a Data Filtering security profile. | 1. Select **Objects > Security Profiles > Data Filtering** and click **Add**.<br>2. Enter a **Name** and a **Description** for the profile. In this example the name is *DF_Profile1* with the description *Detect Social Security Numbers*.<br>3. (Optional) If you want to collect data that is blocked by the filter, select the **Data Capture** check box.<br> You must set a password as described in Step 2 if you are using the data capture feature. |
| Step 2 | (Optional) Secure access to the data filtering logs to prevent other administrators from viewing sensitive data.<br>When you enable this option, you will be prompted for the password when you view logs in **Monitor > Logs > Data Filtering**. | 1. Select **Device > Setup > Content-ID**.<br>2. Click **Manage Data Protection** in the Content-ID Features section.<br>3. Set the password that will be required to view the data filtering logs. |

 © Palo Alto Networks, Inc.

**Data Filtering Configuration Example (Continued)**

Step 3 Define the data pattern that will be used in the Data Filtering Profile.

In this example, we will use the keyword **confidential** and will set the option to search for SSN numbers with dashes (Example - 987-654-4320).

It is helpful to set the appropriate thresholds and define keywords within documents to reduce false positives.

1. From the Data Filtering Profile page click **Add** and select **New** from the **Data Pattern** drop-down. You can also configure data patterns from **Objects > Custom Signatures > Data Patterns**.
2. For this example, name the Data Pattern signature **Detect SS Numbers** and add the description **Data Pattern to detect Social Security numbers**.
3. In the **Weight** section for **SSN#** enter **3**. See Weight and Threshold Values for more details.

4. (Optional) You can also set **Custom Patterns** that will be subject to this profile. In this case, you specify a pattern in the custom patterns **Regex** field and set a weight. You can add multiple match expressions to the same data pattern profile. In this example, we will create a **Custom Pattern** named **SSN_Custom** with a custom pattern of **confidential** (the pattern is case sensitive) and use a weight of **20**. The reason we use the term **confidential** in this example is because we know that our social security Word docs contain this term, so we define that specifically.

| Data Filtering Configuration Example (Continued) | | |
|---|---|---|
| Step 4 | Specify which applications to filter and set the file types. | 1. Set **Applications** to **Any.** This will detect any supported application such as: web-browsing, FTP, or SMTP. If you want to narrow down the application, you can select it from the list. For applications such as Microsoft Outlook Web App that uses SSL, you will need to enable decryption. Also make sure you understand the naming for each application. For example, Outlook Web App, which is the Microsoft name for this application is identified as the application **outlook-web** in the PAN-OS list of applications. You can check the logs for a given application to identify the name defined in PAN-OS.<br>2. Set **File Types** to **doc** and **docx** to only scan doc and docx files. |
| Step 5 | Specify the direction of traffic to filter and the threshold values. | 1. Set the **Direction** to **Both**. Files that are uploaded or downloaded will be scanned.<br>2. Set the **Alert Threshold** to **35.** In this case, an alert will be triggered if 5 instances of Social Security Numbers exist and 1 instance of the term **confidential** exists. The formula is 5 SSN instances with a weight of 3 = 15 plus 1 instance of the term confidential with a weight of 20 = 35.<br>3. Set the **Block Threshold** to **50**. The file will be blocked if the threshold of 50 instances of a SSN and/or the term confidential exists in the file. In this case, if the doc contained 1 instance of the word **confidential** with a weight of 20 that equals 20 toward the threshold, and the doc has 15 Social Security Numbers with a weight of 3 that equals 45. Add 20 and 45 and you have 65, which will exceed the block threshold of 50. |

 © Palo Alto Networks, Inc.

| Data Filtering Configuration Example (Continued) | | |
|---|---|---|
| Step 6 | Attach the Data Filtering profile to the security rule. | 1. Select **Policies > Security** and select the security policy rule to which to apply the profile.<br>2. Click the security policy rule to modify it and then click the **Actions** tab. In the **Data Filtering** drop-down, select the new data filtering profile you created and then click **OK** to save. In this example, the data filtering rule name is **DF_Profile1**.<br>  |
| Step 7 | **Commit** the configuration. | |
| Step 8 | Test the data filtering configuration.<br><br>If you have problems getting Data Filtering to work, you can check the Data Filtering log or the Traffic log to verify the application that you are testing with and make sure your test document has the appropriate number of unique Social Security Number instances. For example, an application such as Microsoft Outlook Web App may seem to be identified as web-browsing, but if you look at the logs, the application is **outlook-web**. Also increase the number of SSNs, or your custom pattern to make sure you are hitting the thresholds. | When testing, you must use real Social Security Numbers and each number must be unique. Also, when defining Custom Patterns as we did in this example with the word **confidential**, the pattern is case sensitive. To keep your test simple, you may want to just test using a data pattern first, then test the SSNs.<br>1. Access a client PC in the trust zone of the firewall and send an HTTP request to upload a .doc or .docx file that contains the exact information you defined for filtering.<br>2. Create a Microsoft Word document with one instance of the term confidential and five Social Security numbers with dashes.<br>3. Upload the file to a website. Use an HTTP site unless you have decryption configured, in which case you can use HTTPS.<br>4. Select **Monitoring > Logs > Data Filtering** logs.<br>5. Locate the log that corresponds to the file you just uploaded. To help filter the logs, use the source of your client PC and the destination of the web server. The action column in the log will show **reset-both**. You can now increase the number of Social Security Numbers in the document to test the block threshold.<br> |

# Set Up File Blocking

This example will describe the basic steps needed to set up file blocking and forwarding. In this configuration, we will configure the options needed to prompt users to continue before downloading .exe files from websites. When testing this example, be aware that you may have other systems between you and the source that may be blocking content.

| **Configure File Blocking** | | |
|---|---|---|
| Step 1 | Create the file blocking profile. | 1. Select **Objects > Security Profiles > File Blocking** and click **Add**.<br>2. Enter a **Name** for the file blocking profile, for example *Block_EXE*. Optionally enter a **Description**, such as *Block users from downloading exe files from websites.* |
| Step 2 | Configure the file blocking options. | 1. Click **Add** to define the profile settings.<br>2. Enter a **Name**, such as *BlockEXE*.<br>3. Set the **Applications** for filtering, for example **web-browsing**.<br>4. Set **File Types** to **exe**.<br>5. Set the **Direction** to **download**.<br>6. Set the **Action** to **continue**. By choosing the continue option, users will be prompted with a response page prompting them to click continue before the file will be downloaded.<br> <br>7. Click **OK** to save the profile. |
| Step 3 | Apply the file blocking profile to a security policy. | 1. Select **Policies > Security** and either select an existing policy or create a new policy as described in Set Up Basic Security Policies.<br>2. Click the **Actions** tab within the policy rule.<br>3. In the Profile Settings section, click the drop-down and select the file blocking profile you configured. In this case, the profile name is *Block_EXE*.<br>4. **Commit** the configuration.<br>If no security profiles have been previously defined, select the **Profile Type** drop-down and select **Profiles**. You will then see the list of options to select the security profiles. |

 © Palo Alto Networks, Inc.

**Configure File Blocking (Continued)**

Step 4 To test your file blocking configuration, access a client PC in the trust zone of the firewall and attempt to download a .exe file from a website in the untrust zone. A response page should display. Click **Continue** to download the file. You can also set other actions, such as alert only, forward (which will forward to WildFire), or block, which will not provide a continue page to the user. The following shows the default response page for File Blocking:

**Example: Default File Blocking Response Page**

Step 5 (Optional) Define custom file blocking response pages (**Device > Response Pages**). This allows you to provide more information to users when they see a response page. You can include information such as company policy information and contact information for a Helpdesk.

When you create a file blocking profile with the action continue or continue-and-forward (used for WildFire forwarding), you can only choose the application web-browsing. If you choose any other application, traffic that matches the security policy will not flow through the firewall due to the fact that the users will not be prompted with a continue page. Also, if the website uses HTTPS, you will need to have a decryption policy in place.

You may want to check your logs to confirm what application is being used when testing this feature. For example, if you are using Microsoft Sharepoint to download files, even though you are using a web-browser to access the site, the application is actually `sharepoint-base`, or `sharepoint-document`. You may want to set the application type to **Any** for testing.

# Prevent Brute Force Attacks

A brute force attack uses a large volume of requests/responses from the same source or destination IP address to break into a system. The attacker employs a trial-and-error method to guess the response to a challenge or a request.

The Vulnerability Protection profile on the firewall includes signatures to protect you from brute force attacks. Each signature has an ID, Threat Name, Severity and is triggered when a pattern is recorded. The pattern specifies the conditions and interval at which the traffic is identified as a brute-force attack; some signatures are associated with another child signature that is of a lower severity and specifies the pattern to match against. When a pattern matches against the signature or child signature, it triggers the default action for the signature.

To enforce protection:

- Attach the vulnerability profile to a security rule. See Set Up Antivirus, Anti-spyware, and Vulnerability Protection.
- Install content updates that include new signatures to protect against emerging threats. See Manage Content Updates.

 © Palo Alto Networks, Inc.

# Customize the Action and Trigger Conditions for a Brute Force Signature

The firewall includes two types of predefined brute force signatures—parent signature and child signature. A child signature is a single occurrence of a traffic pattern that matches the signature. A parent signature is associated with a child signature and is triggered when multiple events occur within a time interval and match the traffic pattern defined in the child signature.

Typically, a child signature is of default action *allow* because a single event is not indicative of an attack. In most cases, the action for a child signature is set to allow so that legitimate traffic is not blocked and threat logs are not generated for non-noteworthy events. Therefore, Palo Alto Networks recommends that you only change the default action after careful consideration.

In most cases, the brute force signature is a noteworthy event because of its recurrent pattern. If you would like to customize the action for a brute-force signature, you can do one of the following:

- Create a rule to modify the default action for all signatures in the brute force category. You can define the action to allow, alert, block, reset, or drop the traffic.
- Define an exception for a specific signature. For example, you can search for a CVE and define an exception for it.

  For a parent signature, you can modify both the trigger conditions and the action; for a child signature only the action can be modified.

To effectively mitigate an attack, the **block-ip address** action is recommended over the drop or reset action for most brute force signatures.

| **Customize the Threshold and Action for a Signature** | | |
|---|---|---|
| Step 1 | Create a new Vulnerability Protection Profile. | 1. Select **Objects > Security Profiles > Vulnerability Protection**.<br>2. Click **Add** and enter a **Name** for the Vulnerability Protection Profile. |
| Step 2 | Create a rule that defines the action for all signatures in a category.<br> | 1. Select **Rules**, click **Add** and enter a **Name** for the rule.<br>2. Set the **Action**. In this example, it is set to **Block**.<br>3. Set **Category** to **brute-force**.<br>4. (Optional) If blocking, specify whether to block server or client, the default is any.<br>5. See Step 3 to customize the action for a specific signature.<br>6. See Step 4 to customize the trigger threshold for a parent signature.<br>7. Click **OK** to save the rule and the profile. |

| Customize the Threshold and Action for a Signature | |
|---|---|
| Step 3 (Optional) Customize the action for a specific signature.<br> <br> | 1. Select **Exceptions** and click **Show all signatures** to find the signature you want to modify.<br>To view all the signatures in the brute-force category, search for ( category contains 'brute-force' ).<br>2. To edit a specific signature, click the predefined default action in the **Action** column.<br>3. Set the action to **allow**, **alert** or **block-ip**.<br>4. If you select block-ip, complete these additional tasks:<br>a. Specify the **Time** period (in seconds) after which to trigger the action.<br>b. In the **Track By** field, define whether to block the IP address by **IP source** or by **IP source and destination**.<br>  <br>5. Click **OK**<br>6. For each modified signature, select the checkbox in the **Enable** column.<br>7. Click **OK**. |
| Step 4 Customize the trigger conditions for a parent signature.<br>A parent signature that can be edited is marked with this icon .<br>In this example, the search criteria was brute force category and CVE-2008-1447. | 1. Click to edit the time attribute and the aggregation criteria for the signature.<br> <br>2. To modify the trigger threshold specify the **Number of Hits** *per x* **seconds**.<br>3. Specify whether to aggregate the number of hits by **source**, **destination** or by **source and destination**.<br>4. Click **OK**. |
| Step 5 Attach this new profile to a security rule. | |
| Step 6 Save your changes. | 1. Click **Commit**. |

© Palo Alto Networks, Inc.

# Best Practices for Securing Your Network from Layer 4 and Layer 7 Evasions

To monitor and protect your network from most Layer 4 and Layer 7 attacks, here are a few recommendations.

- Upgrade to the most current PAN-OS software version and content release version to ensure that you have the latest security updates. See Manage Content Updates and Install Software Updates.
- For web servers, create a security policy to only allow the protocols that the server supports. For example, ensure that only HTTP traffic is allowed to a web server. If you have defined an application override policy for a custom application, make sure to restrict access to specific source zone or set of IP addresses.
- Attach the following security profiles to your security policies to provide signature-based protection.
  - Create a vulnerability protection profile to block all vulnerabilities with severity low and higher.
  - Create a anti-spyware profile to block all spyware.
  - Create an antivirus profile to block all content that matches an antivirus signature.
- Block all unknown applications/traffic using security policy. Typically, the only applications that are classified as unknown traffic are internal or custom applications on your network, or potential threats. Because unknown traffic can be a non-compliant application or protocol that is anomalous or abnormal, or a known application that is using non-standard ports, unknown traffic should be blocked. See Manage Custom or Unknown Applications.
- Create a file blocking profile that blocks Portable Executable (PE) file types for Internet-based SMB (Server Message Block) traffic from traversing the trust to untrust zones, (ms-ds-smb applications).
- Create a zone protection profile that is configured to drop mismatched and overlapping TCP segments, to protect against packet-based attacks.

  By deliberately constructing connections with overlapping but different data in them, attackers can attempt to cause misinterpretation of the intent of the connection. This can be used to deliberately induce false positives or false negatives. An attacker can use IP spoofing and sequence number prediction to intercept a user's connection and inject his/her own data into the connection. PAN-OS uses this field to discard such frames with mismatched and overlapping data. The scenarios where the received segment will be discarded are:
  - The segment received is contained within another segment.
  - The segment received overlaps with part of another segment.
  - The segment completely contains another segment.
- Verify that support for IPv6 is enabled, if you have configured IPv6 addresses on your network hosts. (**Network > Interfaces > Ethernet> IPv6**)

  This allows access to IPv6 hosts and filters IPv6 packets that are encapsulated in IPv4 packets. Enabling support for IPv6 prevents IPv6 over IPv4 multicast addresses from being leveraged for network reconnaissance.

© Palo Alto Networks, Inc.

- Enable support for multicast traffic so that the firewall can enforce policy on multicast traffic. (**Network > Virtual Router > Multicast)**
- Enable the following CLI command to clear the URG bit flag in the TCP header and disallow out-of-band processing of packets.

  The urgent pointer in the TCP header is used to promote a packet for immediate processing by removing it from the processing queue and expediting it through the TCP/IP stack on the host. This process is called out-of-band processing. Because the implementation of the urgent pointer varies by host, to eliminate ambiguity, use the following CLI command to disallow out-of-band processing; the out-of-band byte in the payload becomes part of the payload and the packet is not processed urgently. Making this change allows you to remove ambiguity in how the packet is processed on the firewall and the host, and the firewall sees the exact same stream in the protocol stack as the host for whom the packet is destined.

  ```
  set deviceconfig setting tcp urgent-data clear
  ```

- Enable the following CLI command for disabling the bypass-exceed-queue.

  The bypass exceed queue is required for out of order packets. This scenario is most common in an asymmetric environment where the firewall receives packets out of order. For identification of certain applications (App-ID) the firewall performs heuristic analysis. If the packets are received out of order, the data must be copied to a queue in order to complete the analysis for the application.

  ```
  set deviceconfig setting application bypass-exceed-queue no
  ```

- Enable the following CLI commands for disabling the inspection of packets when the out-of-order packet limit is reached. The Palo Alto Networks firewall can collect up to 64 out-of-order packets per session. This counter identifies that packets have exceeded the 64-packet limit. When the bypass setting is set to **no**, the device drops the out-of-order packets that exceed the 64-packet limit. A commit is required.

  ```
  set deviceconfig setting tcp bypass-exceed-oo-queue no
  set deviceconfig setting ctd bypass-exceed-queue no
  ```

- Enable the following CLI commands for checking the TCP timestamp. The TCP timestamp records when the segment was sent and allows the firewall to verify that the timestamp is valid for that session.

  ```
  set deviceconfig setting tcp check-timestamp-option yes
  ```

- Disable the HTTP Range option. The HTTP Range option allows a client to fetch part of a file only. When a next-generation firewall in the path of a transfer identifies and drops a malicious file, it terminates the TCP session with a RST packet. If the web browser implements the HTTP Range option, it can start a new session to fetch only the remaining part of the file. This prevents the firewall from triggering the same signature again due to the lack of context into the initial session, while at the same time allowing the web browser to reassemble the file and deliver the malicious content. To prevent this, disable the HTTP Range option as follows:

  ```
  set deviceconfig setting ctd skip-block-http-range no
  ```

 © Palo Alto Networks, Inc.

# Passive DNS Collection

Passive DNS is an opt-in feature that enables the firewall to act as a passive DNS sensor and send select DNS information to Palo Alto Networks for analysis in order to improve threat intelligence and threat prevention capabilities. The data collected includes non-recursive (i.e. originating from the local recursive resolver, not individual clients) DNS query and response packet payloads. Data submitted via the Passive DNS Monitoring feature consists solely of mappings of domain names to IP addresses. Palo Alto Networks retains no record of the source of this data and does not have the ability to associate it with the submitter at a future date.

The Palo Alto Networks threat research team uses this information to gain insight into malware propagation and evasion techniques that abuse the DNS system. Information gathered through this data collection is used to improve accuracy and malware detection abilities within PAN-DB URL filtering, DNS-based command-and-control signatures, and WildFire.

DNS responses are only forwarded to the Palo Alto Networks and will only occur when the following requirements are met:

- DNS response bit is set
- DNS truncated bit is not set
- DNS recursive bit is not set
- DNS response code is 0 or 3 (NX)
- DNS question count bigger than 0
- DNS Answer RR count is bigger than 0 or if it is 0, the flags need to be 3 (NX)
- DNS query record type are A, NS, CNAME, AAAA, MX

Passive DNS monitoring is disabled by default, but it is recommended that you enable it to facilitate enhanced threat intelligence. Use the following procedure to enable Passive DNS:

**Enable Passive DNS**

1. Select **Objects > Security Profiles > Anti-Spyware**.
2. Select an existing profile to modify it or configure a new profile.

   The Anti-Spyware profile must be attached to a security policy that governs your DNS server's external DNS traffic.
3. Select the **DNS Signatures** tab and click the **Enable Passive DNS Monitoring** check box.
4. Click **OK** and then **Commit**.

# Content Delivery Network Infrastructure for Dynamic Updates

Palo Alto Networks maintains a Content Delivery Network (CDN) infrastructure for delivering content updates to the Palo Alto Networks devices. The devices access the web resources in the CDN to perform various App-ID and Content-ID functions. For enabling and scheduling the content updates, see Manage Content Updates.

The following table lists the web resources that the firewall accesses for a feature or application:

| Resource | URL | Static Addresses (If a static server is required) |
|---|---|---|
| Application Database | • updates.paloaltonetworks.com:443 | staticupdates.paloaltonetworks.com or the IP address 199.167.52.15 |
| Threat/Antivirus Database | • updates.paloaltonetworks.com:443<br>• downloads.paloaltonetworks.com:443<br>As a best practice, set the update server to updates.paloaltonetworks.com.This allows the Palo Alto Networks device to receive content updates from the server closest to it in the CDN infrastructure. | staticupdates.paloaltonetworks.com or the IP address 199.167.52.15 |
| PAN-DB URL Filtering | *.urlcloud.paloaltonetworks.com<br>Resolves to the primary URL s0000.urlcloud.paloaltonetworks.com and is then redirected to the regional server that is closest:<br>• s0100.urlcloud.paloaltonetworks.com<br>• s0200.urlcloud.paloaltonetworks.com<br>• s0300.urlcloud.paloaltonetworks.com<br>• s0500.urlcloud.paloaltonetworks.com | Static IP addresses are not available. However, you can manually resolve a URL to an IP address and allow access to the regional server IP address. |
| BrightCloud URL Filtering | • database.brightcloud.com:443/80<br>• service.brightcloud.com:80 | Contact BrightCloud Customer Support. |

 © Palo Alto Networks, Inc.

| Resource | URL | Static Addresses (If a static server is required) |
|---|---|---|
| WildFire | • beta.wildfire.paloaltonetworks.com:443/80<br>• beta-s1.wildfire.paloaltonetworks.com:443/80<br>**Note** Beta sites are only accessed by a firewall running a Beta release version.<br>• mail.wildfire.paloaltonetworks.com:25<br>• wildfire.paloaltonetworks.com:443/80 | • mail.wildfire.paloaltonetworks.com:25 or the IP address 54.241.16.83<br>• wildfire.paloaltonetworks.com:443/80 or 54.241.8.199<br>The regional URL/IP addresses are as follows:<br>• ca-s1.wildfire.paloaltonetworks.com:44 or 54.241.34.71<br>• va-s1.wildfire.paloaltonetworks.com:443 or 174.129.24.252<br>• eu-s1.wildfire.paloaltonetworks.com:443 or 54.246.95.247<br>• sg-s1.wildfire.paloaltonetworks.com:443 or 54.251.33.241<br>• jp-s1.wildfire.paloaltonetworks.com:443 or 54.238.53.161<br>• portal3.wildfire.paloaltonetworks.com:443/80 or 54.241.8.199<br>• ca-s3.wildfire.paloaltonetworks.com:443 or 54.241.34.71<br>• va-s3.wildfire.paloaltonetworks.com:443 or 23.21.208.35<br>• eu-s3.wildfire.paloaltonetworks.com:443 or 54.246.95.247<br>• sg-s3.wildfire.paloaltonetworks.com:443 or 54.251.33.241<br>• jp-s3.wildfire.paloaltonetworks.com:443 or 54.238.53.161<br>• wildfire.paloaltonetworks.com.jp:443/80 or 180.37.183.53<br>• wf1.wildfire.paloaltonetowrks.jp:443 or 180.37.180.37<br>• wf2.wildfire.paloaltonetworks.jp:443 or 180.37.181.18<br>• portal3.wildfire.paloaltonetworks.jp:443/80 or 180.37.183.53 |

# Decryption

Palo Alto Networks firewalls provide the capability to decrypt and inspect traffic for visibility, control, and granular security. Decryption on a Palo Alto Networks firewall includes the capability to enforce security policies on encrypted traffic, where otherwise the encrypted traffic might not be blocked and shaped according to your configured security settings. Use decryption on a firewall to prevent malicious content from entering your network or sensitive content from leaving your network concealed as encrypted traffic. Enabling decryption on a Palo Alto Networks firewall can include preparing the keys and certificates required for decryption, creating a decryption policy, and configuring decryption port mirroring. See the following topics to learn about and configure decryption:

- Decryption Overview
- Decryption Concepts
- Configure SSL Forward Proxy
- Configure SSL Inbound Inspection
- Configure SSH Proxy
- Configure Decryption Exceptions
- Configure Decryption Port Mirroring

# Decryption Overview

Secure Sockets Layer (SSL) and Secure Shell (SSH) are encryption protocols used to secure traffic between two entities, such as a web server and a client. SSL and SSH encapsulate traffic, encrypting data so that it is meaningless to entities other than the client and server with the keys to decode the data and the certificates to affirm trust between the devices. Traffic that has been encrypted using the protocols SSL and SSH can be decrypted to ensure that these protocols are being used for the intended purposes only, and not to conceal unwanted activity or malicious content.

Palo Alto Networks firewalls decrypt encrypted traffic by using keys to transform strings (passwords and shared secrets) from ciphertext to plaintext (decryption) and from plaintext back to ciphertext (re-encrypting traffic as it exits the device). Certificates are used to establish the firewall as a trusted third party and to create a secure connection. SSL decryption (both forward proxy and inbound inspection) requires certificates to establish trust between two entities in order to secure an SSL/TLS connection. Certificates can also be used when excluding servers from SSL decryption. You can integrate a hardware security module (HSM) with a firewall to enable enhanced security for the private keys used in SSL forward proxy and SSL inbound inspection decryption. To learn more about storing and generating keys using an HSM and integrating an HSM with your firewall, see Secure Keys with a Hardware Security Module. SSH decryption does not require certificates.

Palo Alto Networks firewall decryption is policy-based, and can be used to decrypt, inspect, and control both inbound and outbound SSL and SSH connections. Decryption policies allow you to specify traffic for decryption according to destination, source, or URL category and in order to block or restrict the specified traffic according to your security settings. The firewall uses certificates and keys to decrypt the traffic specified by the policy to plaintext, and then enforces App-ID and security settings on the plaintext traffic, including Decryption, Antivirus, Vulnerability, Anti-Spyware, URL Filtering, and File-Blocking profiles. After traffic is decrypted and inspected on the firewall, the plaintext traffic is re-encrypted as it exits the firewall to ensure privacy and security. Use policy-based decryption on the firewall to achieve outcomes such as the following:

- Prevent malware concealed as encrypted traffic from being introduced into an corporate network.
- Prevent sensitive corporate information from moving outside the corporate network.
- Ensure the appropriate applications are running on a secure network.
- Selectively decrypt traffic; for example, exclude traffic for financial or healthcare sites from decryption by configuring a decryption exception.

The three decryption policies offered on the firewall, SSL Forward Proxy, SSL Inbound Inspection, and SSH Proxy, all provide methods to specifically target and inspect SSL outbound traffic, SSL inbound traffic, and SSH traffic, respectively. The decryption policies provide the settings for you to specify what traffic to decrypt and decryption profiles can be selected when creating a policy, in order to apply more granular security settings to decrypted traffic, such as checks for server certificates, unsupported modes, and failures. This policy-based decryption on the firewall gives you visibility into and control of SSL and SSH encrypted traffic according to configurable parameters.

You can also choose to extend a decryption configuration on the firewall to include Decryption Port Mirroring, which allows for decrypted traffic to be forwarded as plaintext to a third party solution for additional analysis and archiving.

# Decryption Concepts

To learn about keys and certificates for decryption, decryption policies, and decryption port mirroring, see the following topics:

- Keys and Certificates for Decryption Policies
- SSL Forward Proxy
- SSL Inbound Inspection
- SSH Proxy
- Decryption Exceptions
- Decryption Port Mirroring

## Keys and Certificates for Decryption Policies

Keys are strings of numbers that are typically generated using a mathematical operation involving random numbers and large primes. Keys are used to transform other strings—such as passwords and shared secrets—from plaintext to ciphertext (called *encryption*) and from ciphertext to plaintext (called *decryption*). Keys can be symmetric (the same key is used to encrypt and decrypt) or asymmetric (one key is used for encryption and a mathematically related key is used for decryption). Any system can generate a key.

X.509 certificates are used to establish trust between a client and a server in order to establish an SSL connection. A client attempting to authenticate a server (or a server authenticating a client) knows the structure of the X.509 certificate and therefore knows how to extract identifying information about the server from fields within the certificate, such as its FQDN or IP address (called a *common name* or *CN* within the certificate) or the name of the organization, department, or user to which the certificate was issued. All certificates must be issued by a certificate authority (CA). After the CA verifies a client or server, the CA issues the certificate and signs it using its private key. With a decryption policy configured, an SSL/TLS session between the client and the server is only established if the firewall trusts the CA that signed the server's certificate. In order to establish trust, the firewall must have the server's root CA certificate in its certificate trust list (CTL) and use the public key contained in that root CA certificate to verify the signature. The firewall then presents a copy of the server certificate signed by the Forward Trust certificate for the client to authenticate. You can also configure the firewall to use an enterprise CA as a forward trust certificate for SSL Forward Proxy. If the firewall does not have the server's root CA certificate in it's CTL, the firewall will present a copy of the server certificate signed by the Forward Untrust certificate to the client. The Forward Untrust certificate ensures that clients are prompted with a certificate warning when attempting to access sites hosted by a server with untrusted certificates.

For detailed information on certificates, see Certificate Management.

To control the trusted CAs that your device trusts, use the **Device > Certificate Management > Certificates > Default Trusted Certificate Authorities** tab on the firewall's web interface.

Table: Palo Alto Networks Device Keys and Certificates describes the different keys and certificates used by Palo Alto Networks devices for decryption. As a best practice, use different keys and certificates for each usage.

**Table: Palo Alto Networks Device Keys and Certificates**

| Key/Certificate Usage | Description |
|---|---|
| Forward Trust | The certificate the firewall presents to clients during decryption if the site the client is attempting to connect to has a certificate that is signed by a CA that the firewall trusts. To configure a Forward Trust certificate on the firewall, see Step 2 in the Configure SSL Forward Proxy task. For added security, the forward trust certificate can be stored on a Hardware Security Module (HSM), see Store Private Keys on an HSM. |
| Forward Untrust | The certificate the firewall presents to clients during decryption if the site the client is attempting to connect to has a certificate that is signed by a CA that the firewall does not trust. To configure a Forward Untrust certificate on the firewall, see Step 3 in the Configure SSL Forward Proxy task. |

 © Palo Alto Networks, Inc.

| Key/Certificate Usage | Description |
|---|---|
| SSL Exclude Certificate | Certificates for servers that you want to exclude from SSL decryption. For example, if you have SSL decryption enabled, but have certain servers that you do not want included in SSL decryption, such as the web services for your HR systems, you would import the corresponding certificates onto the firewall and configure them as SSL Exclude Certificates. See Exclude a Server From Decryption. |
| SSL Inbound Inspection | The certificate used to decrypt inbound SSL traffic for inspection and policy enforcement. For this application, you would import the server certificate for the servers for which you are performing SSL inbound inspection, or store them on an HSM (see Store Private Keys on an HSM). |

## SSL Forward Proxy

Use an SSL Forward Proxy decryption policy to decrypt and inspect SSL/TLS traffic from internal users to the web. SSL Forward Proxy decryption prevents malware concealed as SSL encrypted traffic from being introduced to your corporate network; for example, if an employee is using her Gmail account from her corporate office and opens an email attachment that contains a virus, SSL Forward Proxy decryption will prevent the virus from infecting the client system and entering the corporate network.

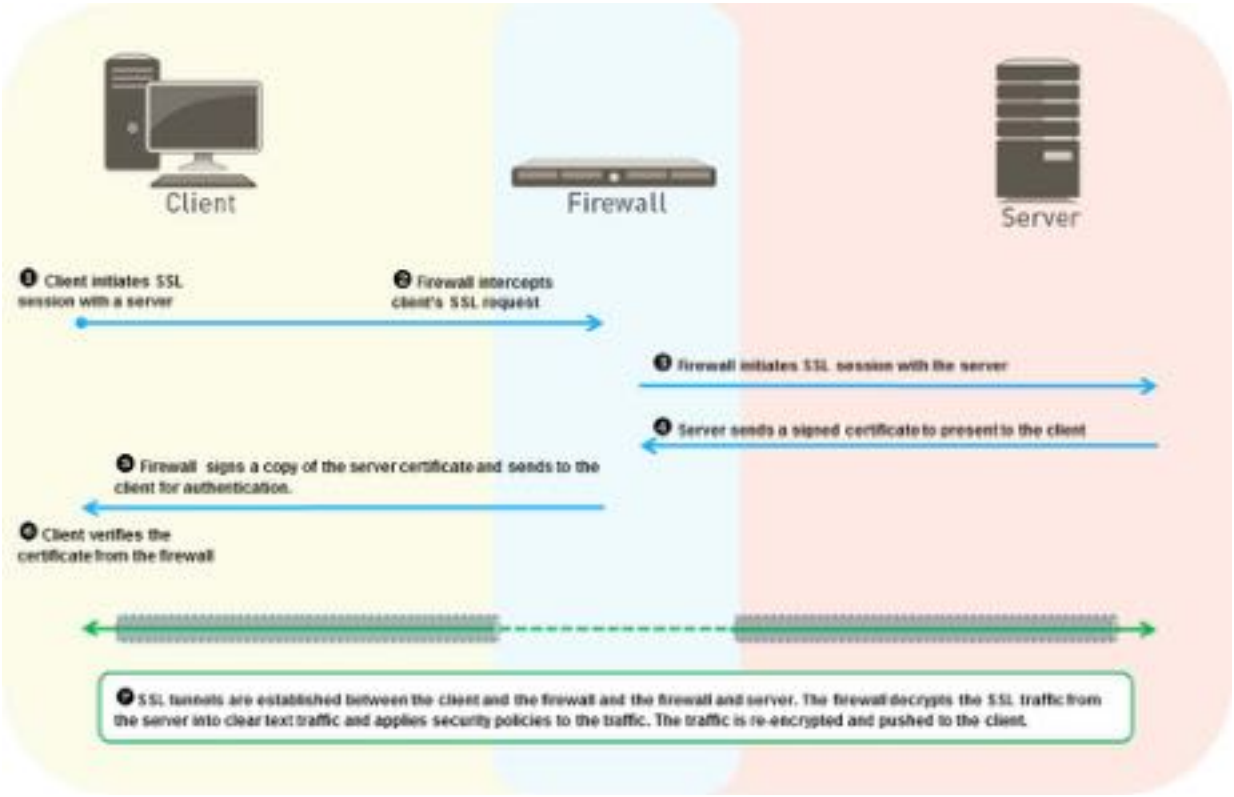
With SSL Forward Proxy decryption, the firewall resides between the internal client and outside server. The firewall uses Forward Trust or Forward Untrust certificates to establish itself a trusted third party to the session between the client and the server (For details on certificates, see Keys and Certificates for Decryption Policies). When the client initiates an SSL session with the server, the firewall intercepts the client's SSL request and forwards the SSL request to the server. The server sends a certificate intended for the client that is intercepted by the firewall. If the server's certificate is signed by a CA that the firewall trusts, the firewall creates a copy of the server's certificate signed by the Forward Trust certificate and sends the certificate to the client to authenticate. If the server's certificate is signed by a CA that the firewall does not trust, the firewall creates a copy of the server's certificate and signs it with the Forward Untrust certificate and sends it to the client. In this case, the client sees a block page warning that the site they're attempting to connect to is not trusted and the client can choose to proceed or terminate the session. When the client authenticates the certificate, the SSL session is established with the firewall functioning as a trusted forward proxy to the site that the client is accessing.

As the firewall continues to receive SSL traffic from the server that is destined for the client, it decrypts the SSL traffic into clear text traffic and applies security policies to the traffic. The traffic is then re-encrypted on the firewall and the firewall forwards the encrypted traffic to the client.

Figure: SSL Forward Proxy shows this process in detail.

 © Palo Alto Networks, Inc.

**Figure: SSL Forward Proxy**



**See** Configure SSL Forward Proxy **for details on configuring SSL Forward Proxy.**

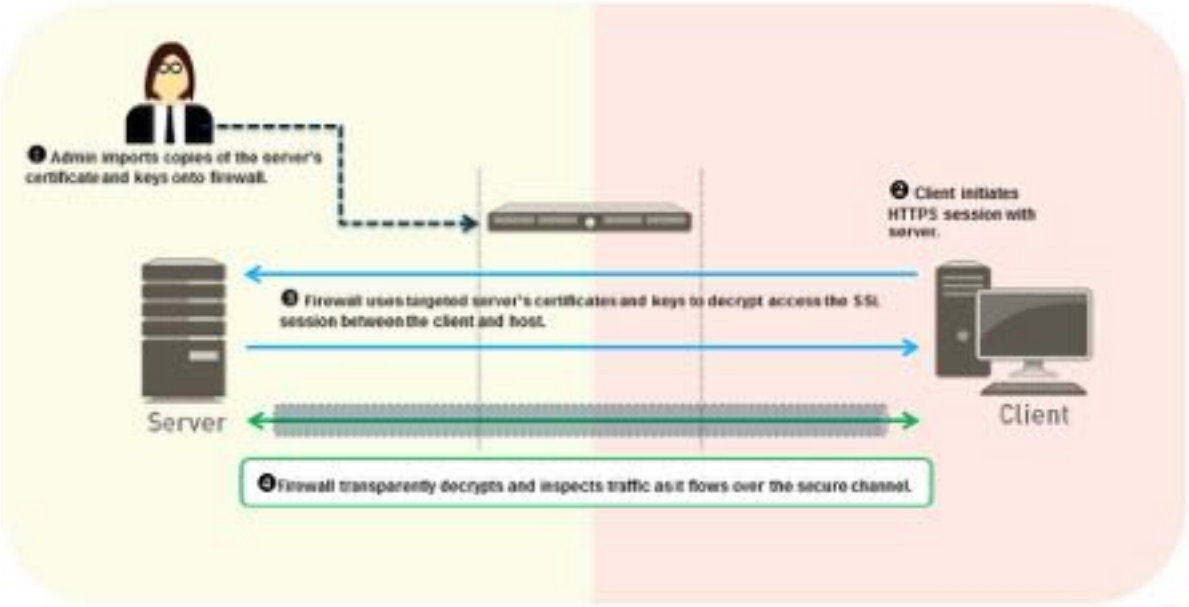
## SSL Inbound Inspection

Use SSL Inbound Inspection to decrypt and inspect inbound SSL traffic from a client to a targeted server (any server you have the certificate for and can import it onto the firewall). For example, if an employee is remotely connected to a web server hosted on the company network and is attempting to add restricted internal documents to his Dropbox folder (which uses SSL for data transmission), SSL Inbound Inspection can be used to ensure that the sensitive data does not move outside the secure company network by blocking or restricting the session.

Configuring SSL Inbound Inspection includes importing the targeted server's certificate and key on to the firewall. Because the targeted server's certificate and key is imported on the firewall, the firewall is able to access the SSL session between the server and the client and decrypt and inspect traffic transparently, rather than functioning as a proxy. The firewall is able to apply security policies to the decrypted traffic, detecting malicious content and controlling applications running over this secure channel.

Figure: SSL Inbound Inspection shows this process in detail.

**Figure: SSL Inbound Inspection**



See Configure SSL Inbound Inspection for details on configuring SSL Inbound Inspection.

 © Palo Alto Networks, Inc.

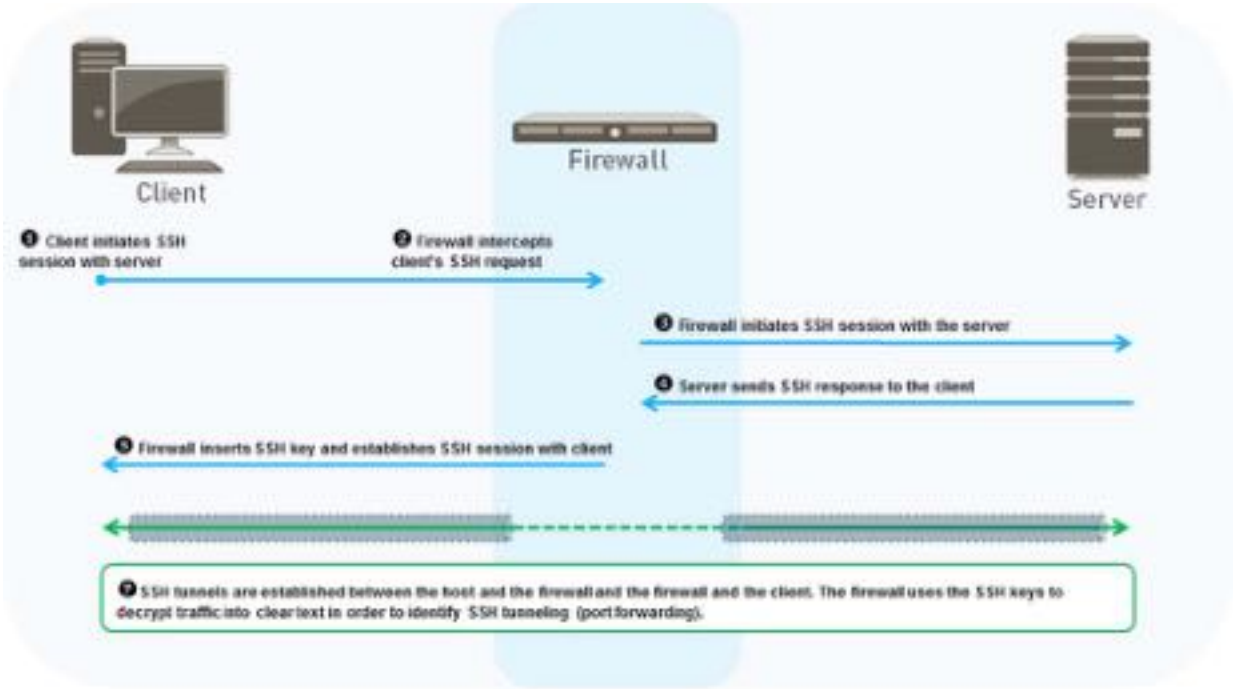
## SSH Proxy

SSH Proxy provides the capability for the firewall to decrypt inbound and outbound SSH connections passing through the firewall, in order to ensure that SSH is not being used to tunnel unwanted applications and content. SSH decryption does not require any certificates and the key used for SSH decryption is automatically generated when the firewall boots up. During the boot up process, the firewall checks to see if there is an existing key. If not, a key is generated. This key is used for decrypting SSH sessions for all virtual systems configured on the device. The same key is also used for decrypting all SSH v2 sessions.

In an SSH Proxy configuration, the firewall resides between a client and a server. When the client sends an SSH request to the server, the firewall intercepts the request and forwards the SSH request to the server. The firewall then intercepts the server's response and forwards the response to the client, establishing an SSH tunnel between the firewall and the client and an SSH tunnel between the firewall and the server, with firewall functioning as a proxy. As traffic flows between the client and the server, the firewall is able to distinguish whether the SSH traffic is being routed normally or if it is using SSH tunneling (port forwarding). Content and threat inspections are not performed on SSH tunnels; however, if SSH tunnels are identified by the firewall, the SSH tunneled traffic is blocked and restricted according to configured security policies.

Figure: SSH Proxy Decryption shows this process in detail.

**Figure: SSH Proxy Decryption**



See Configure SSH Proxy for details on configuring an SSH Proxy policy.

## Decryption Exceptions

Traffic can also be excluded from decryption according to matching criteria (using a decryption policy), a targeted server's traffic can be excluded from decryption (using certificates), and some applications are excluded from decryption by default.

Applications that do not function properly when decrypted by the firewall and are automatically excluded from SSL decryption. The applications that are excluded from SSL decryption by default are excluded because these applications often fail when decrypted due to the application looking for specific details in the certificate that might not be present in the certificate generated for SSL Forward Proxy. Refer to the KB article List of Applications Excluded from SSL Decryption for a current list of applications excluded by default from SSL decryption on the firewall.

You can configure decryption exceptions for certain URL categories or applications that either do not work properly with decryption enabled or for any other reason, including for legal or privacy purposes. You can use a decryption policy to exclude traffic from decryption based on source, destination, and URL category. For example, with SSL decryption enabled, you can exclude traffic that is categorized as financial or health-related from decryption, using the URL category selection. To create a decryption policy that excludes traffic from decryption.

You can also exclude servers from SSL decryption based on the Common Name (CN) in the server's certificate. For example, if you have SSL decryption enabled but have certain servers that you do not want included in SSL decryption, such as the web services for your HR systems, you can exclude those servers from decryption by importing the server certificate onto the firewall and modifying the certificate to be an **SSL Exclude Certificate**.

To exclude traffic from decryption based on application, source, destination, URL category or to exclude a specific server's traffic from decryption, see Configure Decryption Exceptions.

 © Palo Alto Networks, Inc.

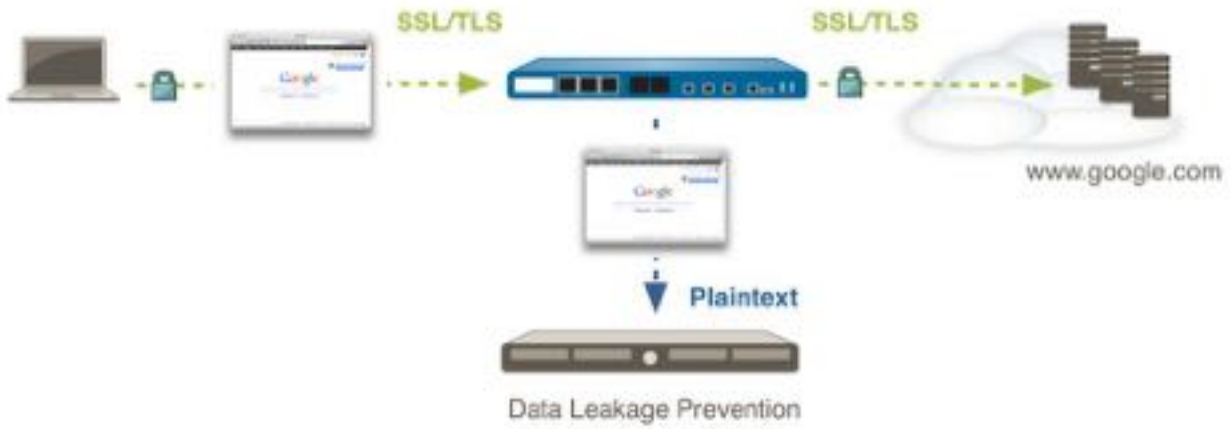
## Decryption Port Mirroring

The Decryption Port mirror feature provides the capability to create a copy of decrypted traffic from a firewall and send it to a traffic collection tool that is capable of receiving raw packet captures–such as NetWitness or Solera–for archiving and analysis. This feature is necessary for organizations that require comprehensive data capture for forensic and historical purposes or data leak prevention (DLP) functionality. Decryption port mirroring is available on PA-7050, PA-5000 Series and PA-3000 Series platforms only and requires that a free license be installed to enable this feature.

Keep in mind that the decryption, storage, inspection, and/or use of SSL traffic is governed in certain countries and user consent might be required in order to use the decryption port mirror feature. Additionally, use of this feature could enable malicious users with administrative access to the firewall to harvest usernames, passwords, social security numbers, credit card numbers, or other sensitive information submitted using an encrypted channel. Palo Alto Networks recommends that you consult with your corporate council before activating and using this feature in a production environment.

Figure: Decryption Port Mirroring shows the process for decryption port mirroring and the section Configure Decryption Port Mirroring describes how to license and use this feature.

**Figure: Decryption Port Mirroring**



# Configure SSL Forward Proxy

Configuring SSL Forward Proxy decryption on the firewall requires setting up the certificates needed for SSL Forward Proxy decryption and creating an SSL Forward Proxy decryption policy. The firewall can use self-signed certificates or certificates signed by an enterprise CA to perform SSL Forward Proxy decryption.

Use the following task to configure SSL Forward Proxy, including how to set up the certificates and create a decryption policy.

| **Configure SSL Forward Proxy** | | |
|---|---|---|
| Step 1 | Ensure that the appropriate interfaces are configured as either virtual wire, Layer 2, or Layer 3 interfaces. | View configured interfaces on the **Network > Interfaces > Ethernet** tab. The **Interface Type** column displays if an interface is configured to be a **Virtual Wire** or **Layer 2**, or **Layer 3** interface. You can select an interface to modify its configuration, including what type of interface it is. |
| Step 2 | Configure the forward trust certificate. Use either a self-signed certificate or a certificate signed by an enterprise CA.<br>**Using self-signed certificates**<br>When the certificate of the server that the client is connecting to is signed by a CA that is on the firewall's trusted CA list, the firewall signs a copy of the server's certificate with a self-signed forward trust certificate to present to the client for authentication. In this case, the self-signed certificate must be imported onto each client system so that the client recognizes the firewall as a trusted CA.<br>Use self-signed certificates for SSL Forward Proxy decryption if you do not use an enterprise CA or if you are only intended to perform decryption for a limited number of client systems (or if you are planning to use a centralized deployment). | To use a self-signed certificate:<br>1. Select **Device > Certificate Management > Certificates**.<br>2. Click **Generate** at the bottom of the window.<br>3. Enter a **Certificate Name**, such as *my-fwd-trust*.<br>4. Enter a **Common Name**, such as **192.168.2.1**. This should be the IP or FQDN that will appear in the certificate. In this case, we are using the IP of the trust interface. Avoid using spaces in this field.<br>5. Leave the **Signed By** field blank.<br>6. Click the **Certificate Authority** check box to enable the firewall to issue the certificate. Selecting this check box creates a certificate authority (CA) on the firewall that is imported to the client browsers, so clients trust the firewall as a CA.<br>7. Click **Generate** to generate the certificate.<br>8. Click the new certificate *my-fwd-trust* to modify it and enable the **Forward Trust Certificate** option.<br>9. Export the forward trust certificate for import into client systems by highlighting the certificate and clicking **Export** at the bottom of the window. Choose PEM format, and do not select the **Export private key** option. Because the certificate is self-signed, import it into the browser trusted root CA list on the client systems in order for the clients to trust it. When importing to the client browser, ensure the certificate is added to the Trusted Root Certification Authorities certificate store. On Windows systems, the default import location is the Personal certificate store. You can also simplify this process by using a centralized deployment, such as an Active Directory Group Policy Object (GPO).<br> If the forward trust certificate is not imported on the client systems, users will see certificate warnings for each SSL site they visit.<br>10. Click **OK** to save. |

© Palo Alto Networks, Inc.

## Configure SSL Forward Proxy

### Using an Enterprise CA

An enterprise CA can issue a signing certificate which the firewall can use to then sign the certificates for sites requiring SSL decryption. Send a Certificate Signing Request (CSR) for the enterprise CA to sign and validate. The firewall can then use the signed enterprise CA certificate for SSL Forward Proxy decryption. Because the enterprise CA is already trusted by the client systems, with this option, you do not need to distribute the certificate to client systems prior to configuring decryption.

To use an enterprise CA signed certificate, generate a CSR:

1. Select **Device > Certificate Management > Certificates** and click **Generate**.
2. Enter a **Certificate Name**, such as *my-fwd-proxy*.
3. In the **Signed By** dropdown, select **External Authority (CSR)**.
4. (Optional) If your enterprise CA requires it, add **Certificate Attributes** to further identify the firewall details, such as Country or Department.
5. Click **OK** to save the CSR. The pending certificate is now displayed on the **Device Certificates** tab.
6. Export the CSR:
   a. Select the pending certificate displayed on the **Device Certificates** tab.
   b. Click **Export** to download and save the certificate file.

   Leave **Export private key** unselected in order to ensure that the private key remains securely on the firewall.
   c. Click **OK**.
   d. Provide the certificate file to your enterprise CA. When you receive the signed enterprise CA certificate from your enterprise CA, save the signed enterprise CA certificate for import onto the firewall.
7. Import the signed enterprise CA onto the firewall:
   a. Select **Device > Certificate Management > Certificates** and click **Import**.
   b. Enter the pending **Certificate Name** exactly (in this case, *my-fwd-trust*). The **Certificate Name** that you enter must exactly match the pending certificate's name in order for the pending certificate to be validated.
   c. Select the signed **Certificate File** that you received from your enterprise CA.
   d. Click **OK**. The certificate is displayed as valid with the Key and CA check boxes selected.
   e. Select the validated certificate, in this case, *my-fwd-proxy*, to enable it as a **Forward Trust Certificate** to be used for SSL Forward Proxy decryption.
   f. Click **OK**.

| Configure SSL Forward Proxy | | |
|---|---|---|
| Step 3 | Configure the forward untrust certificate.<br><br>With SSL Forward Proxy decryption, when the site the client is connecting to uses a certificate signed by a CA that is not in the firewall's trusted CA list, the firewall presents a forward untrust certificate to the client. The forward untrust certificate ensures that clients are prompted with a certificate warning when attempting to access sites with untrusted certificates. | 1. Click **Generate** at the bottom of the certificates page.<br>2. Enter a **Certificate Name**, such as *my-fwd-untrust*.<br>3. Set the **Common Name**, for example **192.168.2.1**. Leave **Signed By** blank.<br>4. Click the **Certificate Authority** check box to enable the firewall to issue the certificate.<br>5. Click **Generate** to generate the certificate.<br>6. Click **OK** to save.<br>7. Click the new *my-ssl-fw-untrust* certificate to modify it and enable the **Forward Untrust Certificate** option.<br> Do not export the forward untrust certificate for import into client systems. If the forward trust certificate is imported on client systems, the users will not see certificate warnings for SSL sites with untrusted certificates.<br>8. Click **OK** to save. |
| Step 4 | (Optional) Create a Decryption profile.<br><br>Decryption profiles can be associated with a decryption policy, enabling the firewall to block and control various aspects of traffic that is being decrypted. An SSL Forward Proxy decryption profile can be used to perform checks for server certificates, unsupported modes, and failures and block or restrict traffic accordingly. For a complete list of checks that can be performed, navigate to **Objects > Decryption Profiles** on the firewall and click the help icon. | 1. Select **Objects > Decryption Profile** and click **Add**.<br>2. Select the **SSL Forward Proxy** tab to block and control specific aspects of SSL tunneled traffic. For example, you can choose to terminate sessions if system resources are not available to process decryption by selecting **Block sessions if resources not available**.<br>3. Click **OK t**o save the profile. |

 © Palo Alto Networks, Inc.

| Configure SSL Forward Proxy | |
|---|---|
| Step 5 Configure a decryption policy. | 1. Select **Policies > Decryption** and click **Add**.<br>2. On the **General** tab, give the policy a descriptive **Name**.<br>3. On the **Source** and **Destination** tabs, select **Any** for the **Source Zone** and **Destination Zone** to decrypt all SSL traffic destined for an external server. If you want to specify traffic from or to certain sources or destinations for decryption, click **Add**.<br>4. In the **URL Category** tab, leave **Any** to decrypt all traffic. If you only want to apply this profile to certain website categories, click **Add**.<br> Selecting a URL Category is useful when excluding certain sites from decryption. See Configure Decryption Exceptions.<br>5. On the **Options** tab, select **Decrypt** and select **SSL Forward Proxy** as the **Type** of decryption to perform.<br>6. (Optional) Select a **Decryption Profile** to apply additional settings to decrypted traffic (see Step 4).<br>7. Click **OK** to save. |
| Step 6 **Commit** the configuration. | With the an SSL Forward Proxy decryption policy enabled, all traffic identified by the policy is decrypted. Decrypted traffic is blocked and restricted according to the profiles configured on the firewall (including the decryption profiles associated with the policy and Antivirus, Vulnerability, Anti-Spyware, URL Filtering, and File-Blocking profiles). Traffic is re-encrypted as it exits the firewall. |

# Configure SSL Inbound Inspection

Configuring SSL Inbound Inspection includes installing the targeted server's certificate on the firewall and creating an SSL Inbound Inspection decryption policy.

Use the following task to configure SSL Inbound Inspection.

| Configure SSL Inbound Inspection | | |
|---|---|---|
| Step 1 | Ensure that the appropriate interfaces are configured as either virtual wire, Layer 2, or Layer 3 interfaces. | View configured interfaces on the **Network > Interfaces > Ethernet** tab. The **Interface Type** column displays if an interface is configured to be a **Virtual Wire** or **Layer 2**, or **Layer 3** interface. You can select an interface to modify its configuration, including what type of interface it is. |
| Step 2 | Ensure that the targeted server's certificate is installed on the firewall. | On the web interface, select **Device > Certificate Management > Certificates > Device Certificates** to view certificates installed on the firewall.<br>To import the targeted server's certificate onto the firewall:<br>1. On the **Device Certificates** tab, select **Import**.<br>2. Enter a descriptive **Certificate Name**.<br>3. Browse for and select the targeted server's **Certificate File**.<br>4. Click **OK**. |
| Step 3 | (Optional) Create a Decryption profile.<br>Decryption profiles can be associated with a decryption policy, enabling the firewall to block and control various aspects of traffic that is being decrypted. An SSL Inbound Inspection decryption profile can be used to perform checks for unsupported modes and failures and block or restrict traffic accordingly. For a complete list of checks that can be performed, select **Objects > Decryption Profiles** and then click the help icon. | 1. Select **Objects > Decryption Profile** and click **Add**.<br>2. Select the **SSL Inbound Inspection** tab to block and control specific aspects of SSL traffic. For example, you can choose to terminate sessions if system resources are not available to process decryption by selecting **Block sessions if resources not available**.<br>3. Click **OK t**o save the profile. |

© Palo Alto Networks, Inc.

| Configure SSL Inbound Inspection | |
|---|---|
| Step 4 Configure a decryption policy. | 1. Select **Policies > Decryption** and click **Add .**<br>2. On the **General** tab, give the policy a descriptive **Name**.<br>3. On the **Destination** tab, **Add** the **Destination Address** of the targeted server.<br>4. In the **URL Category** tab, leave **Any** to decrypt all traffic. If you only want to apply this profile to certain website categories, click **Add**.<br> Selecting a URL Category is useful when excluding certain sites from decryption. See Configure Decryption Exceptions.<br>5. On the **Options** tab, select **Decrypt** and select **SSL Inbound Inspection** as the **Type** of traffic to decrypt.<br>Select the **Certificate** for the internal server that is the destination of the inbound SSL traffic.<br>6. (Optional) Select a **Decryption Profile** to apply additional settings to decrypted traffic.<br>7. Click **OK** to save. |
| Step 5 **Commit** the configuration. | With an SSL Inbound Inspection decryption policy enabled, all SSL traffic identified by the policy is decrypted and inspected. Decrypted traffic is blocked and restricted according to the profiles configured on the firewall (including the decryption profiles associated with the policy and Antivirus, Vulnerability, Anti-Spyware, URL Filtering, and File-Blocking profiles). Traffic is re-encrypted as it exits the firewall. |

# Configure SSH Proxy

Configuring SSH Proxy does not require certificates and the key used to decrypt SSH sessions is generated automatically on the firewall during boot up.

Use the following task to configure SSH Proxy decryption.

| Configure SSH Proxy Decryption | | |
|---|---|---|
| Step 1 | Ensure that the appropriate interfaces are configured as either virtual wire, Layer 2, or Layer 3 interfaces. Decryption can only be performed on virtual wire, Layer 2, or Layer 3 interfaces. | View configured interfaces on the **Network > Interfaces > Ethernet** tab. The **Interface Type** column displays if an interface is configured to be a **Virtual Wire** or **Layer 2**, or **Layer 3** interface. You can select an interface to modify its configuration, including what type of interface it is. |
| Step 2 | (Optional) Create a Decryption profile.<br>Decryption profiles can be associated with a decryption policy, enabling the firewall to block and control various aspects of traffic that is being decrypted. The decryption profile can be used to perform checks for server certificates, unsupported modes, and failures and block or restrict traffic accordingly. For a complete list of checks that can be performed, navigate to **Objects > Decryption Profiles** on the firewall and then click the help icon. | 1. Select **Objects > Decryption Profile** and click **Add**.<br>2. Select the **SSH** tab to block and control specific aspects of SSH tunneled traffic. For example, you can choose to terminate sessions if system resources are not available to process decryption by selecting **Block sessions if resources not available**.<br>3. Click **OK** to save the profile. |
| Step 3 | Configure a decryption policy. | 1. Select **Policies > Decryption** and click **Add**.<br>2. On the **General** tab, give the policy a descriptive **Name**.<br>3. On the **Source** and **Destination** tabs, select **Any** to decrypt all SSH traffic.<br>4. On the **URL Category** tab, select **Any** to decrypt all SSH traffic.<br>5. On the **Options** tab, select **Decrypt** and select **SSH Proxy** as the **Type** of traffic to decrypt.<br>6. (Optional) Select a **Decryption Profile** to apply additional settings to decrypted traffic.<br>7. Click **OK** to save. |
| Step 4 | **Commit** the configuration. | With the an SSH Proxy decryption policy enabled, all SSH traffic identified by the policy is decrypted and identified as either regular SSH traffic or as SSH tunneled traffic. SSH tunneled traffic is blocked and restricted according to the profiles configured on the firewall. Traffic is re-encrypted as it exits the firewall. |

© Palo Alto Networks, Inc.

# Configure Decryption Exceptions

You can purposefully exclude traffic from decryption based on match criteria, such as the application, the traffic's source or destination, or the URL category. You can also exclude a specific server's traffic from decryption. See the following topics to configure Decryption Exceptions:

- Exclude Traffic From Decryption
- Exclude a Server From Decryption

## Exclude Traffic From Decryption

To purposefully exclude applications or certain traffic from other existing SSL or SSH decryption policies, you can create a new decryption policy that defines the traffic to exclude from decryption and with the **No Decrypt** action selected in the policy. You can define traffic for policy-based exclusion according to match criteria, such as application, source, destination, or URL categories. Make sure the decryption policy that excludes traffic from decryption is listed first in your decryption policy list by dragging and dropping the policy above the other decryption policies.

See the following procedure to configure a decryption policy that excludes traffic from SSL or SSH decryption.

| **Exclude Traffic from a Decryption Policy** | | |
|---|---|---|
| Step 1 | Create a decryption policy.<br><br>Use a decryption policy to exclude traffic from decryption according to the traffic's source and destination zones or addresses and URL categories. This example shows how to exclude traffic categorized as financial or health-related from SSL Forward Proxy decryption. | 1. Go to **Policies > Decryption** and click **Add**.<br>2. Give the policy a descriptive **Name**, such as *No-Decrypt-Finance-Health*.<br>3. On the **Source** and **Destination** tabs, select **Any** for the **Source Zone** and **Destination Zone** to apply the *No-Decrypt-Finance-Health* rule to all SSL traffic destined for an external server.<br>4. On the **URL Category** tab, **Add** the URL categories financial-services and health-and-medicine to the policy, specifying that traffic that matches these categories will not be decrypted.<br>5. On the **Options** tab, select **No Decrypt** and select the **Type** of decryption policy you are excluding the traffic from. For example, to exclude traffic categorized as financial or health-related from a separately configured SSL Forward Proxy decryption policy, select **SSL Forward Proxy** as the **Type**.<br>6. Click **OK** to save the *No-Decrypt-Finance-Health* decryption policy. |
| Step 2 | Move the decryption policy to the top of the list of decryption policies. | On the **Decryption > Policies** page, select the policy *No-Decrypt-Finance-Health*, and click **Move Up** until it appears at the top of the list (or you can drag and drop).<br><br>The order in which the decryption policies are listed is the order in which they are applied to network traffic. Moving the policy with the **No Decrypt** action applied to the top of the list ensures that the specified traffic is not decrypted according to another configured policy. |

| Exclude Traffic from a Decryption Policy | |
|---|---|
| Step 3 **Commit** the configuration. | A decryption policy with **No Decrypt** enabled ensures that the specified traffic is remains encrypted as it flows through the firewall, and that the traffic is not decrypted according to other decryption policies configured and listed on the **Policies > Decryption** page. |

## Exclude a Server From Decryption

You can exclude a targeted server's traffic from SSL decryption based on the Common Name (CN) in the server's certificate. For example, if you have SSL decryption enabled, you could configure a decryption exception for server on your corporate network that hosts the web services for your HR systems. See the following procedure to configure modify a server's certificate so that the targeted server's traffic is excluded from decryption:

| Exclude a Server from Decryption | |
|---|---|
| Step 1 | Import the targeted server's certificate onto the firewall:<br>1. On the **Device > Certificate Management > Certificates > Device Certificates** tab, select **Import**.<br>2. Enter a descriptive **Certificate Name**.<br>3. Browse for and select the targeted server's **Certificate File**.<br>4. Click **OK**. |
| Step 2 | Select the targeted server's certificate on the **Device Certificates** tab and enable it as an SSL Exclude Certificate.<br>With the targeted server's certificate imported on the firewall and designated as an SSL Exclude Certificate, the server's traffic is not decrypted as it passes through the firewall. |

 © Palo Alto Networks, Inc.

# Configure Decryption Port Mirroring

Before you can enable decryption port mirroring, you must obtain and install a Decryption Port Mirror license. The license is free of charge and can be activated through the support portal as described in the following procedure. After you install the Decryption Port Mirror license and reboot the firewall, you can enable decryption port mirroring. Enabling decryption port mirroring includes enabling the forwarding of decrypted traffic and configuring a decrypt mirror interface. You can then create a decryption profile that specifies the interface and attach it to a decryption policy. To learn more about implementing Decryption Port Mirroring, see Decryption Port Mirroring.

Use the following procedure to obtain and install a Decryption Port Mirror license and configure Decryption Port Mirroring.

| **Configure Decryption Port Mirroring** | |
|---|---|
| Step 1 Request a license for each device on which you want to enable decryption port mirroring. | 1. Log in to the Palo Alto Networks Support site and navigate to the **Assets** tab.<br>2. Select the device entry for the device you want to license and select **Actions**.<br>3. Select **Decryption Port Mirror**. A legal notice displays.<br>4. If you are clear about the potential legal implications and requirements, click **I understand and wish to proceed**.<br>5. Click **Activate**.<br>  |
| Step 2 Install the Decryption Port Mirror license on firewall. | 1. From the firewall's web interface, select **Device > Licenses**.<br>2. Click **Retrieve license keys from license server**.<br>3. Verify that the license has been activated on the firewall.<br> <br>4. Reboot the firewall (**Device > Setup > Operations**). This feature will not be available for configuration until PAN-OS reloads. |

| Configure Decryption Port Mirroring (Continued) | | |
|---|---|---|
| Step 3 | Enable the ability to mirror decrypted traffic. Superuser permission is required to perform this step. | **On a firewall with a single virtual system:**<br>1. Select **Device > Setup > Content - ID**.<br>2. Select the **Allow forwarding of decrypted content** check box.<br>3. Click **OK** to save.<br>**On a firewall with multiple virtual systems:**<br>1. Select **Device > Virtual System.**<br>2. Select a Virtual System to edit or create a new Virtual System by selecting **Add**.<br>3. Select the **Allow forwarding of decrypted content** check box.<br>4. Click **OK** to save. |
| Step 4 | Configure a decrypt mirror interface. | 1. Select **Network > Interfaces > Ethernet**.<br>2. Select the Ethernet interface that you want to configure for decryption port mirroring.<br>3. Select **Decrypt Mirror** as the **Interface Type**.<br>This interface type will only appear if the Decryption Port Mirror license is installed.<br>4. Click **OK** to save. |
| Step 5 | Configure a Decryption Profile to enable decryption port mirroring. | 1. Select **Objects > Decryption Profile**.<br>2. Select the **Interface** to use for **Decryption Mirroring**.<br>The **Interface** drop-down contains all Ethernet interfaces that have been defined as the type: **Decrypt Mirror**.<br>3. Specify whether to mirror decrypted traffic before or after policy enforcement.<br>By default, the firewall will mirror all decrypted traffic to the interface before security policies lookup, which allows you to replay events and analyze traffic that generates a threat or triggers a drop action. If you want to only mirror decrypted traffic after security policy enforcement, select the **Forwarded Only** check box. With this option, only traffic that is forwarded through the firewall is mirrored. This option is useful if you are forwarding the decrypted traffic to other threat detection devices, such as a DLP device or another intrusion prevention system (IPS).<br>4. Click **OK** to save the decryption profile. |
| Step 6 | Set a decryption policy for decryption port mirroring. | 1. Select **Policies > Decryption**.<br>2. Click **Add** to configure a decryption policy or select an existing decryption policy to edit.<br>3. In the **Options** tab, select **Decrypt** and the **Decryption Profile** created in Step 4.<br>4. Click **OK** to save the policy. |
| Step 7 | Save the configuration. | Click **Commit**. |

# URL Filtering

The Palo Alto Networks URL filtering solution is a powerful PAN-OS feature that is used to monitor and control how users access the web over HTTP and HTTPS. The following topics provide an overview of URL filtering, configuration and troubleshooting information, and best practices for getting the most out of this feature:

- URL Filtering Overview
- URL Filtering Concepts
- PAN-DB Categorization Workflow
- Configure URL Filtering
- Enable Safe Search Enforcement
- URL Filtering Use Case Examples
- Troubleshoot URL Filtering

# URL Filtering Overview

The Palo Alto Networks URL filtering feature compliments the App-ID feature by enabling you to configure your firewall to identify and control access to web (HTTP and HTTPS) traffic. By implementing URL filtering profiles in security policies and by using URL categories as a match criteria in policies (captive portal, decryption, security, and QoS), you will gain complete visibility and control of the traffic that traverses your firewall and will be able to safely enable and control how your users access the web.

The Palo Alto Networks URL filtering solution utilizes a URL filtering database that contains millions of websites and each website is placed in one of approximately 60 different categories. A URL filtering profile that contains the list of categories is then applied to a security policy that allows web traffic (HTTP/HTTPS) from the internal users to the Internet. After the URL filtering profile is applied and the alert or block action is set on a category, you will gain complete visibility into the websites that users access and can then decide which websites or website categories should be allowed, blocked, or logged. You can also define a list of URLs in the URL filtering profile that will always be blocked or allowed and you can create custom URL categories that contains a list of URLs that can be used the same way as the default category list. These same URL categories can also be used as a match criteria in other policies, such as captive portal, decryption, and QoS.

## URL Filtering Vendors

Palo Alto Networks firewalls support two vendors for URL filtering purposes:

- **PAN-DB**—A Palo Alto Networks developed URL filtering database that is tightly integrated into PAN-OS by utilizing high-performance local caching to perform maximum inline performance for URL lookups while a distributed cloud architecture provides coverage for the latest websites. To view a list of PAN-DB URL filtering categories, refer to https://urlfiltering.paloaltonetworks.com/CategoryList.aspx.
- **BrightCloud**—A third-party URL database that is owned by Webroot, Inc. and is integrated into PAN-OS firewalls. For information on the BrightCloud URL database, visit http://brightcloud.com.

## Interaction Between App-ID and URL Categories

The Palo Alto Networks URL filtering feature in combination with Application Identification (App-ID) provides unprecedented protection against a full spectrum of legal, regulatory, productivity, and resource utilization risks. While App-ID gives you control over what applications users can access, URL filtering provides control over related web activity. When combined with User-ID, you can also apply these controls based on users and groups.

With today's application landscape and the way many applications use HTTP and HTTPS, you will need to determine when to use App-ID and when to use URL filtering in order to define comprehensive web access policies. In most cases, if an App-ID signature exists, you will want to use App-ID to control the content at the application level. For example, although you can control access to Facebook and/or LinkedIn using URL filtering, this would not block the use of all related applications, such as email, chat, as well as any new application that is introduced after you implement your policy.

 © Palo Alto Networks, Inc.

In some cases, you will want to use both URL filtering and App-ID, but to ensure that conflicts do not occur in your policies, it is important to understand how these features work together. Palo Alto Networks generates signatures for many applications and those signatures can be very granular in regard to various features within the web-based applications—whereas URL filtering would only apply actions based on a specific website or URL category. For example, you may want to block social networking sites in general, but want to allow a few sites in that category to be accessible to specific departments and then control what features of the website are available to the allowed users. For more information, see URL Filtering Use Case Examples.

© Palo Alto Networks, Inc.

# URL Filtering Concepts

The following topics describe the URL filtering components and how they are used on a Palo Alto Networks firewall:

- URL Categories
- URL Filtering Profiles
- URL Category as Policy Match Criteria

## URL Categories

Each website defined in the URL filtering database is assigned one of approximately 60 different categories. These categories can then be used in a URL filtering profile to block or allow access based on category, or you can configure the firewall to use a category as a match criteria in policy. For example, to block all gaming websites, in the URL filtering profile you would set the block action for the URL category *games*. As an example of using a URL category as a match criteria in a policy, you could use the URL category *streaming-media* in a QoS policy to apply bandwidth controls to all websites that are categorized as streaming media.

By grouping websites into categories, it makes it easy to define actions based on certain types of websites. In addition to the standard URL categories, there are three additional categories:

- **Not-resolved**—Indicates that the website was not found in the local URL filtering database and the firewall was unable to connect to the cloud database to check the category. When a URL category lookup is performed, the firewall first checks the dataplane cache for the URL, if no match is found, it will then check the management plane cache, and if no match is found there, it queries the URL database in the cloud.

  When deciding on what action to take for traffic that is categorized as *not-resolved*, be aware that setting the action to block may be very disruptive to users.

  For more information on troubleshooting lookup issues, see Troubleshoot URL Filtering.

- **Private-ip-addresses**—Indicates that the website is a single domain (no sub-domains), the IP address is in the private IP range, or the URL root domain is unknown to the cloud.

- **Unknown**—The website has not yet been categorized, so it does not exist in the URL filtering database on the firewall or in the URL cloud database.

  When deciding on what action to take for traffic categorized as *unknown*, be aware that setting the action to block may be very disruptive to users because there could be a lot of valid sites that are not in the URL database yet. If you do want a very strict policy, you could block this category, so websites that do not exist in the URL database cannot be accessed.

 © Palo Alto Networks, Inc.

# URL Filtering Profiles

A URL filtering profile is a collection of URL filtering controls that are applied to individual security policies to enforce your web access policy. The firewall comes with a default profile that is configured to block websites such as known malware sites, phishing sites, and adult content sites. You can use the default profile in a security policy, clone it to be used as a starting point for new URL filtering profiles, or add a new URL profile that will have all categories set to allow for visibility into the traffic on your network. You can then customize the newly added URL profiles and add lists of specific websites that should always be blocked or allowed, which provides more granular control over URL categories. For example, you may want to block social-networking sites, but allow some websites that are part of the social-networking category.

The section describes how URL filtering profiles are applied and the various options that can be defined:

- URL Filtering Actions
- Block and Allow Lists
- Safe Search Enforcement
- Container Pages

## URL Filtering Actions

Each URL filtering category can be set to perform the following actions:

| Action | Description |
|---|---|
| Alert | The website is allowed and a log entry is generated in the URL filtering log. |
| Allow | The website is allowed and no log entry is generated. |
| Block | The website is blocked and the user will see a response page and will not be able to continue to the website. A log entry is generated in the URL filtering log. |
| Continue | The user will be prompted with a response page indicating that the site has been blocked due to company policy, but the user is prompted with the option to continue to the website. The continue action is typically used for categories that are considered benign and is used to improve the user experience by giving them the option to continue if they feel the site is incorrectly categorized. The response page message can be customized to contain details specific to your company. A log entry is generated in the URL filtering log.<br> The *Continue* page will not be displayed properly on client machines that are configured to use a proxy server. |
| Override | The user will see a response page indicating that a password is required to allow access to websites in the given category. With this option, the security admin or helpdesk person would provide a password that will grant temporary access to all websites in the given category. A log entry is generated in the URL filtering log.<br> The *Override* page will not be displayed properly on client machines that are configured to use a proxy server. |

| Action | Description |
|---|---|
| None | The *None* action only applies to custom URL categories. The purpose of selecting *None* is to ensure that if multiple URL profiles exist, the custom category will not have any impact on other profiles. For example, if you have two URL profiles and the custom URL category is set to block in one of the profiles, the other profile should have the action set to *None* if you do not want it to apply.<br>Also, in order to delete a custom URL category, it must be set to none in any profile where it is used. |

## Block and Allow Lists

Block and allow lists allow you to define specific URLs or IP addresses in the URL filtering profile that are always allowed or always blocked, regardless of the action defined for the URL category. When entering URLs in the *Block List* or *Allow List*, enter each URL or IP address in a new row separated by a new line. When using wildcards in the URLs, follow these rules:

- Do not include HTTP and HTTPS when defining URLs. For example, enter www.paloaltonetworks.com or paloaltonetworks.com instead of https://www.paloaltonetworks.com.
- Entries in the block list must be an exact match and are case-insensitive.

  For example: If you want to prevent a user from accessing any website within the domain paloaltonetworks.com, you would also add *.paloaltonetworks.com, so whatever domain prefix (http://, www, or a sub-domain prefix such as mail.paloaltonetworks.com) is added to the address, the specified action will be taken. The same applies to the sub-domain suffix; if you want to block paloaltonetworks.com/en/US, you would need to add paloaltonetworks.com/* as well. Block and allow lists support wildcard patterns. The following characters are considered separators:

  .

  /

  ?

  &

  =

  ;

  +

  Every substring that is separated by the characters listed above is considered a token. A token can be any number of ASCII characters that does not contain any separator character or *. For example, the following patterns are valid:

  *.yahoo.com (tokens are: "*", "yahoo" and "com")

  www.*.com (tokens are: "www", "*" and "com")

  www.yahoo.com/search=* (tokens are: "www", "yahoo", "com", "search", "*")

  The following patterns are invalid because the character “*” is not the only character in the token.

  ww*.yahoo.com and www.y*.com

 © Palo Alto Networks, Inc.

## Safe Search Enforcement

Many search engines have a safe search setting that filters out adult images and videos in search query return traffic. On the firewall, you can Enable Safe Search Enforcement so that the firewall will block search results if the end user is not using the strictest safe search settings in the search query. The firewall can enforce safe search for the following search providers: Google, Yahoo, Bing, Yandex, and YouTube. This is a best-effort setting and is not guaranteed by the search providers to work with every website.

To use this feature you must enable the **Safe Search Enforcement** option in a URL filtering profile and attach it to a security policy. The firewall will then block any matching search query return traffic that is not using the strictest safe search settings. There are two methods for blocking the search results:

- Block Search Results that are not Using Strict Safe Search Settings—When an end user attempts to perform a search without first enabling the strictest safe search settings, the firewall blocks the search query results and displays the URL Filtering Safe Search Block Page. By default, this page will provide a URL to the search provider settings for configuring safe search.
- Enable Transparent Safe Search Enforcement—When an end user attempts to perform a search without first enabling the strict safe search settings, the firewall blocks the search results with an HTTP 503 status code and redirects the search query to a URL that includes the safe search parameters. You enable this functionality by importing a new URL Filtering Safe Search Block Page containing the Javascript for rewriting the search URL to include the strict safe search parameters. In this configuration, users will not see the block page, but will instead be automatically redirected to a search query that enforces the strictest safe search options. This safe search enforcement method requires Content Release version 475 or later and is only supported for Google, Yahoo, and Bing searches.

Also, because most search providers now use SSL to return search results, you must also configure a Decryption policy for the search traffic to enable the firewall to inspect the search traffic and enforce safe search.

Safe search enforcement enhancements and support for new search providers is periodically added in content releases. This information is detailed in the Application and Threat Content Release Notes. How sites are judged to be safe or unsafe is performed by each search provider, not by Palo Alto Networks.

Safe search settings differ by search provider as detailed in Table: Search Provider Safe Search Settings.

**Table: Search Provider Safe Search Settings**

| Search Provider | Safe Search Setting Description |
|---|---|
| Google/YouTube | Offers safe search on individual computers or network-wide through Google's safe search virtual IP address:<br><br>**Safe Search Enforcement for Google Searches on Individual Computers**<br><br>In the Google Search Settings, the **Filter explicit results** setting enables safe search functionality. When enabled, the setting is stored in a browser cookie as `FF=` and passed to the server each time the user performs a Google search.<br><br>Appending `safe=active` to a Google search query URL also enables the strictest safe search settings.<br><br>**Safe Search Enforcement for Google and YouTube Searches using a Virtual IP Address**<br><br>Google provides servers that Lock SafeSearch (forcesafesearch.google.com) settings in every Google and YouTube search. By adding a DNS entry for `www.google.com` and `www.youtube.com` (and other relevant Google and YouTube country subdomains) that includes a CNAME record pointing to `forcesafesearch.google.com` to your DNS server configuration, you can ensure that all users on your network are using strict safe search settings every time they perform a Google or YouTube search. Keep in mind, however, that this solution is not compatible with Safe Search Enforcement on the firewall. Therefore, if you are using this option to force safe search on Google, the best practice is to block access to other search engines on the firewall by creating custom URL categories and adding them to the block list in the URL filtering profile.<br><br> If you plan to use the Google Lock SafeSearch solution, consider configuring DNS Proxy (**Network > DNS Proxy**) and setting the inheritance source as the Layer 3 interface on which the firewall receives DNS settings from service provider via DHCP. You would configure the DNS proxy with **Static Entries** for www.google.com and www.youtube.com, using the local IP address for the forcesafesearch.google.com server. |
| Yahoo | Offers safe search on individual computers only. The Yahoo Search Preferences includes three SafeSearch settings: **Strict**, **Moderate**, or **Off**. When enabled, the setting is stored in a browser cookie as `vm=` and passed to the server each time the user performs a Yahoo search.<br><br>Appending `vm=r` to a Yahoo search query URL also enables the strictest safe search settings.<br><br> When performing a search on Yahoo Japan (yahoo.co.jp) while logged into a Yahoo account, end users must also enable the **SafeSearch Lock** option. |
| Bing | Offers safe search on individual computers or through their Bing in the Classroom program. The Bing Settings include three SafeSearch settings: **Strict**, **Moderate**, or **Off**. When enabled, the setting is stored in a browser cookie as `adlt=` and passed to the server each time the user performs a Bing search.<br><br>Appending `adlt=strict` to a Bing search query URL also enables the strictest safe search settings.<br><br>The Bing SSL search engine does not enforce the safe search URL parameters and you should therefore should consider blocking Bing over SSL for full safe search enforcement. |

 © Palo Alto Networks, Inc.

## Container Pages

A container page is the main page that a user accesses when visiting a website, but additional websites may be loaded within the main page. If the **Log Container page only** option is enabled in the URL filtering profile, only the main container page will be logged, not subsequent pages that may be loaded within the container page. Because URL filtering can potentially generate a lot of log entries, you may want to turn on this option, so log entries will only contain those URIs where the requested page file name matches the specific mime-types. The default set includes the following mime-types:

- application/pdf
- application/soap+xml
- application/xhtml+xml
- text/html
- text/plain
- text/xml

If you have enabled the **Log container page** only option, there may not always be a correlated URL log entry for threats detected by Antivirus or Vulnerability Protection.

# URL Category as Policy Match Criteria

URL categories can be used as a match criteria in a policy to provide more granularity in the policy. For example, you may have a decryption policy defined, but you would like specific websites to bypass decryption. To do this, you would configure a decryption policy with the no-decrypt action and a URL category would be defined as match criteria for the policy rule, so the policy would only match traffic flows to websites that are part of the specified category.

The following table describes the policy types that can utilize URL categories:

| Policy Type | Description |
|---|---|
| Captive Portal | To ensure that users authenticate before being allowed access to a specific category, you can attach a URL category as a match criteria for the captive portal policy. |
| Decryption | Decryption policies can use URL categories as a match criteria to determine if specified websites should be decrypted or not. For example, if you have a decryption policy with the action decrypt for all traffic between two zones, there may be specific website categories, such as *financial-services* and/or *health-and-medicine*, that should not be decrypted. In this case, you would create a new decryption policy with the action of *no-decrypt* that precedes the decrypt policy and then defines a list of URL categories as match criteria for the policy. By doing this, each URL category that is part of the no-decrypt policy will not be decrypted. You could also configure a custom URL category to define your own list of URLs that can then be used in the no decrypt policy. |

| Policy Type | Description |
|---|---|
| QoS | A QoS policy can use URL categories to determine throughput levels for specific website categories. For example, you may want to allow the streaming-media category, but limit throughput by adding the URL category as match criteria to the QoS policy. |
| Security | In security policies you can use URL categories both as a match criteria in the **Service/URL Category** tab, and in URL filtering profiles that are attached in the **Actions** tab.<br>If for example, the IT-security group in your company needs access to the hacking category, while all other users are denied access to the category, you must create the following rules:<br>• A security rule that allows the IT-Security group to access content categorized as hacking. The security rule references the *hacking* category in the S**ervices/URL Category** tab and IT-Security group in the **Users** tab.<br>• Another security rule that allows general web access for all users. To this rule you attach a URL filtering profile that blocks the hacking category.<br>The policy that allows access to hacking must be listed before the policy that blocks hacking. This is because security policy rules are evaluated top down, so when a user who is part of the security group attempts to access a hacking site, the policy rule that allows access is evaluated first and will allow the user access to the hacking sites. Users from all other groups are evaluated against the general web access rule which blocks access to the hacking sites. |

 © Palo Alto Networks, Inc.

# PAN-DB Categorization Workflow

This section describes the PAN-DB components and describes the URL categorization resolution workflow that occurs as users access various URLs through the firewall.

▲ PAN-DB URL Categorization Components
▲ PAN-DB URL Categorization Workflow

## PAN-DB URL Categorization Components

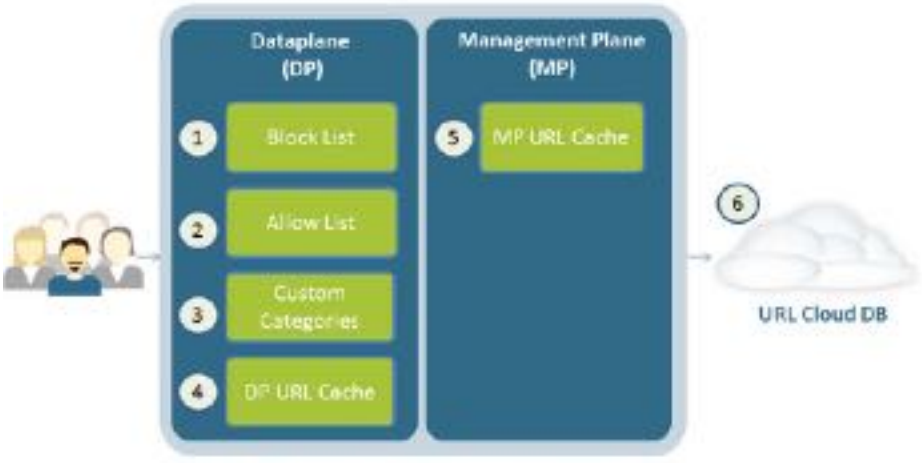
The following table describes the PAN-DB components in detail. The BrightCloud system works similarly, but does not use an initial seed database.

| Component | Description |
|---|---|
| URL Filtering Seed Database | The initial seed database downloaded to the firewall is a small subset of the database that is maintained on the Palo Alto Networks URL cloud servers. The reason this is done is because the full database contains millions of URLs and many of these URLs may never be accessed by your users. When downloading the initial seed database a region is selected (North America, Europe, APAC, Japan) and each region contains a subset of URLs most accessed for the given region. By doing this, the firewall will store a much smaller URL database, which greatly improves lookup performance. If a user accesses a website that is not in the local URL database, the full cloud database is queried and the firewall will then add the new URL to the local database. In other words, the local database on the firewall will be continually populated/customized based on user activity. Note that the local customized URL database will be cleared if the PAN-DB seed database is re-downloaded or if you change the URL database vendor from PAN-DB to BrightCloud. |
| Cloud Service | The PAN-DB cloud service is implemented using Amazon Web Services (AWS). AWS provides a distributed high performance and stable environment for seed database downloads and URL lookups for Palo Alto Networks firewalls and communication is performed over SSL. The AWS cloud systems hold the entire PAN-DB and is updated as new URLs are identified. The PAN-DB cloud service supports an automated mechanism to update the firewall's local URL database if the version does not match. Each time the firewall queries the cloud servers for URL lookups, it will also check for critical updates. If there have been no queries to the cloud servers for more than 30 minutes, the firewall will check for updates on the cloud systems.<br>The cloud system also provides a mechanism to submit URL category change requests. This is performed through the test-a-site service and is available directly from the device (URL filtering profile setup) and from the Palo Alto Networks Test A Site website. You can also submit URL categorization change request directly from URL filtering log on the firewall in the log details section. |

| Component | Description |
|---|---|
| Management Plane (MP) URL Cache | When PAN-DB is activated on the firewall, a seed database is downloaded from one of the PAN-DB cloud servers to initially populate the local cache, which is done to improve lookup performance. Each regional seed database contains the top URLs for the region and the size of the seed database (number of URL entries) also depends on the device platform. The URL MP cache is automatically written to the firewall's local drive every eight hours, before the firewall is rebooted, or when the cloud upgrades the URL database version on the firewall. After rebooting the firewall, the file that was saved to the local drive will be loaded to the MP cache. A least recently used (LRU) mechanism is also implemented in the URL MP cache in case the cache is full. If the cache becomes full, the URLs that have been accessed the least will be replaced by the newer URLs. |
| Dataplane (DP) URL Cache | A subset of the MP cache and is a customized dynamic URL database that is stored in the dataplane (DP) and is used to improve URL lookup performance. The URL DP cache is cleared at each firewall reboot. The number of URLs that are stored in the URL DP cache varies by hardware platform and the current URLs stored in the TRIE (data structure). A least recently used (LRU) mechanism is implemented in the DP cache in case the cache is full. If the cache becomes full, the URLs that have been accessed the least will be replaced by the newer URLs. Entries in the URL DP cache expire after a specified period of time and the expiration period cannot be changed by the administrator. |

## PAN-DB URL Categorization Workflow

When a user attempts to access a URL and the URL category needs to be determined, the firewall will compare the URL with the following components (in order) until a match has been found:



URL Categorization Resolution Process Flow

If a URL query matches an expired entry in the URL DP cache, the cache responds with the expired category, but also sends a URL categorization query to the management plane. This is done to avoid unnecessary delays in the DP, assuming that the frequency of changing categories is low. Similarly, in the URL MP cache, if a URL

 © Palo Alto Networks, Inc.

query from the DP matches an expired entry in the MP, the MP responds to the DP with the expired category and will also send a URL categorization request to the cloud service. Upon getting the response from the cloud, the firewall will resend the updated response to the DP.

As new URLs and categories are defined or if critical updates are needed, the cloud database will be updated. Each time the firewall queries the cloud for a URL lookup or if no cloud lookups have occurred for 30 minute, the database versions on the firewall be compared and if they do not match, an incremental update will be performed.

© Palo Alto Networks, Inc.

# Configure URL Filtering

This section describes the steps required to start using the URL filtering feature. After configuring URL filtering, you can monitor web activity and then determine what actions to take on specific websites and website categories. To control HTTPS traffic, the firewall must have a decryption policy in place between the zones that allow web traffic.

- Enable URL Filtering
- Determine URL Filtering Policy Requirements
- Define Website Controls

© Palo Alto Networks, Inc.

## Enable URL Filtering

To license and enable URL filtering on a Palo Alto Networks firewall:

| Enable URL Filtering | | |
|---|---|---|
| Step 1 | Obtain and install a URL filtering license and confirm that it is installed.<br> <br>The way PAN-DB and BrightCloud function after the URL filtering license expires is different. BrightCloud has an option in the URL profile to either allow all categories or block all categories if the license expires. With PAN-DB, if the license expires, URL filtering will continue to work based on the URL category information that exists in the dataplane and management plane caches, but URL cloud lookups and other cloud-based updates will not function until a valid license is installed. | 1. From **Device > Licenses** in the **License Management** section, select the license install method based on the type of license key you received. This will either be a key that you will retrieve from the license server, an authorization code, or a license file that is manually uploaded.<br>2. After the license is installed, confirm that a valid date is displayed in the **Date Expires field** of the corresponding database. |
| Step 2 | (PAN-DB only) Download the initial seed database and activate PAN-DB URL filtering. | 1. Click **Download** next to **Download Status** in the PAN-DB URL Filtering section.<br>2. Choose a region (North America, Europe, APAC, Japan) and then click **OK** to start the download.<br>3. After the download completes, click **Activate**.<br> <br>If PAN-DB is already the active URL filtering vendor and you click **Re-Download**, this will reactivate PAN-DB by clearing the dataplane and management plane caches and replacing them with the contents of the new seed database. You should avoid doing this unless it is necessary, as you will lose your cache, which is customized based on the web traffic that has previously passed through the firewall based on user activity. |
| Step 3 | (BrightCloud only) Enable cloud lookups for dynamically categorizing a URL if the category is not available on the local database. | 1. Access the CLI on the firewall.<br>2. Enter the following commands to enable Dynamic URL Filtering:<br>**configure**<br>**set deviceconfig setting url dynamic-url yes**<br>**commit** |

| Enable URL Filtering (Continued) | | |
|---|---|---|
| Step 4 | Configure Dynamic Updates for Applications and Threats and if you are using BrightCloud, configure the URL filtering updates.<br><br>The Applications and Threats updates may contain updates for URL filtering related to the Safe Search enforcement option available in the URL Filtering profile. For example, if Palo Alto Networks adds support for a new search provider vendor or if the method used to detect the Safe Search setting for an existing vendor changes, the update will be included in the Application and Threats updates.<br><br>BrightCloud updates include a database of approximately 20 million websites that are stored on the firewall drive, so the URL Filtering update must be scheduled to receive these updates.<br><br> A Threat Prevention license is required to receive content updates, which covers Antivirus and Applications and Threats. | 1. Select **Device > Dynamic Updates**.<br>2. In the **Applications and Threats** section, configure a schedule to receive updates periodically.<br>3. (BrightCloud only) In the **URL Filtering** section, configure a schedule to receive updates periodically. |

 © Palo Alto Networks, Inc.

# Determine URL Filtering Policy Requirements

The recommended practice for deploying URL filtering in your organization is to first start with a passive URL filtering profile that will alert on most categories. After setting the alert action, you can then monitor user web activity for a few days to determine the websites that are being accessed. After doing so, you can then make decisions on the websites and website categories that should be controlled.

- Configure and Apply a Passive URL Filtering Profile
- Monitor Web Activity

## Configure and Apply a Passive URL Filtering Profile

Because the default URL filtering profile blocks risky and threat-prone content, as a best practice, clone this profile when creating a new profile in order to preserve these default settings.

In the procedure that follows, threat-prone sites will be set to block and the other categories will be set to alert, which will cause all websites traffic to be logged. This may potentially create a large amount of log files, so it is best to do this for initial monitoring purposes to determine the types of websites your users are accessing. After determining the categories that your company approves of, those categories should then be set to allow, which will not generate logs. You can also reduce URL filtering logs by enabling the *Log container page only* option in the URL profile, so only the main page that matches the category will be logged, not subsequent pages/categories that may be loaded within the container page.

| **Configure and Apply a Passive URL Filtering Profile** | | |
|---|---|---|
| Step 1 | Clone the default URL filtering profile. | 1. Select **Objects > Security Profiles > URL Filtering**.<br>2. Select the default profile and then click **Clone**. The new profile will be named *default-1*.<br>3. Select the new profile and rename it. For example, rename it to *URL-Monitoring*. |

| Configure and Apply a Passive URL Filtering Profile (Continued) | | |
|---|---|---|
| Step 2 | Configure the action for all categories to *alert*, except for threat-prone categories, which should remain blocked.<br><br>Tip: To select all items in the category list from a Windows system, click the first category then hold down the shift key and click the last category—this will select all categories. Hold the control key (ctrl) down and click items that should be deselected. On a Mac, do the same using the shift and command keys. You could also just set all categories to alert and manually change the recommended categories back to block. | 1. In the section that lists all URL categories, select all categories and then deselect the following categories:<br>• abused-drugs<br>• adult<br>• gambling<br>• hacking<br>• malware<br>• phishing<br>• questionable<br>• weapons<br>2. To the right of the *Action* column heading, mouse over and select the down arrow and then select **Set Selected Actions** and choose **alert**.<br>  <br>3. Click **OK** to save. |
| Step 3 | Apply the URL profile to the security policy that allows web traffic for users. | 1. Select **Policies > Security** and select the appropriate security policy to modify it.<br>2. Select the **Actions** tab and in the **Profile Setting** section, click the drop-down for **URL Filtering** and select the new profile.<br>3. Click **OK** to save. |
| Step 4 | Save the configuration. | Click **Commit**. |
| Step 5 | View the URL filtering logs to determine all of the website categories that your users are accessing. In this example, some categories are set to block, so those categories will also appear in the logs.<br><br>For information on viewing the logs and generating reports, see Monitor Web Activity. | Select **Monitor > Logs > URL Filtering**. A log entry will be created for any website that exists in the URL filtering database that is in a category that is set to any action other than *allow*. |

© Palo Alto Networks, Inc.

## Monitor Web Activity

URL filtering logs and reports show all user web activity for URL categories that are set to alert, block, continue, or override. By monitoring the logs, you can gain a better understanding of the web activity of your user base to determine a web access policy.

This section assumes that a URL profile is configured as described in Configure and Apply a Passive URL Filtering Profile.

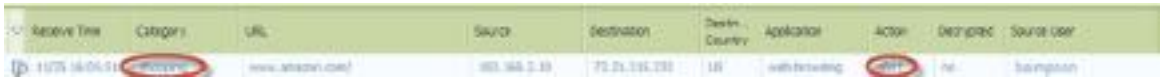
The following topics describe how to monitor web activity:

- Interpret the URL Filtering Logs
- Use the ACC to Monitor Web Activity
- View URL Filtering Reports
- Configure Custom URL Filtering Reports

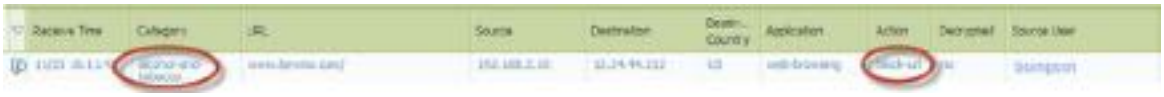
### Interpret the URL Filtering Logs

The following bullet points show examples of the URL filtering logs (**Monitor > Logs > URL filtering**).

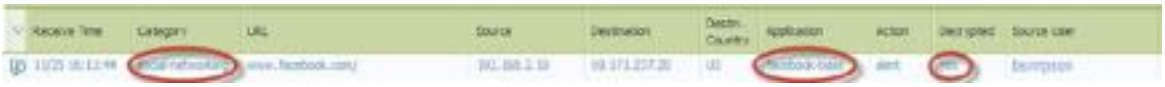
- **Alert log—**In this log the category is shopping and the action is alert.



- **Block log—**In this log, the category alcohol-and-tobacco was set to block, so the action is block-url and the user will see a response page indicating that the website was blocked.



- **Alert log on encrypted website—**In this example, the category is social-networking and the application is facebook-base, which is required to access the Facebook website and other Facebook applications. Because faceboook.com is always encrypted using SSL, the traffic was decrypted by the firewall, which allows the website to be recognized and controlled if needed.



You can also add several other columns to your URL Filtering log view, such as: to and from zone, content type, and whether or not a packet capture was performed. To modify what columns to display, click the down arrow in any column and select the attribute to display.

To view the complete log details and/or request a category change for the given URL that was accessed, click the log details icon in the first column of the log.

## Use the ACC to Monitor Web Activity

For a quick view of the most common categories being accessed in your environment, select the **ACC** tab and scroll down to the **URL Filtering** section. Along the top of this window, you can also set the time range, sort by option, and define how many results will appear. Here you will see the most popular categories that are accessed by your users sorted by the most popular at the top of the list. In this example, *computer-and-internet-info* is the

 © Palo Alto Networks, Inc.

most accessed category, followed by *private-ip-addresses* (internal servers), and *search-engines*. In the drop-down in the upper right of the statistics, you can also choose to list by URL Categories, Blocked URL Categories, and Blocked URLs.

## View URL Filtering Reports

To view the default URL filtering reports, select **Monitor > Reports** and under the **URL Filtering Reports** section, choose one of the reports. You can generate reports on URL Categories, URL users, Web Sites accessed, Blocked Categories, and more. The reports are based on a 24 hour period and the day is selected by choosing a day in the calendar section. You can also export the report to PDF, CSV, or XML.

## View the User Activity Report

This report provides a quick method of viewing user or group activity and also provides an option to view browse time activity.

| Generate a User Activity Report | |
|---|---|
| Step 1 Configure a User Activity Report | 1. Select **Monitor > PDF Reports > User Activity Report**.<br>2. Enter a report **Name** and select the report type. Select **User** to generate a report for one person, or select **Group** for a group of users.<br>You mustEnable User-ID in order to be able to select user or group names. If User-ID is not configured, you can select the type **User** and enter the IP address of the user's computer.<br>3. Enter the Username/IP address for a user report or enter the group name for a user group report.<br>4. Select the time period. You can select an existing time period, or select **Custom**.<br>5. Select the **Include Detailed Browsing** check box, so browsing information is included in the report.<br> |
| Step 2 Run the user activity report and then download the report. | 1. Click **Run Now**.<br>2. After the report is generated, click the **Download User Activity Report** link.<br>  <br>3. After the report is downloaded, click **Cancel** and then click **OK** to save the report. |

© Palo Alto Networks, Inc.

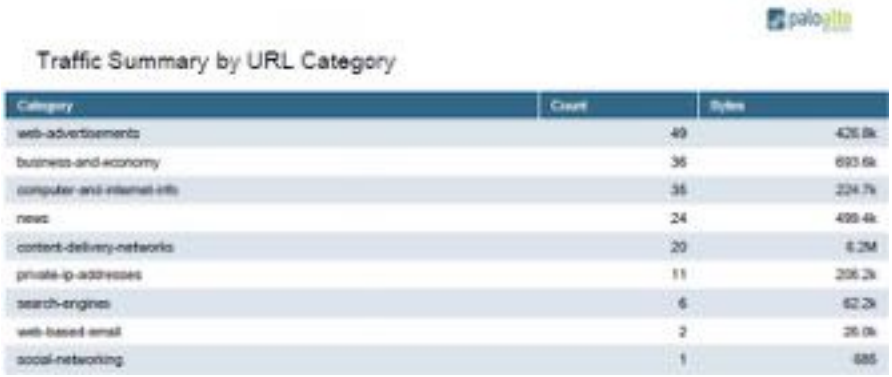
**Generate a User Activity Report (Continued)**

Step 3 View the user activity report by opening the PDF file that was downloaded. The top of the report will contain a table of contents similar to the following:

User Activity Report for 192.168.2.10
Tuesday, December 31, 2013 09:35:47 - 10:35:46

Application Usage 2
Traffic Summary by URL Category 3
Browsing Summary by URL Category 4
Browsing Summary by Website 5
Blocked Browsing Summary by Website 6
Detailed Web Browsing Activity 7

Step 4 Click an item in the table of contents to view details. For example, click *Traffic Summary by URL Category* to view statistics for the selected user or group.



Traffic Summary by URL Category

| Category | Count | Bytes |
|---|---|---|
| web-advertisements | 49 | 426.8k |
| business-and-economy | 36 | 693.6k |
| computer-and-internet-info | 36 | 224.7k |
| news | 24 | 499.4k |
| content-delivery-networks | 20 | 6.2M |
| private-ip-addresses | 11 | 206.2k |
| search-engines | 6 | 62.2k |
| web-based-email | 2 | 26.0k |
| social-networking | 1 | 686 |

## Configure Custom URL Filtering Reports

To generate a detailed report that can also be scheduled, you can configure a custom report and select from a list of all available URL filtering log fields.

**Configure a Custom URL Filtering Report**

| | |
|---|---|
| Step 1 Add a new custom report. | 1. Select **Monitor > Manage Custom Reports** and click **Add**.<br>2. Enter a report name in the **Name** field. For example, *My-URL-Custom-Report*.<br>3. From the **Database** drop-down, select **URL Log**. |

| Configure a Custom URL Filtering Report (Continued) | | |
|---|---|---|
| Step 2 | Configure report options. | 1. Select the **Time Frame** drop-down and select a range.<br>2. (Optional) To customize how the report is sorted and grouped, select **Sort By** and chose the number of items to display (top 25 for example) and then select **Group By** and select an option such as **Category**, and then select how many groups will be defined.<br>3. In the **Available Columns** list, select the fields to include the report. The following columns are typically used for a URL report:<br>• Action<br>• Category<br>• Destination Country<br>• Source User<br>• URL<br> |
| Step 3 | Run the report to check the results. If the results are satisfactory, set a schedule to run the report automatically. | 1. Click the **Run Now** icon to immediately generate the report that will appear in a new tab.<br>2. (Optional) Click the **Schedule** check box to run the report once per day. This will generate a daily report that details web activity over the last 24 hours. To access the report, select **Monitor > Report** and then expand **Custom Reports** on the right column and select the report. |
| Step 4 | Save the configuration. | Click **Commit**. |

© Palo Alto Networks, Inc.

## Define Website Controls

After you Determine URL Filtering Policy Requirements, you should have a basic understanding on what types of websites and website categories that your users are accessing. With this information, you are now ready to customize your URL filtering policies to control how your users access the web. The procedures that follow describe how to change the actions in URL profiles, use the Safe Search Enforcement option, and other features related to controlling content.

| Configure Website Controls | | |
|---|---|---|
| Step 1 | Customize the URL profile to control websites and website categories. | 1. Select **Objects > Security Profiles > URL Filtering** and modify your URL profile.<br>2. In the Category list, select the appropriate action for each URL category you want to control. For example, you may want to block categories such as auctions, gaming, and dating, but allow social-networking. |
| Step 2 | Configure websites that should always be blocked or allowed.<br><br>For example, to reduce URL filtering logs, you may want to enter all of your corporate websites in the allow list, so no log will be generated for those sites. If there is a website this is being overly used and is not work related in any way, you can add those in the block list.<br><br>Items in the block list will always be blocked regardless of the action for the given category, and URLs in the allow list will always be allowed.<br><br>For more information on the proper format and wildcards usage, see Block and Allow Lists. | 1. In the URL filtering profile, enter URLs or IP addresses in the **Block List** and select an action:<br>• **Block**—Block the URL.<br>• **Continue**—Users will be prompted with a response page when visiting a site that matches the defined URL category. If the user clicks *Continue*, the web page will open.<br>• **Override**—The user will be a prompted for a password to continue to the website.<br>• **Alert**—Allow the user to access the website and add an alert log entry in the URL log.<br>2. For the **Allow** list, enter IP addresses or URLs that should always be allowed. Each row must be separated by a new line.<br><br>In the following URL profile, social-networking is blocked, but Facebook is allowed. The corporate website paloaltonetworks.com is also allowed, so no logging will occur. The block list contains a server IP address that will always be blocked.<br><br> <br><br>3. (Optional) Enable Safe Search Enforcement. |
| Step 3 | Enable logging for Container Pages only. | Select the **Log container page only** check box. |

| Configure Website Controls | | |
|---|---|---|
| Step 4 | Save the URL filtering profile. | Click **OK**. |
| Step 5 | (Optional) Enable response pages on the ingress interface (the interface that first receives traffic for your users).<br><br>This option is required if you enable the *continue* action is configured for any URL category. | 1. Select **Network > Network Profiles > Interface Mgmt** and either add a new profile or edit an existing profile.<br>2. Click the **Response Pages** check box to enable.<br>3. Click **OK** to save the profile.<br>4. Select **Network > Interfaces** and then edit the layer 3 interface or VLAN interface that is your ingress interface.<br>5. Click the **Advanced** tab and select the Interface Mgmt profile that has the response page option enabled and select it from the drop-down menu.<br>6. Click **OK** to save the interface configuration. |
| Step 6 | (Optional) Customize URL filtering response pages.<br><br>There are three different response pages for URL filtering:<br>• **URL Filtering and Category Match Block Page**—Access blocked by a URL filtering profile or because the URL category is blocked by a security policy.<br>• **URL Filtering Continue and Override Page**—Page with initial block policy that allows users to bypass the block. With the override page, a password is required for the user to override the policy that blocks the URL.<br>• **URL Filtering Safe Search Block Page**—Access blocked by a security policy with a URL filtering profile that has the Safe Search Enforcement option enabled. The user will see this page if a search is performed using Google, Bing, or Yahoo and their browser or search engine account setting for Safe Search is not set to strict. | 1. Select **Device > Response Pages**.<br>2. Click the URL filtering response page that you would like to modify.<br>3. Select the response page (predefined or shared) and then click the **Export** link and save the file to your desktop.<br> Predefined is the default response page and shared is a custom response page created by an administrator.<br>4. Modify the response page using a text editor and then save the file.<br>5. From the response page dialogue, click **Import** and select the newly modified response page and then click **OK** to import the file.<br>6. The newly imported response page will become the active response page. |

 © Palo Alto Networks, Inc.

| Configure Website Controls | | |
|---|---|---|
| Step 7 | Configure a URL filtering override to create a temporary password that can be used by specific users to access sites that are blocked. | 1. Select **Device > Setup > Content ID**.<br>2. In the **URL Admin Override** section, click **Add** to configure a password.<br>3. (Optional) Set a custom override period by entering a new value in the **URL Admin Override Timeout** field. By default, users can access a blocked URL categories for 15 minutes.<br>4. When setting the password, you can choose **Transparent** or **Redirect**.<br>• **Transparent**—The firewall intercepts the browser traffic and impersonates the original destination URL, issuing an HTTP 401 to invoke authentication. However, because the firewall does not have the real certificate for the destination URL, the browser will display a certificate error to users attempting to access a secure site. Therefore you should only use this mode when absolutely necessary, such as in Layer 2 or virtual wire deployments.<br>• **Redirect**—The firewall intercepts unknown HTTP or HTTPS sessions and redirects them to a Layer 3 interface on the firewall using an HTTP 302 redirect in order to perform authentication. This is the preferred mode because it provides a better end-user experience (no certificate errors). However, it does require additional Layer 3 configuration. Another benefit of the Redirect mode is that it provides the use of session cookies, which enable the user to continue browsing to authenticated sites without requiring re-mapping each time the time-out expires. |
| Step 8 | Save the configuration.<br> To test the URL filtering configuration, simply access a website in a category that is set to block or continue to see if the appropriate action is performed. | Click **Commit**. |

# Enable Safe Search Enforcement

Many search engines have a safe search setting that filters out adult images and videos for search query return traffic. You can configure Safe Search Enforcement on the Palo Alto Networks next-generation firewall to prevent search requests that do not have the strictest safe search settings enabled.

The Safe Search Enforcement for Google and YouTube Searches using a Virtual IP Address is not compatible with Safe Search Enforcement on the firewall.

There are two ways to enforce Safe Search on the firewall:

- Block Search Results that are not Using Strict Safe Search Settings
- Enable Transparent Safe Search Enforcement

## Block Search Results that are not Using Strict Safe Search Settings

By default, when you enable safe search enforcement, when a user attempts to perform a search without using the strictest safe search settings, the firewall will block the search query results and display the URL Filtering Safe Search Block Page. This page provides a link to the search settings page for the corresponding search provider so that the end user can enable the safe search settings. If you plan to use this default method for enforcing safe search, you should communicate the policy to your end users prior to deploying the policy. See Table: Search Provider Safe Search Settings for details on how each search provider implements safe search. The default URL Filtering Safe Search Block Page provides a link to the search settings for the corresponding search provider. You can optionally customize the URL filtering response pages.

Alternatively, to enable safe search enforcement so that it is transparent to your end users, configure the firewall to Enable Transparent Safe Search Enforcement.

 © Palo Alto Networks, Inc.

| Enable Safe Search Enforcement | | |
|---|---|---|
| Step 1 | Enable Safe Search Enforcement in the URL Filtering profile. | 1. Select **Objects > Security Profiles > URL Filtering**.<br>2. Select an existing profile to modify, or clone the default profile to create a new profile.<br>3. On the **Settings** tab, select the **Safe Search Enforcement** check box to enable it.<br>4. (Optional) Restrict users to specific search engines:<br>a. On the **Categories** tab, set the **search-engines** category to **block**.<br>b. For each search engine that you want end users to be able to access, enter the web address in the **Allow List** text box. For example, to allow users access to Google and Bing searches only, you would enter the following:<br>`www.google.com`<br>`www.bing.com`<br>5. Configure other settings as necessary to Define Website Controls.<br>6. Click **OK** to save the profile. |
| Step 2 | Add the URL Filtering profile to the security policy rule that allows traffic from clients in the trust zone to the Internet. | 1. Select **Policies > Security** and select a rule to which to apply the URL filtering profile that you just enabled for Safe Search Enforcement.<br>2. On the **Actions** tab, select the **URL Filtering** profile.<br>3. Click **OK** to save the security policy rule. |
| Step 3 | Enable SSL Forward Proxy decryption.<br>Because most search engines encrypt their search results, you must enable SSL forward proxy decryption so that the firewall can inspect the search traffic and detect the safe search settings. | 1. Add a custom URL category for the search sites:<br>a. Select **Objects > Custom Objects > URL Category** and **Add** a custom category.<br>b. Enter a **Name** for the category, such as SearchEngineDecryption.<br>c. **Add** the following to the Sites list:<br>`www.bing.*`<br>`www.google.*`<br>`search.yahoo.*`<br>d. Click **OK** to save the custom URL category object.<br>2. Follow the steps to Configure SSL Forward Proxy.<br>3. On the **Service/URL Category** tab in the Decryption policy rule, **Add** the custom URL category you just created and then click **OK**. |

| Enable Safe Search Enforcement (Continued) | | |
|---|---|---|
| Step 4 | (Optional, but recommended) Block Bing search traffic running over SSL.<br><br>Because the Bing SSL search engine does not adhere to the safe search settings, for full safe search enforcement, you must deny all Bing sessions that run over SSL. | 1. Add a custom URL category for Bing:<br>a. Select **Objects > Custom Objects > URL Category** and **Add** a custom category.<br>b. Enter a **Name** for the category, such as EnableBingSafeSearch.<br>c. **Add** the following to the Sites list:<br>`www.bing.com/images/*`<br>`www.bing.com/videos/*`<br>d. Click **OK** to save the custom URL category object.<br>2. Create another URL filtering profile to block the custom category you just created:<br>a. Select **Objects > Security Profiles > URL Filtering**.<br>b. **Add** a new profile and give it a descriptive **Name**.<br>c. Locate the custom category in the Category list and set it to **block**.<br>d. Click **OK** to save the URL filtering profile.<br>3. Add a security policy rule to block Bing SSL traffic:<br>a. Select **Policies > Security** and **Add** a policy rule that allows traffic from your trust zone to the Internet.<br>b. On the **Actions** tab, attach the URL filtering profile you just created to block the custom Bing category.<br>c. On the **Service/URL Category** tab **Add** a **New Service** and give it a descriptive **Name**, such as bingssl.<br>d. Select **TCP** as the **Protocol** and set the **Destination Port** to `443`.<br>e. Click **OK** to save the rule.<br>f. Use the **Move** options to ensure that this rule is below the rule that has the URL filtering profile with safe search enforcement enabled. |
| Step 5 | Save the configuration. | Click **Commit**. |

© Palo Alto Networks, Inc.

| Enable Safe Search Enforcement (Continued) | |
|---|---|
| Step 6 Verify the Safe Search Enforcement configuration.<br><br>This verification step only works if you are using block pages to enforce safe search. If you are using transparent safe search enforcement, the firewall block page will invoke a URL rewrite with the safe search parameters in the query string. | 1. From a computer that is behind the firewall, disable the strict search settings for one of the supported search providers. For example, on bing.com, click the **Preferences** icon on the Bing menu bar.<br><br>  <br><br>2. Set the **SafeSearch** option to **Moderate** or **Off** and click **Save**.<br>3. Perform a Bing search and verify that the URL Filtering Safe Search Block page displays instead of the search results:<br><br> <br><br>4. Use the link in the block page to go to the search settings for the search provider and set the safe search setting back to the strictest setting (**Strict** in the case of Bing) and then click **Save**.<br>5. Perform a search again from Bing and verify that the filtered search results display instead of the block page. |

## Enable Transparent Safe Search Enforcement

If you want to enforce filtering of search query results with the strictest safe search filters, but you don't want your end users to have to manually configure the settings, you can enable transparent safe search enforcement as follows. This functionality is supported on Google, Yahoo, and Bing search engines only and requires Content Release version 475 or later.

| **Enable Transparent Safe Search Enforcement** | | |
|---|---|---|
| Step 1 | Make sure the firewall is running Content Release version 475 or later. | 1. Select **Device > Dynamic Updates**.<br>2. Check the **Applications and Threats** section to determine what update is currently running.<br>3. If the firewall is not running the required update or later, click **Check Now** to retrieve a list of available updates.<br>4. Locate the required update and click **Download**.<br>5. After the download completes, click **Install**. |
| Step 1 | Enable Safe Search Enforcement in the URL Filtering profile. | 1. Select **Objects > Security Profiles > URL Filtering**.<br>2. Select an existing profile to modify, or clone the default profile to create a new one.<br>3. On the **Settings** tab, select the **Safe Search Enforcement** check box to enable it.<br>4. (Optional) Allow access to specific search engines only:<br>a. On the **Categories** tab, set the **search-engines** category to **block**.<br>b. For each search engine that you want end users to be able to access, enter the web address in the **Allow List** text box. For example, to allow users access to Google and Bing searches only, you would enter the following:<br>`www.google.com`<br>`www.bing.com`<br>5. Configure other settings as necessary to Define Website Controls.<br>6. Click **OK** to save the profile. |
| Step 2 | Add the URL Filtering profile to the security policy rule that allows traffic from clients in the trust zone to the Internet. | 1. Select **Policies > Security** and select a rule to which to apply the URL filtering profile that you just enabled for Safe Search Enforcement.<br>2. On the **Actions** tab, select the **URL Filtering** profile.<br>3. Click **OK** to save the security policy rule. |

© Palo Alto Networks, Inc.

| Enable Transparent Safe Search Enforcement (Continued) | |
|---|---|
| Step 3 (Optional, but recommended) Block Bing search traffic running over SSL.<br><br>Because the Bing SSL search engine does not adhere to the safe search settings, for full safe search enforcement, you must deny all Bing sessions that run over SSL. | 1. Add a custom URL category for Bing:<br>a. Select **Objects > Custom Objects > URL Category** and **Add** a custom category.<br>b. Enter a **Name** for the category, such as EnableBingSafeSearch.<br>c. **Add** the following to the Sites list:<br>`www.bing.com/images/*`<br>`www.bing.com/videos/*`<br>d. Click **OK** to save the custom URL category object.<br>2. Create another URL filtering profile to block the custom category you just created:<br>a. Select **Objects > Security Profiles > URL Filtering**.<br>b. **Add** a new profile and give it a descriptive **Name**.<br>c. Locate the custom category you just created in the Category list and set it to **block**.<br>d. Click **OK** to save the URL filtering profile.<br>3. **Add** a security policy rule to block Bing SSL traffic:<br>a. Select **Policies > Security** and **Add** a policy rule that allows traffic from your trust zone to the Internet.<br>b. On the **Actions** tab, attach the URL filtering profile you just created to block the custom Bing category.<br>c. On the **Service/URL Category** tab **Add** a **New Service** and give it a descriptive **Name**, such as bingssl.<br>d. Select **TCP** as the **Protocol**, set the **Destination Port** to `443`.<br>e. Click **OK** to save the rule.<br>f. Use the **Move** options to ensure that this rule is below the rule that has the URL filtering profile with safe search enforcement enabled. |

© Palo Alto Networks, Inc.

**Enable Transparent Safe Search Enforcement (Continued)**

**Step 4** Edit the URL Filtering Safe Search Block Page, replacing the existing code with the Javascript for rewriting search query URLs to enforce safe search transparently.

1. Select **Device > Response Pages > URL Filtering Safe Search Block Page**.
2. Select **Predefined** and then click **Export** to save the file locally.
3. Use an HTML editor and replace all of the existing block page text with the following text and then save the file:

```
<html>
<head>
<script>

var s_u = location.href;

//bing
b_n = s_u.search("www.bing.com/")

if (b_n > 0) {
    s_u = s_u + "&adlt=strict";
}

//google
g_n = s_u.search("www.google.com/")

if (g_n > 0) {
    s_u = s_u + "&safe=active";
}

// yahoo
y_n = s_u.search("search.yahoo.com")

if (y_n > 0) {
    s_u = s_u.replace(/&vm=p/ig,"");
    s_u = s_u + "&vm=r";
}

window.location.replace(s_u);

document.getElementById("java_off").innerHTML = 'You are
  being redirected to a safer search!';

</script>
<title>Search Blocked</title>
<meta http-equiv="Content-Type" content="text/html;
  charset=utf-8">
<META HTTP-EQUIV="PRAGMA" CONTENT="NO-CACHE">
<meta name="viewport" content="initial-scale=1.0">
</head>
    <body bgcolor="#e7e8e9" id="java_off">
    Your search is not safesearch enforced!
    Please enable Java script in your browser.
</body>
</html>
```

**Step 5** Import the edited URL Filtering Safe Search Block page onto the firewall.

1. To import the edited block page, select **Device > Response Pages > URL Filtering Safe Search Block Page**.
2. Click **Import** and then enter the path and filename in the **Import File** field or **Browse** to locate the file.
3. (Optional) Select the virtual system on which this login page will be used from the **Destination** drop-down or select **shared** to make it available to all virtual systems.
4. Click **OK** to import the file.

© Palo Alto Networks, Inc.

| Enable Transparent Safe Search Enforcement (Continued) | | |
|---|---|---|
| Step 6 | Enable SSL Forward Proxy decryption.<br><br>Because most search engines encrypt their search results, you must enable SSL forward proxy decryption so that the firewall can inspect the search traffic and detect the safe search settings. | 1. Add a custom URL category for the search sites:<br>a. Select **Objects > Custom Objects > URL Category** and **Add** a custom category.<br>b. Enter a **Name** for the category, such as SearchEngineDecryption.<br>c. **Add** the following to the Sites list:<br>`www.bing.*`<br>`www.google.*`<br>`search.yahoo.*`<br>d. Click **OK** to save the custom URL category object.<br>2. Follow the steps to Configure SSL Forward Proxy.<br>3. On the **Service/URL Category** tab in the Decryption policy rule, **Add** the custom URL category you just created and then click **OK**. |
| Step 7 | Save the configuration. | Click **Commit**. |

# URL Filtering Use Case Examples

The following use cases show how to use App-ID to control a specific set of web-based applications and how to use URL categories as a match criteria in a policy. When working with App-ID, it is important to understand that each App-ID signature may have dependencies that are required to fully control an application. For example, with Facebook applications, the App-ID facebook-base is required to access the Facebook website and to control other Facebook applications. For example, to configure the firewall to control Facebook email, you would have to allow the App-IDs facebook-base and facebook-mail. As another example, if you search Applipedia (the App-ID database) for LinkedIn, you will see that in order to control LinkedIn mail, you need to apply the same action to both App-IDs: linkedin-base and linkedin-mail. To determine application dependencies for App-ID signatures, visit Applipedia, search for the given application, and then click the application for details.

The User-ID feature is required to implement policies based on users and groups and a Decryption policy is required to identify and control websites that are encrypted using SSL.

This section includes two uses cases:

- Use Case: Control Web Access
- Use Case: Use URL Categories in Policy

 © Palo Alto Networks, Inc.

## Use Case: Control Web Access

When using URL filtering to control user website access, there may be instances where granular control is required for a given website. In this use case, a URL filtering policy is applied to the security policy that allows web access for your users and the *social-networking* URL category is set to block, but the allow list in the URL profile is configured to allow the social networking site Facebook. To further control Facebook, the company policy also states that only marketing has full access to Facebook and all other users within the company can only read Facebook posts and cannot use any other Facebook applications, such as email, posting, chat, and file sharing. To accomplish this requirement, App-ID must be used to provide granular control over Facebook.

The first security rule will allow marketing to access the Facebook website as well as all Facebook applications. Because this allow rule will also allow access to the Internet, threat prevention profiles are applied to the rule, so traffic that matches the policy will be scanned for threats. This is important because the allow rule is terminal and will not continue to check other rules if there is a traffic match.

| **Control Web Access** | | |
|---|---|---|
| Step 1 | Confirm that URL filtering is licensed. | 1. Select **Device > Licenses** and confirm that a valid date appears for the URL filtering database that will used. This will either be PAN-DB or BrightCloud.<br>2. If a valid license is not installed, see Enable URL Filtering. |
| Step 2 | Confirm that User-ID is working. User-ID is required to create policies based on users and groups. | 1. To check group mapping, from the CLI, enter the following command:<br>`show user group-mapping statistics`<br>2. To check user mapping, from the CLI, enter the following command:<br>`show user ip-user-mapping-mp all`<br>3. If statistics do not appear and/or IP to user mapping information is not displayed, see User-ID. |
| Step 3 | Set up a URL filtering profile by cloning the default profile. | 1. Select **Objects > Security Profiles > URL Filtering** and select the *default* profile.<br>2. Click the **Clone** icon. A new profile should appear named *default-1*.<br>3. Select the new profile and rename it. |

| Control Web Access (Continued) | | |
|---|---|---|
| Step 4 | Configure the URL filtering profile to block *social-networking* and allow *Facebook*. | 1. Modify the new URL filtering profile and in the **Category** list scroll to *social-networking* and in the **Action** column click on *allow* and change the action to *block*.<br>2. In the **Allow List** box, type *facebook.com*, press enter to start a new line and then type **.facebook.com*. Both of these formats are required, so all URL variants a user may use will be identified, such as facebook.com, www.facebook.com, and https://facebook.com.<br>  <br>3. Click **OK** to save the profile. |
| Step 5 | Apply the new URL filtering profile to the security policy rule that allows web access from the user network to the Internet. | 1. Select **Policies > Security** and click on the policy rule that allows web access.<br>2. On the **Actions** tab, select the URL profile you just created from the **URL Filtering** drop down.<br>  <br>3. Click **OK** to save. |

© Palo Alto Networks, Inc.

**Control Web Access (Continued)**

Step 6 Create the security policy that will allow marketing access the Facebook website and all Facebook applications.

This rule must precede other rules because it is more specific than the other policies and because it is an allow rule, which will terminate when a traffic match occurs.

1. Select **Policies > Security** and click **Add**.
2. Enter a **Name** and optionally a **Description** and **Tag**(s).
3. On the **Source** tab add the zone where the users are connected.
4. On the **User** tab in the **Source User** section click **Add**.
5. Select the directory group that contains your *marketing* users.
6. On the **Destination** tab, select the zone that is connected to the Internet.
7. On the **Applications** tab, click **Add** and add the *facebook* App-ID signature.
8. On the **Actions** tab, add the default profiles for **Antivirus**, **Vulnerability Protection**, and **Anti-Spyware**.

9. Click **OK** to save the security profile.

The *facebook* App-ID signature used in this policy encompasses all Facebook applications, such as facebook-base, facebook-chat, and facebook-mail, so this is the only App-ID signature required in this rule.

With this policy in place, when a marketing employee attempts to access the Facebook website or any Facebook application, the rule matches based on the user being part of the marketing group. For traffic from any user outside of marketing, the rule will be skipped because there would not be a traffic match and rule processing would continue.

**Control Web Access (Continued)**

Step 7 Configure the security policy to block all other users from using any Facebook applications, other than simple web browsing. The easiest way to do this is to clone the marketing allow policy and then modify it.

1. From **Policies > Security** click the marketing Facebook allow policy you created earlier to highlight it and then click the **Clone** icon.
2. Enter a **Name** and optionally enter a **Description** and **Tag**('s).
3. On the **User** tab highlight the marketing group and delete it and in the drop-down select **any**.
4. On the **Applications** tab, click the *facebook* App-ID signature and delete it.
5. Click **Add** and add the following App-ID signatures:
   - facebook-apps
   - facebook-chat
   - facebook-file-sharing
   - facebook-mail
   - facebook-posting
   - facebook-social-plugin
6. On the **Actions** tab in the **Action Setting** section, select **Deny**. The profile settings should already be correct because this rule was cloned.

7. Click **OK** to save the security profile.
8. Ensure that this new deny rule is listed after the marketing allow rule, to ensure that rule processing occurs in the correct order to allow marketing users and then to deny/limit all other users.
9. Click **Commit** to save the configuration.

With these policies in place, any user who is part of the marketing group will have full access to all Facebook applications and any user that is not part of the marketing group will only have read-only access to the Facebook website and will not be able to use Facebook functions such as post, chat, email, and file sharing.

 © Palo Alto Networks, Inc.

## Use Case: Use URL Categories in Policy

URL categories can also be used as a match criteria in the following policy types: captive portal, decryption, security, and QoS. In this use case, URL categories will be used in decryption policies to control which web categories should be decrypted or not decrypted. The first rule is a no-decrypt rule that will not decrypt user traffic if the website category is *financial-services* or *health-and-medicine* and the second rule will decrypt all other traffic. The decryption policy type is *ssl-forward-proxy*, which is used for controlling decryption for all outbound connections performed by users.

**Configure a Decryption Policy Based on URL Category**

Step 1 Create the no-decrypt rule that will be listed first in the decryption policies list. This will prevent any website that is in the *financial-services* or *health-and-medicine* URL categories from being decrypted.

1. Select **Policies > Decryption** and click **Add**.
2. Enter a **Name** and optionally enter a **Description** and **Tag**(s).
3. On the **Source** tab add the zone where the users are connected.
4. On the **Destination** tab enter the zone that is connected to the Internet.
5. On the **URL Category** tab click **Add** and select the *financial-services* and *health-and-medicine* URL categories.
6. On the **Options** tab, set the action to **No Decrypt** and the **Type** to **SSL Forward Proxy**.

7. Click **OK** to save the policy.

Step 2 Create the decryption policy that will decrypt all other traffic. This policy will be listed after the no-decrypt policy.

1. Select the no-decrypt policy you created previously and then click **Clone**.
2. Enter a **Name** and optionally enter a **Description** and **Tag**(s).
3. On the **URL Category** tab, select *financial-services* and *health-and-medicine* and then click the **Delete** icon.
4. On the **Options** tab, set the action to **Decrypt** and the **Type** to **SSL Forward Proxy**.

5. Ensure that this new decryption rule is listed after the no-decrypt rule as shown in the previous screen capture. This will ensure that rule processing occurs in the correct order, so websites in the *financial-services* and *health-and-medicine* are not decrypted
6. Click **OK** to save the policy.

| Configure a Decryption Policy Based on URL Category (Continued) | | |
|---|---|---|
| Step 3 | (BrightCloud only) Enable cloud lookups for dynamically categorizing a URL when it the category is not available on the local database on the firewall. | 1. Access the CLI on the firewall.<br>2. Enter the following commands to enable Dynamic URL Filtering:<br>a. **configure**<br>b. **set deviceconfig setting url dynamic-url yes**<br>c. commit |
| Step 4 | Save the configuration. | Click **Commit**. |

With these two decrypt policies in place, any traffic destined for the *financial-services* or *health-and-medicine* URL categories, the traffic will not be decrypted. All other traffic will be decrypted.

You can also define more granular control over decryption policies by defining decryption profiles, which are used to perform checks such as server certificate checks or blocking sessions with expired certificates. The profile is then added in the **Options** tab of the decryption policy. For a complete list of checks that can be performed, select **Objects > Decryption Profiles** from the firewall and then click the help icon.

Now that you have a basic understanding of the powerful features of URL filtering, App-ID, and User-ID, you can apply similar policies to your firewall to control any application in the Palo Alto Networks App-ID signature database and control any website contained in the URL filtering database.

For help in troubleshooting URL filtering issues, see Troubleshoot URL Filtering.

 © Palo Alto Networks, Inc.

# Troubleshoot URL Filtering

This following topics provide troubleshooting guidelines for diagnosing and resolving common URL filtering problems.

- Problems Activating PAN-DB
- PAN-DB Cloud Connectivity Issues
- URLs Classified as Not-Resolved
- Incorrect Categorization
- URL Database Out of Date

## Problems Activating PAN-DB

The following table describes procedures that you can use to resolve issues with activating PAN-DB.

| Troubleshoot PAN-DB Activation Issues | |
|---|---|
| Step 1 | Access the CLI on the firewall. |
| Step 2 | Verify if PAN-DB has been activated by running the following command:<br>`admin@PA-200> show system setting url-database`<br>If the response is `paloaltonetworks`, then PAN-DB is the active vendor. |
| Step 3 | Verify that the firewall has a valid PAN-DB license by running the following command:<br>`admin@PA-200> request license info`<br>You should see the license entry Feature: PAN_DB URL Filtering. If the license is not installed, you will need to obtain and install a license. See Configure URL Filtering. |
| Step 4 | After the license is installed, download a new PAN-DB seed database by running the following command:<br>`admin@PA-200> request url-filtering download paloaltonetworks region` *<region>* |
| Step 5 | Check the download status by running the following command:<br>`admin@PA-200> request url-filtering download status vendor paloaltonetworks`<br>• If the message is different than `PAN-DB download: Finished successfully`, stop here, there may be a problem connecting to the cloud. Attempt to solve the connectivity issue by performing basic network troubleshooting between the firewall and the Internet. For more information, see PAN-DB Cloud Connectivity Issues.<br>• If the message is `PAN-DB download: Finished successfully`, the firewall successfully downloaded the URL seed database. Try to enable PAN-DB again by running the following command:<br>`admin@PA-200> set system setting url-database paloaltonetworks` |
| Step 6 | If the problems persists, contact Palo Alto Networks support. |

## PAN-DB Cloud Connectivity Issues

To check cloud connectivity, run the following command:

```
admin@pa-200> show url-cloud status
```

If the cloud is accessible, the expected response should be similar to the following:

```
admin@PA-200> show url-cloud status
PAN-DB URL Filtering
License :                          valid
Current cloud server :             s0000.urlcloud.paloaltonetworks.com
Cloud connection :                 connected
URL database version - device :    2013.11.18.000
URL database version - cloud :     2013.11.18.000  ( last update time
2013/11/19
 13:20:51 )
URL database status :              good
URL protocol version - device :    pan/0.0.2
URL protocol version - cloud :     pan/0.0.2
Protocol compatibility status :    compatible
```

If the cloud is note accessible, the expected response will be similar to the following:

```
admin@PA-200> show url-cloud status
PAN-DB URL Filtering
License :                          valid
Cloud connection :                 not connected
URL database version - device :    2013.11.18.000
URL database version - cloud :     2013.11.18.000  ( last update time
2013/11/19
 13:20:51 )
URL database status :              good
URL protocol version - device :    pan/0.0.2
URL protocol version - cloud :     pan/0.0.2
Protocol compatibility status :    compatible
```

The following table describes procedures that you can use to resolve issues based on the output of the show cloud status command, how to ping the URL cloud servers, and what to check if the firewall is in a High Availability (HA) configuration.

 © Palo Alto Networks, Inc.

| Troubleshoot Cloud Connectivity Issues |
|---|
| • PAN-DB URL Filtering license field shows invalid—Obtain and install a valid PAN-DB license.<br>• URL database status is out of date—Download a new seed database by running the following command:<br>• admin@pa-200> request url-filtering download paloaltonetworks region <region><br>• URL protocol version shows not compatible—Upgrade PAN-OS to the latest version.<br>• Attempt to ping the PAN-DB cloud server from the firewall by running the following command:<br>• admin@pa-200> ping source *ip-address* host s0000.urlcloud.paloaltonetworks.com<br>• For example, if your management interface IP address is 10.1.1.5, run the following command:<br>• admin@pa-200> ping source 10.1.1.5 host s0000.urlcloud.paloaltonetworks.com<br>• If the firewall is in an HA configuration, verify that the HA state of the devices supports connectivity to the cloud systems. You can determine the HA state by running the following command:<br>• admin@pa-200> show high-availability state<br>Connection to the cloud will be blocked if the firewall is not in one of the following states:<br>• active<br>• active-primary<br>• active-secondary<br>If the problem persists, contact Palo Alto Networks support. |

## URLs Classified as Not-Resolved

The following table describes procedures you can use to resolve issues where some or all of the URLs being identified by PAN-DB are classified as *Not-resolved*:

| Troubleshoot URLs Classified as Not-Resolved | |
|---|---|
| Step 1 | Check the PAN-DB cloud connection by running the following command:<br>`admin@PA-200> show url-cloud status`<br>The Cloud connection: field should show *connected*. If you see anything other than *connected*, any URL that do not exist in the management plane cache will be categorized as *not-resolved*. To resolve this issue, see PAN-DB Cloud Connectivity Issues. |
| Step 2 | If the cloud connection status shows *connected*, check the current utilization of the firewall. If the firewall's performance is spiking, URL requests may be dropped (may not reach the management plane), and will be categorized as *not-resolved*.<br>To view system resources, run the following command and view the *%CPU* and *%MEM* columns:<br>`admin@PA-200> show system resources`<br>You can also view system resources from the firewall's web interfaces by clicking the **Dashboard** tab and viewing the **System Resources** section. |
| Step 3 | If the problem persist, contact Palo Alto Networks support. |

## Incorrect Categorization

The following steps describe the procedures you can use if you identify a URL that does not have the correct categorization. For example, if the URL *paloaltonetworks.com* was categorized as *alcohol-and-tobacco*, the categorization is not correct; the category should be *computer-and-internet-info*.

| Troubleshoot Incorrect Categorization Issues | |
|---|---|
| Step 1 | Verify the category in the dataplane by running the following command:<br>`admin@PA-200>` show running url <*URL*><br>For example, to view the category for the Palo Alto Networks website, run the following command:<br>`admin@PA-200> show running url paloaltonetworks.com`<br>If the URL stored in the dataplane cache has the correct category (computer-and-internet-info in this example), then the categorization is correct and no further action is required. If the category is not correct, continue to the next step. |
| Step 2 | Verify if the category in the management plane by running the command:<br>`admin@PA-200> test url-info-host` <*URL*><br>For example:<br>`admin@PA-200> test url-info-host paloaltonetworks.com`<br>If the URL stored in the management plane cache has the correct category, remove the URL from the dataplane cache by running the following command:<br>`admin@PA-200> clear url-cache url` <*URL*><br>Next time the device requests the category for this URL, the request will be forwarded to the management plane. This will resolve the issue and no further action is required. If this does not solve the issue, go to the next step to check the URL category on the cloud systems. |
| Step 3 | Verify the category in the cloud by running the following command:<br>`admin@PA-200> test url-info-cloud <URL>` |
| Step 4 | If the URL stored in the cloud has the correct category, remove the URL from the dataplane and the management plane caches.<br>Run the following command to delete a URL from the dataplane cache:<br>`admin@PA-200> clear url-cache url <URL>`<br>Run the following command to delete a URL from the management plane cache:<br>`admin@PA-200> delete url-database url <URL>`<br>Next time the device queries for the category of the given URL, the request will be forwarded to the management plane and then to the cloud. This should resolve the category lookup issue. If problems persist, see the next step to submit a categorization change request. |
| Step 5 | To submit a change request from the web interface, go to the URL log and select the log entry for the URL you would like to have changed. |

 © Palo Alto Networks, Inc.

**Troubleshoot Incorrect Categorization Issues**

Step 6 Click the **Request Categorization** change link and follow instructions. You can also request a category change at the Palo Alto Networks Test A Site website by searching for the URL and then clicking the **Request Change** icon. To view a list of all available categories with descriptions of each category, refer to https://urlfiltering.paloaltonetworks.com/CategoryList.aspx.

If your change request is approved, you will receive an email notification. You then have two options to ensure that the URL category is updated on the firewall:

- Wait until the URL in the cache expires and the next time the URL is accessed by a user, the new categorization update will be put in the cache.
- Run the following command to force an update in the cache:

```
admin@PA-200> request url-filtering update url <URL>
```

## URL Database Out of Date

If you have observed through the syslog or the CLI that PAN-DB is out-of-date, it means that the connection from the firewall to the URL Cloud is blocked. This usually occurs when the URL database on the firewall is too old (version difference is more than three months) and the cloud cannot update the firewall automatically. In order to resolve this issue, you will need to re-download an initial seed database from the cloud (this operation is not blocked). This will result in an automatic re-activation of PAN-DB.

To manually update the database, perform one of the following steps:

– From the web interface, select **Device > Licenses** and in the **PAN-DB URL Filtering** section click the **Re-Download** link.

– From the CLI, run the following command:

```
admin@PA-200> request url-filtering download paloaltonetworks region <region_name>
```

When the seed database is re-download, the URL cache in the management plane and dataplane will be purged. The management plane cache will then be re-populated with the contents of the new seed database.

 © Palo Alto Networks, Inc.

# Quality of Service

Quality of Service (QoS) is a set of technologies that work on a network to guarantee its ability to dependably run high-priority applications and traffic under limited network capacity. QoS technologies accomplish this by providing differentiated handling and capacity allocation to specific flows in network traffic. This enables the network administrator to assign the order in which traffic is handled, and the amount of bandwidth afforded to traffic.

Palo Alto Networks Application Quality of Service (QoS) provides basic QoS applied to networks and extends it to provide QoS to applications and users.

Use the following topics to learn about and configure Palo Alto Networks Application QoS:

- QoS Overview
- QoS Concepts
- Configure QoS
- Configure QoS for a Virtual System
- QoS Use Case Examples

# QoS Overview

Use QoS to prioritize and adjust quality aspects of network traffic. You can assign the order in which packets are handled and allot bandwidth, ensuring preferred treatment and optimal levels of performance are afforded to selected traffic, applications, and users.

Service quality measurements subject to a QoS implementation are bandwidth (maximum rate of transfer), throughput (actual rate of transfer), latency (delay), and jitter (variance in latency). The capability to shape and control these service quality measurements makes QoS of particular importance to high-bandwidth, real-time traffic such as voice over IP (VoIP), video conferencing, and video-on-demand that has a high sensitivity to latency and jitter. Additionally, use QoS to achieve outcomes such as the following:

- Prioritize network and application traffic, guaranteeing high priority to important traffic or limiting non-essential traffic.
- Achieve equal bandwidth sharing among different subnets, classes, or users in a network.
- Allocate bandwidth externally or internally or both, applying QoS to both upload and download traffic or to only upload or download traffic.
- Ensure low latency for customer and revenue-generating traffic in an enterprise environment.
- Perform traffic profiling of applications to ensure bandwidth usage.

Each firewall model supports a maximum number of ports that can be configured with QoS.

QoS implementation on a Palo Alto Networks firewall begins with three primary configuration components that support a full QoS solution:

- QoS Profile
- QoS Policy
- QoS on the physical interface

Each of these options in the QoS configuration task facilitate a broader process that optimizes and prioritizes the traffic flow and allocates and ensures bandwidth according to configurable parameters.

Figure: QoS Traffic Flow shows traffic as it flows from the source, is shaped by the firewall with QoS enabled, and is ultimately prioritized and delivered to its destination.

**Figure: QoS Traffic Flow**

 © Palo Alto Networks, Inc.

The QoS configuration options allow you to control the traffic flow and define it at different points in the flow. The Figure: QoS Traffic Flow indicates where the configurable options define the traffic flow. Use the QoS Profile to define QoS classes and use the QoS Policy to associate QoS classes with selected traffic. Enable the QoS Profile on a physical interface to shape traffic according to the QoS configuration as it flows through the network.

You can configure a QoS Profile and QoS Policy individually or in any order, according to your preference. Each of the QoS configuration options has components that influence the definition of the other options and the QoS configuration options can be used to create a full and granular QoS policy or can be used sparingly with minimal administrator action.

© Palo Alto Networks, Inc.

# QoS Concepts

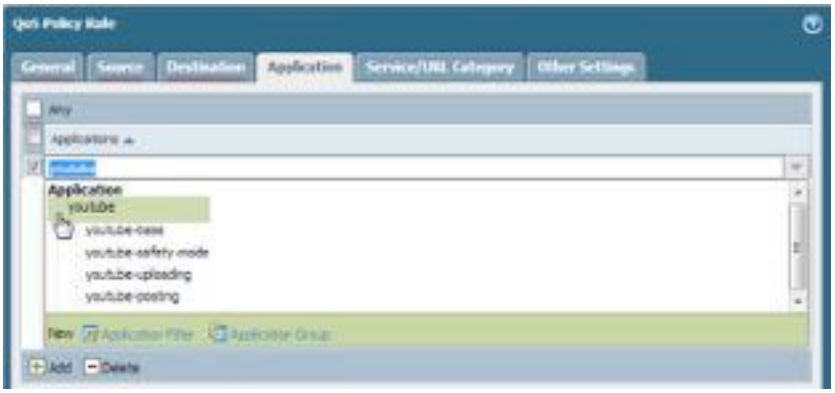
Use the following topics to learn about the different components and mechanisms of a QoS configuration on a Palo Alto Networks firewall:

- QoS for Applications and Users
- QoS Profile
- QoS Classes
- QoS Policy
- QoS Egress Interface
- QoS Cleartext and Tunneled Traffic

## QoS for Applications and Users

A Palo Alto Networks firewall provides basic QoS, controlling traffic leaving the firewall according to network or subnet, and extends the power of QoS to also classify and shape traffic according to application and user. The Palo Alto Networks firewall provides this capability by integrating the features App-ID and User-ID with the QoS configuration. App-ID and User-ID entries that exist to identify specific applications and users in your network are available in the QoS configuration so that you can easily specify applications and users to apply QoS to.

You can use a QoS Policy in the web interface (**Policies** > **QoS**) to apply QoS specifically to an application's traffic:



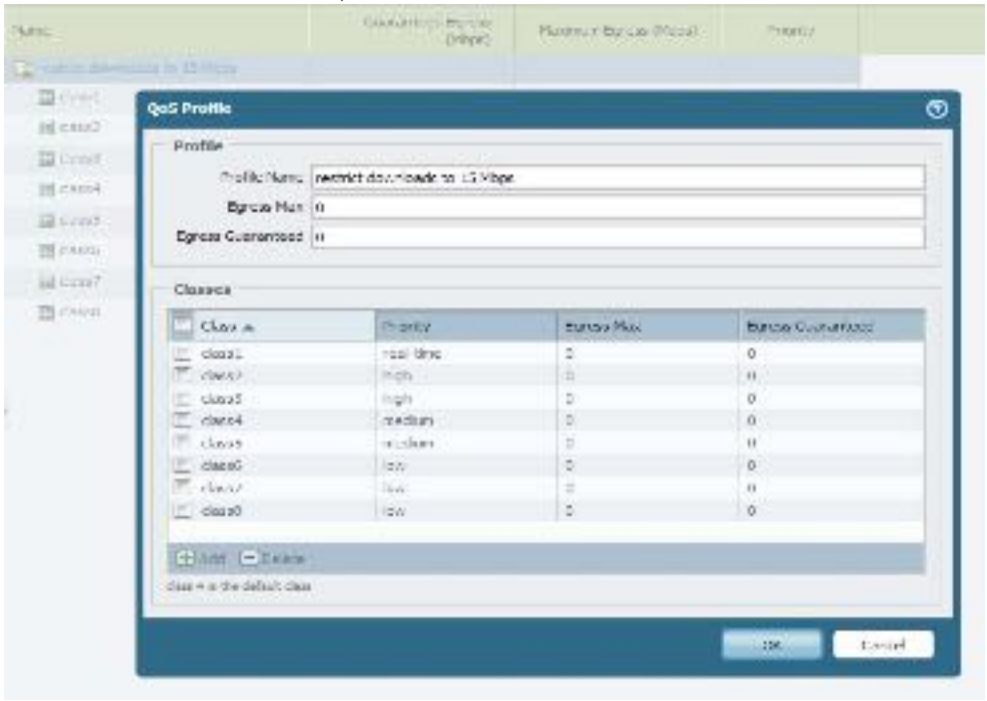
Or to a user's traffic:

See App-ID and User-ID for more information on these features.

© Palo Alto Networks, Inc.

## QoS Profile

Use a QoS profile to define values of up to eight QoS classes contained within that single profile (**Network** > **Network Profiles** > **QoS Profile**):



You enable QoS by applying a QoS profile to the egress interface for network, application or user traffic (or specifically, for cleartext or tunneled traffic). An interface configured with QoS shapes traffic according to the QoS profile class definitions and the traffic associated with those classes in the QoS policy.

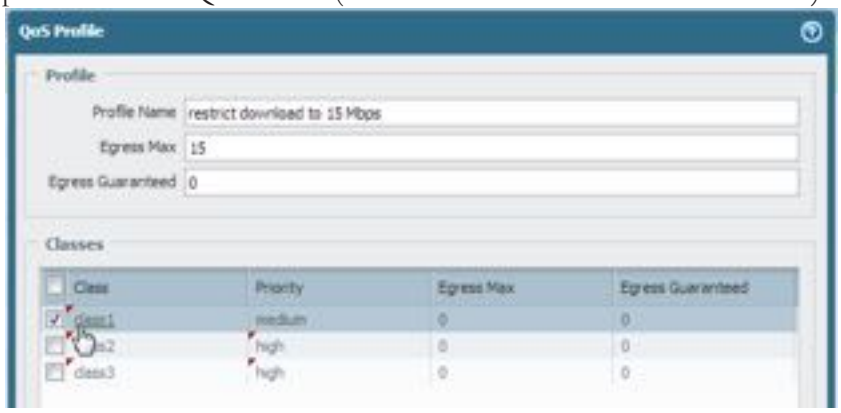
A default QoS Profile is available on the firewall. The default profile and the classes defined in the profile do not have predefined maximum or guaranteed bandwidth limits.

You can set bandwidth limits for a QoS profile and/or set limits for individual QoS classes within the QoS profile. The total guaranteed bandwidth limits of all eight QoS classes in a QoS Profile cannot exceed the total bandwidth allocated to that QoS Profile. Enabling QoS on a physical interface includes setting the maximum bandwidth for traffic leaving the firewall through this interface. A QoS profile's guaranteed bandwidth (the **Egress Guaranteed** field) should not exceed the bandwidth allocated to the physical interface that QoS is enabled on.

For details, see Create a QoS profile.

## QoS Classes

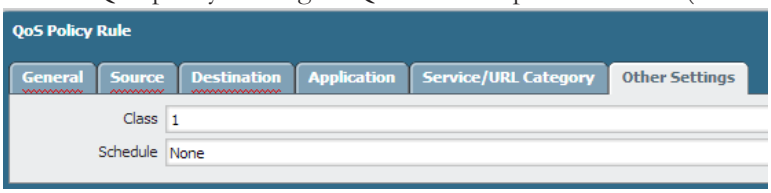
A QoS class determines the priority and bandwidth for traffic it is assigned to. In the web interface, use the QoS profile to define QoS classes (**Network** > **Network Profiles** > **QoS Profile**):



Defining a QoS class includes setting the class's Priority, maximum bandwidth (Egress Max), and guaranteed bandwidth (Egress Guaranteed).

Real-time priority is typically used for applications that are particularly sensitive to latency, such as voice and video applications.

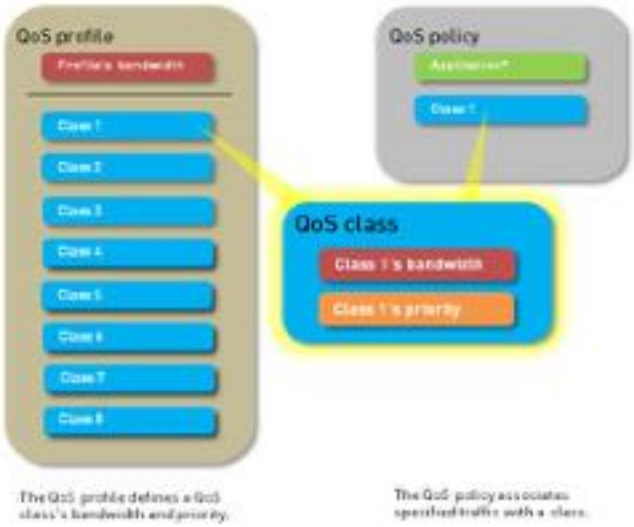
Use the QoS policy to assign a QoS class to specified traffic (**Policies** > **QoS**):



There are up to eight definable QoS classes in a single QoS profile. Unless otherwise configured, traffic that does not match a QoS class is assigned a class of 4.

 © Palo Alto Networks, Inc.

QoS priority queuing and bandwidth management, the fundamental mechanisms of a QoS configuration, are configured within the QoS class definition (see Step 3). Queuing priority is determined by the priority set for a QoS class. Bandwidth management is determined according to the maximum and guaranteed bandwidths set for a QoS class.



The queuing and bandwidth management mechanisms determine the order of traffic and how traffic is handled upon entering or leaving a network:

- **QoS Priority:** One of four QoS priorities can be defined in a QoS class: real-time, high, medium, and low. When a QoS class is associated with specific traffic, the priority defined in that QoS class is assigned to the traffic. Packets in the traffic flow are then queued according to their priority until the network is ready to process them. This method of priority queuing provides the capability to ensure that important traffic, applications, or users takes precedence.
- **QoS Class Bandwidth Management:** QoS class bandwidth management provides the capability to control traffic flows on a network so that traffic does not exceed network capacity, resulting in network congestion, or to allocate specific bandwidth limits to traffic, applications, or users. You can set overall limits on bandwidth using the QoS profile or set limits for individual QoS classes. A QoS profile and QoS classes in the profile have guaranteed and maximum bandwidth limits. The guaranteed bandwidth limit (Egress Guaranteed) ensures that any amount of traffic up to that set bandwidth limit is processed. The maximum bandwidth limit (Egress Max) sets the total limit of bandwidth allocated to either the QoS Profile or QoS Class. Traffic in excess of the Maximum Bandwidth limit is dropped. The total bandwidth limits and guaranteed bandwidth limits of QoS classes in a QoS profile cannot exceed the bandwidth limit of the QoS profile.

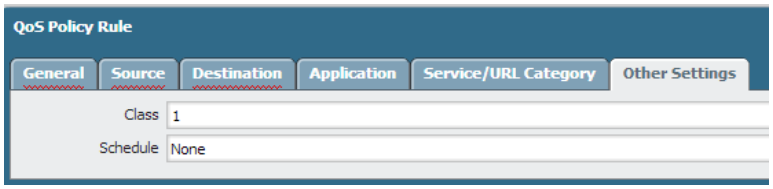
## QoS Policy

In a QoS configuration, the QoS policy identifies traffic requiring QoS treatment (either preferential treatment or bandwidth-limiting) using a defined parameter or multiple parameters and assigns it a class.

Use the QoS Policy, similar to a security policy, to set the criteria that identifies traffic:

- Applications and application groups.
- Source zones, source addresses, and source users.
- Destination zones and destination addresses.
- Services and service groups limited to specific TCP and/or UDP port numbers.
- URL categories, including custom URL categories.

The QoS Policy in the web interface (**Policies** > **QoS**) allows you to associate the criteria used to specify traffic with a QoS class.



## QoS Egress Interface

Enabling a QoS profile on the egress interface of the traffic identified for QoS treatment completes a QoS configuration. The ingress interface for QoS traffic is the interface on which the traffic enters the firewall. The egress interface for QoS traffic is the interface that traffic leaves the firewall from. QoS is always enabled and enforced on a traffic flow's egress interface. The egress interface in a QoS configuration can either be the external- or internal-facing interface of the firewall, depending on the flow of the traffic receiving QoS treatment.

For example, in an enterprise network, if you are limiting employees' download traffic from a specific website, the egress interface in the QoS configuration is the firewall's internal interface, as the traffic flow is from the Internet, through the firewall, and to your company network. Alternatively, when limiting employees' upload traffic to the same website, the egress interface in the QoS configuration is the firewall's external interface, as the traffic you are limiting flows from your company network, through the firewall, and then to the Internet.

See Step 3 to learn how to Identify the egress interface for applications that you identified as needing QoS treatment.

 © Palo Alto Networks, Inc.

## QoS Cleartext and Tunneled Traffic

Within the QoS physical interface configuration, you can provide more granular QoS settings for cleartext traffic and tunneled traffic leaving through the interface. Individual tunnel interfaces can be assigned different QoS Profiles. Cleartext traffic can be assigned different QoS Profiles according to traffic's source interface and source subnet. In this case, a source interface and source subnet can be associated with a QoS Profile. If you choose not to select cleartext or tunneled traffic for unique QoS treatment, enabling QoS on an interface requires selecting a default QoS Profile to determine how to shape traffic for specific tunnel interfaces or, in the case of cleartext traffic, source interfaces and source subnets.

On Palo Alto Networks firewalls, the term "tunneled traffic" refers to tunnel interface traffic, specifically IPSec traffic in tunnel mode.

# Configure QoS

Use the following task to configure Quality of Service (QoS), including how to create a QoS profile, create a QoS policy, and enable QoS on an interface.

| Configure QoS | | |
|---|---|---|
| Step 1 | Identify traffic to apply QoS to.<br><br>This example shows how to use QoS to limit web browsing. | Select **ACC** to view the **Application Command Center** page. Use the settings and charts on the **ACC** page to view trends and traffic related to Applications, URL filtering, Threat Prevention, Data Filtering, and HIP Matches.<br><br>Click any application name to display detailed application information. |
| Step 2 | Identify the egress interface for applications that you identified as needing QoS treatment.<br><br>**Tip:** The egress interface for traffic depends on the traffic flow. If you are shaping incoming traffic, the egress interface is the internal-facing interface. If you are shaping outgoing traffic, the egress interface is the external-facing interface. | Select **Monitor > Logs > Traffic** to view the device's traffic logs.<br><br>To filter and only show logs for a specific application:<br>• If an entry is displayed for the application, click the underlined link in the Application column then click the Submit icon .<br>• If an entry is not displayed for the application, click the Add Log icon and search for the application .<br><br>The **Egress I/F** in the traffic logs displays each application's egress interface. To display the **Egress I/F** column if it is not displayed by default:<br>• Click any column header to add a column to the log:<br>  <br>• Click the spyglass icon to the left of any entry to display a detailed log that includes the application's egress interface listed in the Destination section:<br> <br>In this example, the egress interface for web-browsing traffic is ethernet 1/1. |

 © Palo Alto Networks, Inc.

**Configure QoS (Continued)**

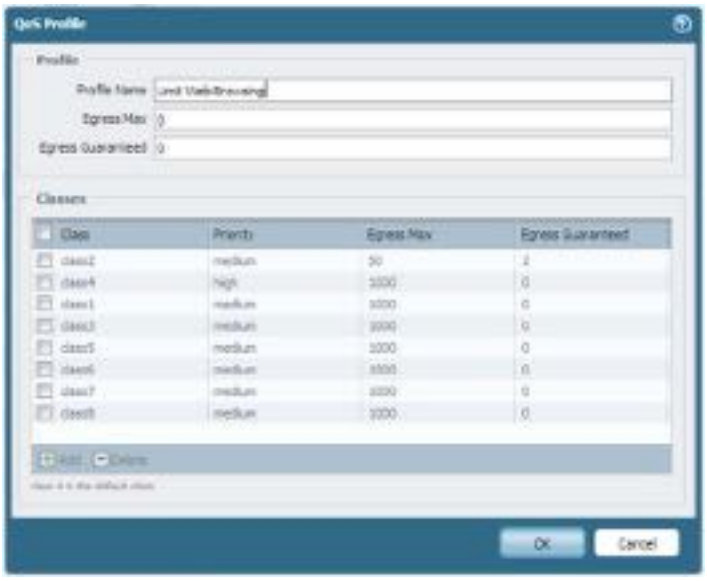
Step 3 Create a QoS profile.

You can edit any existing QoS profile, including the default by clicking the QoS profile name.

1. Select **Network > Network Profiles > QoS Profile** and click **Add** to open the **QoS Profile** dialog.
2. Enter a descriptive **Profile Name**.
3. Enter an **Egress Max** to set the overall bandwidth allocation for the QoS Profile.
4. Enter an **Egress Guaranteed** to set the guaranteed bandwidth for the QoS Profile.

   Any traffic that exceeds the QoS Profile's egress guaranteed limit is best effort but is not guaranteed.
5. In the Classes section, specify how to treat up to eight individual QoS classes:
   a. Click **Add** to add a class to the QoS Profile.
   b. Select the **Priority** for the class.
   c. Enter an **Egress Max** for a class to set the overall bandwidth limit for that individual class.
   d. Enter an **Egress Guaranteed** for the class to set the guaranteed bandwidth for that individual class.
6. Click **OK** to save the QoS Profile.

In the following example, the QoS Profile named Limit Web Browsing limits traffic identified as Class 2 traffic to maximum bandwidth of 50 Mbps and a guaranteed bandwidth of 2 Mbps. Any traffic that is associated with class 2 in a the QoS policy (Step 4) is subject to these limits.



| Configure QoS (Continued) | |
|---|---|
| Step 4 Create a QoS policy. | 1. Select **Policies > QoS** and click **Add** to open the QoS Policy Rule dialog.<br>2. On the **General** tab, give the QoS Policy Rule a descriptive **Name**.<br>3. Specify the traffic to which the QoS Policy Rule will apply. Use the **Source**, **Destination**, **Application**, and **Service/URL Category** tabs to define matching parameters for identifying traffic.<br>For example, select the **Application** tab, click **Add** and select web-browsing to apply the QoS Policy Rule to that application:<br> <br>(Optional) Define additional parameters. For example, on the **Source** tab, click **Add** to limit a specific user's web-browsing, in this case, user1:<br>  <br>4. On the **Other Settings** tab, select a QoS Class to assign to the QoS Policy Rule. For example, assign Class 2 to the user1's web-browsing traffic:<br> <br>5. Click **OK** to save the QoS Policy Rule. |

© Palo Alto Networks, Inc.

**Configure QoS (Continued)**

Step 5 Enable the QoS Profile on a physical interface.

You can configure settings to select cleartext and tunneled traffic for unique QoS treatment, in addition to the QoS configuration on the physical interface:

- To configure specific settings for cleartext traffic using traffic's source interface and source subnet as criteria for QoS identification and treatment, perform Step 5 - 4.
- To apply a QoS profile to a specific tunnel interface(s), perform Step 5 - 5

For more information, see QoS Cleartext and Tunneled Traffic.

It is a best practice to always define the **Egress Max** value for a QoS interface.

1. Select **Network > QoS** and click **Add** to open the QoS Interface dialog.
2. Enable QoS on the physical interface:
   a. On the **Physical Interface** tab, select the **Interface Name** of the interface to apply the QoS Profile to.

      In the example, Ethernet 1/1 is the egress interface for web-browsing traffic (see Step 2).

   b. Select **Turn on QoS feature on this interface**.
3. On the **Physical Interface** tab, select a QoS profile to apply by default to all **Clear Text** traffic.

   (Optional) Use the Tunnel Interface field to apply a QoS profile by default to all tunneled traffic.

For example, enable QoS on ethernet 1/1 and apply the QoS Profile named Limit Web Browsing as the default QoS Profile for clear text traffic.

4. (Optional) On the **Clear Text Traffic** tab, configure more granular QoS settings for cleartext traffic:
   - Set the **Egress Guaranteed** and **Egress Max** bandwidths for clear text traffic.
   - Click **Add** to apply a QoS Profile to selected clear text traffic, further selecting the traffic for QoS treatment according to source interface and source subnet (creating a QoS node).
5. (Optional) On the **Tunneled Traffic** tab, configure more granular QoS settings for tunnel interfaces:
   - Set the **Egress Guaranteed** and **Egress Max** bandwidths for tunneled traffic.
   - Click **Add** to associate a selected tunnel interface with a QoS Profile.
6. Click **OK** to save the QoS Profile.
7. **Commit** the changes to enable the Qos Profile on the interface.

| Configure QoS (Continued) | |
|---|---|
| Step 6 Verify QoS configuration. | Select **Network > QoS** to view the **QoS Policies** page and click the **Statistics** link to view QoS bandwidth, active sessions of a selected QoS node or class, and active applications for the selected QoS node or class.<br>For example, see the statistics for ethernet 1/1 with QoS enabled:<br>  <br>Class 2 traffic limited to 2 Mbps of guaranteed bandwidth and a maximum bandwidth of 50 Mbps.<br>Continue to click the tabs to display further information regarding applications, source users, destination users, security rules and QoS rules.<br>Bandwidth limits shown on the **QoS Statistics** window include a hardware adjustment factor. |

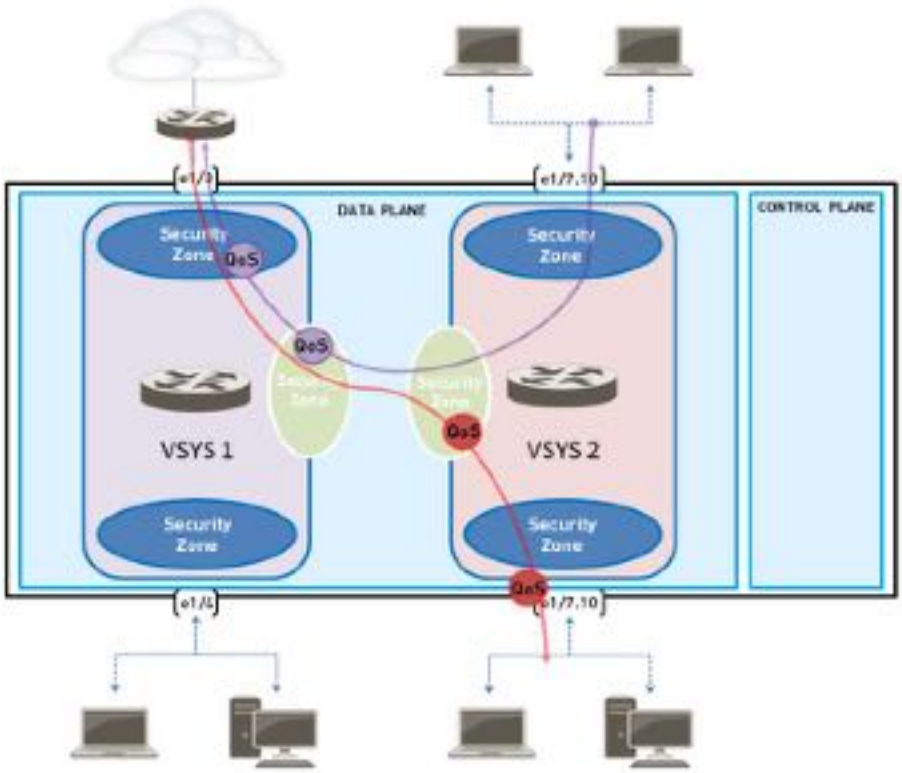
© Palo Alto Networks, Inc.

# Configure QoS for a Virtual System

QoS can be configured for a single or several virtual systems within a Palo Alto Networks firewall. Because a virtual system is an independent firewall, QoS must be configured independently for a single virtual system to apply a QoS configuration to only that virtual system.

Configuring QoS for a virtual system is similar to configuring QoS on a physical firewall, with the exception that configuring QoS for a virtual system requires specifying the traffic flow's source and destination zones and source and destination interfaces. Because a virtual system exists without set physical boundaries (such as a physical interface) that traffic flows through, specifying source and destination zones and interfaces of a traffic flow allows you to control and shape traffic for that virtual system specifically, as a traffic flow spans more than one virtual system in a virtual environment.

The example below shows two virtual systems configured within a firewall. VSYS 1 (purple) and VSYS 2 (red) each have QoS configured to prioritize or limit two distinct traffic flows, indicated by their corresponding purple (VSYS 1) and red (VSYS 2) lines. The QoS nodes indicate the points at which QoS traffic is identified and then shaped in each virtual system.



| Configure QoS in a Virtual System Environment | | |
|---|---|---|
| Step 1 | Confirm that the appropriate interfaces, virtual routers, and security zones are associated with each virtual system. | • To view configured interfaces, select **Network > Interface**.<br>• To view configured zones, select **Network > Zones**.<br>• To view information on defined virtual routers, select **Network > Virtual Routers**. |

| Configure QoS in a Virtual System Environment | |
|---|---|
| Step 2 Identify traffic to apply QoS to. | Select **ACC** to view the **Application Command Center** page. Use the settings and charts on the **ACC** page to view trends and traffic related to Applications, URL filtering, Threat Prevention, Data Filtering, and HIP Matches.<br>To view information for a specific virtual system, select the virtual system from the **Virtual System** drop-down:<br>  <br><br>Click any application name to display detailed application information. |

 © Palo Alto Networks, Inc.

**Configure QoS in a Virtual System Environment**

Step 3 Identify the egress interface for applications that you identified as needing QoS treatment.

In a virtual system environment, QoS is applied to traffic on the traffic's egress point on the virtual system. Depending on a virtual system's configuration and the QoS policy, the egress point of QoS traffic could be associated with a physical interface or could be a configured zone.

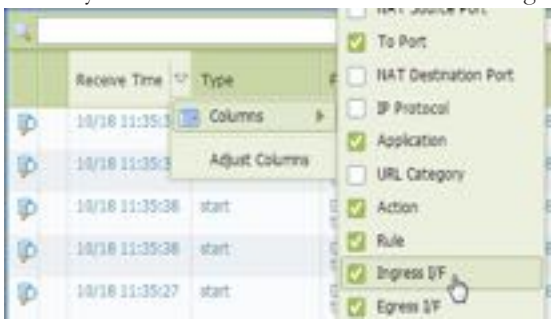
This example shows how to limit web-browsing traffic on vsys 1.

Select **Monitor > Logs > Traffic** to view the device's traffic logs. Each entry has the option to display columns with information necessary to configure QoS in a virtual system environment:

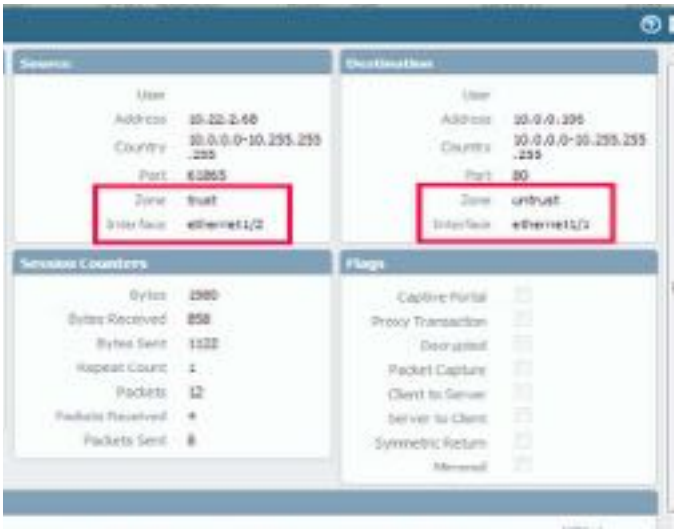
- virtual system
- egress interface
- ingress interface
- source zone
- destination zone

To display the a column if it is not displayed by default:

- Click any column header to add a column to the log:



- Click the spyglass icon to the left of any entry to display a detailed log that includes the application's egress interface, as well as source and destination zones, in the **Source** and **Destination** sections:



For example, for web-browsing traffic from VSYS 1, the ingress interface is ethernet 1/2, the egress interface is ethernet 1/1, the source zone is *trust* and the destination zone is *untrust*.

| Configure QoS in a Virtual System Environment | |
|---|---|
| Step 4 Create a QoS Profile.<br><br>You can edit any existing QoS Profile, including the default by clicking the profile name. | 1. Select **Network > Network Profiles > QoS Profile** and click **Add** to open the QoS Profile dialog.<br>2. Enter a descriptive **Profile Name**.<br>3. Enter an **Egress Max** to set the overall bandwidth allocation for the QoS profile.<br>4. Enter an **Egress Guaranteed** to set the guaranteed bandwidth for the QoS profile.<br><br> Any traffic that exceeds the QoS profile's egress guaranteed limit is best effort but is not guaranteed.<br>5. In the Classes section of the **QoS Profile**, specify how to treat up to eight individual QoS classes:<br>a. Click **Add** to add a class to the QoS Profile.<br>b. Select the **Priority** for the class.<br>c. Enter an **Egress Max** for a class to set the overall bandwidth limit for that individual class.<br>d. Enter an **Egress Guaranteed** for the class to set the guaranteed bandwidth for that individual class.<br>6. Click **OK** to save the QoS profile. |

 © Palo Alto Networks, Inc.

**Configure QoS in a Virtual System Environment**

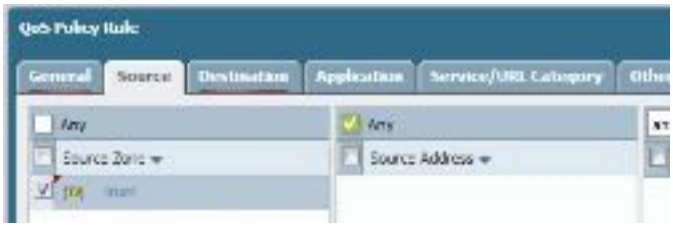
Step 5 Create a QoS policy.

In a multi-VSYS environment, traffic can span more than one virtual system before the ingress point on the virtual system you are configuring QoS for. Specifying source and destination zones for QoS traffic ensures that the traffic is correctly identified as it flows through the specific virtual system (in this example, vsys 1) and QoS is applied to the traffic only for that designated virtual system (and not applied to traffic for other configured virtual systems).

1. Select **Policies > QoS** and click **Add** to open the QoS Policy Rule dialog.
2. On the **General** tab, give the QoS Policy Rule a descriptive **Name**.
3. Specify the traffic to which the QoS policy rule will apply. Use the **Source**, **Destination**, **Application**, and **Service/URL Category** tabs to define matching parameters for identifying traffic.

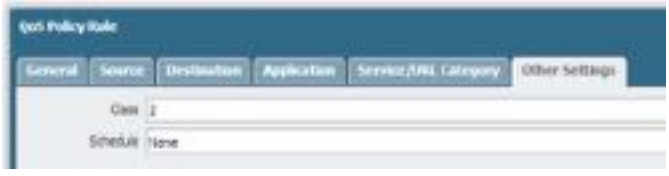
   For example, select the **Application** tab, click **Add** and select web-browsing to apply the QoS Policy Rule to that application:

4. On the **Source** tab, click **Add** to select vsys 1's web-browsing traffic's source zone.



5. On the **Destination** tab, click **Add** to select the vsys 1's web-browsing traffic's destination zone.

6. On the **Other Settings** tab, and select a **QoS Class** to assign to the QoS policy rule. For example, assign Class 2 to web-browsing traffic on vsys 1:



7. Click **OK** to save the QoS policy rule.

| Configure QoS in a Virtual System Environment | |
|---|---|
| Step 6 Enable the QoS Profile on a physical interface.<br><br>It is a best practice to always define the **Egress Max** value for a QoS interface. | 1. Select **Network > QoS** and click **Add** to open the QoS Interface dialog.<br>2. Enable QoS on the physical interface:<br>a. On the **Physical Interface** tab, select the **Interface Name** of the interface to apply the QoS Profile to.<br>In this example, ethernet 1/1 is the egress interface for web-browsing traffic on vsys 1 (see Step 2).<br> <br>b. Select **Turn on QoS feature on this interface**.<br>3. On the **Physical Interface** tab, select the default QoS profile to apply to all **Clear Text** traffic.<br>(Optional) Use the **Tunnel Interface** field to apply a default QoS profile to all tunneled traffic.<br>4. (Optional) On the **Clear Text Traffic** tab, configure additional QoS settings for clear text traffic:<br>• Set the **Egress Guaranteed** and **Egress Max** bandwidths for clear text traffic.<br>• Click **Add** to apply a QoS Profile to selected clear text traffic, further selecting the traffic for QoS treatment according to source interface and source subnet (creating a QoS node).<br>5. (Optional) On the **Tunneled Traffic** tab, configure additional QoS settings for tunnel interfaces:<br>• Set the **Egress Guaranteed** and **Egress Max** bandwidths for tunneled traffic.<br>• Click **Add** to associate a selected tunnel interface with a QoS Profile.<br>6. Click **OK** to save changes.<br>7. **Commit** the changes. |

© Palo Alto Networks, Inc.

| Configure QoS in a Virtual System Environment | |
|---|---|
| Step 7 Verify QoS configuration. | • Select **Network > QoS** to view the QoS Policies page. The **QoS Policies** page verifies that QoS is enabled and includes a **Statistics** link. Click the Statistics link to view QoS bandwidth, active sessions of a selected QoS node or class, and active applications for the selected QoS node or class.<br>• In a multi-VSYS environment, sessions cannot span multiple systems. Multiple sessions are created for one traffic flow if the traffic passes through more than one virtual system. To browse sessions running on the firewall and view applied QoS Rules and QoS Classes, select **Monitor > Session Browser**. |

# QoS Use Case Examples

The following use cases demonstrate how to use QoS in common scenarios:

- QoS for a Single User
- QoS for Voice and Video Applications

© Palo Alto Networks, Inc.

## QoS for a Single User

A CEO finds that during periods of high network usage, she is unable to access enterprise applications respond effectively to critical business communications. The IT admin wants to ensure that all traffic to and from the CEO receives preferential treatment over other employee traffic so that she is guaranteed not only access to but high performance of critical network resources.

### Apply QoS to a Single User

Step 1 The admin creates the QoS profile *CEO_traffic* to define how traffic originating from the CEO will be treated and shaped as it flows out of the company network:

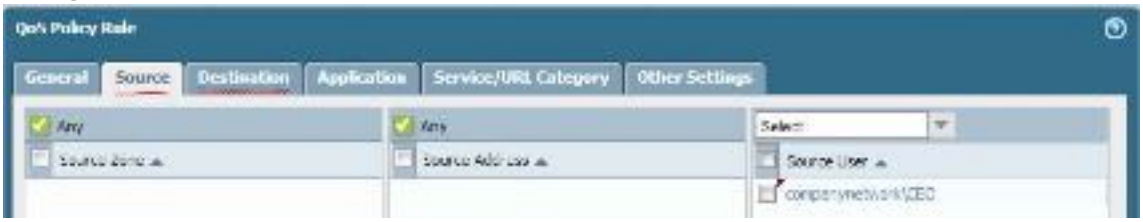
The admin assigns a guaranteed bandwidth (**Egress Guaranteed**) of 50 Mbps to ensure that the CEO will have that amount that bandwidth guaranteed to her at all times (more than she would need to use), regardless of network congestion.

The admin continues by designating Class 1 traffic as high priority and sets the profile's maximum bandwidth usage (**Egress Max**) to 1000 Mbps, the same maximum bandwidth for the interface that the admin will enable QoS on. The admin is choosing to not restrict the CEO's bandwidth usage in any way.

It is a best practice to populate the **Egress Max** field for a QoS profile, even if the max bandwidth of the profile matches the max bandwidth of the interface. The QoS profile's max bandwidth should never exceed the max bandwidth of the interface you are planning to enable QoS on.

**Apply QoS to a Single User (Continued)**

Step 2 The admin creates a QoS policy to identify the CEO's traffic (**Policies** > **QoS**) and assign it the class that he defined in the QoS profile (see Step 1). Because User-ID is configured, the admin uses the **Source** tab in the QoS policy to singularly identify the CEO's traffic by her company network username. (If User-ID is not configured, the administrator could **Add** the CEO's IP address under **Source Address**. See User-ID.):



The admin associates the CEO's traffic with Class 1 (**Other Settings** tab) and then continues to populate the remaining required policy fields; the admin gives the policy a descriptive **Name** (**General** tab) and selects **Any** for the **Source Zone** (**Source** tab) and **Destination Zone** (**Destination** tab):

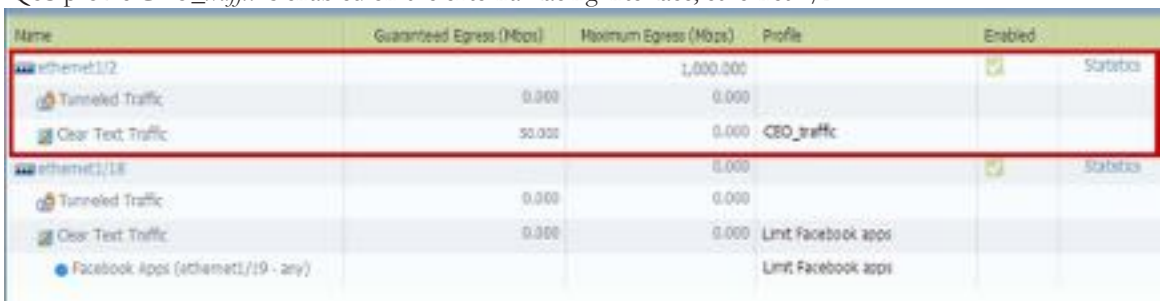
Step 3 Now that Class 1 is associated with the CEO's traffic, the admin enables QoS by checking **Turn on QoS feature on interface** and selecting the traffic flow's egress interface. The egress interface for the CEO's traffic flow is the external-facing interface, in this case, ethernet 1/2:

Because the admin wants to ensure that all traffic originating from the CEO is guaranteed by the QoS profile and associated QoS policy he created, he selects the *CEO_traffic* to apply to **Clear Text** traffic flowing from ethernet 1/2.

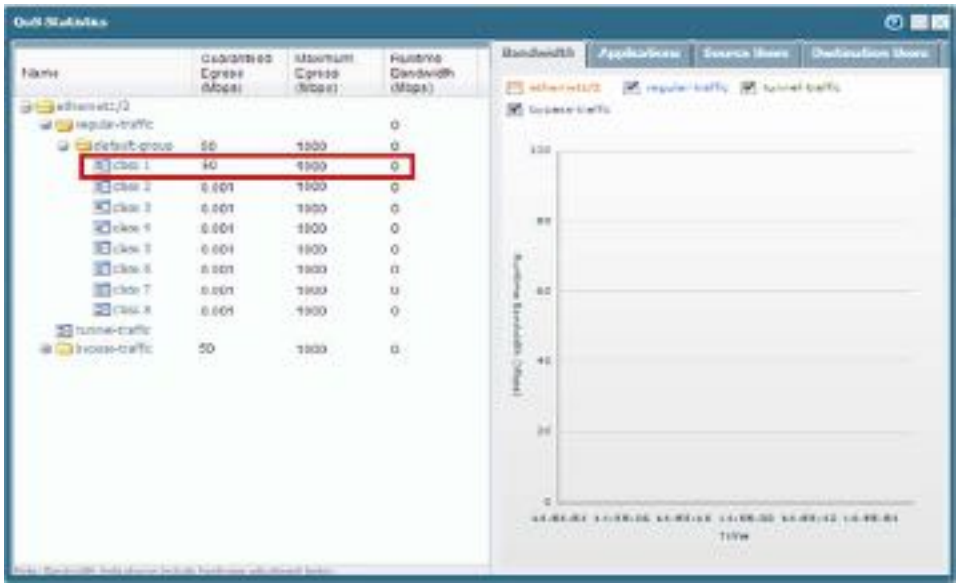
 © Palo Alto Networks, Inc.

**Apply QoS to a Single User (Continued)**

Step 4 After committing the QoS configuration, the admin navigates to the **Network > QoS** page to confirm that the QoS profile *CEO_traffic* is enabled on the external-facing interface, ethernet 1/2:



He clicks **Statistics** to view how traffic originating with the CEO (Class 1) is being shaped as it flows from ethernet 1/2:



This case demonstrates how to apply QoS to traffic originating from a single source user. However, if you also wanted to guarantee or shape traffic to a destination user, you could configure a similar QoS setup. Instead of, or in addition to this work flow, create a QoS policy that specifies the user's IP address as the **Destination Address** on the **Policies > QoS** page (instead of specifying the user's source information, as shown in Step 2) and then enable QoS on the network's internal-facing interface on the **Network > QoS** page (instead of the external-facing interface, as shown in Step 3.)

## QoS for Voice and Video Applications

Voice and video traffic is particularly sensitive to measurements that the QoS feature shapes and controls, especially latency and jitter. For voice and video transmissions to be audible and clear, voice and video packets cannot be dropped, delayed, or delivered inconsistently. A best practice for voice and video applications, in addition to guaranteeing bandwidth, is to guarantee priority to voice and video traffic. In this example, employees at a company branch office are experiencing difficulties and unreliability in using video conferencing and Voice-over-IP (VoIP) technologies to conduct business communications with other branch offices, with partners, and with customers. An IT admin intends to implement QoS in order to address these issues and ensure effective and reliable business communication for the branch employees. Because the admin wants to guarantee QoS to both incoming and outgoing network traffic, he will enable QoS on both the firewall's internal- and external-facing interfaces.

**Ensure Quality for Voice and Video Applications**

Step 1 The admin creates a QoS profile, defining Class 2 so that any traffic associated with Class 2 receives real-time priority and on an interface with a maximum bandwidth of 1000 Mbps, is guaranteed a bandwidth of 250 Mbps at all times, including peak periods of network usage.

Real-time priority is typically recommended for applications affected by latency, and is particularly useful in guaranteeing performance and quality of voice and video applications.

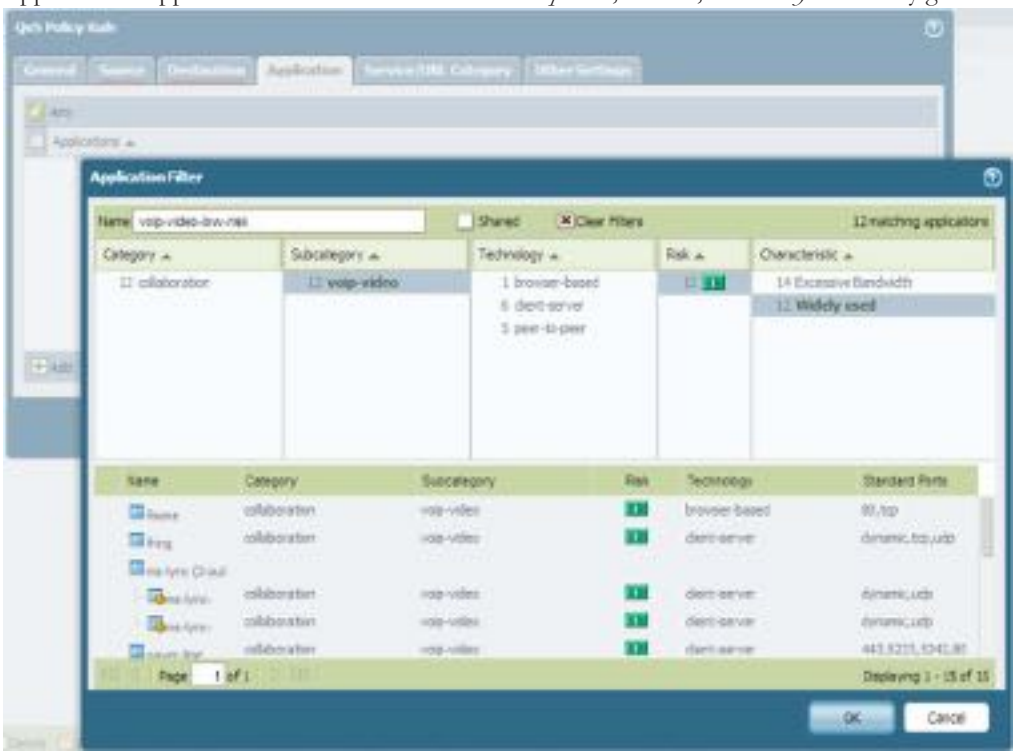
On the **Network > Network Profiles > Qos Profile** page, the admin clicks **Add**, enters the **Profile Name** *ensure voip-video traffic* and defines Class 2 traffic.

 © Palo Alto Networks, Inc.

**Ensure Quality for Voice and Video Applications (Continued)**

Step 2 The admin creates a QoS policy to identify voice and video traffic. Because the company does not have one standard voice and video application, the admin wants to ensure QoS is applied to a few applications that are widely and regularly used by employees to communicate with other offices, with partners, and with customers. On the **Policies > QoS > QoS Policy Rule > Applications** tab, the admin clicks **Add** and opens the **Application Filter** window. The admin continues by selecting criteria to filter the applications he wants to apply QoS to, choosing the Subcategory *voip-video*, and narrowing that down by specifying only voip-video applications that are both low-risk and widely-used.

The application filter is a dynamic tool that, when used to filter applications in the QoS policy, allows QoS to be applied to all applications that meet the criteria of *voip-video*, *low risk*, and *widely used* at any given time.



The admin names the **Application Filter** *voip-video-low-risk* and includes it in the QoS policy:

The admin names the QoS policy *Voice-Video* and associates the *voip-video-low-risk* application filter with Class 2 traffic (as he defined it in Step 1). He is going to use the *Voice-Video* QoS policy for both incoming and outgoing QoS traffic, so he sets **Source** and **Destination** information to **Any**:

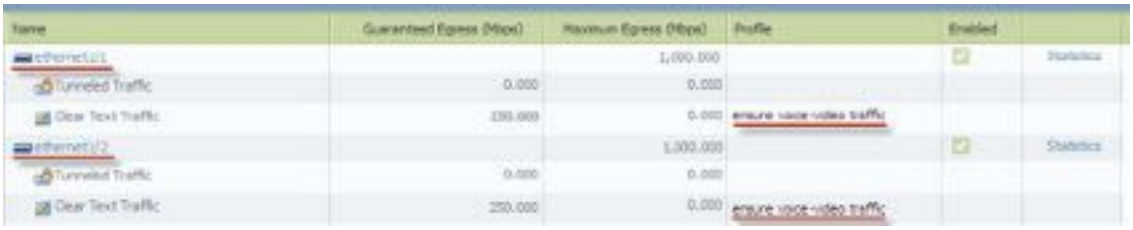
**Ensure Quality for Voice and Video Applications (Continued)**

Step 3 Because the admin wants to ensure QoS for both incoming and outgoing voice and video communications, he enables QoS on the network's external-facing interface (to apply QoS to outgoing communications) and to the internal-facing interface (to apply QoS to incoming communications).

The admin begins by enabling the QoS profile he created in Step 1, *ensure voice-video traffic* (Class 1 in this profile is associated with policy created in Step 2, *Voice-Video*) on the external-facing interface, in this case, ethernet 1/2.

He then enables the same QoS profile *ensure voip-video traffic* on the internal-facing interface, in this case, ethernet 1/1.

Step 4 The admin confirms that QoS is enabled for both incoming and outgoing voice and video traffic:



The admin has successfully enabled QoS on both the network's internal- and external-facing interfaces. Real-time priority is now ensured for voice and video application traffic as it flows both into and out of the network, ensuring that these communications, which are particularly sensitive to latency and jitter, can be used reliably and effectively to perform both internal and external business communications.

# VPNs

Virtual private networks (VPNs) create tunnels that allow users/systems to connect securely over a public network, as if they were connecting over a local area network (LAN). To set up a VPN tunnel, you need a pair of devices that can authenticate each other and encrypt the flow of information between them. The devices can be a pair of Palo Alto Networks firewalls, or a Palo Alto Networks firewall along with a VPN-capable device from another vendor.

- VPN Deployments
- Site-to-Site VPN Overview
- Site-to-Site VPN Concepts
- Set Up Site-to-Site VPN
- Site-to-Site VPN Quick Configs

© Palo Alto Networks, Inc.

# VPN Deployments

The Palo Alto Networks firewall supports the following VPN deployments:

- **Site-to-Site VPN**— A simple VPN that connects a central site and a remote site, or a hub and spoke VPN that connects a central site with multiple remote sites. The firewall uses the IP Security (IPSec) set of protocols to set up a secure tunnel for the traffic between the two sites. See Site-to-Site VPN Overview.
- **Remote User-to-Site VPN**—A solution that uses the GlobalProtect agent to allow a remote user to establish a secure connection through the firewall. This solution uses SSL and IPSec to establish a secure connection between the user and the site. Refer to the GlobalProtect Administrator's Guide.
- **Large Scale VPN**— The Palo Alto Networks GlobalProtect Large Scale VPN (LSVPN) provides a simplified mechanism to roll out a scalable hub and spoke VPN with up to 1024 satellite offices. The solution requires Palo Alto Networks firewalls to be deployed at the hub and at every spoke. It uses certificates for device authentication, SSL for securing communication between all components, and IPSec to secure data. See Large Scale VPN (LSVPN).

**Figure: VPN Deployments**

# Site-to-Site VPN Overview

A VPN connection that allows you to connect two Local Area Networks (LANs) is called a site-to-site VPN. You can configure route-based VPNs to connect Palo Alto Networks firewalls located at two sites or to connect a Palo Alto Networks firewall with a third-party security device at another location. The firewall can also interoperate with third-party policy-based VPN devices; the Palo Alto Networks firewall supports route-based VPN.

The Palo Alto Networks firewall sets up a route-based VPN, where the firewall makes a routing decision based on the destination IP address. If traffic is routed to a specific destination through a VPN tunnel, then it is handled as VPN traffic.

The IP Security (IPSec) set of protocols is used to set up a secure tunnel for the VPN traffic, and the information in the TCP/IP packet is secured (and encrypted if the tunnel type is ESP). The IP packet (header and payload) is embedded in another IP payload, and a new header is applied and then sent through the IPSec tunnel. The source IP address in the new header is that of the local VPN peer and the destination IP address is that of the VPN peer on the far end of the tunnel. When the packet reaches the remote VPN peer (the firewall at the far end of the tunnel), the outer header is removed and the original packet is sent to its destination.

In order to set up the VPN tunnel, first the peers need to be authenticated. After successful authentication, the peers negotiate the encryption mechanism and algorithms to secure the communication. The Internet Key Exchange (IKE) process is used to authenticate the VPN peers, and IPSec Security Associations (SAs) are defined at each end of the tunnel to secure the VPN communication. IKE uses digital certificates or preshared keys, and the Diffie Hellman keys to set up the SAs for the IPSec tunnel.The SAs specify all of the parameters that are required for secure transmission— including the security parameter index (SPI), security protocol, cryptographic keys, and the destination IP address—encryption, data authentication, data integrity, and endpoint authentication.

The following figure shows a VPN tunnel between two sites. When a client that is secured by VPN Peer A needs content from a server located at the other site, VPN Peer A initiates a connection request to VPN Peer B. If the security policy permits the connection, VPN Peer A uses the IKE Crypto profile parameters (IKE phase 1) to establish a secure connection and authenticate VPN Peer B. Then, VPN Peer A establishes the VPN tunnel using the IPSec Crypto profile, which defines the IKE phase 2 parameters to allow the secure transfer of data between the two sites.

**Figure: Site-to-Site VPN**

# Site-to-Site VPN Concepts

A VPN connection provides secure access to information between two or more sites. In order to provide secure access to resources and reliable connectivity, a VPN connection needs the following components:

- IKE Gateway
- Tunnel Interface
- Tunnel Monitoring
- Internet Key Exchange (IKE) for VPN

## IKE Gateway

The Palo Alto Networks firewalls or a firewall and another security device that initiate and terminate VPN connections across the two networks are called the IKE Gateways. To set up the VPN tunnel and send traffic between the IKE Gateways, each peer must have an IP address—static or dynamic—or FQDN. The VPN peers use preshared keys or certificates to mutually authenticate each other.

The peers must also negotiate the mode—main or aggressive—for setting up the VPN tunnel and the SA lifetime in IKE Phase 1. Main mode protects the identity of the peers and is more secure because more packets are exchanged when setting up the tunnel. Main mode is the recommended mode for IKE negotiation if both peers support it. Aggressive mode uses fewer packets to set up the VPN tunnel and is hence faster but a less secure option for setting up the VPN tunnel.

See Set up an IKE Gateway for configuration details.

## Tunnel Interface

To set up a VPN tunnel, the Layer 3 interface at each end must have a logical *tunnel* interface for the firewall to connect to and establish a VPN tunnel. A tunnel interface is a logical (virtual) interface that is used to deliver traffic between two endpoints. Each tunnel interface can have a maximum of 10 IPSec tunnels; this means that up to 10 networks can be associated with the same tunnel interface on the firewall.

The tunnel interface must belong to a security zone to apply policy and it must be assigned to a virtual router in order to use the existing routing infrastructure. Ensure that the tunnel interface and the physical interface are assigned to the same virtual router so that the firewall can perform a route lookup and determine the appropriate tunnel to use.

Typically, the Layer 3 interface that the tunnel interface is attached to belongs to an external zone, for example the untrust zone. While the tunnel interface can either be in the same security zone as the physical interface, for added security and better visibility, you can create a separate zone for the tunnel interface. If you create a separate zone for the tunnel interface, say a VPN zone, you will need to create security policies to enable traffic to flow between the VPN zone and the trust zone.

 © Palo Alto Networks, Inc.

To route traffic between the sites, a tunnel interface does not require an IP address. An IP address is only required if you want to enable tunnel monitoring or if you are using a dynamic routing protocol to route traffic across the tunnel. With dynamic routing, the tunnel IP address serves as the next hop IP address for routing traffic to the VPN tunnel.

If you are configuring the Palo Alto Networks firewall with a VPN peer that performs policy-based VPN, you must configure a local and remote Proxy ID when setting up the IPSec tunnel. Each peer compares the Proxy-IDs configured on it with what is actually received in the packet in order to allow a successful IKE phase 2 negotiation. If multiple tunnels are required, configure unique Proxy IDs for each tunnel interface; a tunnel interface can have a maximum of 250 ProxyIDs. Each Proxy ID counts towards the IPSec VPN tunnel capacity of the firewall, and the tunnel capacity varies by the firewall model.

See Set up an IPSec Tunnel for configuration details.

## Tunnel Monitoring

For a VPN tunnel, you can check connectivity to a destination IP address across the tunnel. The network monitoring profile on the firewall allows you to verify connectivity (using ICMP) to a destination IP address or a next hop at a specified polling interval, and to specify an action on failure to access the monitored IP address.

If the destination IP is unreachable, you either configure the firewall to wait for the tunnel to recover or configure automatic failover to another tunnel. In either case, the firewall generates a system log that alerts you to a tunnel failure and renegotiates the IPSec keys to accelerate recovery.

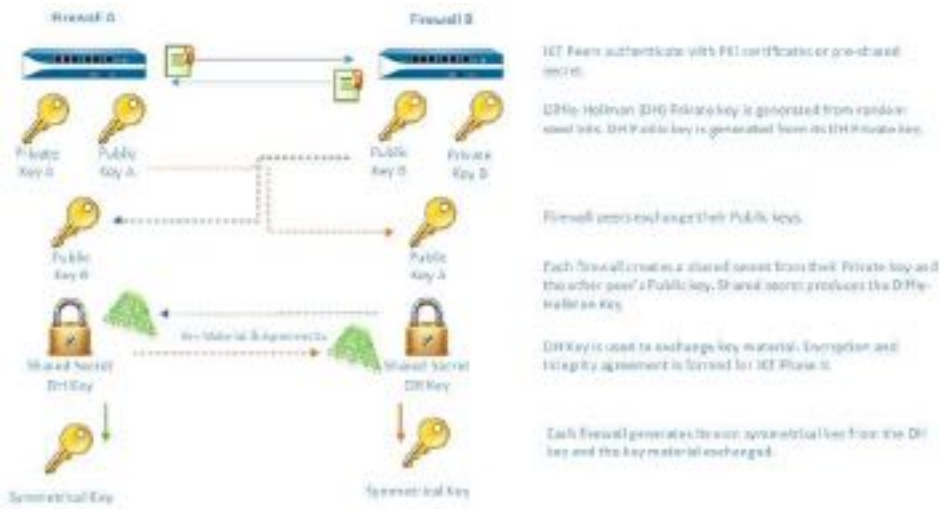
The default monitoring profile is configured to wait for the tunnel to recover; the polling interval is 3 seconds and the failure threshold is 5.

See Set up Tunnel Monitoring for configuration details.

## Internet Key Exchange (IKE) for VPN

The IKE process allows the VPN peers at both ends of the tunnel to encrypt and decrypt packets using mutually agreed upon keys or certificate and method of encryption. The IKE process occurs in two phases: IKE Phase 1 and IKE Phase 2. Each of these phases use keys and encryption algorithms that are defined using cryptographic profiles— IKE crypto profile and IPSec crypto profile—and the result of the IKE negotiation is a Security Association (SA). An SA is a set of mutually agreed upon keys and algorithms that will be used by both VPN peers to allow the flow of data across the VPN tunnel. The following illustration depicts the key exchange process for setting up the VPN tunnel:

© Palo Alto Networks, Inc.



## IKE Phase 1

In this phase, the firewalls use the parameters defined in the IKE Gateway configuration and the IKE Crypto profile to authenticate each other and set up a secure control channel. IKE Phase supports the use of preshared keys or digital certificates (which use public key infrastructure, PKI) for mutual authentication of the VPN peers. Preshared keys are a simple solution for securing smaller networks because they do not require the support of a PKI infrastructure. Digital certificates can be more convenient for larger networks or implementations that require stronger authentication security.

When using certificates, make sure that the CA issuing the certificate is trusted by both gateway peers and that the maximum length of certificates in the certificate chain is 5 or less. With IKE fragmentation enabled, the firewall can reassemble IKE messages with up to 5 certificates in the certificate chain and successfully establish a VPN tunnel.

The IKE-crypto profile defines the following options that are used in the IKE SA negotiation:

- Diffie-Hellman (DH) Group for generating symmetrical keys for IKE. The Diffie Hellman algorithm uses the private key of one party and the public key of the other to create a shared secret, which is an encrypted key that is shared by both VPN tunnel peers. The DH groups supported on the firewall are: Group 1—768 bits; Group 2—1024 bits (the default); Group 5—1536 bits; Group 14—2048 bits.
- Authentication options—sha1; sha 256; sha 384; sha 512; md5
- Encryption algorithms—3des; aes128; aes192; aes256

## IKE Phase 2

After the tunnel is secured and authenticated, in phase 2 the channel is further secured for the transfer of data between the networks. IKE phase 2 uses the keys that were established in Phase 1 of the process and the IPSec Crypto profile, which defines the IPSec protocols and keys used for the SA in IKE Phase 2.

The IPSEC uses the following protocols to enable secure communication:

 © Palo Alto Networks, Inc.

- Encapsulating Security Payload (ESP)—Allows you to encrypt the entire IP packet, and authenticate the source and verify integrity of the data. While ESP requires that you encrypt and authenticate the packet, you can choose to only encrypt or only authenticate by setting the encryption option to Null; using encryption without authentication is discouraged.
- Authentication Header (AH)—Authenticates the source of the packet and verifies data integrity. AH does not encrypt the data payload and is unsuited for deployments where data privacy is important. AH is commonly used when the main concern is to verify the legitimacy of the peer, and data privacy is not required.

**Table: Algorithms Supported for IPSEC Authentication and Encryption**

| ESP | AH |
|---|---|
| Diffie Hellman Exchange options supported | |
| • Group 1—768 bits<br>• Group 2—1024 bits (the default)<br>• Group 5—1536 bits<br>• Group 14—2048 bits.<br>• no-pfs—By default, Perfect Forward Secrecy (pfs) is enabled. With PFS is enabled, a new DH key is generated in IKE phase 2 using one of the groups listed above; this key is independent of the keys exchanged in IKE phase1, and therefore allows for more secure transfer of data.<br>No-pfs implies that the DH key created at phase 1 is not renewed and a single key is used for the IPSEC SA negotiations. Both VPN peers must be enabled or disabled for Perfect Forward Secrecy. | |
| Encryption algorithms supported | |
| • 3des | |
| • aes128 | |
| • aes192 | |
| • aes256 | |
| • aes128ccm16 | |
| • null | |
| Authentication algorithms supported | |
| • md5 | • md5 |
| • sha 1 | • sha 1 |
| • sha 256 | • sha 256 |
| • sha 384 | • sha 384 |
| • sha512 | • sha 512 |
| • none | |

## Methods of Securing IPSec VPN Tunnels (IKE Phase 2)

IPSec VPN tunnels can be secured using manual keys or auto keys. In addition, IPSec configuration options include Diffie-Hellman Group for key agreement, and/or an encryption algorithm and a hash for message authentication.

- **Manual Key**—Manual key is typically used if the Palo Alto Networks firewall is establishing a VPN tunnel with a legacy device, or if you want to reduce the overhead of generating session keys. If using manual keys, the same key must be configured on both peers.

  Manual keys are not recommended for establishing a VPN tunnel because the session keys can be compromised when relaying the key information between the peers; if the keys are compromised, the data transfer is no longer secure.

- **Auto Key**— Auto Key allows you to automatically generate keys for setting up and maintaining the IPSec tunnel based on the algorithms defined in the IPSec Crypto profile.

 © Palo Alto Networks, Inc.

# Set Up Site-to-Site VPN

To set up site-to-site VPN:

- Make sure that your Ethernet interfaces, virtual routers, and zones are configured properly. For more information, see Set Up Interfaces and Zones.
- Create your tunnel interfaces. Ideally, put the tunnel interfaces in a separate zone, so that tunneled traffic can use different policies.
- Set up static routes or assign routing protocols to redirect traffic to the VPN tunnels. To support dynamic routing (OSPF, BGP, RIP are supported), you must assign an IP address to the tunnel interface.
- Define IKE gateways for establishing communication between the peers across each end of the VPN tunnel; also define the cryptographic profile that specifies the protocols and algorithms for identification, authentication, and encryption to be used for setting up VPN tunnels in IKEv1 Phase 1. See Set up an IKE Gateway and Define IKE Crypto Profiles.
- Configure the parameters that are needed to establish the IPSec connection for transfer of data across the VPN tunnel; See Set up an IPSec Tunnel. For IKEv1 Phase-2, see Define IPSec Crypto Profiles.
- (Optional) Specify how the firewall will monitor the IPSec tunnels. See Set up Tunnel Monitoring.
- Define security policies to filter and inspect the traffic.

If there is a deny rule at the end of the security rulebase, intra-zone traffic is blocked unless otherwise allowed. Rules to allow IKE and IPSec applications must be explicitly included above the deny rule.

When these tasks are complete, the tunnel is ready for use. Traffic destined for the zones/addresses defined in policy is automatically routed properly based on the destination route in the routing table, and handled as VPN traffic. For a few examples on site-to-site VPN, see Site-to-Site VPN Quick Configs.

## Set up an IKE Gateway

To set up a VPN tunnel, the VPN peers or gateways must authenticate each other using preshared keys or digital certificates and establish a secure channel in which to negotiate the IPSec security association (SA) that will be used to secure traffic between the hosts on each side.

| Set up an IKE Gateway | | |
|---|---|---|
| Step 1 | Define the new IKE Gateway. | 1. Select **Network > Network Profiles > IKE Gateway** and enter a **Name f**or the new gateway configuration.<br>2. Select the outgoing **Interface** on the firewall.<br>3. From the **Local IP address** drop down list, select the IP address that will be used to as the endpoint for the VPN connection. This is the external facing interface with a publicly routable IP address on the firewall. |
| Step 2 | Define the settings for the peer at the far end of the tunnel. | 1. Select whether the peer uses a **Static** or **Dynamic** IP address in **Peer IP Type**.<br>2. If the **Peer IP Address** is static, enter the IP address of the peer. |
| Step 3 | Select the peer authentication method.<br>This is required for static and dynamic peers. | • For configuring a **Pre-Shared Key**, see Step 4.<br>• For configuring digital **Certificates**, see Step 5. |
| Step 4 | Configure a pre-shared key. | 1. Enter a security key to use for authentication across the tunnel. This key must be the same on both peers.<br>Generate a key that is hard to crack with dictionary attacks; use a pre-shared key generator, if necessary.<br>2. Continue with Step 6. |
| Step 5 | Configure certificate-based authentication.<br>The pre-requisites for certificate-based authentication are as follows:<br>– **Obtain a signed certificate:** See Generate a Certificate on the Firewall or Obtain a Certificate from an External CA.<br>– **Configure the certificate profile**: The certificate profile provides the settings that the IKE gateway uses for negotiating and validating certificate authentication with its peer. See Configure a Certificate Profile. | 1. Select **Certificate** for the **Authentication** method and select the signed certificate from the **Local Certificate** drop-down.<br>If your device is enabled for multi virtual systems, if the certificate belongs to a virtual system, it must be in the same virtual system as the interface used for the IKE gateway.<br>2. From the **Local Identification** drop down list, choose one of the following types and enter the value: IP address, FQDN (hostname), User FQDN (email address), Distinguished Name (subject).<br>3. From the **Peer Identification** drop-down, choose one of the following types and enter the value: IP address, FQDN (hostname), User FQDN (email address), Distinguished Name (subject).<br>4. Select a **Certificate Profile** to use.<br>5. Continue with Step 6. |

 © Palo Alto Networks, Inc.

| Set up an IKE Gateway | | |
|---|---|---|
| Step 6 | Configure the additional parameters for IKE phase 1 negotiations—Exchange mode, Crypto profile, IKE fragmentation, Dead Peer Detection. | 1. Select **Network > Network Profiles > IKE Gateways** and select the **Advanced Phase 1 Options** tab.<br>2. Choose **auto**, **aggressive**, or **main** for the **Exchange Mode**.<br>When a device is set to use the **auto** exchange mode, it can accept both main mode and aggressive mode negotiation requests; however, whenever possible, it initiates negotiation and allows exchanges in main mode.<br> If the exchange mode is not set to auto, you must configure both VPN peers with the same exchange mode to allow each peer to accept negotiation requests.<br>3. Select an existing profile or keep the default profile from **IKE Crypto Profile** drop-down. For details on defining an IKE Crypto profile, see Define IKE Crypto Profiles.<br>4. Select **Passive Mode** if you want the firewall to only respond to IKE connections and never initiate them.<br>5. Select **NAT Traversal Select** to have UDP encapsulation used on IKE and UDP protocols, enabling them to pass through intermediate NAT devices.<br>6. (Only if using certificate-based authentication and the exchange mode is not set as aggressive mode) Select **Enable Fragmentation** to enable the firewall to operate with IKE Fragmentation.<br>7. Select the **Dead Peer Detection** check box and enter an **Interval** (2 - 100 seconds); For **Retry,** define the time to delay (2 - 100 seconds) before attempting to re-check availability.<br>Dead peer detection identifies inactive or unavailable IKE peers by sending an IKE phase 1 notification payload to the peer and waiting for an acknowledgment. |
| Step 7 | Save the changes. | Click **OK** and **Commit**. |

# Define Cryptographic Profiles

A cryptographic profile specifies the ciphers used for authentication and/or encryption between two IKE peers, and the lifetime of the key. The time period between each renegotiation is known as the lifetime; when the specified time expires, the firewall renegotiates a new set of keys.

For securing communication across the VPN tunnel, the firewall requires IKE and IPSec cryptographic profiles for completing IKE phase 1 and phase 2 negotiations, respectively. The firewall includes a *default* IKE crypto profile and a *default* IPSec crypto profile that is ready for use.

- Define IKE Crypto Profiles
- Define IPSec Crypto Profiles

## Define IKE Crypto Profiles

The IKE crypto profile is used to set up the encryption and authentication algorithms used for the key exchange process in IKE Phase 1, and lifetime of the keys which specifies how long the keys are valid. To invoke the profile, you must attach it to the IKE Gateway configuration.

All IKE gateways configured on the same interface or local IP address must use the same crypto profile.

| Define an IKE Crypto Profile | | |
|---|---|---|
| Step 1 | Create a new IKE profile. | 1. Select **Network > Network Profiles > IKE Crypto** and select **Add**.<br>2. Enter a **Name f**or the new profile. |
| Step 2 | Select the DH Group to use for setting up the key exchange. | Click **Add** and select the key strength that you want to use for the DH Group.<br>Select more than one DH group if you are not certain of what is supported by the VPN peer. Prioritize the list of ciphers by strength so that the strongest cipher is used for setting up the tunnel. |
| Step 3 | Select the authentication and encryption algorithm. | Click **Add** and select the **Authentication** and **Encryption** algorithms that you want to use for communication between the IKE peers.<br>Selecting multiple algorithms allows the peers to use the strongest cipher/algorithm that is supported on both IKE peers. |
| Step 4 | Specify the duration for which the key is valid. | Select the **Lifetime** for which the key is valid. The time period between each renegotiation is known as the lifetime; when the specified time expires, the firewall will renegotiate a new set of keys. |
| Step 5 | Save your IKE Crypto profile. | Click **OK** and click **Commit**. |
| Step 6 | Attach the IKE Crypto profile to the IKE Gateway configuration. | See Step 6 in Set up an IKE Gateway. |

 © Palo Alto Networks, Inc.

## Define IPSec Crypto Profiles

The IPSec crypto profile is invoked in IKE Phase 2. It specifies how the data is secured within the tunnel when Auto Key IKE is used to automatically generate keys for the IKE SAs.

| Define the IPSec Crypto Profile | | |
|---|---|---|
| Step 1 | Create a new IPSec profile. | 1. Select **Network > Network Profiles > IPSec Crypto** and select **Add**.<br>2. Enter a **Name f**or the new profile.<br>3. Select the **IPSec Protocol**—ESP or AH—that you want to apply to secure the data as it traverses across the tunnel.<br>4. Click **Add** and select the **Authentication** and **Encryption** algorithms for ESP, and **Authentication** algorithms for AH, so that the IKE peers can negotiate the keys for the secure transfer of data across the tunnel.<br>Selecting multiple algorithms allows the peers to use the strongest cipher/algorithm that is supported on both IKE peers. |
| Step 2 | Select the DH Group to use for the IPSec SA negotiations in IKE phase 2. | 1. Select the key strength that you want to use from the **DH Group** drop down.<br>Select more than one DH group if you are not certain of what key strength is supported by the peer at the other end. The strongest cipher will be used for setting up the tunnel.<br>2. Select **no-pfs**, if you do not want to renew the key that was created at phase 1, the current key is reused for the IPSEC SA negotiations. |
| Step 3 | Specify the duration of the key— time and volume of traffic. | Using a combination of time and traffic volume allows you to ensure safety of data.<br>Select the **Lifetime** or time period for which the key is valid. When the specified time expires, the firewall will renegotiate a new set of keys.<br>Select the **Lifesize** or volume of data after which the keys must be renegotiated. |
| Step 4 | Save your IPSec profile. | Click **OK** and click **Commit**. |
| Step 5 | Attach the IPSec Profile to an IPSec tunnel configuration. | See Step 4 in |

## Set up an IPSec Tunnel

The IPSec tunnel configuration allows you to authenticate and/or encrypt the data (IP packet) as it traverses across the tunnel.

If you are setting up the Palo Alto Networks firewall to work with a peer that supports policy-based VPN, you must define Proxy IDs. Devices that support policy-based VPN, use specific security rules/policies or access-lists (source addresses, destination addresses and ports) for permitting interesting traffic through an IPSec tunnel. These rules are referenced during quick mode/IKE phase 2 negotiation, and are exchanged as Proxy-IDs in the first or the second message of the process. So, if you are configuring the Palo Alto Networks firewall to work with a policy-based VPN peer, for a successful phase 2 negotiation you must define the Proxy-ID so that the setting on both peers is identical. If the Proxy-ID is not configured, because the Palo Alto Networks firewall supports route-based VPN, the default values used as Proxy-ID are source ip: 0.0.0.0/0, destination ip: 0.0.0.0/0 and application: any; and when these values are exchanged with the peer, it results in a failure to set up the VPN connection.

**Set up an IPSec Tunnel**

Step 1 Select **Network > IPSec Tunnels> General** and enter a **Name** for the new tunnel.

Step 2 Select the **Tunnel interface** that will be used to set up the IPSec tunnel.

– To create a new tunnel interface:

1. Select **Network > Interfaces > Tunnel** and click **Add**.
2. In the **Interface Name** field, specify a numeric suffix, such as **.2**.
3. On the **Config** tab, expand the **Security Zone** drop-down to define the zone as follows:

   • To use your trust zone as the termination point for the tunnel, select the zone from the drop-down. Associating the tunnel interface with the same zone (and virtual router) as the external-facing interface on which the packets enter the firewall, mitigates the need to create inter-zone routing.

   • (Recommended) To create a separate zone for VPN tunnel termination, click **New Zone**. In the Zone dialog, define a **Name** for new zone (for example vpn-corp), and click **OK**.
4. In the **Virtual Router** drop-down, select **default**.
5. (Optional) If you want to assign an IPv4 address to the tunnel interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 10.31.32.1/32.
6. If you want to assign an IPv6 address to the tunnel interface, see Step 3.
7. To save the interface configuration, click **OK**.

 © Palo Alto Networks, Inc.

| Set up an IPSec Tunnel | |
|---|---|
| Step 3 (Optional) Enable IPv6 on the tunnel interface. | 1. Select the IPv6 tab on **Network > Interfaces > Tunnel > IPv6**.<br>2. Select the check box to **Enable IPv6 on the interface**.<br>This option allows you to route IPv6 traffic over an IPv4 IPSec tunnel and will provide confidentiality between IPv6 networks. The IPv6 traffic is encapsulated by IPv4 and then ESP. To route IPv6 traffic to the tunnel, you can use a static route to the tunnel, or use OSPFv3, or use a Policy Based Forwarding (PBF) rule to direct traffic to the tunnel.<br>3. Enter the 64-bit extended unique **Interface ID** in hexadecimal format, for example, 00:26:08:FF:FE:DE:4E:29. By default, the firewall will use the EUI-64 generated from the physical interface's MAC address.<br>4. To enter an IPv6 **Address**, click **Add** and enter an IPv6 address and prefix length, for example 2001:400:f00::1/64. If Prefix is not selected, the IPv6 address assigned to the interface will be wholly specified in the address text box.<br>a. Select **Use interface ID as host portion** to assign an IPv6 address to the interface that will use the interface ID as the host portion of the address.<br>b. Select **Anycast** to include routing through the nearest node. |
| Step 4 Select the type of key that will be used to secure the IPSec tunnel. | Continue to one of the following steps, depending on why type of key exchange you are using:<br>• Set up Auto Key exchange.<br>• Set up Auto Key exchange. |
| • Set up Auto Key exchange. | 1. Select the IKE Gateway. To set up an IKE gateway, see Set up an IKE Gateway.<br>2. (Optional) Select the default IPSec Crypto Profile. To create a new IPSec Profile, see Define IPSec Crypto Profiles. |

| Set up an IPSec Tunnel | |
|---|---|
| • Set up a Manual Key exchange. | 1. Set up the parameters for the local firewall:<br>a. Specify the **SPI** for the local firewall. SPI is a 32-bit hexadecimal index that is added to the header for IPSec tunneling to assist in differentiating between IPSec traffic flows; it is used to create the SA required for establishing a VPN tunnel.<br>b. Select the **Interface** that will be the tunnel endpoint, and optionally select the IP address for the local interface that is the endpoint of the tunnel.<br>c. Select the protocol to be used—**AH** or **ESP**.<br>d. For AH, select the **Authentication** method from the drop-down and enter a **Key** and then **Confirm Key**.<br>e. For ESP, select the **Authentication** method from the drop-down and enter a **Key** and then **Confirm Key**. Then, select the **Encryption** method and enter a **Key** and then **Confirm Key**, if needed.<br>2. Set up the parameters that pertain to the remote VPN peer.<br>a. Specify the **SPI** for the remote peer.<br>b. Enter the **Remote Address**, the IP address of the remote peer. |
| Step 5 Protect against a replay attack.<br>A replay attack occurs when a packet is maliciously intercepted and retransmitted by the interceptor. | Select the **Show Advanced Options** check box, select **Enable Replay Protection** to detect and neutralize against replay attacks. |
| Step 6 Preserve the Type of Service header for the priority or treatment of IP packets. | In the **Show Advanced Options** section, select **Copy TOS Header**. This copies the Type of Service (TOS) header from the inner IP header to the outer IP header of the encapsulated packets in order to preserve the original TOS information. |
| Step 7 Enable Tunnel Monitoring.<br>You need to assign an IP address to the tunnel interface for monitoring. | To alert the device administrator to tunnel failures and to provide automatic failover to another tunnel interface.<br>1. Specify a **Destination IP** address on the other side of the tunnel to determine if the tunnel is working properly.<br>2. Select a **Profile** to determine the action on tunnel failure. To create a new profile, see Define a Tunnel Monitoring Profile. |
| Step 8 (Required only if the VPN peer uses policy-based VPN). Create a Proxy ID to identify the VPN peers. | 1. Select **Network > IPSec Tunnels > ProxyID**.<br>2. Click **Add** and enter the IP address for the VPN gateway peers.<br>  |

© Palo Alto Networks, Inc.

| Set up an IPSec Tunnel | |
|---|---|
| Step 9 Save your changes | Click **OK** and **Commit**. |

# Set up Tunnel Monitoring

To provide uninterrupted VPN service, you can use the Dead Peer Detection capability along with the tunnel monitoring capability on the firewall. You can also monitor the status of the tunnel. For details see:

- Define a Tunnel Monitoring Profile
- View the Status of the Tunnels

## Define a Tunnel Monitoring Profile

A tunnel monitoring profile allows you to verify connectivity between the VPN peers; you can configure the tunnel interface to ping a destination IP address at a specified interval and specify the action if the communication across the tunnel is broken.

| **Define a Tunnel Monitoring Profile** | |
|---|---|
| Step 1 | Select **Network > Network Profiles > Monitor**. A default tunnel monitoring profile is available for use. |
| Step 2 | Click **Add**, and enter a **Name** for the profile. |
| Step 3 | Select the **Action** if the destination IP address is unreachable.<br>• **Wait Recover**—the firewall waits for the tunnel to recover. It continues to use the tunnel interface in routing decisions as if the tunnel is still active.<br>• **Fail Over**—forces traffic to a back-up path if one is available. The firewall disables the tunnel interface, and thereby disables any routes in the routing table that use the interface.<br>In either case, the firewall attempts to accelerate the recovery by negotiating new IPSec keys. |
| Step 4 | Specify the **Interval** and **Threshold** to trigger the specified action.<br>The threshold specifies the number of heartbeats to wait before taking the specified action. The range is 2-100 and the default is 5.<br>The Interval measures the time between heartbeats. The range is 2-10 and the default is 3 seconds. |
| Step 5 | Attach the monitoring profile to the IPsec Tunnel configuration. See Enable Tunnel Monitoring. |

## View the Status of the Tunnels

The status of the tunnel informs you about whether or not valid IKE phase-1 and phase-2 SAs have been established, and whether the tunnel interface is up and available for passing traffic.

Because the tunnel interface is a logical interface, it cannot indicate a physical link status. Therefore, you must enable tunnel monitoring so that the tunnel interface can verify connectivity to an IP address and determine if the path is still usable. If the IP address is unreachable, the firewall will either wait for the tunnel to recover or failover. When a failover occurs, the existing tunnel is torn down and routing changes are triggered to set up a new tunnel and redirect traffic.

| **View Tunnel Status** |
|---|
| 1. Select **Network > IPSec Tunnels**. |

 © Palo Alto Networks, Inc.

**View Tunnel Status**

2. View the **Tunnel Status**.
   - Green indicates a valid IPSec SA tunnel.
   - Red indicates that IPSec SA is not available or has expired.
3. View the **IKE Gateway Status**.
   - Green indicates a valid IKE phase-1 SA.
   - Red indicates that IKE phase-1 SA is not available or has expired.
4. View the **Tunnel Interface Status**.
   - Green indicates that the tunnel interface is up.
   - Red indicates that the tunnel interface is down, because tunnel monitoring is enabled and the status is down.

To troubleshoot a VPN tunnel that is not yet up, see Interpret VPN Error Messages.

# Test VPN Connectivity

## Test Connectivity

- Initiate IKE phase 1 by either pinging a host across the tunnel, or use the following CLI command:

  **test vpn ike-sa gateway** *gateway_name*

- Then enter the following command to test if IKE phase 1 is set up:

  **show vpn ike-sa gateway** *gateway_name*

  In the output check if the Security Association displays. If it does not, review the system log messages to interpret the reason for failure.

- Initiate IKE phase 2 by either pinging a host from across the tunnel, or use the following CLI command:

  **test vpn ipsec-sa tunnel** *tunnel_name*

- Then enter the following command to test if IKE phase 1 is set up:

  **show vpn ipsec-sa tunnel** *tunnel_name*

  In the output check if the Security Association displays. If it does not, review the system log messages to interpret the reason for failure.

- To view the VPN traffic flow information, use the following command:

  **show vpn-flow**

```
admin@PA-500> show vpn flow
total tunnels configured:             1
filter - type IPSec, state any

total IPSec tunnel configured:        1
total IPSec tunnel shown:             1

name               id      state    local-ip       peer-ip       tunnel-i/f
------------------------------------------------------------------------------
vpn-to-siteB       5       active    100.1.1.1     200.1.1.1      tunnel.41
```

 © Palo Alto Networks, Inc.

## Interpret VPN Error Messages

The following table lists some of the common VPN error messages that are logged in the system log.

**Table: Syslog Error Messages for VPN Issues**

| If error is this: | Try this: |
|---|---|
| `IKE phase-1 negotiation is failed as initiator, main mode. Failed SA: x.x.x.x[500]-y.y.y.y[500] cookie:84222f276c2fa2e9:0000000000000000 due to timeout.`<br>or<br>`IKE phase 1 negotiation is failed. Couldn't find configuration for IKE phase-1 request for peer IP x.x.x.x[1929]` | • Verify that the public IP address for each VPN peer is accurate in the IKE Gateway configuration,<br>• Verify that the IP addresses can be pinged and that routing issues are not causing the connection failure. |
| `Received unencrypted notify payload (no proposal chosen) from IP x.x.x.x[500] to y.y.y.y[500], ignored...`<br>or<br>`IKE phase-1 negotiation is failed. Unable to process peer's SA payload.` | Check the IKE Crypto profile configuration to verify that the proposals on both sides have a common encryption, authentication, and DH Group proposal. |
| `pfs group mismatched:my: 2peer: 0`<br>or<br>`IKE phase-2 negotiation failed when processing SA payload. No suitable proposal found in peer's SA payload.` | Check the IPSec Crypto profile configuration to verify that<br>• pfs is either enabled or disabled on both VPN peers<br>• the DH Groups proposed by each peer has at least one DH Group in common |
| `IKE phase-2 negotiation failed when processing Proxy ID. Received local id x.x.x.x/x type IPv4 address protocol 0 port 0, received remote id y.y.y.y/y type IPv4 address protocol 0 port 0.` | The VPN peer on one end is using policy-based VPN. You must configure a Proxy ID on the Palo Alto Networks firewall. See Step 8. |

 © Palo Alto Networks, Inc.

# Site-to-Site VPN Quick Configs

The following sections provide instructions for configuring some common VPN deployments:

- Site-to-Site VPN with Static Routing
- Site-to-Site VPN with OSPF
- Site-to-Site VPN with Static and Dynamic Routing

## Site-to-Site VPN with Static Routing

The following example shows a VPN connection between two sites that use static routes. Without dynamic routing, the tunnel interfaces on VPN Peer A and VPN Peer B do not require an IP address because the firewall automatically uses the tunnel interface as the next hop for routing traffic across the sites. However, to enable tunnel monitoring, a static IP address has been assigned to each tunnel interface.

 © Palo Alto Networks, Inc.

| Quick Config: Site-to-Site VPN with Static Routing | |
|---|---|
| Step 1 Configure a Layer 3 interface.<br><br>This interface is used for the IKE phase-1 tunnel. | 1. Select **Network > Interfaces > Ethernet** and then select the interface you want to configure for VPN.<br>2. Select **Layer3** from the **Interface Type** drop-down.<br>3. On the **Config** tab, select the **Security Zone** to which the interface belongs:<br>• The interface must be accessible from a zone outside of your trust network. Consider creating a dedicated VPN zone for visibility and control over your VPN traffic.<br>• If you have not yet created the zone, select **New Zone** from the **Security Zone** drop-down, define a **Name** for the new zone and then click **OK**.<br>4. Select the **Virtual Router** to use.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 192.168.210.26/24.<br>6. To save the interface configuration, click **OK**.<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—ethernet1/7<br>• **Security Zone**—untrust<br>• **Virtual Router**—default<br>• **IPv4**—192.168.210.26/24<br>The configuration for VPN Peer B is:<br>• **Interface**—ethernet1/11<br>• **Security Zone**—untrust<br>• **Virtual Router**—default<br>• **IPv4**—192.168.210.120/24 |

| Quick Config: Site-to-Site VPN with Static Routing | |
|---|---|
| Step 2 Create a tunnel interface and attach it to a virtual router and security zone.<br>  | 1. Select **Network > Interfaces > Tunnel** and click **Add**.<br>2. In the **Interface Name** field, specify a numeric suffix, such as **.1**.<br>3. On the **Config** tab, expand the **Security Zone** drop-down to define the zone as follows:<br>• To use your trust zone as the termination point for the tunnel, select the zone from the drop-down.<br>• (Recommended) To create a separate zone for VPN tunnel termination, click **New Zone**. In the Zone dialog, define a **Name** for new zone (for example *vpn-tun*), and then click **OK**.<br>4. Select the **Virtual Router**.<br>5. (Optional) Assign an IP address to the tunnel interface, select the **IPv4** or **IPv6** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface.<br>With static routes, the tunnel interface does not require an IP address. For traffic that is destined to a specified subnet/IP address, the tunnel interface will automatically become the next hop. Consider adding an IP address if you want to enable tunnel monitoring.<br>6. To save the interface configuration, click **OK**.<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—tunnel.11<br>• **Security Zone**—vpn_tun<br>• **Virtual Router**—default<br>• **IPv4**—172.19.9.2/24<br>The configuration for VPN Peer B is:<br>• **Interface**—tunnel.12<br>• **Security Zone**—vpn_tun<br>• **Virtual Router**—default<br>• **IPv4**—192.168.69.2/24 |
| Step 3 Configure a static route, on the virtual router, to the destination subnet.<br> | 1. Select **Network > Virtual Router** and click the router you defined in step 4 above.<br>2. Select **Static Route**, click **Add**, and enter a new route to access the subnet that is at the other end of the tunnel.<br>In this example, the configuration for VPN Peer A is:<br>• **Destination**—192.168.69.0/24<br>• **Interface**—tunnel.11<br>The configuration for VPN Peer B is:<br>• **Destination**—172.19.9.0/24<br>• **Interface**—tunnel.12 |

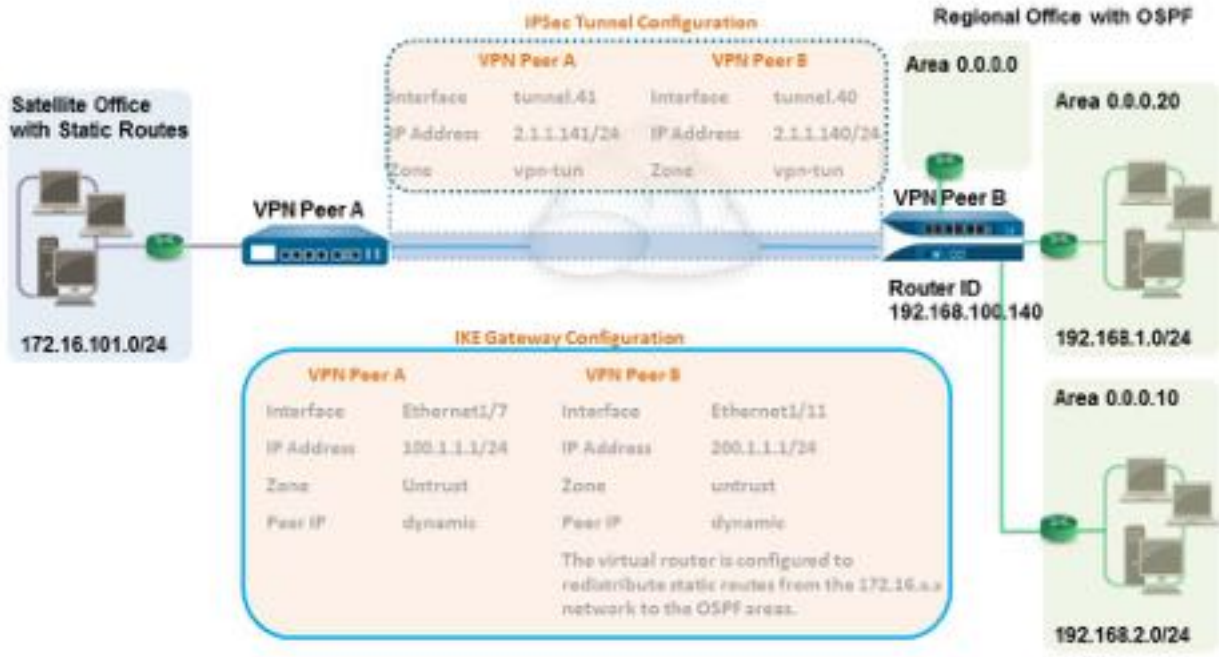
## Site-to-Site VPN with Static and Dynamic Routing

In this example, one site uses static routes and the other site uses OSPF. When the routing protocol is not the same between the locations, the tunnel interface on each firewall must be configured with a static IP address. Then, to allow the exchange of routing information, the firewall that participates in both the static and dynamic routing process must be configured with a *Redistribution profile*. Configuring the redistribution profile, enables the virtual router to redistribute and filter routes between protocols—static routes, connected routes, and hosts—from the static autonomous system to the OSPF autonomous system. Without this redistribution profile, each protocol functions on its own and does not exchange any route information with other protocols running on the same virtual router.

In this example, the satellite office has static routes and all traffic destined to the 192.168.x.x network is routed to tunnel.41. The virtual router on VPN Peer B participates in both the static and the dynamic routing process and is configured with a redistribution profile in order to propagate (*export*) the static routes to the OSPF autonomous system.



| Quick Config: Site-to-Site VPN with Static and Dynamic Routing | | |
|---|---|---|
| Step 1 | Configure the Layer 3 interfaces on each firewall. | 1. Select **Network > Interfaces > Ethernet** and then select the interface you want to configure for VPN.<br>2. Select **Layer3** from the **Interface Type** drop-down.<br>3. On the **Config** tab, select the **Security Zone** to which the interface belongs:<br>• The interface must be accessible from a zone outside of your trust network. Consider creating a dedicated VPN zone for visibility and control over your VPN traffic.<br>• If you have not yet created the zone, select **New Zone** from the **Security Zone** drop-down, define a **Name** for the new zone and then click **OK**.<br>4. Select the **Virtual Router** to use.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 192.168.210.26/24.<br>6. To save the interface configuration, click **OK**.<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—ethernet1/7<br>• **Security Zone**—untrust<br>• **Virtual Router**—default<br>• **IPv4**—100.1.1.1/24<br>The configuration for VPN Peer B is:<br>• **Interface**—ethernet1/11<br>• **Security Zone**—untrust<br>• **Virtual Router**—default<br>• **IPv4**—200.1.1.1/24 |
| Step 2 | Set up the Crypto profiles (IKE Crypto profile for phase 1 and IPSec Crypto profile for phase 2).<br>Complete this task on both peers and make sure to set identical values. | 1. Select **Network > Network Profiles > IKE Crypto**. In this example, we use the default profile.<br> <br>2. Select **Network > Network Profiles > IPSec Crypto**. In this example, we use the default profile.<br> |

© Palo Alto Networks, Inc.

| Quick Config: Site-to-Site VPN with Static and Dynamic Routing | |
|---|---|
| Step 3 Set up the IKE Gateway.<br><br>With pre-shared keys, to add authentication scrutiny when setting up the IKE phase-1 tunnel, you can set up Local and Peer Identification attributes and a corresponding value that is matched in the IKE negotiation process. | 1. Select **Network > Network Profiles > IKE Gateway.**<br>2. Click **Add** and configure the options in the **General** tab**.**<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—ethernet1/7<br>• **Local IP address**—100.1.1.1/24<br>• **Peer IP type**—dynamic<br>• **Preshared keys**—enter a value<br>• **Local identification**—select **FQDN(hostname)** and enter the value for VPN Peer A.<br>• **Peer identification**—select **FQDN(hostname)** and enter the value for VPN Peer B<br>The configuration for VPN Peer B is:<br>• **Interface**—ethernet1/11<br>• **Local IP address**—200.1.1.1/24<br>• **Peer IP address**—dynamic<br>• **Preshared keys**—enter same value as on Peer A<br>• **Local identification**—select **FQDN(hostname)** and enter the value for VPN Peer B<br>• **Peer identification**—select **FQDN(hostname)** and enter the value for VPN Peer A<br>3. Select the IKE Crypto profile you created earlier to use for IKE phase 1. |

| Quick Config: Site-to-Site VPN with Static and Dynamic Routing | |
|---|---|
| Step 4 Create a tunnel interface and attach it to a virtual router and security zone.<br> | 1. Select **Network > Interfaces > Tunnel** and click **Add**.<br>2. In the **Interface Name** field, specify a numeric suffix, say, **.41**.<br>3. On the **Config** tab, expand the **Security Zone** drop-down to define the zone as follows:<br>• To use your trust zone as the termination point for the tunnel, select the zone from the drop-down.<br>• (Recommended) To create a separate zone for VPN tunnel termination, click **New Zone**. In the Zone dialog, define a **Name** for new zone (for example *vpn-tun*), and then click **OK**.<br>4. Select the **Virtual Router**.<br>5. Assign an IP address to the tunnel interface, select the **IPv4** or **IPv6** tab, click **Add** in the IP section, and enter the IP address and network mask/prefix to assign to the interface, for example 172.19.9.2/24.<br>This IP address will be used to route traffic to the tunnel and to monitor the status of the tunnel.<br>6. To save the interface configuration, click **OK**.<br>In this example, the configuration for VPN Peer A is:<br>• **Interface**—tunnel.41<br>• **Security Zone**—vpn_tun<br>• **Virtual Router**—default<br>• **IPv4**—2.1.1.141/24<br>The configuration for VPN Peer B is:<br>• **Interface**—tunnel.42<br>• **Security Zone**—vpn_tun<br>• **Virtual Router**—default<br>• **IPv4**—2.1.1.140/24 |
| Step 5 Specify the interface to route traffic to a destination on the 192.168.x.x network. | 1. On VPN Peer A, select the virtual router.<br>2. Select **Static Routes**, and **Add** tunnel.41 as the **Interface** for routing traffic with a **Destination** in the 192.168.x.x network. |

© Palo Alto Networks, Inc.

| Quick Config: Site-to-Site VPN with Static and Dynamic Routing | |
|---|---|
| Step 6 Set up the static route and the OSPF configuration on the virtual router and attach the OSPF areas with the appropriate interfaces on the firewall. | 1. On VPN Peer B, select **Network > Virtual Routers**, and select the default router or add a new router.<br>2. Select **Static Routes** and **Add** the tunnel IP address as the next hop for traffic in the 172.168.x.x. network.<br>Assign the desired route metric; using a lower the value makes the a higher priority for route selection in the forwarding table.<br>3. Select **OSPF** (for IPv4) or **OSPFv3** (for IPv6) and select **Enable**.<br>4. In this example, the OSPF configuration for VPN Peer B is:<br>• Router ID: 192.168.100.140<br>• Area ID: 0.0.0.0 is assigned to the interface Ethernet 1/12 Link type: Broadcast<br>• Area ID: 0.0.0.10 that is assigned to the interface Ethernet1/1 and Link Type: Broadcast<br>• Area ID: 0.0.0.20 is assigned to the interface Ethernet1/15 and Link Type: Broadcast |
| Step 7 Create a redistribution profile to inject the static routes into the OSPF autonomous system.<br> <br> | 1. Create a redistribution profile on VPN Peer B.<br>a. Select **Network > Virtual Routers**, and select the router you used above.<br>b. Select **Redistribution Profiles,** and click **Add**.<br>c. Enter a Name for the profile and select **Redist** and assign a **Priority** value. If you have configured multiple profiles, the profile with the lowest priority value is matched first.<br>d. Set **Source Type** as **static**, and click **OK**. The static route defined in Step 6-2 will be used for the redistribution.<br>2. Inject the static routes in to the OSPF system.<br>a. Select **OSPF> Export Rules** (for IPv4) or **OSPFv3> Export Rules** (for IPv6).<br>b. Click **Add**, and select the redistribution profile that you just created.<br>c. Select how the external routes are brought into the OSPF system. The default option, **Ext2** calculates the total cost of the route using only the external metrics. To use both internal and external OSPF metrics, use **Ext1.**<br>d. Assign a **Metric** (cost value) for the routes injected into the OSPF system. This option allows you to change the metric for the injected route as it comes into the OSPF system.<br>e. Click **OK** to save the changes. |

| Quick Config: Site-to-Site VPN with Static and Dynamic Routing | |
|---|---|
| Step 8 Set up the IPSec Tunnel. | 1. Select **Network > IPSec Tunnels**.<br>2. Click **Add** and configure the options in the **General** tab.<br>In this example, the configuration for VPN Peer A is:<br>• **Tunnel Interface**—tunnel.41<br>• **Type**—Auto Key<br>• **IKE Gateway**—Select the IKE Gateway defined above.<br>• **IPSec Crypto Profile**—Select the IKE Gateway defined above.<br>The configuration for VPN Peer B is:<br>• **Tunnel Interface**—tunnel.40<br>• **Type**—Auto Key<br>• **IKE Gateway**—Select the IKE Gateway defined above.<br>• **IPSec Crypto Profile**—Select the IKE Gateway defined above.<br>3. Select **Show Advanced Options**, select **Tunnel Monitor**, and specify a Destination IP address to ping for verifying connectivity.<br>4. To define the action on failure to establish connectivity, see Define a Tunnel Monitoring Profile. |
| Step 9 Create policies to allow traffic between the sites (subnets). | 1. Select **Policies > Security**.<br>2. Create rules to allow traffic between the untrust and the vpn-tun zone and the vpn-tun and the untrust zone for traffic originating from specified source and destination IP addresses. |

# Large Scale VPN (LSVPN)

The GlobalProtect Large Scale VPN (LSVPN) feature on the Palo Alto Networks next-generation firewall simplifies the deployment of traditional hub and spoke VPNs, enabling you to quickly deploy enterprise networks with several branch offices with a minimum amount of configuration required on the remote *satellite* devices. This solution uses certificates for device authentication and IPSec to secure data.

LSVPN enables site-to-site VPNs between Palo Alto Networks firewalls. To set up a site-to-site VPN between a Palo Alto Networks firewall and another device, see VPNs.

The following topics describe the LSVPN components and how to set them up to enable site-to-site VPN services between Palo Alto Networks firewalls:

- LSVPN Overview
- Create Interfaces and Zones for the LSVPN
- Enable SSL Between GlobalProtect LSVPN Components
- Configure the Portal to Authenticate Satellites
- Configure GlobalProtect Gateways for LSVPN
- Configure the GlobalProtect Portal for LSVPN
- Prepare the Satellite Device to Join the LSVPN
- Verify the LSVPN Configuration
- LSVPN Quick Configs

# LSVPN Overview

GlobalProtect provides a complete infrastructure for managing secure access to corporate resources from your remote sites. This infrastructure includes the following components:

- **GlobalProtect Portal**—Provides the management functions for your GlobalProtect LSVPN infrastructure. Every satellite that participates in the GlobalProtect LSVPN receives configuration information from the portal, including configuration information to enable the satellites (the spokes) to connect to the gateways (the hubs). You configure the portal on an interface on any Palo Alto Networks next-generation firewall.
- **GlobalProtect Gateways**—A Palo Alto Networks firewall that provides the tunnel end point for satellite connections. The resources that the satellites access is protected by security policy on the gateway. It is not required to have a separate portal and gateway; a single firewall can function both as portal and gateway.
- **GlobalProtect Satellite**—A Palo Alto Networks firewall at a remote site that establishes IPSec tunnels with the gateway(s) at your corporate office(s) for secure access to centralized resources. Configuration on the satellite firewall is minimal, enabling you to quickly and easily scale your VPN as you add new sites.

The following diagram illustrates how the GlobalProtect LSVPN components work together.

 © Palo Alto Networks, Inc.

# Create Interfaces and Zones for the LSVPN

You must configure the following interfaces and zones for your LSVPN infrastructure:

- **GlobalProtect portal**—Requires a Layer 3 interface for GlobalProtect satellites to connect to. If the portal and gateway are on the same firewall, they can use the same interface. The portal must be in a zone that is accessible from your branch offices.
- **GlobalProtect gateways**—Requires three interfaces: a Layer 3 interface in the zone that is reachable by the remote satellites, an internal interface in the trust zone that connects to the protected resources, and a logical tunnel interface for terminating the VPN tunnels from the satellites. Unlike other site-to-site VPN solutions, the GlobalProtect gateway only requires a single tunnel interface, which it will use for tunnel connections with all of your remote satellites (point-to-multipoint). If you plan to use dynamic routing, you must assign an IP address to the tunnel interface.
- **GlobalProtect satellites**—Requires a single tunnel interface for establishing a VPN with the remote gateways (up to a maximum of 25 gateways). If you plan to use dynamic routing, you must assign an IP address to the tunnel interface.

For more information about portals, gateways, and satellites see LSVPN Overview.

| Set Up Interfaces and Zones for the GlobalProtect LSVPN | |
|---|---|
| Step 1 Configure a Layer 3 interface.<br><br>The portal and each gateway and satellite all require a Layer 3 interface to enable traffic to be routed between sites.<br><br>If the gateway and portal are on the same firewall, you can use a single interface for both components.<br><br>IPv6 addresses are not supported with LSVPN. | 1. Select **Network > Interfaces > Ethernet** and then select the interface you want to configure for GlobalProtect LSVPN.<br>2. Select **Layer3** from the **Interface Type** drop-down.<br>3. On the **Config** tab, select the **Security Zone** to which the interface belongs:<br>• The interface must be accessible from a zone outside of your trust network. Consider creating a dedicated VPN zone for visibility and control over your VPN traffic.<br>• If you have not yet created the zone, select **New Zone** from the **Security Zone** drop-down, define a **Name** for the new zone and then click **OK**.<br>4. Select the **Virtual Router** to use.<br>5. To assign an IP address to the interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 203.0.11.100/24.<br>6. To save the interface configuration, click **OK**. |

**Set Up Interfaces and Zones for the GlobalProtect LSVPN (Continued)**

| | | |
|---|---|---|
| Step 2 | On the firewall(s) hosting GlobalProtect gateway(s), configure the logical tunnel interface that will terminate VPN tunnels established by the GlobalProtect satellites.<br><br>IP addresses are not required on the tunnel interface unless plan to use dynamic routing. However, assigning an IP address to the tunnel interface can be useful for troubleshooting connectivity issues.<br><br>Make sure to enable User-ID in the zone where the VPN tunnels terminate. | 1. Select **Network > Interfaces > Tunnel** and click **Add**.<br>2. In the **Interface Name** field, specify a numeric suffix, such as **.2**.<br>3. On the **Config** tab, expand the **Security Zone** drop-down to define the zone as follows:<br>• To use your trust zone as the termination point for the tunnel, select the zone from the drop-down.<br>• (Recommended) To create a separate zone for VPN tunnel termination, click **New Zone**. In the Zone dialog, define a **Name** for new zone (for example *lsvpn-tun*), select the **Enable User Identification** check box, and then click **OK**.<br>4. Select the **Virtual Router**.<br>5. (Optional) If you want to assign an IP address to the tunnel interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 203.0.11.33/24.<br>6. To save the interface configuration, click **OK**. |
| Step 3 | If you created a separate zone for tunnel termination of VPN connections, create a security policy to enable traffic flow between the VPN zone and your trust zone. For example, the following policy rule enables traffic between the *lsvpn-tun* zone and the *L3-Trust* zone.<br>  <br> | |
| Step 4 | Save the configuration. | Click **Commit**. |

# Enable SSL Between GlobalProtect LSVPN Components

All interaction between the GlobalProtect components occurs over an SSL connection. Therefore, you must generate and/or install the required certificates before configuring each component so that you can reference the appropriate certificate(s) and/or certificate profiles in the configurations for each component. The following sections describe the supported methods of certificate deployment, descriptions and best practice guidelines for the various GlobalProtect certificates, and provide instructions for generating and deploying the required certificates:

▲ About Certificate Deployment

▲ Deploy Server Certificates to the GlobalProtect LSVPN Components

## About Certificate Deployment

There are two basic approaches to deploying certificates for GlobalProtect LSVPN:

- **Enterprise Certificate Authority**—If you already have your own enterprise certificate authority, you can use this internal CA to issue an intermediate CA certificate for the GlobalProtect portal to enable it to issue certificates to the GlobalProtect gateways and satellites.
- **Self-Signed Certificates**—You can generate a self-signed root CA certificate on the firewall and use it to issue server certificates for the portal, gateway(s), and satellite(s). As a best practice, create a self-signed root CA certificate on the portal and use it to issue server certificates for the gateways and satellites. This way, the private key used for certificate signing stays on the portal.

## Deploy Server Certificates to the GlobalProtect LSVPN Components

The GlobalProtect LSVPN components use SSL/TLS to mutually authenticate. Before deploying the LSVPN, you must issue server certificates to the portal and gateways. You do not need to create server certificates for the satellite devices because the portal will issue a server certificate for each satellite during the first connection.

In addition, you must import the root CA certificate used to issue the server certificates onto each firewall that you plan to host as a gateway or satellite. Finally, on each gateway and satellite participating in the LSVPN, you must configure a certificate profile that will enable them to establish an SSL/TLS connection using mutual authentication.

The following workflow shows the best practice steps for deploying SSL certificates to the GlobalProtect LSVPN components:

You do not need to issue server certificates for the satellite devices because the portal will issue them as part of the satellite registration process.

| Deploy SSL Server Certificates to the GlobalProtect Components | | |
|---|---|---|
| Step 1 | On the firewall hosting the portal, create the root CA certificate for issuing self-signed certificates for the GlobalProtect components. | To use self-signed certificates, you must first create the root CA certificate that will be used to sign the certificates for the GlobalProtect components as follows:<br>1. To create a root CA certificate, select **Device > Certificate Management > Certificates > Device Certificates** and then click **Generate**.<br>2. Enter a **Certificate Name**, such as *LSVPN_CA*. The certificate name cannot contain any spaces.<br>3. Do not select a value in the **Signed By** field (this is what indicates that it is self-signed).<br>4. Select the **Certificate Authority** check box and then click **OK** to generate the certificate. |
| Step 2 | Generate server certificates for the GlobalProtect portal and gateway(s).<br>You must issue a unique self-signed server certificate for the portal and for each GlobalProtect gateway. The best practice is to issue all of the required certificates on the portal, so that the signing certificate (with the private key) does not have to be exported.<br> If the GlobalProtect portal and gateway are on the same firewall interface, you can use the same server certificate for both components. | Use the root CA on the portal to generate server certificates for each gateway you plan to deploy:<br>1. Select **Device > Certificate Management > Certificates > Device Certificates** and then click **Generate**.<br>2. Enter a **Certificate Name**. The Certificate Name cannot contain any spaces.<br>3. Enter the FQDN (recommended) or IP address of the interface where you plan to configure the gateway in the **Common Name** field.<br>4. In the **Signed By** field, select the *LSVPN_CA* you created previously.<br>5. In the Certificate Attributes section, click **Add** and define the attributes to uniquely identify the gateway. Keep in mind that if you add a **Host Name** attribute (which populates the SAN field of the certificate), it must exactly match the value you defined for the **Common Name**.<br>6. **Generate** the certificate. |

 © Palo Alto Networks, Inc.

| Deploy SSL Server Certificates to the GlobalProtect Components (Continued) | |
|---|---|
| Step 3 Deploy the self-signed server certificates to the gateways.<br><br>**Best Practices:**<br>• Export the self-signed server certificates issued by the root CA from the portal and import them onto the gateways.<br>• Be sure to issue a unique server certificate for each gateway.<br>• The Common Name (CN) and, if applicable, the Subject Alternative Name (SAN) fields of the certificate must match the IP address or fully qualified domain name (FQDN) of the interface where you configure the gateway. | 1. On the portal, select **Device > Certificate Management > Certificates > Device Certificates**, select the gateway certificate you want to deploy, and click **Export**.<br>2. Select **Encrypted Private Key and Certificate (PKCS12)** from the **File Format** drop-down.<br>3. Enter (and re-enter) a **Passphrase** to encrypt the private key associated with the certificate and then click **OK** to download the PKCS12 file to your computer.<br>4. On the gateway, select **Device > Certificate Management > Certificates > Device Certificates** and click **Import**.<br>5. Enter a **Certificate Name**.<br>6. Enter the path and name to the **Certificate File** you just downloaded from the portal, or **Browse** to find the file.<br>7. Select **Encrypted Private Key and Certificate (PKCS12)** as the **File Format**.<br>8. Enter the path and name to the PKCS12 file in the **Key File** field or **Browse** to find it.<br>9. Enter and re-enter the **Passphrase** you used to encrypt the private key when you exported it from the portal and then click **OK** to import the certificate and key. |
| Step 4 Import the root CA certificate used to issue server certificates for the LSVPN components.<br><br>You must import the root CA certificate onto all gateways and satellites. For security reasons, make sure you export the certificate only, and not the associated private key. | 1. Download the root CA certificate from the portal.<br>a. Select **Device > Certificate Management > Certificates > Device Certificates**.<br>b. Select the root CA certificate used to issue certificates for the LSVPN components and click **Export**.<br>c. Select **Base64 Encoded Certificate (PEM)** from the **File Format** drop-down and click **OK** to download the certificate. (Do not export the private key.)<br>2. On the firewalls hosting the gateways and satellites, import the root CA certificate.<br>a. Select **Device > Certificate Management > Certificates > Device Certificates** and click **Import**.<br>b. Enter a **Certificate Name** that identifies the certificate as your client CA certificate.<br>c. **Browse** to the **Certificate File** you downloaded from the CA.<br>d. Select **Base64 Encoded Certificate (PEM)** as the **File Format** and then click **OK**.<br>e. Select the certificate you just imported on the **Device Certificates** tab to open it.<br>f. Select **Trusted Root CA** and then click **OK**.<br>g. **Commit** the changes. |

| Deploy SSL Server Certificates to the GlobalProtect Components (Continued) | | |
|---|---|---|
| Step 5 | Create a certificate profile.<br>The GlobalProtect LSVPN portal and each gateway require a certificate profile that specifies which certificate to use to authenticate the satellites. | 1. Select **Device > Certificate Management > Certificate Profile** and click **Add** and enter a profile **Name**.<br>2. Make sure **Username Field** is set to **None**.<br>3. In the **CA Certificates** field, click **Add**, select the Trusted Root CA certificate you imported in Step 4.<br>4. (Optional, but recommended) Enable use of CRL and/or OCSP to enable certificate status verification.<br>5. Click **OK** to save the profile. |
| Step 6 | Save the configuration. | Click **Commit**. |

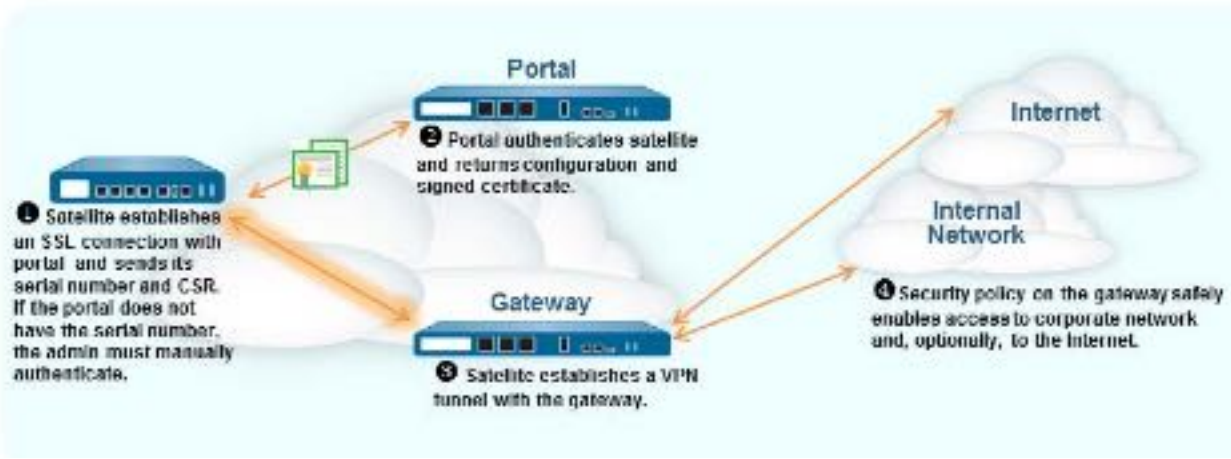
© Palo Alto Networks, Inc.

# Configure the Portal to Authenticate Satellites

In order to register with the LSVPN, each satellite must establish an SSL/TLS connection with the portal. After establishing the connection, the portal authenticates the satellite device to ensure that is authorized to join the LSVPN. After successfully authenticating the satellite, the portal will issue a server certificate for the satellite and push the LSVPN configuration specifying the gateways to which the satellite can connect and the root CA certificate required to establish an SSL connection with the gateways.

There are two ways that the satellite can authenticate to the portal during its initial connection:

- **Serial number**—You can configure the portal with the serial number of the satellite firewalls that are authorized to join the LSVPN. During the initial satellite connection to the portal, the satellite presents its serial number to the portal and if the portal has the serial number in its configuration, the satellite will be successfully authenticated. You add the serial numbers of authorized satellites when you configure the portal. See Configure the Portal.
- **Username and password**—If you would rather provision your satellites without manually entering the serial numbers of the satellite devices into the portal configuration, you can instead require the satellite administrator to authenticate when establishing the initial connection to the portal. Although the portal will always look for the serial number in the initial request from the satellite, if it cannot identify the serial number, the satellite administrator must provide a username and password to authenticate to the portal. Because the portal will always fall back to this form of authentication, you must create an authentication profile in order to commit the portal configuration. This requires that you set up an authentication profile for the portal LSVPN configuration even if you plan to authenticate satellites using the serial number.



The following workflow describes how to set up the portal to authenticate satellites against an existing authentication service. GlobalProtect LSVPN supports external authentication using a local database, LDAP (including Active Directory), Kerberos, or RADIUS.

| Set Up Satellite Authentication | | |
|---|---|---|
| Step 1 | Create a server profile on the portal.<br><br>The server profile instructs the firewall how to connect to an external authentication service to validate the authentication credentials provided by the satellite administrator.<br><br>If you are using local authentication, you can skip this step and instead add a local user configuration for authenticating the satellite administrator.<br><br> If you are using LDAP to connect to Active Directory (AD), you must create a separate LDAP server profile for every AD domain. | 1. Select **Device > Server Profiles** and select type of profile (**LDAP**, **Kerberos**, or **RADIUS**).<br>2. Click **Add** and enter a **Name** for the profile, such as *LSVPN-Auth*.<br>3. (LDAP only) Select the **Type** of LDAP server you are connecting to.<br>4. Click **Add** in the Servers section and then enter information required to connect to the authentication service, including the server **Name**, **IP Address** (or FQDN), and **Port**.<br>5. (RADIUS and LDAP only) Specify settings to enable the firewall to authenticate to the authentication service as follows:<br>• RADIUS—Enter the shared **Secret** when adding the server entry.<br>• LDAP—Enter the **Bind DN** and **Bind Password**.<br>6. (LDAP and Kerberos only) Specify where to search for credentials in the directory service:<br>• LDAP—The **Base** DN specifies where in the LDAP tree to begin searching for users and groups. This field should populate automatically when you enter the server address and port. If it doesn't, check the service route to the LDAP server.<br>• Kerberos—Enter the Kerberos **Realm** name.<br>7. Specify the **Domain** name (without dots, for example `acme` not `acme.com`).<br>8. Click **OK** to save the server profile. |
| Step 2 | Create an authentication profile.<br><br>The authentication profile specifies which server profile to use to authenticate satellites. | 1. Select **Device > Authentication Profile** and click **Add**.<br>2. Enter a **Name** for the profile and then select the **Authentication** type (**Local Database, LDAP**, **Kerberos**, or **RADIUS**).<br>3. Select the **Server Profile** you created in Step 1.<br>4. (LDAP AD) Enter **sAMAccountName** as the **Login Attribute**.<br>5. Click **OK**. |
| Step 3 | Save the configuration. | Click **Commit**. |

 © Palo Alto Networks, Inc.

# Configure GlobalProtect Gateways for LSVPN

Because the GlobalProtect configuration that the portal delivers to the satellites includes the list of gateways the satellite can connect to, it is a good idea to configure the gateways before configuring the portal.

- ▲ Prerequisite Tasks
- ▲ Configure the Gateway

## Prerequisite Tasks

Before you can configure the GlobalProtect gateway, you must have completed the following tasks:

- ❒ Created the interfaces (and zones) for the interface where you plan to configure each gateway. You must configure both the physical interface and the virtual tunnel interface. See Create Interfaces and Zones for the LSVPN.
- ❒ Set up the gateway server certificates and certificate profile required for enable GlobalProtect satellite and gateway to establish a mutual SSL/TLS connection. See Enable SSL Between GlobalProtect LSVPN Components.

## Configure the Gateway

After you have completed the Prerequisite Tasks, configure each GlobalProtect gateway to participate in the LSVPN as follows:

| Configure the Gateway for LSVPN | | |
|---|---|---|
| Step 1 | Add a gateway. | 1. Select **Network > GlobalProtect > Gateways** and click **Add**.<br>2. On the **General** tab, enter a **Name** for the gateway. The gateway name should not contain any spaces and as a best practice it should include the location or other descriptive information that will help identify the gateway.<br>3. (Optional) Select the virtual system to which this gateway belongs from the **Location** field. |
| Step 2 | Specify the network information to enable satellites to connect to the gateway.<br><br>If you have not yet created the network interface for the gateway, see Create Interfaces and Zones for the LSVPN for instructions. If you haven't yet created a server certificate for the gateway, see Deploy Server Certificates to the GlobalProtect LSVPN Components. | 1. Select the **Interface** that satellites will use for ingress access to the gateway.<br>2. Select the **IP Address** for gateway access.<br>3. Select the **Server Certificate** for the gateway from the drop-down. |

| Configure the Gateway for LSVPN (Continued) | | |
|---|---|---|
| Step 3 | Select the certificate profile for the gateway to use to authenticate satellites attempting to establish tunnels.<br><br>If you have not yet set up the certificate profile, see Enable SSL Between GlobalProtect LSVPN Components for instructions. | Select the **Certificate Profile** to you created for SSL communication between the LSVPN components. |
| Step 4 | Configure the tunnel parameters and enable tunneling. | 1. On the GlobalProtect Gateway dialog, select **Satellite Configuration > Tunnel Settings**.<br>2. Select the **Tunnel Configuration** check box to enable tunneling.<br>3. Select the **Tunnel Interface** you defined in Step 2 in Create Interfaces and Zones for the LSVPN.<br>4. (Optional) If you want to preserve the Type of Service (ToS) information in the encapsulated packets, select the **Copy TOS** check box. |
| Step 5 | (Optional) Enable tunnel monitoring.<br><br>Tunnel monitoring enables satellite devices to monitor its gateway tunnel connection, allowing it to failover to a backup gateway if the connection fails. Failover to another gateway is the only type of tunnel monitoring profile supported with LSVPN. | 1. Select the **Tunnel Monitoring** check box.<br>2. Specify the **Destination IP** address the satellite devices should use to determine if the gateway is active. Alternatively, if you configured an IP address for the tunnel interface, you can leave this field blank and the tunnel monitor will instead use the tunnel interface to determine if the connection is active.<br>3. Select **Failover** from the **Tunnel Monitor Profile** drop-down (this is the only supported tunnel monitor profile for LSVPN). |
| Step 6 | Select the Crypto Profile to use when establishing tunnel connections.<br><br>The crypto profile specifies the type IPSec encryption and/or the authentication method for securing the data that will traverse the tunnel. Because both tunnel endpoints in an LSVPN are trusted firewalls within your organization, you can typically use the default profile, which uses ESP-DH group2-AES 128 with SHA-1 encryption.<br><br>However, if you require a different mix of encryption and authentication mechanisms, you can optionally create a custom IPSec crypto profile. | Select **default** from the **IPSec Crypto Profile** drop-down or, optionally, select **New IPSec Crypto Profile** to define a new profile. For details on the authentication and encryption options in the crypto profile, refer to the online help. |

 © Palo Alto Networks, Inc.

| Configure the Gateway for LSVPN (Continued) | | |
|---|---|---|
| Step 7 | Configure the network settings to assign the satellites during establishment of the IPSec tunnel.<br><br> You can also configure the satellite device to push the DNS settings to its local clients by configuring a DHCP server on the firewall hosting the satellite. In this configuration, the satellite will push DNS settings it learns from the gateway to the DHCP clients. | 1. On the GlobalProtect Gateway dialog, select **Satellite Configuration > Network Settings**.<br>2. (Optional) If clients local to the satellite device need to resolve FQDNs on the corporate network, configure the gateway to push DNS settings to the satellites in one of the following ways:<br>• Manually define the **Primary DNS**, **Secondary DNS**, and **DNS Suffix** settings to push to the satellites.<br>• If the gateway has an interface that is configured as a DHCP client, you can set the **Inheritance Source** to that interface and the GlobalProtect satellites will be assigned the same settings received by the DHCP client.<br>3. To specify the **IP Pool** of addresses to assign the tunnel interface on the satellite devices when the VPN is established, click **Add** and then specify the IP address range(s) to use. If you are using dynamic routing, make sure that the IP address pool you designate for satellites does not overlap with the IP addresses you manually assigned to the tunnel interfaces on your gateways and satellites.<br>4. To define what destination subnets to route through the tunnel click **Add** in the **Access Route** area and then enter the routes as follows:<br>• If you want to route all traffic from the satellites through the tunnel, leave this field blank. Note that in this case, all traffic except traffic destined for the local subnet will be tunneled to the gateway.<br>• To route only some traffic through the gateway (called *split tunneling*), specify the destination subnets that must be tunneled. In this case, the satellite will route traffic that is not destined for a specified access route using its own routing table. For example, you may choose to only tunnel traffic destined for your corporate network, and use the local satellite to safely enable Internet access.<br>• If you want to enable routing between satellites, enter the summary route for the network protected by each satellite. |
| Step 8 | (Optional) Define what routes, if any, the gateway will accept from satellites.<br><br>By default, the gateway will not add any routes satellites advertise to its routing table. If you do not want the gateway to accept routes from gateways, you do not need to complete this step. | 1. To enable the gateway to accept routes advertised by satellites, select **Satellite Configuration > Route Filter**.<br>2. Select the **Accept published routes** check box.<br>3. To filter which of the routes advertised by the satellites to add to the gateway routing table, click **Add** and then define the subnets to include. For example, if all the satellites are configured with subnet 192.168.x.0/24 on the LAN side, configuring a permitted route of 192.168.0.0/16 to enable the gateway to only accept routes from the satellite if it is in the 192.168.0.0/16 subnet. |

| Configure the Gateway for LSVPN (Continued) | |
|---|---|
| Step 9 Save the gateway configuration. | 1. Click **OK** to save the settings and close the GlobalProtect Gateway dialog.<br>2. **Commit** the configuration. |

 © Palo Alto Networks, Inc.

# Configure the GlobalProtect Portal for LSVPN

The GlobalProtect portal provides the management functions for your GlobalProtect LSVPN. Every satellite system that participates in the LSVPN receives configuration information from the portal, including information about available gateways as well as the certificate it needs in order to connect to the gateways.

The following sections provide procedures for setting up the portal:

- Prerequisite Tasks
- Configure the Portal
- Define the Satellite Configurations

## Prerequisite Tasks

Before you can configure the GlobalProtect portal, you must have completed the following tasks:

- ☐ Created the interfaces (and zones) for the firewall interface where you plan to configure the portal. See Create Interfaces and Zones for the LSVPN.
- ☐ Issued the portal server certificate, gateway server certificates, and set up the portal to issue server certificates for the satellites. See Enable SSL Between GlobalProtect LSVPN Components.
- ☐ Defined the authentication profile that will be used to authenticate GlobalProtect satellites in the event that the serial number is not available. See Configure the Portal to Authenticate Satellites.
- ☐ Configured the global protect gateways. See Configure GlobalProtect Gateways for LSVPN.

## Configure the Portal

After you have completed the Prerequisite Tasks, configure the GlobalProtect portal as follows:

| **Configure the Portal for LSVPN** | |
|---|---|
| Step 1 Add the portal. | 1. Select **Network > GlobalProtect > Portals** and click **Add**.<br>2. On the **Portal Configuration** tab, enter a **Name** for the portal. The portal name should not contain any spaces.<br>3. (Optional) Select the virtual system to which this portal belongs from the **Location** field. |

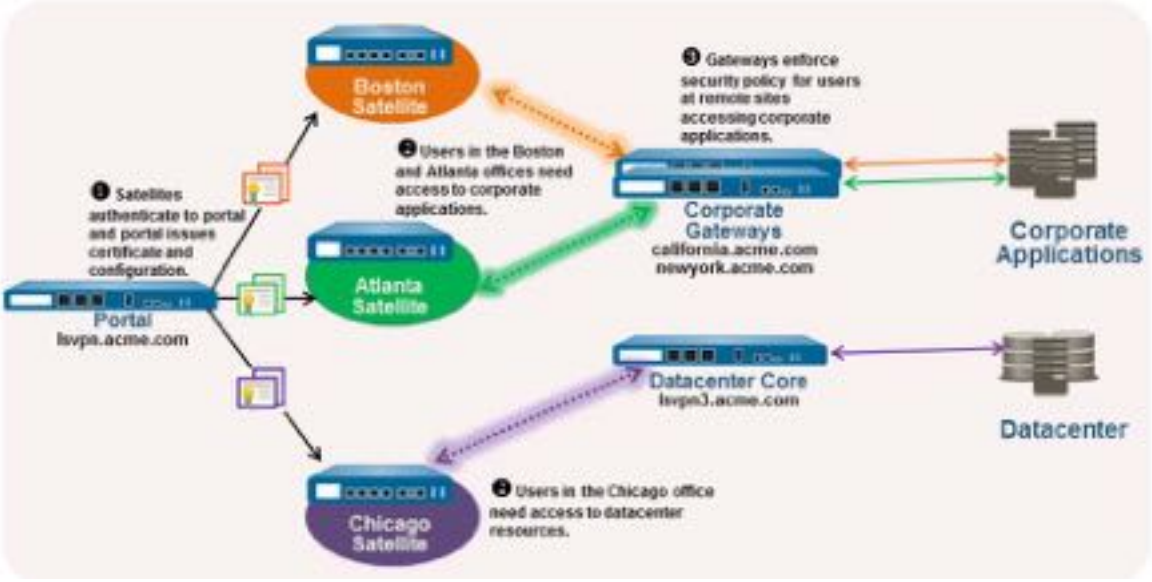
| Configure the Portal for LSVPN (Continued) | | |
|---|---|---|
| Step 2 | Specify the network information to enable satellites to connect to the portal.<br><br>If you have not yet created the network interface for the portal, see Create Interfaces and Zones for the LSVPN for instructions. If you haven't yet created a server certificate for the portal and issued gateway certificates, see Deploy Server Certificates to the GlobalProtect LSVPN Components. | 1. Select the **Interface** that satellites will use for ingress access to the portal.<br>2. Select the **IP Address** for satellite access to the portal.<br>3. Select the **Server Certificate** you generated to enable the satellite to establish SSL connection with the portal. |
| Step 3 | Specify an authentication profile for authenticating satellite devices.<br><br>Even if you plan to manually configure the portal with the serial numbers of the satellites, you must define an authentication profile or you will not be able to save the configuration. | • Select the **Authentication Profile** you defined for authenticating satellites.<br>• If you have not yet set up the authentication profile, select **New Authentication Profile** to create one now. See Configure the Portal to Authenticate Satellites for instructions. If the portal is unable to validate the serial number of a connecting satellite, it will fall back to the authentication profile and therefore you must configure an authentication profile in order to save the portal configuration. |
| Step 4 | Continue with defining the configurations to push to the satellites, or, if you have already created the satellite configurations, save the portal configuration. | Click **OK** to save the portal configuration or continue to Define the Satellite Configurations. |

## Define the Satellite Configurations

When a GlobalProtect satellite connects and successfully authenticates to the GlobalProtect portal, the portal delivers a satellite configuration, which specifies what gateways the satellite can connect to. If all your satellites will use the same gateway and certificate configurations, you can create a single satellite configuration to deliver to all satellites upon successful authentication. However, if you require different satellite configurations—for example if you want one group of satellites to connect to one gateway and another group of satellites to connect to a different gateway—you can create a separate satellite configuration for each. The portal will then use the enrollment username/group name or the serial number of the satellite device to determine which satellite configuration to deploy. As with security rule evaluation, the portal looks for a match starting from the top of the list. When it finds a match, it delivers the corresponding configuration to the satellite.

For example, the following figure shows a network in which some branch offices require VPN access to the corporate applications protected by your perimeter firewalls and another site needs VPN access to the datacenter.

 © Palo Alto Networks, Inc.



Use the following procedure to create one or more satellite configurations.

| Create a GlobalProtect Satellite Configuration | | |
|---|---|---|
| Step 1 | Specify the certificates required to enable satellites to participate in the LSVPN. | 1. Select **Network > GlobalProtect > Portals** and select the portal configuration for which you want to add a satellite configuration and then select the **Satellite Configuration** tab.<br>2. In the **Trusted Root CA** field, click **Add** and then select the CA certificate used to issue the gateway server certificates. The portal will deploy the root CA certificate you add here to all satellites as part of the configuration to enable the satellite to establish an SSL connection with the gateways. As a best practice, all of your gateways should use the same issuer.<br>If the root CA certificate used to issue your gateway server certificates is not on the portal, you can **Import** it now. See Enable SSL Between GlobalProtect LSVPN Components for details on how to import a root CA certificate.<br>3. Select the Root CA certificate that the portal will use to issue certificates to satellites upon successfully authenticating them from the **Issuing Certificate** drop-down. |
| Step 2 | Add a satellite configuration.<br>The satellite configuration specifies the GlobalProtect LSVPN configuration settings to deploy to the connecting satellites. You must define at least one satellite configuration. | In the Satellite Configuration section, click **Add** and enter a **Name** for the configuration.<br>If you plan to create multiple configurations, make sure the name you define for each is descriptive enough to allow you to distinguish them. |

| Create a GlobalProtect Satellite Configuration (Continued) | |
|---|---|
| Step 3 Specify which satellites to deploy this configuration to.<br><br>The portal uses the **Enrollment User/User Group** settings and/or **Devices** serial numbers to match a satellite to a configuration. Therefore, if you have multiple configurations, be sure to order them properly. As soon as the portal finds a match, it will deliver the configuration. Therefore, more specific configurations must precede more general ones. See Step 6 for instructions on ordering the list of satellite configurations. | Specify the match criteria for the satellite configuration as follows:<br>• To restrict this configuration to satellite devices with specific serial numbers, select the **Devices** tab, click **Add**, and enter serial number (you do not need to enter the satellite hostname; it will be automatically added when the satellite connects). Repeat this step for each satellite you want to receive this configuration.<br>• Select the **Enrollment User/User Group** tab, click **Add**, and then select the user or group you want to receive this configuration. Satellites that do not match on serial number will be required to authenticate as a user specified here (either an individual user or group member).<br><br>Before you can restrict the configuration to specific groups, you must Map Users to Groups. |
| Step 4 Specify the gateways that satellites with this configuration can establish VPN tunnels with.<br><br>Routes published by the gateway are installed on the satellite as static routes. The metric for the static route is 10x the routing priority. If you have more than one gateway, make sure to also set the routing priority to ensure that routes advertised by backup gateways have higher metrics compared to the same routes advertised by primary gateways. For example, if you set the routing priority for the primary gateway and backup gateway to 1 and 10 respectively, the satellite will use 10 as the metric for the primary gateway and 100 as the metric for the backup gateway. | 1. On the **Gateways** tab, click **Add**.<br>2. Enter a descriptive **Name** for the gateway. The name you enter here should match the name you defined when you configured the gateway and should be descriptive enough identify the location of the gateway.<br>3. Enter the FQDN or IP address of the interface where the gateway is configured in the **Gateways** field. The address you specify must exactly match the Common Name (CN) in the gateway server certificate.<br>4. (Optional) If you are adding two or more gateways to the configuration, the **Routing Priority** helps the satellite pick the preferred gateway. Enter a value in the range of 1-25, with lower numbers having the higher priority (that is, the gateway the satellite will connect to if all gateways are available). The satellite will multiply the routing priority by 10 to determine the routing metric. |
| Step 5 Save the satellite configuration. | 1. Click **OK** to save the satellite configuration.<br>2. If you want to add another satellite configuration, repeat Step 2 through Step 5. |
| Step 6 Arrange the satellite configurations so that the proper configuration is deployed to each satellite. | • To move a satellite configuration up on the list of configurations, select the configuration and click **Move Up**.<br>• To move a satellite configuration down on the list of configurations, select the configuration and click **Move Down**. |

 © Palo Alto Networks, Inc.

| Create a GlobalProtect Satellite Configuration (Continued) | |
|---|---|
| Step 7 Save the portal configuration. | 1. Click **OK** to save the settings and close the GlobalProtect Portal dialog.<br>2. **Commit** your changes. |

# Prepare the Satellite Device to Join the LSVPN

In order to participate in the LSVPN, the satellite devices require a minimal amount of configuration. Because the required configuration is minimal, you can pre-configure the devices before shipping them to your branch offices for installation.

| Prepare the Satellite Device to Join the GlobalProtect LSVPN | | |
|---|---|---|
| Step 1 | Configure a Layer 3 interface. | This is the physical interface the satellite will use to connect to the portal and the gateway. This interface must be in a zone that allows access outside of the local trust network. As a best practice, create a dedicated zone for VPN connections for visibility and control over traffic destined for the corporate gateways. |
| Step 2 | Configure the logical tunnel interface for the tunnel to use to establish VPN tunnels with the GlobalProtect gateways.<br> IP addresses are not required on the tunnel interface unless plan to use dynamic routing. However, assigning an IP address to the tunnel interface can be useful for troubleshooting connectivity issues. | 1. Select **Network > Interfaces > Tunnel** and click **Add**.<br>2. In the **Interface Name** field, specify a numeric suffix, such as **.2**.<br>3. On the **Config** tab, expand the **Security Zone** drop-down and select an existing zone or create a separate zone for VPN tunnel traffic by clicking **New Zone** and defining a **Name** for new zone (for example *lsvpnsat*).<br>4. In the **Virtual Router** drop-down, select **default**.<br>5. (Optional) If you want to assign an IP address to the tunnel interface, select the **IPv4** tab, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 2.2.2.11/24.<br>6. To save the interface configuration, click **OK**. |

 © Palo Alto Networks, Inc.

| Prepare the Satellite Device to Join the GlobalProtect LSVPN (Continued) | | |
|---|---|---|
| Step 3 | If you generated the portal server certificate using a Root CA that is not trusted by the satellites (for example, if you used self-signed certificates), import the root CA certificate used to issue the portal server certificate.<br><br>The root CA certificate is required to enable the satellite device to establish the initial connection with the portal to obtain the LSVPN configuration. | 1. Download the CA certificate that was used to generate the portal server certificates. If you are using self-signed certificates, export the root CA certificate from the portal as follows:<br>a. Select **Device > Certificate Management > Certificates > Device Certificates**.<br>b. Select the CA certificate, and click **Export**.<br>c. Select **Base64 Encoded Certificate (PEM)** from the **File Format** drop-down and click **OK** to download the certificate. (You do not need to export the private key.)<br>2. Import the root CA certificate you just exported onto each satellite as follows.<br>a. Select **Device > Certificate Management > Certificates > Device Certificates** and click **Import**.<br>b. Enter a **Certificate Name** that identifies the certificate as your client CA certificate.<br>c. **Browse** to the **Certificate File** you downloaded from the CA.<br>d. Select **Base64 Encoded Certificate (PEM)** as the **File Format** and then click **OK**.<br>e. Select the certificate you just imported on the **Device Certificates** tab to open it.<br>f. Select **Trusted Root CA** and then click **OK**. |
| Step 4 | Configure the IPSec tunnel configuration. | 1. Select **Network > IPSec Tunnels** and click **Add**.<br>2. On the **General** tab, enter a descriptive **Name** for the IPSec configuration.<br>3. Select the **Tunnel Interface** you created for the satellite.<br>4. Select **GlobalProtect Satellite** as the **Type**.<br>5. Enter the IP address or FQDN of the portal as the **Portal Address**.<br>6. Select the Layer 3 **Interface** you configured for the satellite.<br>7. Select the **Local IP Address** to use on the selected interface. |

| Prepare the Satellite Device to Join the GlobalProtect LSVPN (Continued) | |
|---|---|
| Step 5 (Optional) Configure the satellite to publish local routes to the gateway.<br><br>Pushing routes to the gateway enables traffic to the subnets local to the satellite via the gateway. However, you must also configure the gateway to accept the routes as detailed in Step 8 in Configure the Gateway. | 1. To enable the satellite to push routes to the gateway, on the **Advanced** tab select **Publish all static and connected routes to Gateway**.<br><br>If you select this check box, the firewall will forward all static and connected routes from the satellite to the gateway. However, to prevent the creation of routing loops, the firewall will automatically apply route filters, such as the following:<br>• Default routes<br>• Routes within a virtual router other than the virtual router associated with the tunnel interface<br>• Routes using the tunnel interface<br>• Routes using the physical interface associated with the tunnel interface<br>2. (Optional) If you only want to push routes for specific subnets rather than all routes, click **Add** in the Subnet section and specify which subnet routes to publish. |
| Step 6 Save the satellite configuration. | 1. Click **OK** to save the IPSec tunnel settings.<br>2. Click **Commit**. |
| Step 7 If required, provide the credentials to allow the satellite to authenticate to the portal.<br><br>This step is only required if the portal was unable to find a serial number match in its configuration or if the serial number didn't work. In this case, the satellite will not be able to establish the tunnel with the gateway(s). | 1. Select **Network > IPSec Tunnels** and click the **Gateway Info** link in the Status column of the tunnel configuration you created for the LSVPN.<br>2. Click the **enter credentials** link in the **Portal Status** field and username and password required to authenticate the satellite to the portal.<br><br>After the portal successfully authenticates to the portal, it will receive its signed certificate and configuration, which it will use to connect to the gateway(s). You should see the tunnel establish and the **Status** change to **Active**.<br><br> |

© Palo Alto Networks, Inc.

# Verify the LSVPN Configuration

After configuring the portal, gateways, and satellite devices, verify that the satellites are able to connect to the portal and gateway and establish VPN tunnels with the gateway(s).

| Verify the LSVPN Configuration | | |
|---|---|---|
| Step 1 | Verify satellite connectivity with portal. | From the firewall hosting the portal, verify that satellites are successfully connecting by selecting **Network > GlobalProtect > Portal** and clicking **Satellite Info** in the Info column of the portal configuration entry.<br> |
| Step 1 | Verify satellite connectivity with the gateway(s). | On each firewall hosting a gateway, verify that satellites are able to establish VPN tunnels by selecting **Network > GlobalProtect > Gateways** and click **Satellite Info** in the Info column of the gateway configuration entry. Satellites that have successfully established tunnels with the gateway will display on the **Active Satellites** tab.<br> |
| Step 1 | Verify LSVPN tunnel status on the satellite. | On each firewall hosting a satellite, verify the tunnel status by selecting **Network > IPSec Tunnels** and verify active Status as indicated by a green icon.<br> |

# LSVPN Quick Configs

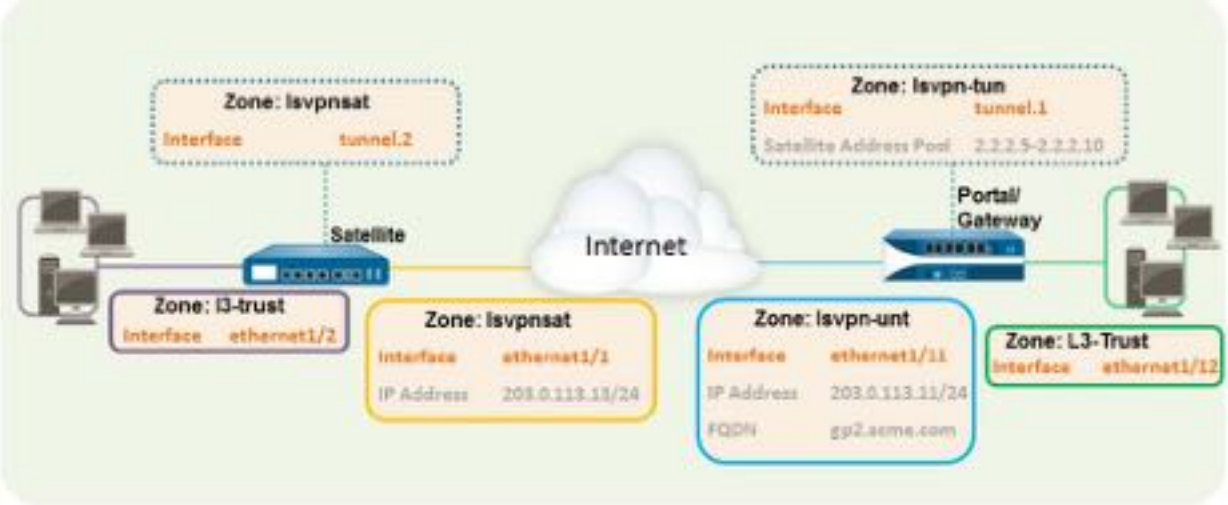
The following sections provide step-by-step instructions for configuring some common GlobalProtect LSVPN deployments:

- Basic LSVPN Configuration with Static Routing
- Advanced LSVPN Configuration with Dynamic Routing

 © Palo Alto Networks, Inc.

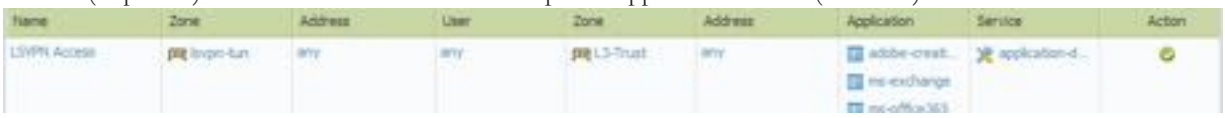
# Basic LSVPN Configuration with Static Routing

This quick config shows the fastest way to get up and running with LSVPN. In this example, a single firewall at the corporate headquarters site is configured as both a portal and a gateway. Satellite devices can be quickly and easily deployed with minimal configuration for optimized scalability.



The following workflow shows the steps for setting up this basic configuration:

| Quick Config: Basic LSVPN with Static Routing | | |
|---|---|---|
| Step 1 | Configure a Layer 3 interface. | In this example, the Layer 3 interface on the portal/gateway requires the following configuration:<br>• **Interface**—ethernet1/11<br>• **Security Zone**—lsvpn-unt<br>• **IPv4**—203.0.113.11/24 |
| Step 2 | On the firewall(s) hosting GlobalProtect gateway(s), configure the logical tunnel interface that will terminate VPN tunnels established by the GlobalProtect satellites.<br>To enable visibility into users and groups connecting over the VPN, enable User-ID in the zone where the VPN tunnels terminate. | In this example, the Tunnel interface on the portal/gateway requires the following configuration:<br>• **Interface**—tunnel.1<br>• **Security Zone**—lsvpn-tun |
| Step 3 | Create the security policy rule to enable traffic flow between the VPN zone where the tunnel terminates (lsvpn-tun) and the trust zone where the corporate applications reside (L3-Trust). | |



| Quick Config: Basic LSVPN with Static Routing (Continued) | | |
|---|---|---|
| Step 4 | Issue a self-signed server certificate for the portal/gateway.<br><br>The certificate subject name must match the FQDN or IP address of the Layer 3 interface you create for the portal/gateway. | 1. On the firewall hosting the portal, create the root CA certificate for issuing self-signed certificates for the GlobalProtect components. In this example, the root CA certificate, *lsvpn-CA*, will be used to issue the server certificate for the portal/gateway. In addition, the portal will use this root CA certificate to sign the CSRs from the satellite devices.<br>2. Generate server certificates for the GlobalProtect portal and gateway(s).<br><br>Because the portal and gateway will be on the same interface in this example, they can share a server certificate. In this example, the server certificate is named *lsvpnserver*. |
| Step 5 | Create a certificate profile. | In this example, the certificate profile, *lsvpn-profile*, references the root CA certificate *lsvpn-CA*. The gateway will use this certificate profile to authenticate satellites attempting to establish VPN tunnels. |
| Step 6 | Configure an authentication profile for the portal to use if the satellite serial number is not available. | 1. Create a server profile on the portal.<br>2. Create an authentication profile. In this example, the profile *lsvpn-sat* is used to authenticate satellites. |
| Step 7 | Configure the Gateway for LSVPN. | Select **Network > GlobalProtect > Gateways** and **Add** a configuration. This example requires the following gateway configuration:<br>• **Interface**—ethernet1/11<br>• **IP Address**—203.0.113.11/24<br>• **Server Certificate**—lsvpnserver<br>• **Certificate Profile**—lsvpn-profile<br>• **Tunnel Interface**—tunnel.1<br>• **Primary DNS**/**Secondary DNS**—4.2.2.1/4.2.2.2<br>• **IP Pool**—2.2.2.111-2.2.2.120<br>• **Access Route**—10.2.10.0/24 |
| Step 8 | Configure the Portal for LSVPN. | Select **Network > GlobalProtect > Portal** and **Add** a configuration. This example requires the following portal configuration:<br>• **Interface**—ethernet1/11<br>• **IP Address**—203.0.113.11/24<br>• **Server Certificate**—lsvpnserver<br>• **Authentication Profile**—lsvpn-sat |

 © Palo Alto Networks, Inc.

| Quick Config: Basic LSVPN with Static Routing (Continued) | |
|---|---|
| Step 9 Create a GlobalProtect Satellite Configuration. | On the **Satellite Configuration** tab in the portal configuration, **Add** a Satellite Configuration and a Trusted Root CA and specify the CA the portal will use to issue certificates for the satellites. In this example the required settings are as following:<br>• **Gateway**—203.0.113.11<br>• **Issuing Certificate**—lsvpn-CA<br>• **Trusted Root CA**—lsvpn-CA |
| Step 10 Prepare the Satellite Device to Join the LSVPN. | The satellite configuration in this example requires the following settings:<br>Interface Configuration<br>• Layer 3 interface—ethernet1/1, 203.0.113.13/24<br>• Tunnel interface—tunnel.2<br>• Zone—lsvpnsat<br>Root CA Certificate from Portal<br>• lsvpn-CA<br>IPSec Tunnel Configuration<br>• **Tunnel Interface**—tunnel.2<br>• **Portal Address**—203.0.113.11<br>• **Interface**—ethernet1/1<br>• **Local IP Address**—203.0.113.13/24<br>• **Publish all static and connected routes to Gateway**—enabled |

# Advanced LSVPN Configuration with Dynamic Routing

In larger LSVPN deployments with multiple gateways and many satellites, investing a little more time in the initial configuration to set up dynamic routing will simplify the maintenance of gateway configurations because access routes will update dynamically. The following example configuration shows how to extend the basic LSVPN configuration to configure OSPF as the dynamic routing protocol.

Setting up an LSVPN to use OSPF for dynamic routing requires the following additional steps on the gateways and the satellites:

- Manual assignment of IP addresses to tunnel interfaces on all gateways and satellites.
- Configuration of OSPF point-to-multipoint (P2MP) on the virtual router on all gateways and satellites. In addition, as part of the OSPF configuration on each gateway, you must manually define the tunnel IP address of each satellite as an OSPF neighbor. Similarly, on each satellite, you must manually define the tunnel IP address of each gateway as an OSPF neighbor.

Although dynamic routing requires additional setup during the initial configuration of the LSVPN, it reduces the maintenance tasks associated with keeping routes up to date as topology changes occur on your network.

The following figure shows an LSVPN dynamic routing configuration. This example shows how to configure OSPF as the dynamic routing protocol for the VPN.

For a basic setup of a LSVPN, follow the steps in Basic LSVPN Configuration with Static Routing. You can then complete the steps in the following workflow to extend the configuration to use dynamic routing rather than static routing.

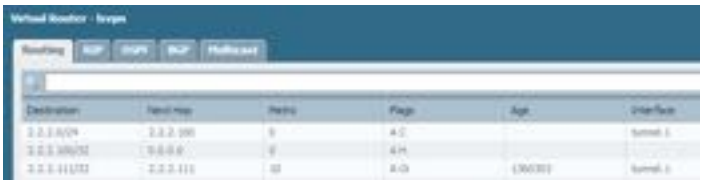
 © Palo Alto Networks, Inc.

| Quick Config: LSVPN with Dynamic Routing | |
|---|---|
| Step 1 Add an IP address to the tunnel interface configuration on each gateway and each satellite.<br><br>**Important:**<br><br>The IP addresses you assign to the satellite tunnel interfaces must be on separate subnets from the IP addresses you assign to the gateway tunnel interfaces. In addition, the IP addresses you assign to satellites must not overlap with the designated IP pool defined in the gateway configuration or the devices will not be able to establish adjacencies. | Complete the following steps on each gateway and each satellite:<br>1. Select **Network > Interfaces > Tunnel** and select the tunnel configuration you created for the LSVPN to open the Tunnel Interface dialog.<br>If you have not yet created the tunnel interface, see Step 2 in Quick Config: Basic LSVPN with Static Routing.<br>2. On the **IPv4** tab, click **Add** and then enter an IP address and subnet mask. For example, to add an IP address for the gateway tunnel interface you would enter 2.2.2.100/24.<br>3. Click **OK** to save the configuration. |
| Step 2 Configure the dynamic routing protocol on the gateway.<br>  | To configure OSPF on the gateway:<br>1. Select **Network > Virtual Routers** and select the virtual router associated with your VPN interfaces.<br>2. On the **Areas** tab, click **Add** to create the backbone area, or, if it is already configured, click on the area ID to edit it.<br>3. If you are creating a new area, enter an **Area ID** on the **Type** tab.<br>4. On the **Interface** tab, click **Add** and select the tunnel **Interface** you created for the LSVPN.<br>5. Select **p2mp** as the **Link Type**.<br>6. Click **Add** in the Neighbors section and enter the IP address of the tunnel interface of each satellite device, for example 2.2.2.111.<br>7. Click **OK** twice to save the virtual router configuration and then **Commit** the changes on the gateway.<br>8. Repeat this step each time you add a new satellite to the LSVPN. |
| Step 3 Configure the dynamic routing protocol on the satellite.<br>  | To configure OSPF on the satellite:<br>1. Select **Network > Virtual Routers** and select the virtual router associated with your VPN interfaces.<br>2. On the **Areas** tab, click **Add** to create the backbone area, or, if it is already configured, click on the area ID to edit it.<br>3. If you are creating a new area, enter an **Area ID** on the **Type** tab.<br>4. On the **Interface** tab, click **Add** and select the tunnel **Interface** you created for the LSVPN.<br>5. Select **p2mp** as the **Link Type**.<br>6. Click **Add** in the Neighbors section and enter the IP address of the tunnel interface of each GlobalProtect gateway, for example 2.2.2.100.<br>7. Click **OK** twice to save the virtual router configuration and then **Commit** the changes on the gateway.<br>8. Repeat this step each time you add a new gateway. |

**Quick Config: LSVPN with Dynamic Routing (Continued)**

Step 4 Verify that the gateways and satellites are able to form router adjacencies.

- On each satellite and each gateway, confirm that peer adjacencies have formed and that routing table entries have been created for the peers (that is, the satellites have routes to the gateways and the gateways have routes to the satellites). Select **Network > Virtual Router** and click the **More Runtime Stats** link for the virtual router you are using for the LSVPN. On the Routing tab, verify that the LSVPN peer has a route.



- On the **OSPF > Interface** tab, verify that the **Type** is **p2mp**.

- On the **OSPF > Neighbor** tab, verify that the firewalls hosting your gateways have established router adjacencies with the firewalls hosting your satellites and vice versa. Also verify that the **Status** is **Full**, indicating that full adjacencies have been established.

# Networking

All Palo Alto Networks next-generation firewalls provide a flexible networking architecture that includes support for dynamic routing, switching, and VPN connectivity, enabling you to deploy the firewall into nearly any networking environment. When configuring the Ethernet ports on your firewall, you can choose from virtual wire, Layer 2, or Layer 3 interface deployments. In addition, to allow you to integrate into a variety of network segments, you can configure different types of interfaces on different ports. The following sections provide basic information on each type of deployment. For more detailed deployment information, refer to Designing Networks with Palo Alto Networks Firewalls and for information on route distribution, refer to Understanding Route Redistribution and Filtering.

The following topics describe how to integrate Palo Alto Networks next-generation firewalls into your network.

- Interface Deployments
- Configure a Virtual Router
- Configure Static Routes
- Configure RIP
- Configure OSPF
- Configure BGP

# Interface Deployments

- Virtual Wire Deployments
- Layer 2 Deployments
- Layer 3 Deployments
- Tap Mode Deployments

## Virtual Wire Deployments

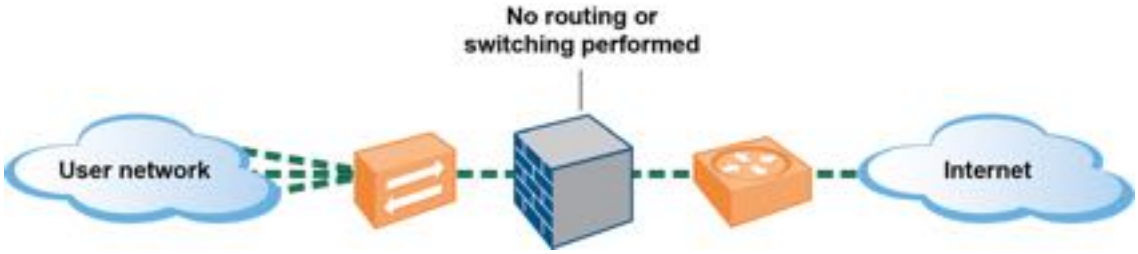
In a virtual wire deployment, the firewall is installed transparently on a network segment by binding two ports together and should be used only when no switching or routing is needed.

A virtual wire deployment allows the following conveniences:

- Simplifies installation and configuration.
- Does not require any configuration changes to surrounding or adjacent network devices.

The "default-vwire" that is shipped as the factory default configuration, binds together Ethernet ports 1 and 2 and allows all untagged traffic. You can, however, use a virtual wire to connect any two ports and configure it to block or allow traffic based on the virtual LAN (VLAN) tags; the VLAN tag "0" indicates untagged traffic. You can also create multiple subinterfaces, add them into different zones and then classify traffic according to a VLAN tag, or a combination of a VLAN tag with IP classifiers (address, range, or subnet) to apply granular policy control for specific VLAN tags or for VLAN tags from a specific source IP address, range, or subnet.

**Figure: Virtual Wire Deployment**



### Virtual Wire Subinterfaces

Virtual wire subinterfaces provide flexibility in enforcing distinct policies when you need to manage traffic from multiple customer networks. It allows you to separate and classify traffic into different zones (the zones can belong to separate virtual systems, if required) using the following criteria:

- **VLAN tags** —The example in Figure: Virtual Wire Deployment with Subinterfaces (VLAN Tags only), shows an Internet Service Provider (ISP) using virtual wire subinterfaces with VLAN tags to separate traffic for two different customers.

 © Palo Alto Networks, Inc.

- **VLAN tags in conjunction with IP classifiers (address, range, or subnet)**— The following example shows an Internet Service Provider (ISP) with two separate virtual systems on a firewall that manages traffic from two different customers. On each virtual system, the example illustrates how virtual wire subinterfaces with VLAN tags and IP classifiers are used to classify traffic into separate zones and apply relevant policy for customers from each network.

| Virtual Wire Subinterface Workflow | |
|---|---|
| Step 1 | Configure two Ethernet interfaces as type virtual wire, and assign these interfaces to a virtual wire. |
| Step 2 | Create subinterfaces on the parent Virtual Wire to separate CustomerA and CustomerB traffic. Make sure that the VLAN tags defined on each pair of subinterfaces that are configured as virtual wire(s) are identical. This is essential because a virtual wire does not switch VLAN tags. |
| Step 3 | Create new subinterfaces and define IP classifiers. This task is optional and only required if you wish to add additional subinterfaces with IP classifiers for further managing traffic from a customer based on the combination of VLAN tags and a specific source IP address, range or subnet.<br><br>You can also use IP classifiers for managing untagged traffic. To do so, you must create a sub-interface with the vlan tag "0", and define sub-interface(s) with IP classifiers for managing untagged traffic using IP classifiers |

IP classification may only be used on the subinterfaces associated with one side of the virtual wire. The subinterfaces defined on the corresponding side of the virtual wire must use the same VLAN tag, but must not include an IP classifier.

**Figure: Virtual Wire Deployment with Subinterfaces (VLAN Tags only)**

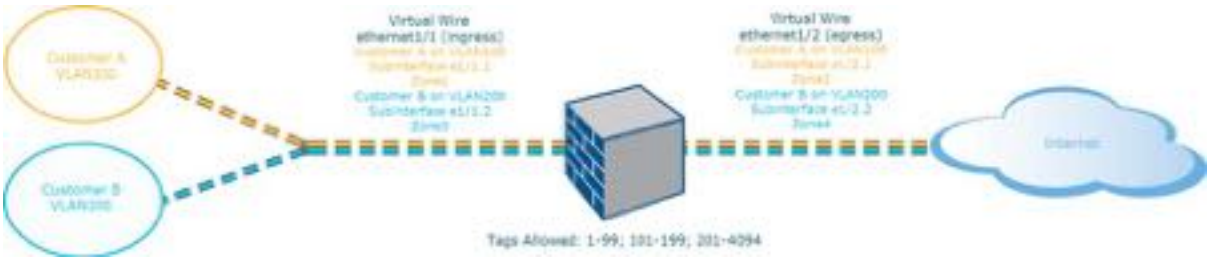


Figure: Virtual Wire Deployment with Subinterfaces (VLAN Tags only) depicts CustomerA and CustomerB connected to the firewall through one physical interface, ethernet1/1, configured as a Virtual Wire; it is the ingress interface. A second physical interface, ethernet1/2, is also part of the Virtual Wire; it is the egress interface that provides access to the Internet. For CustomerA, you also have subinterfaces ethernet1/1.1 (ingress) and ethernet1/2.1 (egress). For CustomerB, you have the subinterface ethernet1/1.2 (ingress) and ethernet1/2.2 (egress). When configuring the subinterfaces, you must assign the appropriate VLAN tag and zone in order to apply policies for each customer. In this example, the policies for CustomerA are created between Zone1 and Zone2, and policies for CustomerB are created between Zone3 and Zone4.

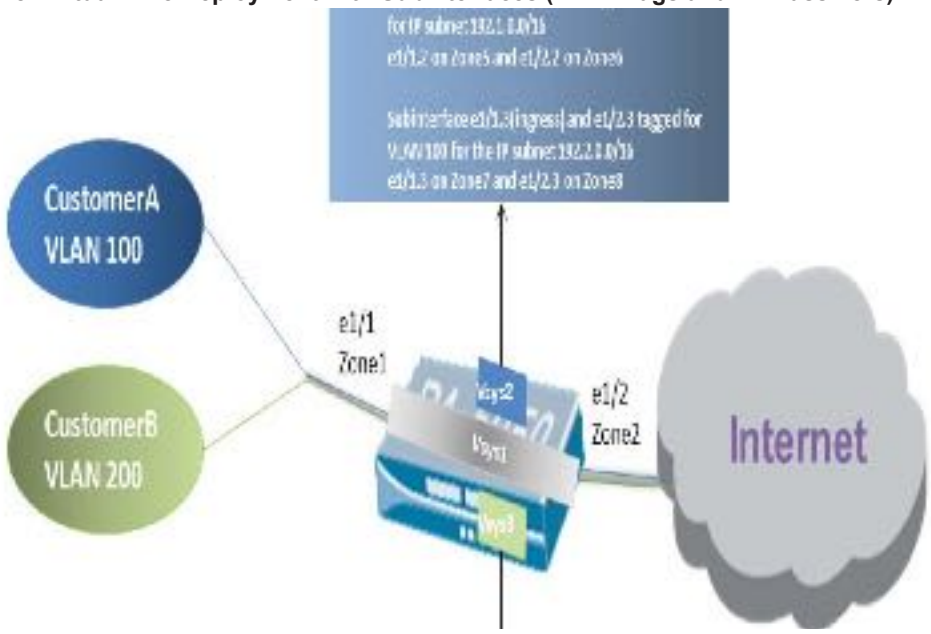
When traffic enters the firewall from CustomerA or CustomerB, the VLAN tag on the incoming packet is first matched against the VLAN tag defined on the ingress subinterfaces. In this example, a single subinterface matches the VLAN tag on the incoming packet, hence that subinterface is selected. The policies defined for the zone are evaluated and applied before the packet exits from the corresponding subinterface.

The same VLAN tag must not be defined on the parent virtual wire interface and the subinterface. Verify that the VLAN tags defined on the Tag Allowed list of the parent virtual wire interface (**Network > Virtual Wires**) are not included on a subinterface.

Figure: Virtual Wire Deployment with Subinterfaces (VLAN Tags and IP Classifiers) depicts CustomerA and CustomerB connected to one physical firewall that has two virtual systems (vsys), in addition to the default virtual system (vsys1). Each virtual system is an independent virtual firewall that is managed separately for each customer. Each vsys has attached interfaces/subinterfaces and security zones that are managed independently.

**Figure: Virtual Wire Deployment with Subinterfaces (VLAN Tags and IP Classifiers)**



Vsys1 is set up to use the physical interfaces ethernet1/1 and ethernet1/2 as a virtual wire; ethernet1/1 is the ingress interface and ethernet1/2 is the egress interface that provides access to the Internet. This virtual wire is configured to accept all tagged and untagged traffic with the exception of VLAN tags 100 and 200 that are assigned to the subinterfaces.

CustomerA is managed on vsys2 and CustomerB is managed on vsys3. On vsys2 and vsys3, the following vwire subinterfaces are created with the appropriate VLAN tags and zones to enforce policy measures.

| Customer | Vsys | Vwire Subinterfaces | Zone | VLAN Tag | IP Classifier |
|---|---|---|---|---|---|
| A | 2 | e1/1.1 (ingress)<br>e1/2.1 (egress) | Zone3<br>Zone4 | 100<br>100 | None |
| | 2 | e1/1.2 (ingress)<br>e1/2.2 (egress) | Zone5<br>Zone6 | 100<br>100 | IP subnet<br>192.1.0.0/16 |
| | 2 | e1/1.3 (ingress)<br>e1/2.3 (egress) | Zone7<br>Zone8 | 100<br>100 | IP subnet<br>192.2.0.0/16 |
| B | 3 | e1/1.4 (ingress)<br>e1/2.4 (egress) | Zone9<br>Zone10 | 200<br>200 | None |

 © Palo Alto Networks, Inc.

When traffic enters the firewall from CustomerA or CustomerB, the VLAN tag on the incoming packet is first matched against the VLAN tag defined on the ingress subinterfaces. In this case, for CustomerA, there are multiple subinterfaces that use the same VLAN tag. Hence, the firewall first narrows the classification to a subinterface based on the source IP address in the packet. The policies defined for the zone are evaluated and applied before the packet exits from the corresponding subinterface.

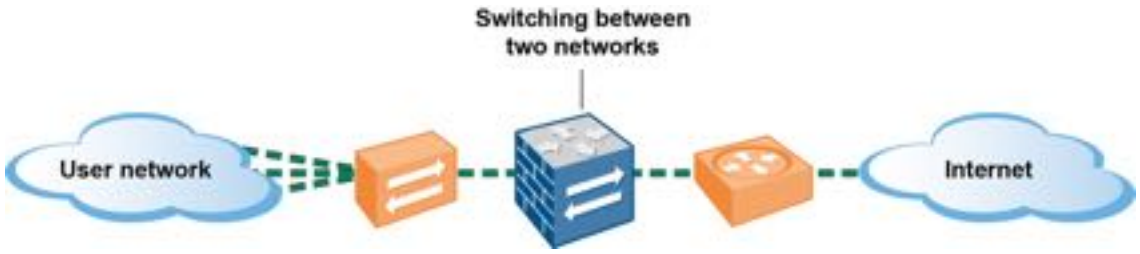
For return-path traffic, the firewall compares the destination IP address as defined in the IP classifier on the customer-facing subinterface and selects the appropriate virtual wire to route traffic through the accurate subinterface.

The same VLAN tag must not be defined on the parent virtual wire interface and the subinterface. Verify that the VLAN tags defined on the Tag Allowed list of the parent virtual wire interface (**Network > Virtual Wires**) are not included on a subinterface.

## Layer 2 Deployments

In a Layer 2 deployment, the firewall provides switching between two or more networks. Each group of interfaces must be assigned to a VLAN object in order for the firewall to switch between them. The firewall will perform VLAN tag switching when layer 2 subinterfaces are attached to a common VLAN object. Choose this option when switching is required.

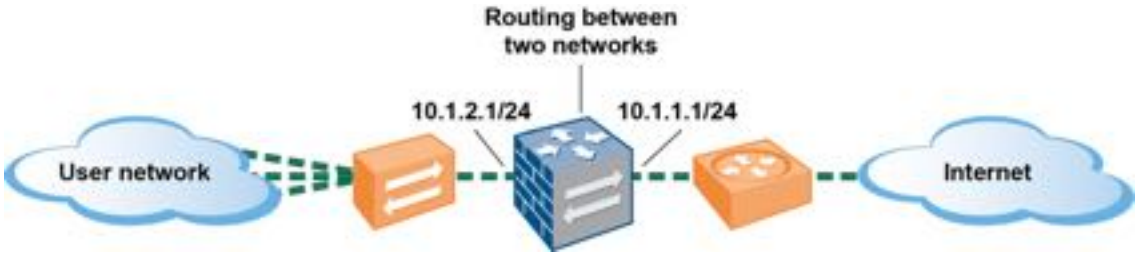
**Figure: Layer 2 Deployment**



## Layer 3 Deployments

In a Layer 3 deployment, the firewall routes traffic between multiple ports. An IP address must be assigned to each interface and a virtual router must be defined to route the traffic. Choose this option when routing is required.

**Figure: Layer 3 Deployment**



In addition, because the firewall must route traffic in a Layer 3 deployment, you must configure a virtual router. See Configure a Virtual Router.

### Point-to-Point Protocol over Ethernet Support

You can configure the firewall to be a Point-to-Point Protocol over Ethernet (PPPoE) termination point to support connectivity in a Digital Subscriber Line (DSL) environment where there is a DSL modem but no other PPPoE device to terminate the connection.

You can choose the PPPoE option and configure the associated settings when an interface is defined as a Layer 3 interface.

PPPoE is not supported in HA active/active mode.

### DHCP Client

You can configure the firewall interface to act as a DHCP client and receive a dynamically assigned IP address. The firewall also provides the capability to propagate settings received by the DHCP client interface into a DHCP server operating on the firewall. This is most commonly used to propagate DNS server settings from an Internet service provider to client machines operating on the network protected by the firewall.

DHCP client is not supported in HA active/active mode.

## Tap Mode Deployments

A network tap is a device that provides a way to access data flowing across a computer network. Tap mode deployment allows you to passively monitor traffic flows across a network by way of a switch SPAN or mirror port.

The SPAN or mirror port permits the copying of traffic from other ports on the switch. By dedicating an interface on the firewall as a tap mode interface and connecting it with a switch SPAN port, the switch SPAN port provides the firewall with the mirrored traffic. This provides application visibility within the network without being in the flow of network traffic.

When deployed in tap mode, the firewall is not able to take action, such as blocking traffic or applying QoS traffic control.

 © Palo Alto Networks, Inc.

# Configure a Virtual Router

The firewall uses virtual routers to obtain routes to other subnets by manually defining a route (static routes) or through participation in Layer 3 routing protocols (dynamic routes). The best routes obtained through these methods are used to populate the firewall's IP route table. When a packet is destined for a different subnet, the Virtual Router obtains the best route from this IP route table and forwards the packet to the next hop router defined in the table.

The Ethernet interfaces and VLAN interfaces defined on the firewall receive and forward the Layer 3 traffic. The destination zone is derived from the outgoing interface based on the forwarding criteria, and policy rules are consulted to identify the security policies to be applied. In addition to routing to other network devices, virtual routers can route to other virtual routers within the same firewall if a next hop is specified to point to another virtual router.

You can configure the virtual router to participate with dynamic routing protocols (BGP, OSPF, or RIP) as well as adding static routes. You can also create multiple virtual routers, each maintaining a separate set of routes that are not shared between virtual routers, enabling you to configure different routing behaviors for different interfaces.

Each Layer 3 interface, loopback interface, and VLAN interface defined on the firewall must be associated with a virtual router. While each interface can belong to only one virtual router, multiple routing protocols and static routes can be configured for a virtual router. Regardless of the static routes and dynamic routing protocols configured for a virtual router, a common general configuration is required. The firewall uses Ethernet switching to reach other devices on the same IP subnet.

The following Layer 3 routing protocols are supported from Virtual Routers:

- RIP
- OSPF
- OSPFv3
- BGP

| **Define a Virtual Router General Configuration** | | |
|---|---|---|
| Step 1 | Gather the required information from your network administrator. | • Interfaces that you want to route<br>• Administrative distances for Static, OSFP internal, OSPF external, IBGP, EBGP and RIP |
| Step 2 | Create the virtual router and name it. | 1. Select **Network > Virtual Routers>.**<br>2. Click **Add** and enter a name for the virtual router.<br>3. Select interfaces to apply to the virtual router.<br>4. Click **OK**. |
| Step 3 | Select interfaces to apply to the virtual router. | 1. Click **Add** in the Interfaces box.<br>2. Select an already defined interface from the drop-down.<br>3. Repeat Step 2 for all interfaces that you want to add to the virtual router. |

© Palo Alto Networks, Inc.

| Define a Virtual Router General Configuration (Continued) | | |
|---|---|---|
| Step 4 | Set Administrative Distances for static and dynamic routing. | 1. Set Administrative Distances as required.<br>• **Static** — Range: 10-240, Default: 10<br>• **OSPF Internal** — Range: 10-240, Default: 30<br>• **OSPF External** — Range: 10-240, Default: 110<br>• **IBGP** —Range: 10-240, Default: 200<br>• **EBGP** —Range: 10-240, Default: 20<br>• **RIP** —Range: 10-240, Default: 120 |
| Step 5 | Save virtual router general settings. | Click **OK** to save your settings. |
| Step 6 | Commit your changes. | Click **Commit**. The device may take up to 90 seconds to save your changes. |

© Palo Alto Networks, Inc.

# Configure Static Routes

The following procedure shows how to integrate the firewall into the network using static routing.

| Set Up Interfaces and Zones | | |
|---|---|---|
| Step 1 | Configure a default route to your Internet router. | 1. Select **Network > Virtual Router** and then select the **default** link to open the Virtual Router dialog.<br>2. Select the **Static Routes** tab and click **Add**. Enter a **Name** for the route and enter the route in the **Destination** field (for example, 0.0.0.0/0).<br>3. Select the **IP Address** radio button in the **Next Hop** field and then enter the IP address and netmask for your Internet gateway (for example, 208.80.56.1).<br>4. Click **OK** twice to save the virtual router configuration. |
| Step 2 | Configure the external interface (the interface that connects to the Internet). | 1. Select **Network > Interfaces** and then select the interface you want to configure. In this example, we are configuring Ethernet1/3 as the external interface.<br>2. Select the **Interface Type**. Although your choice here depends on your network topology, this example shows the steps for **Layer3**.<br>3. In the **Virtual Router** drop-down, select **default**.<br>4. On the **Config** tab, select **New Zone** from the **Security Zone** drop-down. In the Zone dialog, define a **Name** for new zone, for example Untrust, and then click **OK**.<br>5. To assign an IP address to the interface, select the **IPv4** tab and **Static** radio button. Click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 208.80.56.100/24.<br>6. To enable you to ping the interface, select **Advanced > Other Info**, expand the **Management Profile** drop-down, and select **New Management Profile**. Enter a **Name** for the profile, select **Ping** and then click **OK**.<br>7. To save the interface configuration, click **OK**. |

© Palo Alto Networks, Inc.

| Set Up Interfaces and Zones (Continued) | | |
|---|---|---|
| Step 3 | Configure the interface that connects to your internal network.<br><br>In this example, the interface connects to a network segment that uses private IP addresses. Because private IP addresses cannot be routed externally, you will have to configure NAT. See Configure NAT Policies for details. | 1. Select **Network > Interfaces** and select the interface you want to configure. In this example, we are configuring Ethernet1/4 as the internal interface.<br>2. Select **Layer3** from the **Interface Type** drop down.<br>3. On the **Config** tab, expand the **Security Zone** drop-down and select **New Zone**. In the Zone dialog, define a **Name** for new zone, for example Trust, and then click **OK**.<br>4. Select the same Virtual Router you used in Step 2, default in this example.<br>5. To assign an IP address to the interface, select the **IPv4** tab and the **Static** radio button, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 192.168.1.4/24.<br>6. To enable you to ping the interface, select the management profile that you created in Step 2-6.<br>7. To save the interface configuration, click **OK**. |
| Step 4 | Configure the interface that connects to the DMZ. | 1. Select the interface you want to configure.<br>2. Select **Layer3** from the **Interface Type** drop down. In this example, we are configuring Ethernet1/13 as the DMZ interface.<br>3. On the **Config** tab, expand the **Security Zone** drop-down and select **New Zone**. In the Zone dialog, define a **Name** for new zone, for example DMZ, and then click **OK**.<br>4. Select the Virtual Router you used in Step 2, default in this example.<br>5. To assign an IP address to the interface, select the **IPv4** tab and the **Static** radio button, click **Add** in the IP section, and enter the IP address and network mask to assign to the interface, for example 10.1.1.1/24.<br>6. To enable you to ping the interface, select the management profile that you created in Step 2-6.<br>7. To save the interface configuration, click **OK**. |
| Step 5 | Save the interface configuration. | Click **Commit**. |
| Step 6 | Cable the firewall. | Attach straight through cables from the interfaces you configured to the corresponding switch or router on each network segment. |
| Step 7 | Verify that the interfaces are active.<br>  | From the web interface, select **Network > Interfaces** and verify that icon in the Link State column is green. You can also monitor link state from the **Interfaces** widget on the **Dashboard**. |

 © Palo Alto Networks, Inc.

# Configure RIP

RIP was designed for small IP networks and relies on hop count to determine routes; the best routes have the fewest number of hops. RIP is based on UDP and uses port 520 for route updates. By limiting routes to a maximum of 15 hops, the protocol helps prevent the development of routing loops, but also limits the supported network size. If more than 15 hops are required, traffic is not routed. RIP also can take longer to converge than OSPF and other routing protocols. The firewall supports RIP v2.

| **Configure RIP** | | |
|---|---|---|
| Step 1 | Configure general virtual router configuration settings. | See Configure a Virtual Router for details. |
| Step 2 | Configure general RIP configuration settings. | 1. Select the **RIP** tab.<br>2. Select the **Enable** check box to enable the RIP protocol.<br>3. Select the **Reject Default Route** check box if you do not want to learn any default routes through RIP. This is the recommended default setting.<br>4. De-select the **Reject Default Route** check box if you want to permit redistribution of default routes through RIP. |
| Step 3 | Configure interfaces for the RIP protocol. | 1. Select the **Interfaces** subtab.<br>2. Select an interface from the drop-down in the Interface configuration box.<br>3. Select an already defined interface from the drop-down.<br>4. Select the **Enable** check box.<br>5. Select the **Advertise** check box to advertise a default route to RIP peers with the specified metric value.<br>6. You can optionally select a profile from the **Auth Profile** drop-down. See Step 5 for details.<br>7. Select normal, passive or send-only from the **Mode** drop-down.<br>8. Click **OK**. |
| Step 4 | Configure RIP timers. | 1. Select the **Timers** sub-tab.<br>2. Enter a value in the **Interval Seconds (sec)** box that defines the length of the timer interval in seconds. This duration is used for the remaining RIP timing fields. Default: 1. Range: 1 - 60.<br>3. Enter a value in the **Update Intervals** box that defines the number of intervals between route update announcements Default: 30. Range: 1 - 3600.<br>4. Enter a value in the **Delete Intervals** box that defines the number of intervals between the time that the route expires to its deletion Default: 180. Range: 1 - 3600.<br>5. Enter a value in the **Expire Intervals** box that defines the number of intervals between the time that the route was last updated to its expiration Default: 120. Range: 1 - 3600. |

© Palo Alto Networks, Inc.

| Configure RIP | |
|---|---|
| Step 5 (Optional) Configure Auth Profiles. | By default, the firewall does not use RIP authentication for the exchange between RIP neighbors. Optionally, you can configure RIP authentication between RIP neighbors by either a simple password or using MD5 authentication.<br>**Simple Password RIP authentication**<br>1. Select the **Auth Profiles** sub tab.<br>2. Click **Add**.<br>3. Enter a name for the authentication profile to authenticate RIP messages.<br>4. Select **Simple Password** as the **Password Type**.<br>5. Enter a simple password and then confirm.<br>**MD5 RIP authentication**<br>1. Select the **Auth Profiles** subtab.<br>2. Click **Add**.<br>3. Enter a name for the authentication profile to authenticate RIP messages.<br>4. Select **MD5** as the **Password Type**.<br>5. Click **Add**.<br>6. Enter one or more password entries, including:<br>• Key-ID Range 0-255<br>• Key<br>7. You can optionally select **Preferred** status.<br>8. Click **OK**. to specify the key to be used to authenticate outgoing message.<br>9. Click **OK** again in the **Virtual Router - RIP Auth Profile** configuration box. |

# Configure OSPF

Open Shortest Path First (OSPF) is an interior gateway protocol (IGP) which is most often used to dynamically manage network routes in large enterprise network. It determines routes dynamically by obtaining information from other routers and advertising routes to other routers by way of Link State Advertisements (LSAs). The information gathered from the LSAs is used to construct a topology map of the network. This topology map is shared across routers in the network and used to populate the IP routing table with available routes.

Changes in the network topology are detected dynamically and used to generate a new topology map within seconds. A shortest path tree is computed of each route. Metrics associated with each routing interface are used to calculate the best route. These can include distance, network throughput, link availability etc. Additionally, these metrics can be configured statically to direct the outcome of the OSPF topology map.

Palo Alto networks implementation of OSPF fully supports the following RFCs:

- RFC 2328 (for IPv4)
- RFC 5340 (for IPv6)

The following topics provide more information about the OSPF and procedures for configuring OSPF on the firewall:

▲ OSPF Concepts
▲ Configure OSPF
▲ Configure OSPFv3
▲ Configure OSPF Graceful Restart
▲ Confirm OSPF Operation

Also refer to How to Configure OSPF Tech Note.

## OSPF Concepts

The following topics introduce the OSPF concepts you will need to understand in order to configure the firewall to participate in an OSPF network:

▲ OSPFv3
▲ OSPF Neighbors
▲ OSPF Areas
▲ OSPF Router Types

## OSPFv3

OSPFv3 provides support for the OSPF routing protocol within an IPv6 network. As such, it provides support for IPv6 addresses and prefixes. It retains most of the structure and functions in OSPFv2 (for IPv4) with some minor changes. The following are some of the additions and changes to OSPFv3:

- **Support for multiple instances per link**—With OSPFv3 you can run multiple instances of the OSPF protocol over a single link. This is accomplished by assigning an OSPFv3 instance ID number. An interface that is assigned to an instance ID drops packets that contain a different ID.
- **Protocol Processing Per-link**—OSPFv3 operates per-link instead of per-IP-subnet as on OSPFv2.
- **Changes to Addressing**—IPv6 addresses are not present in OSPFv3 packets, except for LSA payloads within link state update packets. Neighboring routers are identified by the Router ID.
- **Authentication Changes**—OSPFv3 doesn't include any authentication capabilities. Configuring OSPFv3 on a firewall requires an authentication profile that specifies Encapsulating Security Payload (ESP) or IPv6 Authentication Header (AH).The re-keying procedure specified in RFC 4552 is not supported in this release.
- **Support for multiple instances per-link**—Each instance corresponds to an instance ID contained in the OSPFv3 packet header.
- **New LSA Types**—OSPFv3 supports two new LSA types: Link LSA and Intra Area Prefix LSA.

All additional changes are described in detail in RFC 5340.

## OSPF Neighbors

Two OSPF-enabled routers connected by a common network and in the same OSPF area that form a relationship are OSPF neighbors. The connection between these routers can be through a common broadcast domain or by a point-to-point connection. This connection is made through the exchange of hello OSPF protocol packets. These neighbor relationships are used to exchange routing updates between routers.

## OSPF Areas

OSPF operates within a single autonomous system (AS). Networks within this single AS however, can be divided into a number of Areas. By default, Area 0 is created. Area 0 can either function alone or act as the OSPF backbone for a larger number of Areas. Each OSPF area is named using a 32-bit identifier which in most cases written in the same dot-decimal notation as an IP4 address. For example, Area 0 is usually written as 0.0.0.0.

The topology of an area is maintained in its own link state database and is hidden from other areas which reduces the amount routing traffic required by OSPF. Topology is then shared in a summarized form between areas by a connecting router.

 © Palo Alto Networks, Inc.

### OSPF Area Types

**Backbone Area**—The backbone are (Area 0) is the core of an OSPF network. All other areas are connected to it and all traffic between areas must traverse it. All routing between areas is distributed through the backbone area. While all other OSPF areas must connect to the backbone area, this connection doesn't need to be direct and can be made through a virtual link.

**Normal OSPF Area**—In a normal OSPF area there are no restrictions; the area can carry all types of routes.

**Stub OSPF Area**—A stub area does not receive routes from other Autonomous Systems. Routing from the stub area is performed through the default route to the backbone area.

**NSSA Area**—The Not So Stubby Area (NSSA) is a type of stub area that can import external routes with some limited exceptions.

### OSPF Router Types

Within an OSPF area, routers are divided into the following categories.

**Internal Router**—A router with that only has OSPF neighbor relationships with devices in the same area.

**Area Border router (ABR)**—A router that has OSPF neighbor relationships with devices in multiple areas. ABRs gather topology information from their attached areas and distribute it to the backbone area.

**Backbone router**—A backbone router is any OSPF router that is attached to the OSPF backbone. Since ABRs are always connected to the backbone, they are always classified as backbone routers.

**Autonomous System Boundary Router (ASBR)**—An ASBR is a router that attaches to more than one routing protocol and exchanges routing information between them.

## Configure OSPF

OSPF determines routes dynamically by obtaining information from other routers and advertising routes to other routers by way of Link State Advertisements (LSAs). The router keeps information about the links between it and the destination and can make highly efficient routing decisions. A cost is assigned to each router interface, and the best routes are determined to be those with the lowest costs, when summed over all the encountered outbound router interfaces and the interface receiving the LSA.

Hierarchical techniques are used to limit the number of routes that must be advertised and the associated LSAs. Because OSPF dynamically processes a considerable amount of route information, it has greater processor and memory requirements than does RIP.

| **Configure OSPF** | | |
|---|---|---|
| Step 1 | Configure general virtual router configuration settings. | See Configure a Virtual Router for details. |

| Configure OSPF (Continued) | | |
|---|---|---|
| Step 2 | Configure general OSPF configuration settings. | 1. Select the **OSPF** tab.<br>2. Select the **Enable** check box to enable the OSPF protocol.<br>3. Select the **Reject Default Route** check box if you do not want to learn any default routes through OSPF. This is the recommended default setting.<br>4. De-select the **Reject Default Route** check box if you want to permit redistribution of default routes through OSPF. |

© Palo Alto Networks, Inc.

**Configure OSPF (Continued)**

| | |
|---|---|
| Step 3 Configure Areas Type for the OSFP protocol | 1. Select the **Areas** sub tab and click **Add**.<br>2. Enter an Area ID for the area in x.x.x.x format. This is the identifier that each neighbor must accept to be part of the same area.<br>3. Select the **Type** sub-tab.<br>4. Select one of the following from the area **Type** drop down box:<br>• **Normal** – There are no restrictions; the area can carry all types of routes.<br>• **Stub** – There is no outlet from the area. To reach a destination outside of the area, it is necessary to go through the border, which connects to other areas. If you select this option, configure the following:<br>– **Accept Summary** – Link state advertisements (LSA) are accepted from other areas. If this option on a stub area Area Border Router (ABR) interface is disabled, the OSPF area will behave as a Totally Stubby Area (TSA) and the ABR will not propagate any summary LSAs.<br>– **Advertise Default Route** – Default route LSAs will be included in advertisements to the stub area along with a configured metric value in the configured range: 1-255.<br>• **NSSA** (Not-So-Stubby Area) – The firewall can only leave the area by routes other than OSPF routes. If selected, configure **Accept Summary** and **Advertise Default Route** as described for **Stub**. If you select this option, configure the following:<br>– **Type** – Select either **Ext 1** or **Ext 2** route type to advertise the default LSA.<br>– **Ext Ranges** – Click **Add** in the section to enter ranges of external routes that you want to enable or suppress advertising for.<br>5. **Priority**—Enter the OSPF priority for this interface (0-255). It is the priority for the router to be elected as a designated router (DR) or as a backup DR (BDR) according to the OSPF protocol. When the value is zero, the router will not be elected as a DR or BDR.<br>• **Auth Profile**—Select a previously-defined authentication profile.<br>• **Timing**—It is recommended that you keep the default timing settings.<br>• **Neighbors**—For p2pmp interfaces, enter the neighbor IP address for all neighbors that are reachable through this interface.<br>6. Select **normal**, **passive** or **send-only** as the **Mode**.<br>7. Click **OK**. |

| Configure OSPF (Continued) | | |
|---|---|---|
| Step 4 | Configure Areas Range for the OSFP protocol | 1. Select the **Range** subtab.<br>2. Click **Add** to aggregate LSA destination addresses in the area into subnets.<br>3. **Advertise** or **Suppress** advertising LSAs that match the subnet, and click **OK**. Repeat to add additional ranges. |
| Step 5 | Configure Areas Interfaces for the OSFP protocol | 1. Select the **Interface** subtab.<br>2. Click **Add** and enter the following information for each interface to be included in the area, and click **OK**.<br>• **Interface**—Select an interface from the drop down box.<br>• **Enable**—Selecting this option causes the OSPF interface settings to take effect.<br>• **Passive**—Select the check box to if you do not want the OSPF interface to send or receive OSPF packets. Although OSPF packets are not sent or received if you choose this option, the interface is included in the LSA database.<br>• **Link type**—Choose **Broadcast** if you want all neighbors that are accessible through the interface to be discovered automatically by multicasting OSPF hello messages, such as an Ethernet interface. Choose **p2p** (point-to-point) to automatically discover the neighbor. Choose **p2mp** (point-to-multipoint) when neighbors must be defined manually. Defining neighbors manually is allowed only for p2mp mode.<br>• **Metric** — Enter an OSPF metric for this interface. Default: 10. Range: 0-65535.<br>• **Priority** — Enter an OSPF priority for this interface. This is the priority for the router to be elected as a designated router (DR) or as a backup DR (BDR). Default: 1. Range: 0 - 255. If zero is configured, the router will not be elected as a DR or BDR.<br>• **Auth Profile** — Select a previously-defined authentication profile.<br>• **Timing** — The following OSPF timing settings can be set here: Hello Interval, Dead Counts, Retransmit Interval and Transit Delay. Palo Alto Networks recommends that you retain the default timing settings.<br>• If **p2mp** is selected for **Link Type**, interfaces, enter the neighbor IP addresses for all neighbors that are reachable through this interface. |

© Palo Alto Networks, Inc.

| Configure OSPF (Continued) | |
|---|---|
| Step 6 Configure Areas Virtual Links. | 1. Select the **Virtual Link** sub tab.<br>2. Click **Add** and enter the following information for each virtual link to be included in the backbone area, and click **OK**:<br>• **Name** — Enter a name for the virtual link.<br>• **Neighbor ID** — Enter the router ID of the router (neighbor) on the other side of the virtual link.<br>• **Transit Area** — Enter the area ID of the transit area that physically contains the virtual link.<br>• **Enable** — Select to enable the virtual link.<br>• **Timing** — It is recommended that you keep the default timing settings.<br>• **Auth Profile** — Select a previously-defined authentication profile. |
| Step 7 (Optional) Configure Auth Profiles. | By default, the firewall does not use OSPF authentication for the exchange between OSPF neighbors. Optionally, you can configure OSPF authentication between OSPF neighbors by either a simple password or using MD5 authentication.<br>**Simple Password OSPF authentication**<br>1. Select the **Auth Profiles** subtab.<br>2. Click **Add**.<br>3. Enter a name for the authentication profile to authenticate OSPF messages.<br>4. Select **Simple Password** as the **Password Type**.<br>5. Enter a simple password and then confirm.<br>**MD5 OSPF authentication**<br>1. Select the **Auth Profiles** subtab.<br>2. Click **Add**.<br>3. Enter a name for the authentication profile to authenticate OSPF messages.<br>4. Select **MD5** as the **Password Type**.<br>5. Click **Add**.<br>6. Enter one or more password entries, including:<br>• Key-ID Range 0-255<br>• Key<br>• Select the **Preferred** option to specify that the key be used to authenticate outgoing messages.<br>7. Click **OK**.<br>8. Click **OK** again in the **Virtual Router - OSPF Auth Profile** configuration box. |

| Configure OSPF (Continued) | | |
|---|---|---|
| Step 8 | Configure Advanced OSPF options. | 1. Select the **Advanced** subtab.<br>2. Select the **RFC 1583 Compatibility** check box to assure compatibility with RFC 1583.<br>3. Configure a value for the **SPF Calculation Delay** (sec) timer.<br>This timer allows you to tune the delay time between receiving new topology information and performing an SPF calculation. Lower values enable faster OSPF re-convergence. Routers peering with the firewall should be tuned in a similar manner to optimize convergence times.<br>4. Configure a value for the **LSA Interval (sec)** time, This timer specifies the minimum time between transmissions of two instances of the same LSA (same router, same type, same LSA ID). This is equivalent to MinLSInterval in RFC 2328. Lower values can be used to reduce re-convergence times when topology changes occur. |

## Configure OSPFv3

| Configure OSPFv3 | | |
|---|---|---|
| Step 1 | Configure general virtual router configuration settings. | See Configure a Virtual Router for details. |
| Step 2 | Configure general OSPF configuration settings. | 1. Select the **OSPF** tab.<br>2. Select the **Enable** check box to enable the OSPF protocol.<br>3. Select the **Reject Default Route** check box if you do not want to learn any default routes through OSPF. This is the recommended default setting.<br>4. De-select the **Reject Default Route** check box if you want to permit redistribution of default routes through OSPF. |
| Step 3 | Configure general OSPFv3 configuration settings. | 1. Select the **OSPFv3** tab.<br>2. Select the **Enable** check box to enable the OSPF protocol.<br>3. Select the **Reject Default Route** check box if you do not want to learn any default routes through OSPFv3 This is the recommended default setting.<br>De-select the **Reject Default Route** check box if you want to permit redistribution of default routes through OSPFv3. |

© Palo Alto Networks, Inc.

| Configure OSPFv3 (Continued) | | |
|---|---|---|
| Step 4 | Configure Auth Profile for the OSFPv3 protocol.<br><br>While OSPFv3 doesn't include any authentication capabilities of its own, instead, it relies entirely on IPsec to secure communications between neighbors. | When configuring an authentication profile you must use Encapsulating Security Payload (ESP) or IPv6 Authentication Header (AH).<br><br>**ESP OSPFv3 authentication**<br>1. Select the **Auth Profiles** subtab.<br>2. Click **Add**.<br>3. Enter a name for the authentication profile to authenticate OSPFv3 messages.<br>4. Specify a Security Policy Index (**SPI**). The SPI must match between both ends of the OSPFv3 adjacency. The SPI number must be a HEX value between 00000000 and FFFFFFFF.<br>5. Select **ESP** for **Protocol**.<br>6. Select a **Crypto Algorithm** from the drop down box.<br>You can enter none or one of the following algorithms: SHA1, SHA256, SHA384, SHA512 or MD5.<br>7. If a **Crypto Algorithm** other than none was selected, enter a value for **Key** and then confirm.<br><br>**AH OSPFv3 authentication**<br>1. Select the **Auth Profiles** subtab.<br>2. Click **Add**.<br>3. Enter a name for the authentication profile to authenticate OSPFv3 messages.<br>4. Specify a Security Policy Index (**SPI**). The SPI must match between both ends of the OSPFv3 adjacency. The SPI number must be a HEX value between 00000000 and FFFFFFFF.<br>5. Select **AH** for **Protocol**.<br>6. Select a **Crypto Algorithm** from the drop-down.<br>You must enter one of the following algorithms: SHA1, SHA256, SHA384, SHA512 or MD5.<br>7. Enter a value for **Key** and then confirm.<br>8. Click **OK**.<br>9. Click **OK** again in the Virtual Router - OSPF Auth Profile dialog. |

| Configure OSPFv3 (Continued) | |
|---|---|
| Step 5 Configure Areas Type for the OSFP protocol. | 1. Select the **Areas** subtab.<br>2. Click **Add**.<br>3. Enter an Area ID. This is the identifier that each neighbor must accept to be part of the same area.<br>4. Select the **General** sub-tab.<br>5. Select one of the following from the area **Type** drop-down:<br>• **Normal** – There are no restrictions; the area can carry all types of routes.<br>• **Stub** – There is no outlet from the area. To reach a destination outside of the area, it is necessary to go through the border, which connects to other areas. If you select this option, configure the following:<br>– **Accept Summary** – Link state advertisements (LSA) are accepted from other areas. If this option on a stub area Area Border Router (ABR) interface is disabled, the OSPF area will behave as a Totally Stubby Area (TSA) and the ABR will not propagate any summary LSAs.<br>– **Advertise Default Route** – Default route LSAs will be included in advertisements to the stub area along with a configured metric value in the configured range: 1-255.<br>• **NSSA** (Not-So-Stubby Area) – The firewall can only leave the area by routes other than OSPF routes. If selected, configure **Accept Summary** and **Advertise Default Route** as described for **Stub**. If you select this option, configure the following:<br>– **Type** – Select either **Ext 1** or **Ext 2** route type to advertise the default LSA.<br>– **Ext Ranges** – Click **Add** in the section to enter ranges of external routes that you want to enable or suppress advertising for. |
| Step 6 Associate an OSPFv3 authentication profile to an area or an interface. | **To an Area**<br>1. Select the **Areas** subtab.<br>2. Select an existing area from the table**.**<br>3. Select a previously defined **Authentication Profile** from the **Authentication** drop-down on the **General** subtab.<br>4. Click **OK**.<br>**To an Interface**<br>1. Select the **Areas** subtab.<br>2. Select an existing area from the table**.**<br>3. Select the **Interface** subtab and click **Add**.<br>4. Select the authentication profile you want to associate with the OSPF interface from the **Auth Profile** drop- down. |

© Palo Alto Networks, Inc.

| Configure OSPFv3 (Continued) | |
|---|---|
| Step 7 (Optional) Configure Export Rules | 1. Select the **Export** subtab.<br>2. Click **Add**.<br>3. Select the **Allow Redistribute Default Route** check box to permit redistribution of default routes through OSPFv3.<br>4. Select the name of a redistribution profile. The value must be an IP subnet or valid redistribution profile name.<br>5. Select a metric to apply for **New Path Type**.<br>6. Specify a **New Tag** for the matched route that has a 32-bit value.<br>7. Assign a metric for the new rule.<br>The value can be: 1 - 65535.<br>8. Click **OK**. |
| Step 8 Configure Advanced OSPFv3 options. | 1. Select the **Advanced** subtab.<br>2. Select the **Disable Transit Routing for SPF Calculation** check box if you want the firewall to participate in OSPF topology distribution without being used to forward transit traffic.<br>3. Configure a value for the **SPF Calculation Delay** (sec) timer.<br>This timer allows you to tune the delay time between receiving new topology information and performing an SPF calculation. Lower values enable faster OSPF re-convergence. Routers peering with the firewall should be tuned in a similar manner to optimize convergence times.<br>4. Configure a value for the **LSA Interval (sec) time**, This timer specifies the minimum time between transmissions of two instances of the same LSA (same router, same type, same LSA ID). This is equivalent to MinLSInterval in RFC 2328. Lower values can be used to reduce re-convergence times when topology changes occur.<br>5. Configure the Graceful Restart section as described in Configure OSPF Graceful Restart. |

## Configure OSPF Graceful Restart

OSPF Graceful Restart directs OSPF neighbors to continue using routes through a device during a short transition when it is out of service. This increases network stability by reducing the frequency of routing table reconfiguration and the related route flapping that can occur during short periodic down times.

For a Palo Alto Networks firewall this involves the following operations:

- **Firewall as a restarting device**—In a situation where the firewall will be down for a short period of time or is unavailable for short intervals, it sends Grace LSAs to its OSPF neighbors. The neighbors must be configured to run in Graceful Restart Helper mode. In Helper Mode, the neighbors receive the Grace LSAs that inform it that the firewall will perform a graceful restart within a specified period of time defined as the **Grace Period**. During the grace period, the neighbor continues to forward routes through the firewall and to send LSAs that announce routes through the firewall. If the firewall resumes operation before expiration

of the grace period, traffic forwarding will continue as before without network disruption. If the firewall does not resume operation after the grace period has expired, the neighbors will exit helper mode and resume normal operation which will involve reconfiguring the routing table to bypass the firewall.

- **Firewall as a Graceful Restart Helper—**In a situation where neighboring routers may be down for a short periods of time the firewall can be configured to operate in Graceful Restart Helper mode. If configured in this mode, the firewall will be configured with a **Max Neighbor Restart Time**. When the firewall receives the Grace LSAs from its OSFP neighbor, it will continue to route traffic to the neighbor and advertise routes through the neighbor until either the grace period or max neighbor restart time expires. If neither expires before the neighbor returns to service, traffic forwarding continues as before without network disruption. If either period expires before the neighbor returns to service, the firewall will exit helper mode and resume normal operation which will involve reconfiguring the routing table to bypass the neighbor.

| **Configure OSPF Graceful Restart** | |
|---|---|
| Step 1 | Select **Network > Virtual Routers** and select the virtual router you want to configure. |
| Step 2 | Select **OSPF > Advanced**. |
| Step 3 | Verify that the following check boxes are selected (they are enabled by default).<br>**Enable Graceful Restart, Enable Helper Mode, and Enable Strict LSA checking.**<br>All should remain selected unless required by your topology. |
| Step 4 | Configure a **Grace Period** in seconds. |
| Step 5 | Configure a **Max Neighbor Restart Time** in seconds. |

## Confirm OSPF Operation

Once an OSPF configuration has been committed, you can use any of the following operations to confirm that OSPF operating:

- View the Routing Table
- Confirm OSPF Adjacencies
- Confirm that OSPF Connections are Established

### View the Routing Table

By viewing the routing table, you can see whether OSPF routes have been established. The routing table is accessible from either the web interface or the CLI. If you are using the CLI, use the following commands:

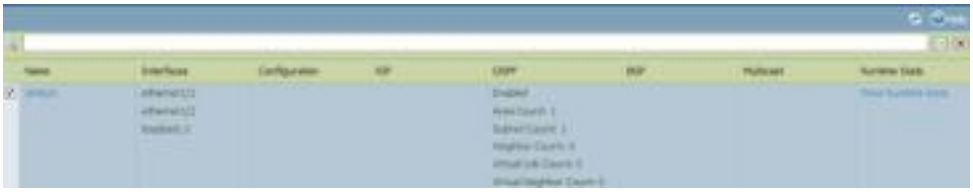
- `show routing route`
- `show routing fib`

The following procedure describes how to use the web interface to view the route table.

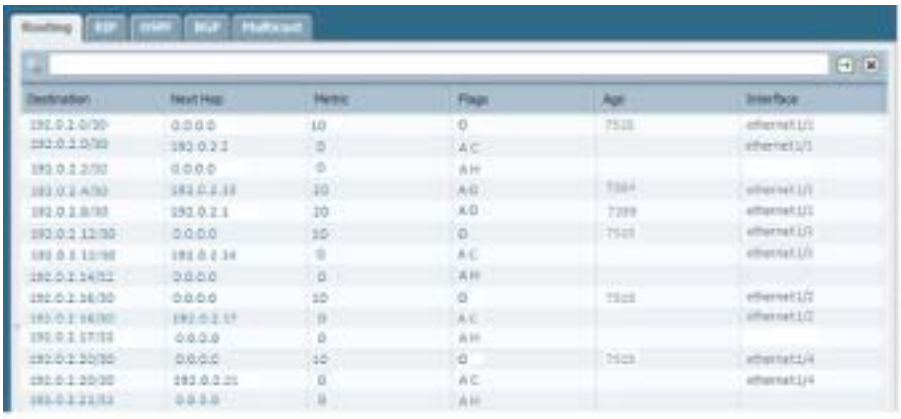
 © Palo Alto Networks, Inc.

**View the Routing Table**

Step 1 Select **Network > Virtual Routers**



Step 2 Select the **Routing** tab and examine the **Flags** column of the routing table for routes that were learned by OSPF.

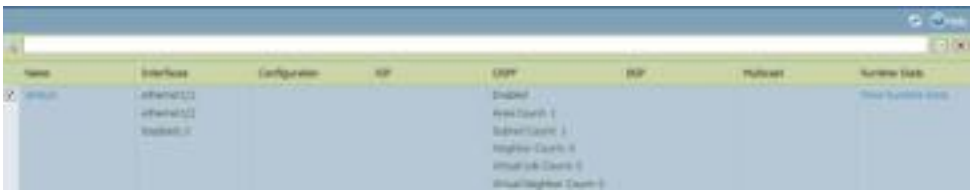


## Confirm OSPF Adjacencies

By viewing the **Neighbor** tab as described in the following procedure, you can confirm that OSPF adjacencies have been established.

**View the Neighbor Tab to Confirm OSPF Adjacencies**

Step 1 Select **Network > Virtual Routers**.



**View the Neighbor Tab to Confirm OSPF Adjacencies**

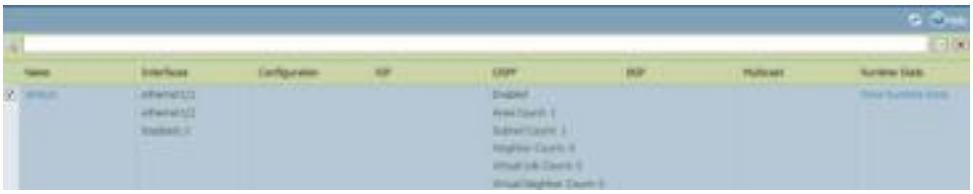
Step 2 Select **OSPF > Neighbor** and examine the **Status** column to determine if OSPF adjacencies have been established.

## Confirm that OSPF Connections are Established

By viewing the system log, you can confirm that OSPF connections have been established as described in the following procedure:

**Examine the System Log**

Step 1 Select **Monitor> System** and look for messages confirm that OSPF adjacencies have been established.



Step 2 Select **OSPF > Neighbor** sub tab and examine the **Status** column to determine if OSPF adjacencies have been established.

 © Palo Alto Networks, Inc.

# Configure BGP

The Border Gateway Protocol (BGP) is the primary Internet routing protocol. BGP determines network reachability based on IP prefixes that are available within autonomous systems (AS), where an AS is a set of IP prefixes that a network provider has designated to be part of a single routing policy.

In the routing process, connections are established between BGP peers (or neighbors). If a route is permitted by the policy, it is stored in the routing information base (RIB). Each time the local firewall RIB is updated, the firewall determines the optimal routes and sends an update to the external RIB, if export is enabled.

Conditional advertisement is used to control how BGP routes are advertised. The BGP routes must satisfy conditional advertisement rules before being advertised to peers.

BGP supports the specification of aggregates, which combine multiple routes into a single route. During the aggregation process, the first step is to find the corresponding aggregation rule by performing a longest match that compares the incoming route with the prefix values for other aggregation rules.

For more information on BGP, refer to How to Configure BGP Tech Note.

The firewall provides a complete BGP implementation that includes the following features:

- Specification of one BGP routing instance per virtual router.
- Routing policies based on route-map to control import, export and advertisement, prefix-based filtering, and address aggregation.
- Advanced BGP features that include route reflector, AS confederation, route flap dampening, and graceful restart.
- IGP-BGP interaction to inject routes to BGP using redistribution profiles.

BGP configuration consists of the following elements:

- Per-routing-instance settings, which include basic parameters such as local route ID and local AS and advanced options such as path selection, route reflector, AS confederation, route flap, and dampening profiles.
- Authentication profiles, which specify the MD5 authentication key for BGP connections.
- Peer group and neighbor settings, which include neighbor address and remote AS and advanced options such as neighbor attributes and connections.
- Routing policy, which specifies rule sets that peer groups and peers use to implement imports, exports, conditional advertisements, and address aggregation controls.

| **Configure BGP** | | |
|---|---|---|
| Step 1 | Configure general virtual router configuration settings. | See Configure a Virtual Router for details. |

| Configure BGP (Continued) | | |
|---|---|---|
| Step 2 | Configure standard BGP configuration settings. | 1. Select the **BGP** tab.<br>2. Select the **Enable** check box to enable the BGP protocol.<br>3. Assign an IP address to the virtual router in the **Router ID** box.<br>4. Enter the number of the AS to which the virtual router belongs in the **AS Number** box, based on the router ID. Range: 1-4294967295 |
| Step 3 | Configure general BGP configuration settings. | 1. Select **BGP > General**.<br>2. Select the **Reject Default Route** check box to ignore any default routes that are advertised by BGP peers.<br>3. Select the **Install Route** check box to install BGP routes in the global routing table.<br>4. Select the **Aggregate MED** check box to enable route aggregation even when routes have different Multi-Exit Discriminator (MED) values.<br>5. Enter a value for the **Default Local Preference** that specifies a value than can be used to determine preferences among different paths.<br>6. Select one of the following values for the AS format for interoperability purposes:<br>• 2 Byte (default value)<br>• 4 Byte<br>7. Enable or disable each of the following values for **Path Selection**:<br>• **Always Compare MED** — Enable this comparison to choose paths from neighbors in different autonomous systems.<br>• **Deterministic MED Comparison** — Enable this comparison to choose between routes that are advertised by IBGP peers (BGP peers in the same autonomous system).<br>8. Click **Add** to include a new authentication profile and configure the following settings:<br>• **Profile Name**—Enter a name to identify the profile.<br>• **Secret/Confirm Secret**—Enter and confirm a passphrase for BGP peer communications. |

© Palo Alto Networks, Inc.

| Configure BGP (Continued) | |
|---|---|
| Step 4 Configure BGP Advanced settings (Optional) | 1. On the **Advanced** subtab, select **Graceful Restart** and configure the following timers:<br>• **Stale Route Time (sec)**—Specifies the length of time in seconds that a route can say in the stale state. Range: 1 - 3600 seconds. Default: 120 seconds.<br>• **Local Restart Time (sec)**—Specifies the length of time in seconds that the local device waits to restart. This value is advertised to peers. Range: 1 - 3600 seconds. Default: 120 seconds.<br>• **Max Peer Restart Time (sec)**—Specifies the maximum length of time in seconds that the local device accepts as a grave period restart time for peer devices. Range: 1 - 3600 seconds. Default: 120 seconds.<br>2. Specify an IPv4 identifier to represent the reflector cluster in the **Reflector Cluster ID** box.<br>3. Specify the identifier for the AS confederation to be presented as a single AS to external BGP peers in the **Confederation Member AS** box.<br>4. Click **Add** and enter the following information for each Dampening Profile that you want to configure, select **Enable**, and click **OK**:<br>• **Profile Name**—Enter a name to identify the profile.<br>• **Cutoff**—Specify a route withdrawal threshold above which a route advertisement is suppressed. Range: 0.0-1000.0. Default: 1.25.<br>• **Reuse**—Specify a route withdrawal threshold below which a suppressed route is used again. Range: 0.0-1000.0. Default: 5.<br>• **Max Hold Time (sec)**—Specify the maximum length of time in seconds that a route can be suppressed, regardless of how unstable it has been. Range: 0-3600 seconds. Default: 900 seconds.<br>• **Decay Half Life Reachable (sec)**—Specify the length of time in seconds after which a route's stability metric is halved if the route is considered reachable Range: 0-3600 seconds. Default: 300 seconds.<br>• **Decay Half Life Unreachable (sec)**—Specify the length of time in seconds after which a route's stability metric is halved if the route is considered unreachable. Range: 0 - 3600 seconds. Default: 300 seconds.<br>5. Click **OK**. |

| Configure BGP (Continued) | |
|---|---|
| Step 5 Configure the BGP peer group. | 1. Select the **Peer Group** subtab and click **Add**.<br>2. Enter a **Name** for the peer group and select **Enable**.<br>3. Select the **Aggregated Confed AS Path** check box to include a path to the configured aggregated confederation AS.<br>4. Select the **Soft Reset with Stored Info** check box to perform a soft reset of the firewall after updating the peer settings.<br>5. Specify the type of peer or group from the **Type** drop down box and configure the associated settings (see below in this table for descriptions of Import Next Hop and Export Next Hop).<br>• **IBGP—Export Next Hop:** Specify **Original** or **Use self**<br>• **EBGP Confed—Export Next Hop:** Specify **Original** or **Use self**<br>• **EBGP Confed—Export Next Hop:** Specify **Original** or **Use self**<br>• **EBGP—Import Next Hop:** Specify **Original** or **Use self**, **Export Next Hop:** Specify **Resolve** or **Use self**. Select **Remove Private AS** if you want to force BGP to remove private AS numbers.<br>6. Click **OK** to save. |
| Step 6 Configure Import and Export rules.<br>The import/export rules are used to import/export routes from/to other routers. For example, importing the default route from your Internet Service Provider. | 1. Select the **Import** tab and then click **Add** and enter a name in the **Rules** field and select the **Enable** check box.<br>2. Click **Add** and select the **Peer Group** to which the routes will be imported from.<br>3. Click the **Match** tab and define the options used to filter routing information. You can also define the Multi-Exit Discriminator (MED) value and a next hop value to routers or subnets for route filtering. The MED option is an external metric that lets neighbors know about the preferred path into an AS. A lower value is preferred over a higher value.<br>4. Click the **Action** tab and define the action that should occur (allow/deny) based on the filtering options defined in the **Match** tab. If **Deny** is selected, no further options need to be defined. If the **Allow** action is selected, define the other attributes.<br>5. Click the **Export** tab and define export attributes, which are similar to the **Import** settings, but are used to control route information that is exported from the firewall to neighbors.<br>6. Click **OK** to save. |

© Palo Alto Networks, Inc.

| Configure BGP (Continued) | | |
|---|---|---|
| Step 7 | Configure conditional advertising, which allows you to control what route to advertise in the event that a different route is not available in the local BGP routing table (LocRIB), indicating a peering or reachability failure. This is useful in cases where you want to try and force routes to one AS over another, for example if you have links to the Internet through multiple ISPs and you want traffic to be routed to one provider instead of the other unless there is a loss of connectivity to the preferred provider. | 1. Select the **Conditional Adv** tab, click **Add** and enter a name in the **Policy** field.<br>2. Select the **Enable** check box.<br>3. Click **Add** and in the **Used By** section enter the peer group(s) that will use the conditional advertisement policy.<br>4. Select the **Non Exist Filter** tab and define the network prefix(es) of the preferred route. This specifies the route that you want to advertise, if it is available in the local BGP routing table. If a prefix is going to be advertised and matches a Non Exist filter, the advertisement will be suppressed.<br>5. Select the **Advertise Filters** tab and define the prefix(es) of the route in the Local-RIB routing table that should be advertised in the event that the route in the non-exist filter is not available in the local routing table. If a prefix is going to be advertised and does not match a Non Exist filter, the advertisement will occur. |
| Step 8 | Configure aggregate options to summaries routes in the BGP configuration.<br><br>BGP route aggregation is used to control how BGP aggregates addresses. Each entry in the table results in one aggregate address being created. This will result in an aggregate entry in the routing table when at least one or more specific route matching the address specified is learned. | 1. Select the **Aggregate** tab, click **Add** and enter a name for the aggregate address.<br>2. In the **Prefix** field, enter the network prefix that will be the primary prefix for the aggregated prefixes.<br>3. Select the **Suppress Filters** tab and define the attributes that will cause the matched routes to be suppressed.<br>4. Select the **Advertise Filters** tab and define the attributes that will cause the matched routes to always be advertised to peers. |
| Step 9 | Configure redistribution rules.<br><br>This rule is used to redistribute host routes and unknown routes that are not on the local RIB to the peers routers. | 1. Select the Redist Rules tab and click Add.<br>2. In the **Name** field, enter an IP subnet or select a redistribution profile. You can also configure a new redistribution profile from the drop-down menu if needed.<br>3. Click the **Enable** check box to Enable the rule.<br>4. In the **Metric** field, enter the route metric that will be used for the rule.<br>5. In the **Set Origin** drop down, select incomplete, igp, or egp.<br>6. Optionally set MED, local preference, AS path limit and community values. |

# PAN-OS 6.0 Release Information

This release note provides important information about Palo Alto Networks® PAN-OS® 6.0 software, including an overview of new features introduced in this release and a list of known issues. For instructions on how to upgrade the firewall to PAN-OS 6.0 and configure the new features, refer to the New Features Guide.

For the most up-to-date information, refer to the online version of the PAN-OS 6.0 Release Notes on the Technical Documentation portal.

- Features Introduced in PAN-OS 6.0
- Changes to Default Behavior
- Associated Software Versions
- Known Issues

The client certificate used by PAN-OS and Panorama to authenticate to the PAN-DB cloud service, the WildFire cloud service, and the WF-500 appliance expired on January 21, 2016. The expiration results in an outage of these services.

To avoid an outage, either upgrade to content release version 550 (or a later version) or upgrade PAN-OS and Panorama instances running a PAN-OS or Panorama 6.0 release to PAN-OS (or Panorama) 6.0.12 or a later release.

# Features Introduced in PAN-OS 6.0

The following topics describe the new features introduced in the PAN-OS 6.0 release. This release requires content version 401 or later. For details on how to use the new features, refer to the New Features Guide.

- App-ID
- Content Inspection Features
- GlobalProtect Features
- Management Features
- Networking Features
- Panorama Features
- User-ID Features
- Virtualization Features

© Palo Alto Networks, Inc.

## App-ID

The following App-ID™ features are introduced in PAN-OS 6.0. For more details about these features and for instructions on configuring them, refer to Application Identification Features in the New Features Guide:

| New Application Identification Feature | Description |
|---|---|
| **Support for Hardware Security Modules** | You can now offload the certificate signing functions for SSL forward proxy, SSL inbound inspection, and the master key storage functions to a dedicated hardware security module (HSM) for enhanced key management security. This release supports the use of the following HSMs: SafeNet Luna SA and Thales nShield Connect. HSM support is generally required when FIPS 140-2 Level 3 protection for CA keys is required. The use of an HSM is supported on PA-7050, PA-3000 Series, PA-4000 Series, PA-5000 Series firewalls, VM-Series firewalls (VM 100, VM-200, VM-300, and VM-1000), and on the M-100 appliance. To configure a firewall to operate with an HSM, navigate to **Device > Setup > HSM**. |
| **Option to Disable SIP ALG** | By default, a Session Initiation Protocol (SIP) application-level gateway (ALG) performs NAT on the payload and opens dynamic pinholes for media ports. However, some SIP endpoints have NAT intelligence embedded in their clients. Because the firewall must not modify the signaling sessions in this case, you can now disable the SIP ALG functionality depending on the SIP applications in use in your environment. When SIP ALG is disabled, if App-ID determines that a session is SIP, the payload is not translated and open dynamic pinholes are not opened. To disable the SIP ALG, navigate to **Objects > Applications** and then customize the **ALG** option on the SIP application. |

© Palo Alto Networks, Inc.

## Content Inspection Features

The following Content Inspection features are introduced in PAN-OS 6.0. For more details about these features and for instructions on configuring them, refer to Content Inspection Features in the New Features Guide:

| New Content Inspection Feature | Description |
|---|---|
| **DNS Sinkholing** | This feature adds a new sinkhole action to the DNS signatures within the Anti-Spyware profile. Sinkholing enables the firewall to forge a response to a DNS query for a known malicious domain, causing the malicious domain name to resolve to an IP address that you define. You can use this feature to identify infected hosts on the protected network using DNS traffic in situations where the firewall cannot see the infected client's DNS query (for example, when the firewall is north of the local DNS server). This feature can also be used to redirect malicious traffic to a honeypot or any other target host.<br>Enable sinkholing for the DNS signature collection by selecting the **sinkhole** action in the **DNS Signatures** tab of an Anti-Spyware profile and specifying an IPv4 and/or IPv6 address to use as the sinkhole (the default is the localhost, which will cut off communication). The sinkhole address can be an address of a live server or an unused address on your network. After enabling DNS sinkholing, you can identify infected clients by filtering the traffic logs or by building a custom report that checks for sessions to the IP address you defined as the sinkhole address. |
| **Extended Packet Capture** | A new extended-capture option has been added to Anti-Spyware and Vulnerability Protection profiles for rules and exceptions defined in the profile. Previously, when selecting packet capture, only the first trigger packet would be captured when a threat was detected in traffic matching the profiles. With the **extended-capture** option enabled, the firewall can capture from 1 to 50 packets, which provides much more context when analyzing the threat logs. To define the number of packets to capture, navigate to **Device > Setup > Content-ID** and then edit the **Threat Detection Settings** section. You can then view the extended packet captures from the threat logs (**Monitor > Logs > Threat**) by locating the log entry you want to investigate and then clicking the green arrow (Packet Capture) icon in the second column. |
| **Passive DNS** | This is an opt-in feature that enables the firewall to act as a passive DNS sensor and send select DNS information to Palo Alto Networks for analysis to improve threat intelligence and threat prevention capabilities. The data collected includes non-recursive DNS query and response packet payloads (such as payloads originating from the local recursive resolver, not individual clients). This information is used by the Palo Alto Networks threat research team to gain insight into malware propagation and evasion techniques that abuse the DNS system.<br>Information gathered through this data collection is used to improve accuracy and malware detection abilities within PAN-DB URL filtering, DNS-based command-and-control signatures, and the WildFire™ security service. Passive DNS monitoring is disabled by default but it is recommended that you enable it to facilitate enhanced threat intelligence. To enable this option select the **Enable Passive DNS Monitoring** check box on the **DNS Signatures** tab of the Anti-Spyware profile dialog for the Anti-Spyware profile that is attached to the security policy governing your DNS server's external DNS traffic. |

 © Palo Alto Networks, Inc.

| New Content Inspection Feature | Description |
|---|---|
| **URL Filtering Search Engine Cached Site Enhancement** | An enhancement has been made to the URL filtering engine such that URL filtering policies will also be applied when end-users attempt to view the Google and Internet Archive cached copies of websites. |
| **URL Filtering Translation Site Filtering Enhancement** | An enhancement has been made to the URL filtering engine such that URL filtering policies will also be applied to any URLs that are entered into translation sites such as Google Translate. This will ensure that website translation tools are not used to bypass URL filtering policies. |
| **URL Filtering Safe Search Enforcement** | This feature prevents users from viewing the search results unless the strictest safe search option is set in their browsers for and when searching using one of the top three search providers (Google, Bing, and Yahoo). If the strictest safe search option is not set in the browser, users will see a block page instructing them how to set the option for the given search provider. To enable this option, select the **Safe Search Enforcement** check box in the URL Filtering profile. Safe search will then be enforced whenever a user request matches a security policy rule with the corresponding URL Filtering profile attached.<br>Starting in PAN-OS 6.0.1, YouTube Safety Mode is supported as part of URL Filtering Safe Search Enforcement. YouTube Safety Mode ensures that YouTube search results only appear when the strictest safe search option is set in the user's browser.<br>Additionally, Safe Search Enforcement support for the Yandex search engine was added in content release version 446.<br>Finally, transparent safe search enforcement is supported with content release version 475 or later. |
| **WildFire Report Incorrect Verdict Option** | When viewing a WildFire analysis report for a sample that has been analyzed by WildFire, a new feature called **Report Incorrect Verdict** is now available in the report. This option enables you to resubmit the sample to the Palo Alto Networks threat team if you feel the verdict is a false positive or false negative. The threat team will perform further analysis on the sample to determine if it should be reclassified. If a file that was previously identified as malicious is determined to be benign (false positive), the signature for the file will be disabled in an upcoming antivirus signature update. Similarly if a file that was previously identified as benign is determined to be malicious (false negative), a new signature will be generated and distributed in the next content update. After the investigation is complete, you will receive an email (if provided on the submission form) notifying you of the outcome. |
| **WildFire Sandbox Operating Systems** | Microsoft Windows 7 32/bit has been added to the WildFire environment. When a dynamic analysis is performed on a file, it will be run in Windows XP and Windows 7. On a WF-500 WildFire appliance, you will need to select an image that will contain Windows XP or Windows 7 as well as a combination of other applications, such as different versions of Adobe Reader, and MS Office. |

© Palo Alto Networks, Inc.

| New Content Inspection Feature | Description |
|---|---|
| **Additional File Type Support Added to WildFire** | As part of the WildFire subscription, the following advanced file types are now supported: Microsoft Office (.doc/.docx, .xls/.xlsx, and .ppt/.pptx); Portable Document Format (.pdf); Java Applet (.jar and .class); and Android Application Package (.apk).<br>With a WildFire subscription, all listed file types can be submitted to WildFire from a PAN-OS firewall running PAN-OS 6.0 or later release versions using the WildFire web interface, a File Blocking profile in a security policy, or by manual upload to the WildFire portal at https://wildfire.paloaltonetworks.com. If you do not have a WildFire subscription, the firewall will forward only PE files. You can, however, manually upload any of the other supported file types to the WildFire portal.<br> The WF-500 WildFire appliance does not support APK file analysis. |
| **WildFire Analysis Report Enhancement** | The WildFire analysis report is now integrated with the logging features of the firewall and no longer requires a WildFire subscription. In addition, several new enhancements have been made to the report, including the ability to:<br>• Export the full report to a PDF by clicking **Download PDF**.<br>• Download the file sample that was analyzed.<br>• View the analysis results for each virtual environment in which the file was analyzed by clicking the corresponding **Virtual Machine** tab in the **Dynamic Analysis** section of the report. For example, click the **Virtual Machine 1** tab to view the Windows XP analysis results or click the **Virtual Machine 2** tab to see the analysis results for Windows 7. New virtual machine tabs will display as new environments are added. Each sandbox environment has its own configuration of applications and software used in the file analysis, such as which version of Adobe Reader, Flash, and MS Office are used in the file analysis on the specific virtual machine.<br>• View all processes or filter by an individual process.<br>• Re-submit the file sample to Palo Alto Networks for reevaluation if you think the file verdict (benign/malware) is incorrect by clicking **Report Incorrect Verdict**. |
| **WildFire Logging Update** | When a firewall is configured with a file blocking profile and security policy to forward files to WildFire for analysis, a WildFire subscription is no longer required to receive the WildFire Submissions logs on the firewall. A Subscription is still required to forward files to a WF-500 WildFire appliance and/or to forward the advanced file types that are now supported in PAN-OS 6.0 to either the WildFire cloud or a WildFire appliance. |
| **WildFire Report Integration** | Previously, in order to view the WildFire detailed report, you had to link to the report hosted on the WildFire cloud or the WildFire appliance. This report has now been integrated into the report on the firewall. Now, the WildFire Log Details report contains two tabs:<br>• **Details** tab-Shows the session details.<br>• **WildFire Analysis Report** tab-Shows the WildFire detailed report, which was previously hosted on the WildFire cloud or WildFire appliance.<br>Panorama™ no longer requires all managed firewalls to forward files to the same WildFire system so long as Panorama and the managed firewalls are running a PAN-OS 6.0 or later release version. |

 © Palo Alto Networks, Inc.

| New Content Inspection Feature | Description |
|---|---|
| **WildFire Submissions Log Forwarding** | Previously, you could only forward WildFire logs if you configured threat log forwarding for medium severity logs (which included WildFire logs with a malicious verdict) and/or informational severity logs (which included WildFire logs with a benign verdict). You can now configure the firewall to automatically forward WildFire Submissions logs independently of the threat log forwarding configuration. To enable WildFire Submissions log forwarding, configure the **WildFire Settings** in the log forwarding profile (**Objects > Log Forwarding**) to specify which WildFire logs (**Benign** and/or **Malicious** verdict) to forward to which log destinations (SNMP trap receiver, Panorama, syslog server, or email alert). |
| **WildFire API Enhancements** | The WildFire API syntax has changed for some web interface operations. For example, the file hash for sample files are now included in the logs, which you can use to query using the /get/report method. In addition, you can also now download WildFire PDF reports using the web interface and you can submit sample files to WildFire for the new files types that are now supported. For details on using the WildFire web interface in PAN-OS 6.0, refer to the WildFire Administrator's Guide. |

## GlobalProtect Features

The following GlobalProtect™ features are introduced in PAN-OS 6.0. For more details about these GlobalProtect features and for instructions on configuring them, refer to GlobalProtect Features in the New Features Guide.

| New GlobalProtect Feature | Description |
|---|---|
| **GlobalProtect Mobile Security Manager** | Provides, management, visibility, and automated configuration deployment for the mobile devices-either company provisioned or employee owned-on your network. With Mobile Security Manager you can create user- and/or HIP-based deployment policies that allow you to push application configurations (such as email and VPN configurations) to your employees' mobile devices. The Mobile Security Manager requires the devices it manages to check-in regularly to ensure that the device is in compliance, pushing new configuration to devices if the device status changes (for example, if the Mobile Security Manager determines it has an app with malware installed) or to push an updated policy to the device. You can also perform certain actions on a managed device from the Mobile Security Manager, such as locking the device, sounding an alarm to help locate the device, or even wiping a device that has been compromised. In addition, the GlobalProtect gateways can retrieve extended HIP report information for the devices managed by the Mobile Security Manager and use the information to enforce security policies for devices that connect to your network. The Mobile Security Manager runs on the GP-100 appliance. |
| **Agent Deployment Customization** | All GlobalProtect agent customization settings can now be set in the Windows registry (`HKEY_LOCAL_MACHINE\SOFTWARE\Palo Alto Networks\GlobalProtect\Settings\`) or the Mac global plist file (`/Library/Preferences/com.paloaltonetworks.GlobalProtect.settings.plist`). This enables deployment of GlobalProtect agent settings to client systems prior to their first connection to the GlobalProtect portal. For Windows clients, this also enables simplified deployment via group policy, as well as the option to automatically deploy the settings in the Windows Installer (MSIEXEC). Note that settings defined in the GlobalProtect portal client configuration take precedence over settings defined in the Windows Registry or the Mac plist.<br><br>In addition, the following new configuration options have been added to the **Network > GlobalProtect > Portals Agent** tab in the **Configs** dialog:<br>• **Show GlobalProtect icon—**Disabling this option makes GlobalProtect invisible to the end user by removing the icon from the system tray and preventing the user from having any interaction with the GlobalProtect agent user interface.<br>• **Allow user to change portal address—**Disabling this option prevents users from manually changing the portal address pushed to the client in the portal configuration file.<br>• **Allow user to continue if portal server certificate is invalid—**Disabling this option prevents users from continuing if there is a warning screen indicating a man-in-the-middle (MITM) attack, |
